According to results of this study, if HC2 is used as triage test, referrals for Colposcopy will be reduced to 10.97% of original referrals and 30% of high grade CIN cases could be missed. However, if Cytology is used as triage test, referrals for Colposcopy will be reduced to 13.08% of the original referrals and 30% of high grade CIN cases could be missed.

THE VAGINAL MICROBIOTA AFTER EXCISIONAL TREATMENT FOR CERVICAL INTRAEPITHELIAL NEOPLASIA
A. Mitra¹, D. MacIntyre¹, Y. Lee¹, A. Smith², J. Marchesi², D. Lyons³, P. Bennett¹, M. Kyrgiou¹
¹Imperial College London, Institute of Reproductive & Developmental Biology- Surgery & Cancer, London, United Kingdom
²Cardiff University, Department of Biosciences, Cardiff, United Kingdom
³Imperial College London, Centre for Digestive & Gut Health- Surgery & Cancer, London, United Kingdom
⁴Imperial College Healthcare NHS Trust, Obstetrics & Gynaecology, London, United Kingdom

Aims

The vaginal microbiota (VMB) is usually Lactobacillus spp. dominant appears to protect the female reproductive tract against infections including HPV. CST (community state type) III and the high-diversity VMB deplete of Lactobacillus spp. CST IV have both been associated with higher rates of HPV acquisition, persistence and increased severity of cervical intraepithelial neoplasia (CIN). These CST’s have also been associated with pre-term birth (PTB); a known complication of excisional treatment.

We aimed to investigate the impact of excisional treatment for CIN on VMB composition.

Method

Interventions: Vaginal swabs collected immediately prior to treatment, and at 6 month follow-up. Bacterial DNA was extracted and sequenced using the Illumina MiSeq platform.

Results

One hundred and three women provided both pre- and post-treatment samples. Excisional treatment did not significantly alter the distribution of CSTs within the cohort, and diversity remained significantly greater compared to normal, healthy untreated controls. There was no association with post-treatment CST and HPV status. LEfSe identified Streptococcus agalactiae (Group B streptococcus) to be significantly overrepresented after treatment.

Conclusion

Excisional treatment did not significantly alter VMB composition. CST III and IV remained at a higher prevalence than in normal controls, which may be due to intrinsic host factors rather than as a result of disease, and these may also predispose them to PTB and risk of disease recurrence. Furthermore, Streptococcus agalactiae which has been associated with PTB risk, may add to the risk in this patient cohort.
THE IMPACT OF SURGICAL TREATMENT ON THE PSYCHOLOGICAL STATE OF PATIENTS SUFFERING FROM PREMALIGNANT LESIONS OF CERVIX

S. Buzadzic1, V. Kesic2, M. Mitrovic1, S. Aksam3

1Clinic of gynecology and obstetrics, Clinical center Serbia, Postoperative department, Belgrade, Serbia
2Clinic of gynecology and obstetrics, Clinical center Serbia, Gynecological oncology department, Belgrade, Serbia
3Clinic of gynecology and obstetrics, Clinical center Serbia, High-risk pregnancies, Belgrade, Serbia

Aims

The aim of this research is to discover how important is to patients treated from premalignant cervical disease to preserve possibility of conception after treatment.

Method

The research was conducted at Clinic of gynecology and obstetrics, Clinical center Serbia, during 2016., on the sample of women aged 18 to 40 years, with diagnosed premalignant cervical lesions. Psychological state and their attitudes about pregnancy were analyzed.

Psychological state was examined through questionnaire included in the project "Cancer and pregnancy". It is focused on course of disease, fear of recurrence, relations with partner and future pregnancy and is composed of 12 categorical type questions. These questions are designed as multiple-answer or one-answer possibility.

Attitudes about pregnancy were examined in more then 10 questions on four-graded Likert scale.

Results

The mean age of patients included in study was 33 years. 58.3% were without children while 27.8% had previous intervention or operation on cervix.

Majority of patients had positive attitude about pregnancy, while 19.4% didn't want to have children.

About half were concerned about future pregnancy and main issues were fear of recurrence, possible difficulties with conception and fear of preterm birth.

Also, quality of relationship with partner had positive impact on their attitude about pregnancy. Regarding planning of reproduction, women who wanted to have children, feared the most from possibility of recurrence.

Conclusion

This research indicates how important for young patients is education about course of premalignant cervical lesions, therapy and possible pregnancy outcome.

They should face the disease and choose minimally invasive, but effective treatment.

CERVICAL CYTOLOGICAL SCREENING AND IMMUNOHISTOCHEMISTRY IN THE DIAGNOSIS AND PROGNOSIS OF CERVICAL PRECANCER

D. Mocuta¹, C. Aur²
¹Faculty of Medicine and Pharmacy Oradea- County Clinical Hospital, Obstetrics-Gynecology, Oradea, Romania
²Faculty of Medicine and Pharmacy- County Clinical Hospital of Oradea, Obstetrics-Gynecology, Oradea, Romania

Aims

Malignant transformation of cervix is a model of cancer that can be completely prevented and diagnosed by clinical and laboratory features. One of the factors which decrease morbidity and mortality in cervical cancer is annual performance of cervical cytology. We tried to find a combined method to evaluate cervical precancer – cervical cytology and immunohistochemistry.

Method

We took in study a group of patients with cervical cancer and precancer admitted in our hospital. For the patients diagnosed by cytology with intraepithelial cervical lesions or with clinical and citological suspicion of cervical neoplasia, we made the cervical biopsy and on these samples there were performed the histopathology and immunohistochemical tests. The immunohistocemical markers used in our study were E-cadherin, p53, Ki-67.

Results

The results obtained, helped us to make the differential diagnosis and appreciate the prognosis or the medical management in each patient's case. In cancerous lesions and H-SIL, the increased proliferation rate is put in evidence by the presence of Ki-67, so, the immunostaining for Ki-67 was more intense. Same reaction appears for p53, the immunostaining for p53 being pronounced with worsening of the cervical lesions. The expression of E-cadherin was increased in L-SIL, lower in H-SIL and more decreased and with citoplasmatic model in cancerous lesions.

Conclusion

We already know the importance of screening for cervical cancer, but we consider very useful to combine cytological examination and immunohistochemical markers. Using clinical examination and these two methods, we can get better results for the diagnosis, therapy and prognosis of our patients.
MILD ENDOMETRIAL DYSPLASIA IN CESAREAN SCAR ABDOMINAL ENDOMETRIOSIS – AN EARLY PREMALIGNANT TRANSFORMATION OF ECTOPIC ENDOMETRIUM

M.J. Moniat, M. Bogusiewicz, D. Lewkowicz, A. Semczuk
1Medical University, II'nd Department of Operative Gynecology, Lublin, Poland
2Medical University, Department of Pathology, Lublin, Poland

Aims

Incidence of cesarean scar endometriosis varies between 0.03 and 0.45% of women who underwent abdominal delivery. Malignant transformation of cesarean scar endometriosis is exceptionally rare. The present case shows an early stage of potentially malignant transformation of endometriotic tissue localized in a cesarean section abdominal wall scar.

Method

The 40-year-old patient was referred to gynecological ward due to recurrent pain and presence of tumor in the cesarean section scar. The medical history revealed a cesarean delivery 7 years earlier followed by aggravating pain that had started 6 months after surgery. Since 3 years a painful mass measuring around 4 cm localized in the right edge of the cesarean scar had been observed. Typically for cesarean scar endometriosis the pain was more pronounced around menstruation. The patient was obese (BMI 42.7 kg/m²) and hypertensive. Family history revealed a colorectal cancer in patients' mother.

Results

The patient was scheduled for surgery aiming at complete removal of endometriotic lesion. During the surgery two endometriotic tumors infiltrating abdominal fascia and rectal muscles were excised: one measuring around 4 cm located in the right edge of the cesarean scar and the other measuring around 5 cm located 5 cm beneath the umbilicus in the sagittal line. The pathological examination revealed endometriotic tissue with fibrosis and mild dysplasia of endometrial glands. Immunohistochemical staining showed CKMNF 116 (+), CKAE1/AE3(+), CD 10 (+), Vimentin (+/-), CD 68 (+).

Conclusion

Ectopic cesarean scar endometrial tissue, especially in the presence of recognized risk factors, may undergo premalignant transformation analogous to eutopic endometrium.

GIANT LIPOLEIOMYOMA OF THE UTERINE CORPUS SIMULATING MALIGNANCY: A CASE REPORT IN PATIENTS WITH MULTIPLE SCLEROSIS.

L. Mosca¹, A. Cafiero², G. Balbi², D. Colesanti³, C. Gallo⁴, L. Cobellis³

¹Università della Campania Luigi Vanvitelli, Della Donna- del Bambino- di Chirurgia Generale e Specialistica, Napoli, Italy
²Azienda Ospedaliera Sant’Anna e San Sebastiano, Ginecologia ed Ostetricia, Caserta, Italy
³Azienda Ospedaliera Sant’Anna e San Sebastiano- Università degli Studi della Campania Luigi Vanvitelli, Ginecologia ed Ostetricia, Caserta, Italy
⁴Azienda Ospedaliera Sant’Anna e San Sebastiano, Anestesia d’Urgenza ed Intensiva, Caserta, Italy

Aims

Uterine leiomyoma is the most common benign pathology in women and lipoleiomyoma is an extremely rare and specific type of leiomyoma with an incidence ranging between 0.03% and 0.2%, but to keep in mind in differential diagnosis with malignant sarcoma. Here, we report an unusual case of giant lipoleiomyoma in a patient with multiple sclerosis.

Method

Case: A 54-year-old woman admitted to our Hospital for tiredness, and pelvic pain for the last 6 months. Sonography and abdominal magnetic resonance imaging (MRI) showed a giant semisolid mass that filled whole abdominal cavity from pelvis to subdiaphragmatic area. On operation, total abdominal hysterectomy with a uterus of size 24 × 23 × 13cm and weighing 4.6 kg, completely occupied by the mass, and bilateral salpingo-ophorectomy were performed. The histopathology revealed a lipoleiomyoma with extensive cystic and fatty degeneration without any malignancy.
Results

Discussion: The diagnosis of leiomyoma is done usually with pelvic ultrasound but sometimes it is difficult to reach a correct diagnosis, especially in cases of giant and pedunculated lipoleiomyoma that included fatty tissue which may mimick malignancy

Conclusion

Intramural giant lipoleiomyoma, albeit represents a rare event should be kept in mind in the differential diagnosis of leiomyosarcoma.
TYPES AND MULTIPLE INFECTION OF HPV ARE RELATED TO VIRAL PERSISTENCE AND CIN RECURRENCE AFTER LASER SURGERY

A. Nishikawa1, T. Mariya2, A. Baba1, S. Ayumi1, I. Yamanaka1, T. Nihei2

1Sapporo Medical Center NTT EC, Obstetrics and Gynecology, Sapporo, Japan
2Obihiro kyokai hospital, Dept. OB/GYN, Obihiro- Hokkaido, Japan

Aims

In order to elucidate the factors related to HPV persistence and CIN recurrence after Laser surgery, we examined the details of infected HPV genotypes in 334 cases with CIN.

Method

Cases were recruited from CIN cases treated in our hospital from 2007 to 2011, and observed until December 2014. One hundred and four of the cases were treated by laser conization, while the other 230 cases by laser vaporization. Surgical procedure was selected on the basis of colposcopic examination, pathological grade, and patient’s hope for pregnancy. All cases examined infected HPV genotypes before and after treatment using the multiplex PCR method.

Results

There were no significant differences in cure rates, HPV persistence rates or recurrence rates between conization and vaporization. Persistent HPV infection after treatment was the independent risk factor of recurrence (RR, 9.25; 95%CI 3.06-27.98; p<0.001) in multivariate analysis. And, multiple-type HPV infection before treatment was the independent risk factor of the persistence of HPV infection (RR, 2.04; 95%CI 1.10-3.78; p=0.024). Types 16, 18 and 33 showed a higher potential for recurrence than the other types of HPV.

Conclusion

Multiple HPV infections are a risk factor of HPV persistence. Furthermore, types 16, 18 and 33 infections generate a high risk for the recurrence of CIN. In addition, HPV persistent cases, especially, HPV 16, 18 and 33 showed higher recurrence rates, thus may require more intensive follow up than HPV cleared cases.
POSSIBILITIES OF REDUCING NON-COMPLIANCE IN CERVICAL CANCER SCREENING PROGRAMME IN POLAND

A. Prusaczyk¹, R. Koc¹, S. Szafraniec-Buryło², E. Prokurat³, P. Zuk³, I. Sakowska¹, A. Prusaczyk³, M. Guzek¹, A. Kordowska¹, E. Dmoch-Gajzlerska⁴, M. Bidzinski⁵

³Medical and Diagnostic Centre, Cardiology, Siedlce, Poland
⁴Medical University of Warsaw, Faculty of Health Sciences - Gynaecological and Obstetrics Department, Warsaw, Poland
⁵Memorial Cancer Center - Institute of Oncology, Department of Gynecological Oncology, Warsaw, Poland

Aims

The aim was to map potential targets to improve participation in a cervical cancer screening programme.

Method

In 2016 150 female patients from rural region in Poland responded to questionnaire. Patients belonged to integrated care organization - Medical and Diagnostic Centre in Siedlce, Poland. The respondents were 25-63 years old (mean 42), of whom 33 (22%) had higher education. In the screening programme cervical tests were to be repeated every 3 years or more often. In the group 5 women (3.3%) had positive their own or family/friends history of abnormal test results. The average time from the last cervical screening test was 18 months.

Results

Of 150 patients, 140 participated in screening programme every 3 years or more often. 80 needed reminders and/or incentives to do the next cervical screening test on time and 70 remembered the date. 148 patients received in total 773 invitations (through public media, leaflets, letters, sms, phone calls, face-to-face invitations from doctors, midwives, nurse coordinators, family members or friends. 118 patients declared, that invitations were crucial for the decision to participate. Patients were more prone to participate if the invitation was polite, with easy to understand and well-defined aim and language, provided possibility of doing additional tests and choosing time, or if the date was proposed in the invitation, the staff was competent, polite, and the office was well equipped.

Conclusion

Repeated invitations and patients’ education are very important in reducing non-compliance.
COMPARISON BETWEEN OVARIAN MALIGNANCY ALGORITHM (ROMA) AND IOTA RISK MODEL (LR2) FOR DIFFERENTIAL DIAGNOSIS OF ADNEXAL MASSES: REAL-WORLD STUDY

7University of Brescia, Dept. of Gynecology and Obstetrics, Brescia, Italy
8Azienda Ospedaliera "Spedali Civili", Dept. of Gynecology and Obstetrics, Brescia, Italy

Aims

To compare IOTA logistic regression model (LR2) with Ovarian Malignancy Algorithm (ROMA) in predicting malignancy in women with pelvic masses.

Method

Multicenter prospective study enrolling consecutively 371 unselected patients (mirroring clinical practice) with suspicious pelvic masses: benign 285pts; borderline 15pts; malignant 71pts (of which epithelial ovarian cancer -EOC 63pts). LR2 and ROMA diagnostic performances were estimated and compared.

Results

**Results.** LR2 and ROMA had similar diagnostic performances in discriminating benign from EOC patients both in pre and postmenopause (Table 1; AUC: area under ROC curve).

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

When using clinical recommended cut-offs, LR2 and ROMA presented comparable sensitivity and specificity in premenopause. In postmenopause, ROMA showed higher specificity and LR2 higher sensitivity. Risk calculated with LR2 and ROMA slightly agreed in patients with benign disease (pre and postmenopause: Cohen’s Kappa 0.07 and 0.20), whereas fairly or moderately agreed in patients with malignancy (pre and postmenopause: Cohen’s Kappa 0.23 and 0.56). AUC of LR2 and ROMA combination (logistic regression equation) was significantly higher in premenopausal patients compared to AUC for ROMA alone (AUC 0.943 vs 0.907, p=0.03). Mean predicted probability of malignancy increased by 0.155 when using LR2+ROMA in comparison to LR2 alone (0.620 vs 0.775), whereas decreased by 0.039 for benign tumors (0.095 vs 0.056); integrated discrimination improvement was 0.155+0.039=0.194.

Conclusion

Although LR2 and ROMA used individually show a comparable diagnostic performance, when used in combination they appear to differentiate EOC from pelvic masses more efficiently.
THE EVALUATION OF ABNORMAL PAP SMEAR RESULTS IN NORTHWEST REGION OF TURKEY

B. Dincgez Cakmak1, A.E. Yumru2, V. Sal2, M. Tekelioglu2
1 Saglik Bilimleri University Bursa Yuksek Ihtisas Research and Training Hospital, Obstetrics and Gynecology, Bursa, Turkey
2 Saglik Bilimleri University Sisli Hamidiye Etfal Research and Training Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

Cervical cancer is a common malignancy affecting women in worldwide. Early detection of preinvasive cervical lesions are very crucial to avoid the progression of lesions to cervical cancer and decrease morbidity and mortality. Cervicovaginal cytology (pap smear) is a widely used screening tool for early diagnosis of cervical lesions. Abnormal results of pap smear results consists of premalignant or malignant cervical lesions. The aim of the study is to evaluate the prevalence of abnormal pap-smear results in northwest region of Turkey.

Method

In this study, we retrospectively analysed the pap smear results of patients who admitted to a high volume research and training hospital over 10 year period. The demographic, clinical characteristics of patients and pap smear results were recorded from medical records.

Results

A total of 13520 smear results were evaluated. Out of all, 12438 (92%) were appropriate for determining cervical abnormalities whereas the remaining are insufficient for reporting. Abnormal smear results were detected in 1368 (11%) patients. ASCUS was detected in 598 (43.7%) patients, LGSIL in 472 (34.5%) patients, HGSIL in 189 (13.8%) patients, ASCH in 48 (3.5%) patients and AGC in 26 (1.9%) and cervical cancer in 35 (2.6%) patients. Patients who have malign or high grade lesions were significantly younger, had multiple partner and higher smoking rates as compared to benign and low grade cervical lesions.

Conclusion

Cervical cancer is still one of the leading causes of cancer related mortality and morbidity. Cervicovaginal cytology, which has been progressively widened in our country as a screening tool nowadays, is a great helper for detecting early cervical lesions especially in younger ages.
DIAGNOSTICS AND PREINVASIVE DISEASE

OVARIAN GOITER CANCERATED BY THE WAY OF TWO RARE CASES EXPERIMENT OF DEPARTMENT OF ENDOCRINOLOGY ALGIERS ALGERIA

S. Hadjarab1, F. Hadjarab2, K. Bouzid2, S. Mimouni1

1Pierre Marie Curie D'Alger, Endocrinology, Alger, Algeria
2Pierre Marie Curie D'Alger, Medical Oncology, Alger, Algeria

Aims

The ovarian goiter are rare endocrine ovarian tumors are embryonic tumors differentiated which belong to the group of the germinal ovarian tumors

Method

the frequency of the goiter at 7% among the whole of the tératoma.

Exceptionally this fabric will be the object of a malignant degeneration whose frequency is estimated 5 and 10%, they demonstrators often like benign ovarian tumors and their often histological discovery is remotely made operational act which consists in general of a simple ovariectomy.

We report in this work two cases of cancerated ovarian goiter,

Results

-the first woman old with the diagnosis 51 years, married multipara operated there is 13 years for a right ovarian tumour (17x14x10 cm) stage IA discovered with pelvic ichnography following a pelvic painful symptomatology, and whose histological results conclude with a cancerated ovarian goiter, endocrinal exploration found a thyroid gland clinically and echo graphically normal with euthyoidie clinical and biological, tumoral markers (bhcg, and esparto foetoproteines) no treatment complementary was added, patient is under monitoring, alive with 13 years passing.

the second 60 years, multipara, operated for right ovarian tumor discovered with the imagery, pelvic echography, the histological results returning in favour of an ovarian goitre with the discovery of a papillary carcinoma within an ovarian goitre, exploration thyroid returned normal, a thyroidectomy was practised patient is alive with a 4 years passing.

Conclusion

the ovarian goiter is very rare, the degeneration is exceptional and the treatment is especially surgical, but the monitoring is obligatory because occurred of late metastases is possible.
EXCEPTIONAL ONE CASE OF A REVEALING PELVIC METASTASIS OF A CANCER OF THE THYROID

S. Hadjarab¹, F. Hadjarab², K. Bouzid², S. Mimouni¹
¹Pierre Marie Curie D'Alger, Endocrinology, Alger, Algeria
²Pierre Marie Curie D'Alger, Medical Oncology, Alger, Algeria

Aims

We report in poster the exceptional case of a revealing pelvic metastasis of a bladder-like cancer of the thyroid

Method

Remote metastases occur at 10 to 15% of the patients with cancer of the thyroid

half among it are present during the initial diagnosis, 10 years after the thyroid tumor, lung, bone, brain, liver and skin

Results

woman operated in 2007 for a bulky mass retro peritoneal with vertebral lysis in the scanner abdominal pelvic exploration per finds a mass retro peritoneal hemorrhagic

results are evocative of a probable metastasis of a bladder-like carcinoma of thyroid origin.

thyroid exploration: standard goiter lb with thyroid nodule media lobar left

Thyroid scinti scanning: t left nodule lobar projected in frigid zone. she undergoes 4 months after her pelvic surgery, a total thyroidectomy with bilateral ganglionic clearing

the thyroidectomy is in favor of a bladder like carcinoma good differentiated process infiltrates capsule T4 of the

Complementary treatment will suit it therapy the ichnography made 3 months after its last cure of will go therapy showed a hydronéphrose stage I on the left by low obstruction urethral probably in keeping with its pelvic metastasis by uterine left which measures 66x45 mm of diameter.

complement of radiotherapy to sacrum : 65 Gy the evolution: relative clinical stabilization, and after a 9 years retreat, patient is always alive without thyroid or ganglionic repetition.

Conclusion

In spite of its exceptional character, a pelvic metastatic process must lead the clinician to explore the thyroid gland systematically, i

IN CONNECTION WITH A RARE OF BLADDER-LIKE MICROCANCER OF THYROID OF OVARIAN SEAT

S. Hadjarab\textsuperscript{1}, F. Hadjarab\textsuperscript{2}, K. Bouzid\textsuperscript{2}, S. Mimouni\textsuperscript{1}

\textsuperscript{1}Pierre Marie Curie D'Alger, Endocrinology, Alger, Algeria
\textsuperscript{2}Pierre Marie Curie D'Alger, Medical Oncology, Alger, Algeria

Aims

Our case illustrates an exceptional situation in which the modest amount of thyroid fabric contained in the tératome is a micro hearth of bladder-like cancer little differentiated from the thyroid one.

Method

Patient the 49 years old, She presented brutally 4 years ago of the pelvic pains associated with métrorragies

Pelvicechography found a right ovarian mass. 20 months ago, she undergoes a right annexectomy

The examination anatomopathologic find on the level of the right ovary a cyst without vegetation endo or exophytic

The histology aspects of cyst dermoide with several fabrics. The multiple fragments shonw near a thyroid fabric, with fitting trabéculaire and very rare small thyroid blisters

These aspects are suspect of little differentiae bladder-like carcinoma.

with micro hearth (1 mm diameter) with bladder-like carcinoma with the thyroid one.

Results

The assessment hormonal thyroïdien (FT4 and TSHus) normal confirms the state of euthyroidie After a 20 months retre at, the patientis alive with normal rates

HCG with 0.10 ng/ml (VN: 0 – 0.1 normal 1 ng/ml ) and Alpha 1 Foetoproteins in 1.60 UI/ml (VN: 0.5 – 5.5 UI/ml).

Pelvicechography abdomino and to scan it pelvic does not find a repetition

Conclusion

the ovarian tératomes require a long-term monitoring because of the diagnostic difficulties on the one and the occurred potential one of late metastases on the other hand. the discovery of a micro hearth of bladder-like cancer of thyroid within an ovarian cyst dermoide underlines the interest to practise histological examinations meticulous person of totality of the operation and examinations immunohistochim.
Aims

to presented exceptionnel and rare metastases to ovary from medullar thyroid cancer

Method

The medullary thyroid carcinoma is an uncommon malignant tumor

-Patient was Operated Thyroidectomy sub total , , anatomopathologists favor of a medullary carcinoma of the thyroid following by Radiotherapy mediastinal cervical

A chemotherapy adriamycine 60mg/ m2

ibone scintis canning : hyper fixation disseminated on the skeleton in keeping with multiple bone localizations

patient have presented a pelvic pain, pelvic echo graph, in urgency : two suspect ovary tumors

median laparotomy :In exploration the surgeon was discovered two ovary tumors

hysterectomy with total bilateral Annexectomy , curage ganglionic pelvic i

The examined anatomopathologic : ovarian metastasis bilateral of a medullary carcinoma of thyroid,
pelvic clearing out:(17N- /17N)

Results

, Tc scan Thoracic –abdominal –pelvic :objectived multiples disease ganglionic cervical thoracic, mediastinal and pulmonary, hepatic and ganglionic , bone pains. presence the recidivism and evolution of disease

Decision to treated the patient with target therapy (Sorafinib) =. 800mg/day , uninterrupted , so we realized 4 cycle and evaluation after them.
good evolution with disappearance of the bone pains and decrease of diameter of disease

Response showed in imaging was estimate : 60% , the patient is alive with a 24 months passing

Conclusion

- the diagnosis of the thyroid medullary carcinoma is often realized in a advanced stage, metastases distance has which constitutes a factor of graphite as well as the increase brutal or progressive of the rate of ACE , the targeted therapy currently constitutes a prospect for the treatment for the metastatic forms.
Comparing the Results of Operative Hysteroscopy Was Performed in Patients with Active Bleeding With and Without Uterine Evacuation Before the Procedure

M. Sayyah-Melli1, V. Rahmani1, N. Behravan1

1Women’s Reproductive Health Research Center- Tabriz University of Medical Sciences, Ob & Gyn, Tabriz, Iran

Aims

Having a clear vision during operative hysteroscopy is a very important issue. In a bloody environment with massive contents the vision is usually obscured. The aim of this study was to compare the results of operative hysteroscopy was performed in patients with active bleeding with and without uterine evacuation before the procedure.

Method

An analytic prospective study was designed to compare the intraoperative and postoperative outcomes of performing operative hysteroscopy in a population of women who referred to oncologic center of a teaching hospital in Tabriz, Iran, from Jan. 2015 to Feb. 2017. A total of 80 women with active uterine bleeding due to uterine pathology or misoprostol effect were evaluated in two equal groups either with or without (group 1 and 2) uterine evacuation before the procedure. Brightness of procedure, duration of surgery, amount of bleeding and complications were analyzed by SPSS 18.

Results

Group 1 and 2 had bright vision in 90.8% and 20.0%, respectively (p<0.001). In group 1, there was less severe bleeding than group 2 (grade I vs grade IV) (p<0.01). Mean procedure time between groups ranged between 10.2 min and 60.8 min, respectively (p<0.001). There was no significant difference between groups in post-operative complications except for hematocrit level which was lower and hospital stay was significantly higher for group 2 (p<0.01).

Conclusion

This study provided evidence that evacuation of the uterine contents before operative hysteroscopy in patients with active bleeding have a large effect on the surgical procedure. It is efficient, effective, and easy.
WHY REBRAND THE MOST SUCCESSFUL BRAND IN GYNAECOLOGY, THE PAP SMEAR?

B.C. Schmid

Royal Hospital for Women, Gynaecological Oncology, Randwick, Australia

Aims

To assess the preferred term for cervical cancer screening (“HPV test” versus a hypothetical “New Pap smear”), and what role brand perception has in women towards the brand “Pap smear” in future cervical cancer screening programs. Proportion of women preferring either “HPV test” or “New Pap smear”, and associating cervical cancer with a sexually transmitted infection (STI).

Method

Web-based survey.

Cross-sectional, non-interventional.

1473 women (769 from Australia, 704 from the Unites States).

Web-based survey, descriptive statistics.

Results

The majority (1029, 70±2%) preferred the term New Pap smear over the HPV test (444, 30±2%). 980 (67±2%) did not consider cervical cancer to be caused by a STI. Subgroup analysis did not reveal a clear relationship between test preference and association of cervical cancer with a STI. Analyses based on age or household income showed no clear correlation.

Conclusion

The “Pap smear” is an accepted and trusted term by patients in cervical cancer screening. It is essential that the transition from cytology to human papillomavirus DNA test-based cervical screening is optimized and high participation is not only maintained but improved. If we change the brand we stand to lose the trust of women which has taken decades to develop. Maintaining the brand “Pap smear” for future cervical cancer screening programs based on human papillomavirus testing will enhance participation rates and may minimize the potential negative effects of screening for a STI.
A CASE OF UTERINE RELAPSE IN A YOUNG WOMAN WITH A HISTORY OF ALL (ACUTE LYMPHOBLASTIC LEUKEMIA)

R. Schwab¹, M.J.B. Battista¹, K. Künzel¹, A. Dionysopoulou¹, V. Bake¹, A. Hasenburg¹
¹Unimedizin Mainz, Klinik und Poliklinik für Geburtshilfe und Frauengesundheit, Mainz, Germany

Aims

Autopsy studies showed an incidence of 11-50% regarding the genital tract as extramedullar site of recurrence in patients with leukemia, though cases of antemortem recognition are sparse. There is need for an early identification of genital tract involvement in relapsing ALL.

Method

A 24 year old woman with a history of B-cell ALL (acute lymphoblastic leukemia) and two previous allogenic bone marrow transplantations was referred to our department with pelvic discomfort but without vaginal bleeding or discharge.

A transvaginal ultrasound examination revealed an abnormal uterine mass resembling a myoma. Because of rising levels of LDH (lactate dehydrogenase) and without evidence of other sites of recurrence, an uterine metastasis was suspected.

To differentiate between myoma and metastasis in order to determine the optimal therapy we performed a transcervical needle biopsy.

Results

Microscopic and immunohistochemical examinations of the biopsy specimen revealed proliferation of leukemic cells. Because of the young age of the patient we preformed a salvage therapy (abdominal hysterectomy and bilateral salpingoopectomy). Histopathological processing revealed a leukemic infiltration of the myometrium but no infiltration of the ovaries.

Conclusion

Leukemic infiltration of the uterus is difficult to diagnose because of nonspecific symptoms.

Transcervical needle biopsy is an useful tool to determine the origin of an suspected uterine mass in young patients who wish to preserve fertility.
THE ANALGESIC EFFICACY OF FORCED COUGHING DURING CERVICAL PUNCH BIOPSY: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY

Y. Segev1, O. Lavie1, E. Balan2, A.T. Goldstein3, E. Siegler1
1Carmel Medical Center, Obstetrics and Gynecology, Haifa, Israel
2Carmel Medical Center, Anesthesiology, Haifa, Israel
3Schneider's Children Medical Center, Department of Pediatrics, Petah Tikva, Israel

Aims

To assess the efficacy of forced coughing as a pain-reducing technique during cervical punch biopsy compared to a control group.

Method

The study is a prospective randomized-control trial. The study group comprised 90 women who underwent cervical punch biopsies during investigation of abnormal Pap smear test results. The women were randomly assigned to "cough" and control groups. Pain was measured on a 10-cm visual analogue scale (VAS) during different stages of the procedure, and compared to assess the effect of forced coughing on pain level during biopsy.

Results

VAS pain score during biopsies was significantly lower in the "cough" group. The median pain level in the "cough" group was 1.5, compared to 4 in the control group. Eighty percent of the women in the "cough" group reported a pain level of 2 or less compared to 40% of the women in the "control" group (P = 0.0002). In the second biopsy, 69% of the women reported VAS ≤ 2 in the cough group compared to 28% of the patients in the control group. Forced coughing was shown both to reduce anxiety regarding the prospect of future cervical procedures and to decrease patients' desire for future pain management. This was true for 32% of the women in the "control" group compared to 12% of the women in the "cough" group (P=0.05).

Conclusion

Forced coughing provides significant pain relief during cervical punch biopsy and reduces the patients' fear and desire for pain medications in future procedures.
AGE ADJUSTED TREATMENT OF CERVICAL INTRAEPITHELIAL NEOPLASIA 1 (CIN 1) LESIONS BY SUPERFICIAL OR REGULAR LOOP EXCISION OF TRANSFORMATION ZONE (LLETZ)

Y. Segev¹, L. Fuchs², O. Lavie¹, L. Machulki¹, E. Siegler¹

¹Carmel Medical Center, Obstetrics and Gynecology, Haifa, Israel
²Beilinson Medical Center, Orthopedics, Petah Tikva, Israel

Aims

The dispute about Cervical Intraepithelial Neoplasia (CIN 1) disease is between opinions that it is a transient HPV infection or first step in neoplasia continuum with progression to CIN 2-3 and Cancer. The guidelines of CIN 1 are observation for 24 month, and consider ablation or excision treatment after 24 months. CIN 2-3 is diagnosed between 12-22% in women treated because CIN1 lesion. We aimed to to evaluate the correct pathological diagnosis in treatment of CIN1 lesion with LLETZ, while adjusting the cone depth to the patients’ age.

Method

A retrospective study of 329 women diagnosed with CIN 1 on a cervical biopsy and treated by LLETZ. In patients under 35 years old, a thin superficial LLETZ was performed, and in women over 35 years old a regular LLETZ was performed.

Results

The final pathological diagnosis was CIN 2-3 in 14.6% of the women. The average excision height was 0.639 cm in women under 35 years old, 0.822 cm in women 36-45 years old, and 0.962 cm in women over 46 years old (p<0.0001). When comparing excision length less than 0.8cm to excision length over 0.9cm, positive margins rates and recurrence rates were similar in both groups.

Conclusion

CIN 2- 3 was diagnosed in 14.6% of the women, and because the mean depth of excision in young women is 0.639 cm, we recommend considering LLETZ procedure which enables a correct pathological diagnosis. The excisional depth should be adjusted to age and fertility status, with minimal risk of future premature delivery.
THE IMPACT OF INTRAUTERINE DEVICES AND ORAL CONTRACEPTIVES ON COMPLICATIONS AFTER CONIZATION

M. Sobocan¹, A. Pintarić¹, D. Arko², I. Takac²

¹Faculty of Medicine- University of Maribor, Department of Obstetrics and Gynecology, Maribor, Slovenia
²University Medical Center Maribor- Ljubljanska ulica 5- 2000 Maribor, Department of Obstetrics and Gynecology, Maribor, Slovenia

Aims

Recent literature supports the impact of contraceptives (local and systemic) on the cervical canal microbiome and mucous. In relation to the findings we investigated the potential impact of combined oral contraceptives (COC) and intrauterine devices (IUDs) on postoperative bleeding, discharge and pain after conization.

Method

This cross-sectional study analyzes single center data on postoperative complications experienced by patients after conization between the years 2005 to 2015 at the University Medical Center Maribor, Slovenia. Physicians recorded at the follow up exam 4-6 weeks after conization the amount of postoperative pain, bleeding and discharge as well as type of contraception patients were using. Statistical analysis was done through descriptive data analysis and the Mann Whitney-U test using the SPSS programme.

Results

A total of 717 women were included in the study. 69 % of women (n=497) in the study were using COC, 7.8 % (n=56) were IUD users and the rest of women compromised the control group (n=164). There was a significant difference in the amount of moderate discharge between groups (p>0.029) in favor of IUDs (reducing discharge). Whilst not statistically significant, there is a tendency of IUDs also reducing perception of pain (p>0.078). Other parameters between IUD usage and COC usage were statistically insignificant.

Conclusion

IUD properties may present a positive impact on the postoperative discharge following conization. Further studies are needed to evaluate differences between hormone and gold/copper IUDs as well as larger studies on specific oral contraceptive substances.

HPV-DNA GENOTYPING IN WOMEN WITH CERVICAL INTRAEPITHELIAL NEOPLASIA UNDERGOING TO CONIZATION: COMPARISON BETWEEN CERVICAL CYTOBRUSH AND CORRESPONDING SELF-COLLECTED URINE SAMPLES

F. Sorbi1, F. Malentacchi1, C. Bussani1, G. Fantappiè1, D. Pavone1, I. Turrini1, F. Petraglia1, I. Noci1, M. Fambrini1

1University of Florence, Department of Experimental and Clinical Biomedical Sciences - Division of Obstetrics and Gynecology, Florence, Italy

Aims

To evaluate the feasibility and assess the concordance of the HPV genotyping both in cervical samples and corresponding self-collected urine by PCR-HPV specific detection kit in women with CIN in a colposcopic referral population. To correlate the genotype detection both cervical and self-collected urine sample with the grade of CIN.

Method

Design: Cross-sectional single centre study.
Patients: Women undergoing conization for CIN at cervical biopsy.
Intervention: Cervical brush and urine samples were collected before conization. A first void urine specimen was self-collected by patients and brought to the outpatient clinic. Cervical samples was collected with cytobrush. HPV genotype was assessed by Linear Array (Roche) procedure.

Results

134 patients were enrolled. HPV genotypes were detected in 81% of cervical samples and only in 57% of corresponding urine. By classifying the samples on CIN, the worse the grade of CIN the better detection of HPV was observed in both biospecimens. HPV was present in CIN1 (n= 31) in 45% and in 29% of cervical and urine samples, while the percentages raised to 92% and 66% respectively for CIN>1 (CIN2= 47 and CIN3=56). This trend was confirmed by chi-square statistical analysis in CIN1 versus CIN2 and CIN3 (p=0.006 for cervix and p=0.039 for urine). A statistically significant increase of poly-infection was observed in CIN>1 compared to CIN1 in both samples (p=0.001 cervical, p= 0.008 urine).

Conclusion

This study shows that urine can be used for HPV genotyping in CIN2+ lesions. The concordance of HPV genotype detection between cervical and urine samples depend on the grade of CIN.
DIAGNOSTICS AND PREINVASIVE DISEASE

ACCEPTABILITY OF URINE SELF-COLLECTED SAMPLES FOR CERVICAL CANCER SCREENING
F. Sorbi¹, G. Fantappié¹, D. Pavone¹, I. Turrini¹, F. Petraglia¹, I. Noci¹, M. Fambrini¹
¹University of Florence, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy

Aims

To investigate the acceptability of urine self-collection samples for cervical cancer screening

Method

Design: Cross-sectional single centre study
Patients: Women undergoing conization for CIN at cervical biopsy.
Intervention: Prior to conization, we administrated a questionnaire on acceptability of urine sampling for cervical cancer screening. The questionnaire was a validated seven item-survey developed to elucidate factors related to compliance to cervical cancer prevention program.

Results

160 patients were enrolled. The mean age of our population was 43.4 +/- SD 9.4 years (range 28-66). Level of education in our population was secondary 42.5% and tertiary 57.5%. Half of individuals reported that at least once the adherence to cervical cancer screening program with Pap test had represented a problem in their daily life. Sixty patients reported to have thought not to attend to cervical cancer screening program. Among these, 18 patients have missed at least one screening call. Given reason not to attend screening, 10 patients answered fear, 54 time needed to attend screening, 9 pain related to cervical sampling, 32 discomfort, 40 organizationals difficulties with the fixed execution date of the PAP test recommended by regional ICC screening service, 15 lack of knowledge about ICC screening program.

Conclusion

The results of our review suggest that urine self-collection method is well-accepted and may therefore encourage greater participation in cervical cancer screening programs.
SUBJECTIVE ULTRASOUND ASSESSMENT AND MULTIVARIABLE-PREDICTIVE MODELS IN DISCRIMINATING MALIGNANT FROM BENIGN OVARIAN TUMORS IN REFERRAL CENTER FOR GYNECOLOGIC ONCOLOGY

M. Stukan¹, M. Badocha²

¹Gdynia Oncology Center - Pomeranian Hospitals, Gynecologic Oncology Department, Gdynia, Poland
²Gdańsk University of Technology, Department of Probability and Biomathematics, Gdańsk, Poland

Aims

The aim was to develop a predictive model and compare it with subjective ultrasound assessment (SUA) in preoperative discriminating malignant from benign ovarian tumors, thus enabling optimal treatment planning in referral center for gynecologic oncology.

Method

A prospective, observational study on 280 consecutive patients undergoing surgery for adnexal masses (53.1% malignant) and preoperative standardized transvaginal and abdominal ultrasound examination with predefined definitions was performed. Stepwise logistic regression (SLG) with lowest possible AIC and BIC (Akaike and Bayesian information criterion) values were used to develop the model on 160 cases. On an independent group of 120 patients the model was tested and compared with SUA, risk of malignancy (RMI) and International Ovarian Tumor Analysis (IOTA) models: ADNEX, LR2.

Results

Univariate analysis revealed that age, hormonal status (HS), ascites, bilateral (BL) and multilocular lesions, solid components (SC), metastases in abdominal cavity, Doppler parameters: color score (CS), resistance (RI), pulsatility indices, peak systolic velocity, Cancer Antigen (CA) 125, platelet count and D-dimer level were significant in predicting malignancy. SLG revealed final model consisting of 6 factors (SC, BL, HS, CA125, CS, RI)-area under the receiver operator characteristic curve (AUC) 0.974. In a testing set, sensitivity, specificity and positive predictive values were 77.0%, 93.2%, 92.1% respectively. For other models – ADNEX: 81.9%, 93.2%, 92.6%; LR2: 63.9%, 96.6% (88.4-99.0), 95.1% (83.8-98.6); RMI: 77.0%, 89.8%, 88.7%; for SUA: 90.1%, 93.2% (83.8-97.3), 93.2% (83.8-97.3) respectively.

Conclusion

SUA by gynecologist oncologist has better or comparable clinical usefulness as multivariable-predictive models in discriminating malignant from benign ovarian tumors.
IS GENOTYPING OF UGT1A1 REALLY USEFUL FOR GYNECOLOGIC CANCER PATIENTS TREATED WITH IRINOTECAN-BASED CHEMOTHERAPY?

M. Takano¹, T. Yoshikawa¹, M. Morikazu², A. Tadashi², S. Hiroaki², K. Kento², I. Hirok², I. Hideki², N. Masaya², S. Takahiro², N. Takahiro², M. Hiroko², G. Tomoko², S. Hidenori², K. Yoshiihiro³, F. Kenichi²

¹National Defense Medical College, Clinical Oncology, Tokorozawa, Japan
²National Defense Medical College, Obstetrics and Gynecology, Tokorozawa, Japan
³Ohki Memorial Kikuchi Cancer Institute for Women, Gynecologic Oncology, Tokorozawa, Japan

Aims

Genotyping of UGT1A1*28 and *6 was supported by national insurances since 2008 in Japan, however, there still exists argument which patients receive the test.

Method

Medical records of gynecologic patients treated with irinotecan-based therapy between 2003 and 2015 in our hospital were reviewed. Until 2007, dose reduction of irinotecan was based on physical status or previous myelosuppression (Non-UGT group). Since 2008, doses of irinotecan were modified by choice of physicians according to UGT1A1*28/*6 genotype (UGT-group). Adverse effects at the 1st cycle were compared.

Results

217 cases were treated with irinotecan-based therapy: 59 with cervix, 30 with uterine corpus, and 128 with mullerian cancers. 109 patients underwent UGT1A1 genotyping: 66 (61%) with wild-type, 39 (35%) with hetero-type, and 5 (5%) with homo-type/double hetero-type. Irinotecan dose was modified in 25% in UGT group, and 11% in non-UGT group. In UGT group, Grade3/4 non-hematologic (17% vs. 26%, p=0.13) and Grade4 hematologic toxicities (11% vs. 19%, p=0.08) were reduced. Of note, grade4 non-hematologic toxicities were not observed in UGT-group (0% vs. 5%, p=0.02).

Conclusion

Tailor-made chemotherapy according to UGT1A1 genotyping enabled us to reduce severe toxicities in gynecologic patients treated with irinotecan. Further investigations including response rates at reduced doses are needed to facilitate UGT1A1 genotyping.
Even though the image does not contain a document, I will create a representation of the text based on the content provided.

**Partial Genotyping in Cervical Cancer Screening**

*Comparing Co-Testing with Primary HPV Partial Genotyping in Cervical Cancer Screening*

*S.K. Tay¹, L.E.A. Oon², R. Goh³*

¹Singapore General Hospital, Obstetrics and Gynecology, Singapore, Singapore
²Singapore General Hospital, Molecular Pathology, Singapore, Singapore
³Singapore General Hospital, Anatomical Pathology, Singapore, Singapore

**Aims**

To compare the detection rate of CIN2+, the number of colposcopy needed per case of CIN2+, and the number of repeat test required in 12 months between co-test and primary HPV with 16/18 genotyping.

**Method**

This is a retrospective database analysis on women above 24 years old who had undertaken both liquid-based cytology and HPV test with partial genotyping for HPV 16/18/12HRHPV (Roche, USA). Women who had a history of cervical neoplasia or being followed up for abnormal cytology were excluded. The cytology and HPV DNA test were done in two independent laboratories on split aliquots of the same sample. The two screening strategies were: (1) co-testing in which abnormal results were defined by cytology showing CIN, ASCUS with 12hrHPV positive, and HPV16 and/or 18 positive; and (2) primary HPV screening with reflex LBC for 12hrHPV positives. The clinical outcomes were detection rate of CIN2+, number of colposcopy per case of CIN2+, and the number of repeat test needed by the strategy protocol.

**Results**

The mean age of the subjects was 45.1 (95% CI 22.2-68.0) years old. Of the 4912 evaluable subjects, 28 cases of CIN2+ were detected. The number of colposcopy per case of CIN2+ and number of repeat test required was 5.7 and 231 (5.11%) respectively for co-test and 6.5 and 261 (5.3%) respectively for the primary HPV strategy. None of these clinical outcomes showed a difference between the two strategies.

**Conclusion**

Primary HPV test with 16/18 partial genotyping is preferred to co-test in cervical cancer screening.
STAGING, AGE CHARACTERISTICS AND ACCOMPANYING ILLNESSES IN PATIENTS WITH GYNECOLOGICAL CANCER

K. Tzoneva¹, G. Chakalova¹, V. Melamed¹
¹Specialized Hospital for Treatment of Oncological Diseases, Gynecologic, Sofia, Bulgaria

Aims

The aim of the study was to determine the stage, localization, age and accompanying illnesses in gynecological cancer patients.

Method

400 patients with oncogyneological cancer operated for the period 01.01.2014-27.04.2015. With malignant neoplasms of the uterus are 140 patients (92 in the I stage, 12 in the II stage, 35 in the III stage and 1 in the IV stage). With cervical cancer are 130 patients (52 in the I stage, 51 in the II stage, 25 in the III stage and 2 in the IV stage). Ovarian cancer and tube cancer are 82 patients (20 - I stage, 5 - II stage, 52 - III stage and 5 - IV stage). 48 patients with the vulva and the vagina cancer (12 in the I stages, 23 in the II stage, 12 in the III stage and 1 - IV stage). The patients are between 18 and 91 years of age (up to 30 years are 6 patients, from 31 to 50 years are 113, from 51 to 70 years are 206 and over 70 are 75). There are 94 patients with no accompanying diseases (23.5%). In 306 patients (76.5%) there are 707 accompanying diseases (Arterial hypertension - 202 patients, diabetes mellitus - 52, drug allergy - 47 obesity - 44, other - 362)

Results

The patients prevail in the first clinical stages, the most frequent localization is endometrial cancer, are over 50 years of age, the patients have more than one concomitant diseases.

Conclusion

With increasing age, the number of concomitant diseases increases.
DIAGNOSTICS AND PREINVASIVE DISEASE

INTRAEPITHELIAL VULVAR NEOPLASIA ON IMMUNOSUPPRESSED PATIENTS: CLINICAL PRESENTATION, TREATMENT AND EVOLUTION ON A RISK POPULATION

C. Villalain González1, V. Iglesias Miguel1, A. Olloqui Escalona2, Á. Diez Álvarez2, Á. Tejerizo García2, M.D.L.R. Oliver Pérez2, V. Bravo Violeta2

1Hospital Universitario 12 de octubre, Obstetrics and Gynecology, Madrid, Spain
2Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecologic Oncology and Endoscopy, Madrid, Spain

Aims

To evaluate basal characteristics and evolution of vulvar intraepithelial neoplasia (VIN) on immunocompetent (IC) and immunosuppressed (IS) patients in our setting.

Method

We evaluated 27 consecutive cases of vulvar HSIL (11 IS and 16 IC) diagnosed and treated in our Cervical Pathology Consults between 2008-2016. In our center all IS patients undergo yearly check-up on Cervical Pathology consultation with colposcopy, vaginoscopy and vulvoscopy.

Results

12.5% of IC patients had a history of HPV infection vs 91% on IS (all of which had prior conization or hysterectomy due to cervical affection). Most frequent consultation motive on IC was vulvar leucoplasia and condyloma whereas on IS diagnosis was made on routine follow-up performed on all IS patients at our center.

Mean age (standard deviation) at diagnosis on IC and IS was 59.1(6.6) vs. 41.9(2.3). Relapse was diagnosed on 25% vs. 91%, with a mean relapse free survival of 4.2(1.8) vs. 1.6(0.7) years respectively.

Initial treatment was surgical on all cases with 25% vs. 27% of occult invasion on IC and IS. On recurrences on IC imiquimod treatment was offered on 50% of cases with good results and 50% were offered surgical management with further recurrences. On IS patients they were managed with surgery except for two cases treated with laser and one with brachytherapy due to an associated VAIN lesion, both are disease free at the moment.

Conclusion

IS patients should be screened for VIN on specific consults as lesions present usually asymptomatic, earlier in life and have a higher recurrence rate.
DIAGNOSTICS AND PREINVASIVE DISEASE

PELVIC MASS ORIGINATING FROM THE RIGHT OVARY CAUSING HYDRONEPHROSIS AND IMPRESSION OF THE ILIAC VEINS - REMOVED WITH ROBOTIC-ASSISTED LAPAROSCOPY

P. Widschwendter¹, J. Wolfgang¹, D. Hoffmeister¹
¹Medical University, Obstetrics and Gynecology, Ulm, Germany

Aims

Pelvic masses causing hydronephrosis and insufficiency of the kidney is a severe complication. Early diagnosis and adequate surgery are mandatory to treat those patients.

Method

We present a 27 year old, otherwise healthy woman with unspecific pelvic pain on the right side. Sonography showed a severe hydronephrosis. Urethrocystoscopy was performed with insertion of ureteral splints. Three weeks later a scintigraphy of the kidneys showed a loss of function of the right kidney. MRI detected a cystic and solid pelvic mass, originating from the right ovary and impressing both the right iliac veins and the ureter. CA 125 was elevated, while other tumor-specific markers and several routine blood parameters were within the normal range. Differential diagnosis were endometriosis and ovarian masses as well as mesenchymal tumors.

Results

The surgery was performed by robotic-assisted laparoscopy. The pelvic mass was severely stucked on to the right pelvic side wall. Dissection started from cranial with exposing the ureter and freeing it out of the mass. The right uterosacral ligament was completely thickened and shortened. Dissection of the internal and external iliac vessels on the right pelvic side wall revealed the cystic and solid mass between the vessels. The tumor was freed to all sides and excised without injury of the vessels and the ureter. The final histological report confirmed the diagnosis of a deep infiltrating endometriotic nodule.

Conclusion

Robotic-assisted laparoscopy is save in a highly complex situs with pelvic masses causing hydronephrosis and compression of iliac veins.
LYMPH NODE RATIO AND OUTCOME IN OVARIAN CANCER – A RETROSPECTIVE SINGLE CENTER ANALYSIS

P. Widschwendter1, F. Schuh1, N. DeGregorio1, W. Janni1, T. Friedl1, C. Scholz1, E. Bauer1

1Medical University, Obstetrics and Gynecology, Ulm, Germany

Aims

Nodal stage is an important prognostic factor in ovarian cancer. However, limited data is available on the additional prognostic value of the lymph node ratio (LNR), defined as the ratio of the number of positive lymph nodes to the number of resected lymph nodes.

Method

We retrospectively analysed patients with operable ovarian cancer that underwent surgery with complete lymphadenectomy at the Department of Obstetrics and Gynaecology of the University Hospital Ulm between 2000 and 2012. The prognostic value of lymph node involvement and LNR on overall survival (OS) was analysed using Kaplan-Meier estimates and Cox regressions. Median follow up was 5 years.

Results

Of 280 patients included, 131 (46.8%) patients had positive lymph nodes (median 4, range 1 – 61). Lymph node involvement was a significant and strong prognostic factor for OS (hazard ratio [HR] 3.46, 95% confidence interval [CI] 2.39 – 5.01, p < 0.001). In patients with positive lymph nodes, a higher LNR (as continuous variable) was significantly associated with poor OS in univariate analysis (HR 2.20, 95% CI 1.13 – 4.26, p = 0.020). However, a multivariate cox regression adjusted for age, body mass index, histopathological grading, tumor histology, and residual disease showed no independent significant effect of LNR (HR 1.52, 95% CI 0.70 – 3.71, p = 0.296).

Conclusion

In patients with ovarian cancer and lymph node involvement, the LNR is discussed as a potentially useful additional prognostic factor; however, our study could not show a significant independent prognostic value of LNR with respect to OS.
THE VALUE OF NEUTROPHIL/LYMPHOCYTE RATIO, PLATELET/LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME IN THE PREDICTION OF POSITIVE SURGICAL MARGINS AFTER COLD KNIFE CONIZATION

I. Yalcin1, E. Sari1, H. Sahin1, M. Meydanli1, T. Gungor1

1Zekai Tahir Burak Women Health Care Education and Research Hospital, Gynecologic Oncology, ANKARA, Turkey

Aims

To evaluate the utility of complete blood count to predict positive surgical margins after cold knife conization.

Method

Woman who underwent cold knife conization because of biopsy - proven high-grade squamous intraepithelial lesions (HSIL) between 2009 and 2013 were retrospectively analyzed. The relation between the positive surgical margins and age, height of cone, depth of cone, diameter of cone, complete blood count parameters was assessed. Standard statistical tests were used.

Results

Out of 231 woman in total, primarily referring 63 surgical margin positive women were included as the study group (Group 1), 168 surgical margin negative women were selected as the control group (Group 2). The mean age of the patients was 41.9 years. The conization results were microinvasive carcinoma, high-grade squamous lesion (HSIL), low-grade squamous lesion (LSIL) and no residual disease for 5, 107, 36 and 20 patients, respectively. 52 women in Group 1 underwent either repeat excisional procedure or simple hysterectomy and 24 of them showed residual disease. There was no statistically significant difference in regard to neutrophil/lymphocyte ratio, platelet/lymphocyte ratio and mean platelet volume (MPV) occurred between two groups (p=0.79, p=0.86 and p=0.51 respectively).

Conclusion

Neutrophil/lymphocyte ratio, platelet/lymphocyte ratio and mean platelet volume does not seem to be useful in predicting positive surgical margins after cold knife conization.
LA VAGE OF THE UTERINE CAVITY FOR OVARIAN CANCER DIAGNOSIS: A FEASIBILITY STUDY

E. Maritschnegg¹, N. Pecha¹, F. Heitz², A. Bartakova³, F. Trillsch⁴, C. Grimm¹, R. Zeillinger¹, P. Speiser¹
¹Medical University of Vienna, Department of Obstetrics and Gynecology, Vienna, Austria
²Kliniken Essen Mitte, Department of Gynaecology and Gynaecologic Oncology, Essen, Germany
³Charles University in Prague, Department of Gynecology and Obstetrics, Pilsen, Czech Republic
⁴University Medical Center Hamburg-Eppendorf, Department of Gynecology and Gynecologic Oncology, Hamburg, Germany

Aims

75% of ovarian cancer patients are diagnosed at an advanced stage. We previously introduced a new diagnostic concept, based on a lavage of the uterine cavity to collect shed cancer cells. After the design of a new catheter specifically for this purpose we conducted a feasibility study.

Method

In the course of the study the performance of the catheter (n=93), as well as the level of pain compared to the insertion of an intrauterine device (IUD) (n=18) which was placed four weeks afterwards were evaluated. 16 gynecologists of four centers performed the uterine lavage, using four different batches of the catheter.

Results

In 92/93 cases it was possible to collect a uterine lavage sample. Dilatation had to be applied in a lower proportion of pre-menopausal, compared to post-menopausal women (p=0.0088). Insertion of the catheter was more difficult in patients with cancer, than women with benign, or no gynecological diseases (p=0.009). The discomfort experienced during the uterine lavage was rated with a median VAS score of 1.6, the insertion of an IUD with 1.0, both using local anesthesia. No participant had to use medication, developed a fever or other symptoms requiring a doctor’s visit. Both procedures took 6.5 minutes on average.

Conclusion

The results of the feasibility study show that the catheter, together with the lavage protocol represents an easy and reliable way of collecting target cells present in the uterine cavity. The procedure is well tolerated. Therefore, it carries the potential to be used as a screening tool.
ENDOMETRIAL CANCER

ESGO7-0690

HE4 IS SUPERIOR TO CA125 IN THE DETECTION OF RECURRENT DISEASE IN THE FOLLOW-UP OF HIGH RISK ENDOMETRIAL CANCER PATIENTS

K. Abbink¹, P.L.M. Zusterzeel¹, A. Geurts-Moespot², T. van Herwaarden², J.M.A. Pijnenborg¹, F.C.G.J. Sweep², L.F.A.G. Massuger¹

¹Radboud University Medical Centre, Gynecologic oncologie, Nijmegen, The Netherlands
²Radboud University Medical Centre, Laboratory Medicine, Nijmegen, The Netherlands

Aims

To date, biomarkers are not routinely used in endometrial cancer diagnosis, prognosis and follow-up. The purpose of this study was to evaluate whether serum HE4 was related to clinicopathological risk factors and outcome. Secondly, the role of serum HE4 and CA125 was assessed as indicators of recurrent disease during follow-up.

Method

156 patients with endometrial cancer were included in this retrospective study between 1999 and 2009. Serum HE4 and CA125 were analyzed at primary diagnosis, during follow-up, and at the time of recurrence. The cut-off values for HE4 and CA125 were 70 pmol/l and 35 U/Ml, respectively. Correlations with clinicopathological factors were studied in univariate and multivariate survival analyses. Lead time was calculated to determine which marker was elevated prior to the detection of recurrent disease.

Results

Serum levels of HE4 and CA125 at diagnosis were significantly associated with: high tumor grade, LVSI, lymph node involvement and advanced stage. High HE4 was an independent prognostic factor for reduced disease-free, and overall survival: HR 3.11 and 3.11, respectively. Eighty-four (31%) patients experienced a recurrence; FIGO I/II N = 20 (41%) and III/IV N = 28 (59%). At time of recurrence, 75% of the patients had an elevated HE4, whereas only 54% had an elevated CA125. Elevated HE4 preceded recurrent disease with a mean of 131 days to elevated CA125.

Conclusion

High serum HE4 was an independent risk factor for reduced DFS and OS. HE4 is superior to CA125 in the detection of recurrent disease during follow-up of high risk endometrial cancer patients.

PREDICTIVE VALUE OF THE PLASMINOGEN ACTIVATOR SYSTEM IN PATIENTS WITH ENDOMETRIAL CANCER

K. Abbink¹, F.C.G.J. Sweep², A. Geurts-Moespot², R. van der Steen², L.F.A.G. Massuger¹, P.L.M. Zusterzeel¹

¹Radboud University Medical Centre, Gynecologic oncology, Nijmegen, The Netherlands
²Radboud University Medical Centre, Laboratory Medicine, Nijmegen, The Netherlands

Aims

The plasminogen activator system (PAS) is involved in cancer invasion and metastasis of many carcinomas. The purpose of this study was to evaluate the performance of preoperative serum levels of the PAS (PAI-I, PAI-II, tPA and uPA) in the prediction of recurrent disease in endometrial cancer (EC).

Method

Preoperative sera was collected of 173 patients with a diagnosis of EC between 1999-2009. Serum concentrations PAI-I, PAI-II, tPA and uPA were assessed by an enzyme-linked immunosorbent assay (ELISA) and correlated with histopathological results. An area under the curve was performed.

Results

Fourty-eight patients (31%) had recurrent disease; FIGO I/II N = 20 (41%) and III/IV N = 28 (59%). Serum concentrations of PAI-I, PAI-II and tPA were higher in the recurrence group than in the group who remained disease free (median), 168,3 vs 77,2 ng/ml; p<0.001; 7,41 vs 4.52 ng/ml; p<0.001; and 12,6 vs 7,1 ng/ml; p<0.001, respectively. uPA levels were not significant. The area under the curve (AUC) was 0.72 for PAI-I, 0.71 for PAI-II, 0.78 for tPA and 0.51 for uPA.

Conclusion

Levels of PAI-I, PAI-II and tPA at primary diagnosis correlate with an increased risk of EC recurrence. Preoperative serum concentration of tPA seems the best predictor of recurrent disease compared to other determinants of the PAS and may have an additional value in the preoperative work-up and decision making on the treatment of EC.

ENDEOMETRIAL PATHOLOGY IN ASYMPTOMATIC WOMEN RECEIVING TAMOXIFEN FOR BREAST CANCER

A. Aboulnasr¹, I. Saad El Din², M. Salem³, G. Abdel Moety⁴, M. Elmahy⁴

¹Faculty of medicine - Cairo university, Gynecology and Obstetrics, Cairo, Egypt
²Faculty of Medicine- Cairo University, Medical Oncology, Cairo, Egypt
³Faculty of Medicine - Cairo University, Pathology, Cairo, Egypt
⁴Faculty of Medicine - Cairo University, Gynecology and Obstetrics, Cairo, Egypt

Aims

To investigate the necessity of screening for endometrial pathology in asymptomatic women receiving tamoxifen for breast cancer.

Method

121 women who received tamoxifen 20 mg/day for at least one year as an adjuvant therapy for breast cancer underwent two-dimensional Transvaginal sonography (TVS). 21 postmenopausal asymptomatic women with thin endometrial thickness < 5mm were excluded. 100 women underwent hysteroscopy and directed endometrial biopsy. 36 were symptomatic and 64 were asymptomatic based on the presence or absence of abnormal uterine bleeding.

Results

Among the 100 women who were finally analyzed, endometrial thickness was significantly higher in symptomatic (18.58 + 7.82mm) compared with asymptomatic (12.95 + 5.48mm) patients. (p < 0.001). Endometrial pathologies were diagnosed in symptomatic group (26 cases, 72.22%) as well as in asymptomatic group (32 cases, 50%) (p = 0.031). Pathologic diagnoses were 3 cases well differentiated endometrioid adenocarcinoma, 23 cases endometrial hyperplasia (4 with atypia) and 32 cases polyps (14 hyperplastic). All cases of endometrial carcinoma were symptomatic. However, 60.9% (14 cases) of hyperplasia and 56.3% (18 cases) of polyps were asymptomatic.

Conclusion

Endometrial hyperplasia and hyperplastic polyps are frequently diagnosed in asymptomatic tamoxifen receiving women. These premalignant lesions worth screening and treatment. Screening using TVS is simple, noninvasive and informative. Hysteroscopy and directed endometrial biopsy are mandatory if endometrium is thickened.

4Yas Women Hospital- Tehran University of Medical Sciences- Iran, Pathology, Tehran, Iran
5Yas Women Hospital- Tehran University of Medical Sciences- Iran, Ob/Gyn-Infertility, Tehran, Iran

Aims

A case of uterine tumor resembling ovarian sex cord tumor (UTROSCT) is presented in this paper. This is a very rare subtype of endometrial stromal sarcomas.

Method

A 30 y old nulligravid woman was referred with endometrial sampling histologically abnormal. She was obese and had past medical history of PCOD. She did undergo hysteroscopy and polypectomy four months ago. This was done following work up for infertility and a 15 mm endometrial polyp was found. Pathological examination of endometrial polyp revealed uterine tumor resembling ovarian sex cord tumor.

Uterine tumor resembling ovarian sex cord tumor, stromal sarcoma with sex cord like differentiation and endometrioid carcinoma with sertoliform differentiation were in pathological differential diagnosis.

On IHC staining Inhibin, calretinin and CD99 were positive and EMA, CK and desmin were negative. CD 10 was focally positive.

According to IHC results uterine tumor resembling ovarian sex cord tumor was the primary diagnosis.

Results

Conservative management was considered. Hysteroscopic evaluation was performed 6 months later and no pathology was found. She underwent ovarian stimulation and got pregnant. It was a normal twin dichorionic diamniotic pregnancy. At 20 weeks of pregnancy, due to premature preterm rupture of membranes, pregnancy was terminated.

The treatment schedule for this patient is hystroscopic evaluation every year to early detection of recurrent tumor.

Conclusion

According to literature review most of UTROSCT cases are treated by hysterectomy and just in few cases conservative management is considered.
ENDOMETRIAL CANCER

ESGO7-0141

ENDOMETRIAL STROMAL SARCOMA OF THE UTERUS: A CASE REPORT
G. Gonzalez

1University of Santo Tomas Hospital, Obstetrics and Gynecology, Metro Manila, Philippines

Aims

1. Present a rare case of uterine malignancy
2. Discuss endometrial stromal sarcoma, its incidence, pathology and clinical presentation
3. Review the management done in the case
4. Discuss its prognosis

Method

Adhesolysis, Bilateral salpingo-oophorectomy followed by extrafascial hysterectomy and omental biopsy

Results

A fractional curettage was done which showed Endometrial Stromal Sarcoma with extension to the endocervix. With this histopathologic diagnosis, laparotomy was done. There were multiple implants noted on the paracolic gutters, subdiaphragmatic area, posterior peritoneum, serosa of the rectosigmoid, and transverse colon. On extrafascial hysterectomy, there was an irregular nodular growth involving the endometrium with varying degrees of penetration to myometrium. Histopathologic diagnosis showed Metastatic Low Grade Endometrial Stromal Sarcoma.

Conclusion

Endometrial Stromal Sarcoma is a rare uterine tumor. A proper preoperative diagnosis is difficult and in most cases the diagnosis is confirmed after hysterectomy for a presumed benign disease. Endometrial sampling, ultrasound, magnetic resonance imaging and other diagnostic procedures can provide clues. Total abdominal hysterectomy with bilateral salpingo-oopherectomy is the main line of management. For early disease complete cure is achievable.

The case highlights the necessity for high degree of suspicion and proper preoperative diagnosis in this rare type of tumor.
HARMONISATION OF BIOBANKING STANDARDS IN ENDOMETRIAL CANCER RESEARCH (HASTEN): SURGICAL AND PATIENT DATA COLLECTION, STANDARD OPERATIVE PROCEDURE FOR TISSUE AND FLUID COLLECTION, PROCESSING AND STORAGE

M. Adishesh1, A. Fyson1, B. Decruze2, J. Kirwar2, H. Werner3, D. Hapangama1
1Institute of Translational Medicine, Women's Health Research, Liverpool, United Kingdom
2Liverpool Women's Hospital, Gynaecology, Liverpool, United Kingdom
3Haukeland University Hospital, Obstetrics and Gynaecology, Bergen, Norway

Aims

Endometrial cancer (EC) is the most common gynaecological cancer. Incidence of EC is predicted to escalate by a further 50 - 100% by 2025 with a parallel increase in associated mortality. Variations in the collection, processing and storage of bio-specimens can affect the internal and external validity and thus the generalisability of the scientific data. We aimed to harmonise the collection of bio-specimens and the associated essential clinical data relevant to EC and to develop standard operative procedures for the collection, processing and storage of EC-biospecimens.

Method

We designed EC research tools, which were evaluated and revised through three consensus rounds – to obtain local/regional, national and European consensus. Modified final tools were disseminated to a group of multi-disciplinary panel members (n=40) representing all stakeholders in EC research, and a modified Delphi technique was used to generate consensus.

Results

We devised three research tools: patient data collection tool, surgical data collection tool, biospecimen tool and a standard operating procedure. The final consensus demonstrated unanimous agreement with the minimal surgical and patient data collection tools. A high level of agreement was also observed for the standard tool.

Conclusion

We here present the final versions of the forms, which are freely available and easily accessible to all EC researchers. We believe that these tools will facilitate rapid progression in EC research; both in future collaborations and in large-scale multi-centre studies, in integrating data from various studies and finally, in uncomplicated clinical translation of new scientific discoveries for the benefit of EC patients.
Aims

Telomeres are transcribed into telomeric repeat containing RNA (TERRA). Transcriptional regulation and functions of TERRA in human cells are not well understood, yet TERRA is postulated to have a regulatory function in telomeres and telomerase activity. Endometrial cancer is a hormonally driven cancer with high telomerase activity. We examined the expression levels and hormonal regulation of TERRA in the context of endometrial cancer.

Method

The expression of 3 different TERRAs (chromosome 1, chromosome 16 and chromosome 20) and hTERC were examined with qRT-PCR in normal (proliferative, secretory, postmenopausal), endometrial hyperplasia and endometrial cancer tissue samples (total=45). The telomerase activity was assessed with TRAP assay and hormone regulation of TERRA was assessed in vitro using the endometrial cancer cell line Ishikawa.

Results

TERRA mRNA levels for chromosomes 20 were significantly lower in endometrial cancers (both endometrioid and type 2, P<0.05) and proliferating benign endometrial tissues compared with the quiescent postmenopausal endometrium and changed according to the cycle phase suggesting a hormonal regulation. Similar pattern of mRNA levels were seen with Chromosome 1 whilst the opposite was true for the Chromosome 16 TERRA and hTERC values.

Conclusion

Our preliminary data suggest a differential expression and hormone regulation of TERRA mRNA in proliferative endometrial tissue, warranting further study.
INCIDENTAL FINDING OF BENIGN METASTASIZING LEIOMYOMA WITH PULMONARY AND MULTIPLE LYMPH NODE METASTASES IN A PATIENT WITH ENDOMETRIAL CANCER

S. Akar¹, N.S. Uğraş², G. Şahin¹, A. Gül¹, Ç. Çelik¹
¹Selcuk University Medical School, Gynecologic Oncology, Konya, Turkey
²Selcuk University Medical School, Medical Pathology, Konya, Turkey

Aims

Benign metastasizing leiomyoma (BML) is a rare benign smooth muscle proliferation located outside the uterus occurring in association with uterine leiomyoma. We aim to present a unique concomitant case of endometrial cancer and BML with pulmonary and lymph node involvement. To our knowledge there are no published cases of BML occurring synchronously with endometrial cancer.

Method

50 year-old premenopausal patient with a history of three cesarean sections and asthma was diagnosed with endometrial cancer on endometrial sampling performed due to abnormal uterine bleeding. Pulmonary nodules seen on chest CT were concerning for metastases. She underwent staging surgery for endometrial cancer. Final pathology report was consistent with a diagnosis of stage IA endometrioid adenocarcinoma of the uterus and multiple foci of BML involving the resected lymph nodes.

Results

BML involvement of lymph nodes is very rare. The disease mainly affects women before menopause and those with a history of uterine surgery as in this case. Due to an increase in number of uterine surgeries in past years, the incidence of BML might be higher than before. The inductive effect of estrogen on both type I endometrial cancer and BML as well as increase in uterine surgeries such as cesarean section may increase the coexistence of both disorders. The coexistence may be more common than thought.

Conclusion

Although histologically benign, BML can be mistaken for metastases in a patient with concomitant malignancy. Clinicians and pathologists should be alert about specific features of BML to avoid misdiagnosing BML as metastases when it coexists with endometrial cancer.

ESGO7-0694

LOW GRADE NEUROENDOCRINE TUMOR OF THE ENDOMETRIUM; A CASE REPORT
S. Akar¹, C. Uğurluoğlu², G. Şahin¹, A. Gül¹, Ç. Çelik¹
¹Selçuk University Medical School, Department of Obstetrics and Gynecology- Division of Gynecologic Oncology, Konya, Turkey
²Selçuk University Medical School, Department of Medical Pathology, Konya, Turkey

Aims
Endometrium is the least common gynecologic site for neuroendocrine (NE) tumors. The aim of the case report is to present and discuss a very rare NE tumor of the endometrium. A review of literature shows 94 cases of high grade uterine NE tumors. To our knowledge, only two cases of primary and one case of metastatic low grade (carcinoid) NE tumor of the endometrium have been described. Such tumors may present with postmenopausal bleeding and may require no further treatment after hysterectomy.

Method
71 year-old woman with postmenopausal bleeding underwent endometrial sampling with a presumptive diagnosis of carcinosarcoma. Blood work-up was normal and there was no manifestation of the carcinoid syndrome. The patient underwent a total abdominal hysterectomy with bilateral salpingoopherectomy and staging surgery. Definitive diagnosis was that of a low-grade NE tumor (carcinoid) arising from a polypoid growth within the endometrium. The patient was not placed on further treatment. No signs of recurrence were seen at postoperative 23 months.

Results
To our knowledge there are two other cases of primary low grade NE tumors of the endometrium, presented in the literature. In line with these cases, the age at presentation was past 70 and the presenting symptom appears to be postmenopausal bleeding. After resection of the tumor, patients may not need further treatment.

Conclusion
The rarity of such tumors naturally poses a diagnostic challenge and the initial endometrial sample may be misdiagnosed as a more aggressive tumor. However, after a hysterectomy, surveillance may be all that is necessary.
ENDOMETRIAL CANCER

ESGO7-1096

ANALYSIS OF BCL-2, PTEN, P53 AND KI-67 EXPRESSIONS IN ENDOMETRIAL CANCER ARISING FROM ENDOMETRIAL POLYP: PRELIMINARY RESULTS

L. Atasoy¹, U.E. Kuscu², H. Akilli¹, A. Haberal³, A. Ayhan³
¹Baskent University School of Medicine, Obstetric and Gynecology, Ankara, Turkey
²Baskent University School of Medicine, Obstetric and Gynecology Division of Gynecologic Oncology, Ankara, Turkey
³Baskent University School of Medicine, Obstetric and Gynecology Division of Gynecologic Oncology, Ankara, Turkey

Aims

To compare expression of Ki-67, bcl-2, p53 and PTEN between endometrium cancer arising from endometrial polyp and benign endometrial polyps.

Method

The study was performed retrospectively on 40 patients treated at our institution between 2006-2011. Patients were postmenopausal women. The patients who have hormone replacement therapy, tamoxifen therapy, who didn't undergo full staging operation were excluded from study. Endometrial cancer arising from endometrial polyp was detected at %8 (26/323) of endometrial cancer cases. A total of 20 cases that have endometrial cancer arising from endometrial polyp that meet study criteria were included consecutively to study. For each malign case, one case that has benign endometrial polyp diagnosed at hysterectomy specimen was included to study.

Results

The Ki-67 score was significantly higher in endometrial cancer arising from endometrial polyp group in comparison to the benign polyps (p<0.05). However, the bcl-2 expression was significantly lower in the endometrial cancer arising from endometrial polyp when compared to the benign polyps (p<0.05). PTEN and p53 expressions were not different between groups (p>0.05).

In patients with endometrial cancer, Ki-67, Bcl-2, PTEN and p53 expressions were not different among histological type, stage, grade, myometrial invasion, polyp size and lymphovascular space invasion with an exception of p53. p53 expression was significantly increased in higher grade tumors (p<0.05).

Conclusion

There is an inhibition of apoptosis and a decrease in proliferation in benign endometrial polyps. Possibly, at carcinogenesis step of endometrial cancer developed from benign polyp, other additional mutations cause reverse effect and they increase proliferation and prevent the apoptosis inhibition.

REGIONAL RECURRENCE RATES OF STAGE I ENDOMETRIAL CARCINOMA PATIENTS TREATED WITH ADJUVANT BRACHYTHERAPY

1Ege University Faculty of Medicine, Radiation Oncology, IZMIR, Turkey
2Ege University Faculty of Medicine, Radiation Oncology, IZMIR, Turkey
3Onkomer Radiotherapy Center, Radiation Oncology, Izmir, Turkey
4Tepecik Education and Research Hospital, Obstetrics and Gynecology- Division of Gynecological Oncology, Izmir, Turkey
5Ege University Faculty of Medicine, Obstetrics and Gynecology- Division of Gynecological Oncology, IZMIR, Turkey
6Tepecik Education and Research Hospital, Internal Medicine- Department of Medical Oncology, Izmir, Turkey

Aims

After the publication of PORTEC 2 in 2010, there had been an increasing use of brachytherapy in stage I medium risk and HIR (high intermediate risk) patients. Our aim is to investigate the relapse patterns in stage I endometrial carcinoma patients treated with adjuvant brachytherapy.

Method

189 patients who underwent brachytherapy between January 2011 and December 2015 were retrospectively reviewed. Brachytherapy was performed with Iridium 192 source as 3x 700 cGy in 5 mm periphery of vagina.

Results

All cases were endometrioid type endometrial adenocarcinoma. Stage and grade distribution is as follows IA G3 (1.1%), IB G2 (72.5%), IB G3 (1.6%), IC G1 (5.8%) and IC G2 (19%). Within a median of 32 months (range:12-72 m) of follow-up there was no local recurrence. Five patients had regional (pelvic /paraaortic) recurrence. Operation could not be performed due to the unresectability of the recurrent tumor,besides morbidity and mortality risks of the surgery therefore chemotherapy and /or radiotherapy was administered as salvage treatment. 3-year DFS was 96%. In univariate analysis, LVI (p: 0.06), high grade tumor histopathology (p: 0.008), tumor size ≥ 5 cm (p: 0.01) and the number of dissected median pelvic lymph nodes ≤ 15 (p: 0.05) were found to be negative prognostic factors for 3-year DFS.

Conclusion

In stage I endometrial cancer patients brachytherapy is a preferred adjuvant treatment method and provides high local control rates. However in case of regional recurrence cure rates are low. Determination of further molecular prognostic factors is required to better understand the tumor biology.
ROBOTIC SENTINEL LYMPH NODE MAPPING IN EARLY ENDOMETRIAL CANCER

M.M. Naki¹, F. Alkhan¹, E. Karabuk¹, M. Gungor², M.F. Kose¹
¹Acibadem Atakent University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
²Acibadem Maslak Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

To demonstrate Step-by-step sentinel lymph node mapping in early stage endometrial cancer

Method

A 64-year-old lady presented with postmenopausal bleeding. Patient had endometrial biopsy. The histopathology was endometrioid adenocarcinoma FIGO Grade 1. Patient was planned for robotic sentinel lymph node mapping and surgical staging. For sentinel lymph node mapping 1 cc indocyanine green (ICG) applied at 3 and 9 o’clock of the cervix, after the anesthesia. Surgery started, two sentinel lymph nodes excised from bilateral internal iliac region. Then hysterectomy done. The specimens sent for frozen section. The result showed no metastasis in the sentinel lymph nodes by the myometrial invasion was more than 50%. Therefore, bilateral pelvic lymph nodes dissection done

Results

The patient was discharged on 2nd postoperative day. The final histopathology was endometrioid adenocarcinoma FIGO Grade II and myometrial invasion was 32%. No metastasis in pelvic lymph nodes were found

Conclusion

Minimal invasive surgery such robotic reduces postoperative morbidities. The sentinel lymph node mapping in endometrial cancer can prevent the complications that may be associated with complete pelvic lymph node dissection.

ESGO7-0936

SENTINEL LYMPH NODE MAPPING ALGORITHM IN ENDOMETRIAL CANCER WITH NEAR-INFRARED FLUORESCENT IMAGING AND INDOCYANINE GREEN: A VALIDATION STUDY USING LAPAROSCOPIC SYSTEM

S. Taşkin, Y.E. Şükür, D. Altin, C. Cansiz Ersöz, B. Turgay, D. Kankaya, M. Güngör, F. Ortaç

1Ankara University Faculty of Medicine, Gynecology and Obstetrics, Ankara, Turkey
2Ankara University Faculty of Medicine, Pathology, Ankara, Turkey
3Acıbadem University Faculty of Medicine, Gynecology and Obstetrics, İstanbul, Turkey

Aims

To validate and evaluate feasibility of Memorial Sloan Kettering Cancer Center –Sentinel Lymph Node Algorithm (MSK-SLN algorithm) to detect lymph node metastasis (LNM) in clinical early stages endometrial cancer by using near-infrared fluorescent imaging and indocyanine green (NIR/ICG) integrated laparoscopic system.

Method

Clinically early stages endometrial cancer patients were included in this prospective study. ICG was injected to the uterine cervix and NIR/ICG integrated laparoscopic system was used during the operations. SLN and/or suspicious lymph nodes were resected. Side specific lymphadenectomy were done when mapping was not achieved. Systematic lymphadenectomy was completed following SLN algorithm steps. External validation was performed by evaluating histopathologic results of SLN algorithm steps. Comparison of SLN algorithm steps and systematic lymphadenectomy histopathologic results were used for internal validation.

Results

Seventy-one eligible patients were analyzed. There were 8 (11.2%) patients with LNM. One of them was isolated para-aortic node metastasis. SLN algorithm was able to detect all pelvic metastases. Negative predictive value, sensitivity and falsenegative rate were 98.4%, 87.5% and 1.5%, respectively. There was non-SLN involvement in addition to SLN metastasis in approximately half of the patients with pelvic LNM.

Conclusion

All pelvic node metastases could be detected by SLN algorithm using NIR/ICG integrated laparoscopic system. SLN algorithm may be incapable to diagnose isolated para-aortic metastasis. Using the whole algorithm, instead of removing only mapped nodes, increases detection rate and decreases false negative rate. SLN algorithm for clinical early stage uterine cancer can be used more prevalently with laparoscopic systems.

9Ghent University Hospital, Gynaecologic Oncology, Ghent, Belgium
10CHR de la Citadelle, Obstetrics and Gynaecology, Liège, Belgium
11Leuven Cancer Institute, Gynaecologic Oncology, Leuven, Belgium

Aims

The EFFECT project is a multi-centric prospective observational registration project evaluating the quality and effectiveness of uterine cancer treatments in Belgium.

Method

41 quality indicators (QI) were selected based on literature and consensus of national experts. Data was collected through an online registration module (optional) developed by the Belgian Cancer Registry. All patients diagnosed with uterine cancer in the 2012-2016 period were eligible. QI descriptive statistics and funnel plots are reported here.

Results

3316 new diagnoses were registered by 58 hospitals. Median age was 69 years and main histology was endometrioid adenocarcinoma (71.7%). 98.1% of cases were discussed at a multidisciplinary team meeting (low variability between hospitals); 86.0% of surgical patients had a pre-operative biopsy (high variability, see figure QI 4); 78.4% of patients with clinical stage I underwent a TH/BSO (high variability); 52.6% of clinical stage I endometrial carcinoma patients had minimally invasive surgery (high variability). 74.4% of stage I grade III patients had lymphadenectomy (high variability). 30-day post-operative mortality was 0.4%.

Figure: Funnel plot showing the proportion of surgical patients who had a pre-operative biopsy (QI 4), showing all hospitals (dots) and Belgian average (86.0%, solid black line).
Conclusion

QoC of uterine cancer is heterogeneous in Belgium, with surgical management being particularly variable. Further analysis will assess whether QoC has improved over the study period.

LOSS OF C-MET EXPRESSION IN MALIGNANT ENDOMETRIAL TUMORS: AN IMMUNOHISTOCHEMISTRY STUDY

N. Anfinan¹
¹King Abdulaziz University Hospital, Obstetric and gynecology, Jeddah, Saudi Arabia

Aims

This study portrays the immunostaining of c-Met in endometrial neoplasms, and assesses its value as diagnostic and prognostic marker.

Method

This study retrospectively recruited 102 cases that include 72 and 30 cases of malignant and benign endometrial tissues respectively.

Tissue microarrays and immunostaining were used to show the phenotype of c-met.

Results

A total number of 13 (18.05%) tumor cases were positive for c-met immunostaining. Yallow to brown cytoplasmic and/or membranous expression of c-met was detected in 2/9 (22.2%) of papillary serous endometrial carcinomas, 9/53 (17%) of endometrioid adenocarcinomas, and one case of each endometrial stromal sarcoma and malignant mixed Mullerian tumor. Twenty three (76.6%) control cases showed positive immunostaining. c-Met immunostaining was common in the cytoplasm more than membranes in malignant tumors while it was cytoplasmic and membranous in benign tissues. Significant different c-Met immunostaining distribution was observed between tumor cases and control group (P-Value = 0.0000). Furthermore, inverse odds ratio shows that tumor cases are 14.92 times less likely of having positive c-Met immunostaining (odds ratio 0.067 with 95% confidence interval 0.024-0.189). This study did not find relation between c-Met expression and disease recurrence, survival or any of the other clinicopathological parameters in endometrial tumors.

Conclusion

This study in favor of c-Met expression is not a valuable factor for tumor development, recurrence, and survival in endometrial tumors. Greater c-Met staining was seen in normal and benign endometrial tissue compared to endometrial carcinomas. Loss of c-Met expression gives an indication for endometrial tumors.

TRANSVAGINAL ULTRASOUND-GUIDED MYOMETRIAL INJECTION OF RADIOTRACER (TUMIR) FOR SENTINEL NODE DETECTION IN ENDOMETRIAL CANCER

M. Ángeles1, M. Del Pino1, P. Paredes1, J. Pahisa1, P. Fusté1, S. Martínez1, F. Migliorelli1, S. Escura1, N. Carreras1, A. Torné1

1Hospital Clinic of Barcelona, Gynecology, Barcelona, Spain

Aims

to determine accuracy of TUMIR for sentinel lymph node (SLN) detection in endometrial cancer (EC).

Method

during 2005-2017, 132 patients with high-risk EC were prospectively recruited. Twenty-four hours before surgery, 5-8ml of 99mTc-nanocolloid (92-148MBq) were injected into two spots (anterior and posterior myometrium) using an ultrasound-guided transvaginal puncture. SLN was localized preoperatively by lymphoscintigraphy and intraoperatively with gamma probe. After SLN biopsy, patients underwent pelvic and paraaortic lymphadenectomy. Performance of technique for detection of SLN and accuracy to predict Lymph Node (LN) status were analysed.

Results

TUMIR was achieved in all patients without serious adverse effects. SLN was identified in 96/132 (72.7%) patients. Drainage location is shown in Table 1. In 88/96 (91.7%) patients, SLN was resected during surgery, with a final detection rate of 66.7%. After lymphadenectomy, LN were positive in 12/88 (13.6%) patients, with paraaortic involvement in 5/88 (5.7%) cases. From 88 patients with SLN resected, 145 SLN were obtained. Table 2 shows histological diagnosis of SLN and corresponding lymphadenectomy. Sensibility and negative predictive value of TUMIR to diagnose LN metastasis were 84.2% (IC95%: 62.4-94.5) and 97.7% (IC95%: 93.4-99.2), respectively.

Conclusion

TUMIR has good accuracy for detecting SLN in high-risk EC.
OUTCOMES OF ROBOTIC SURGERY FOR HIGH RISK ENDOMETRIAL CANCER: A MULTICENTRIC STUDY.

6Centre Olympe de Gouges CHU Bretonneau, Chirurgie gynécologique, Tours, France
7Hopital Jeanne de Flandre, Chirurgie gynécologique, Lille, France

Aims

Endometrial cancers are the most common gynecological cancers in developed countries. High risk in ESMO guidelines require complete lymph node staging. This surgery is associated with an increased morbidity. The aim of this study is to evaluate the outcomes of robot-assisted management of high risk endometrial cancers.

Method

This is a retrospective, multicenter, descriptive study including patients with high risk endometrial cancer (ESMO high risk groups) surgically treated by robot-assisted laparoscopy between January 2010 and January 2017. All patients had a total hysterectomy with bilateral salpingo-oophorectomy, pelvic and para-aortic lymph node dissections. The primary endpoint for assessing the feasibility of the procedure was the conversion rate. The secondary endpoints were the rates of intra- and postoperative complications using the CLAVIEN-DINDO classification.

Results

Sixty-seven patients were included: serous carcinoma (42%), grade 3 endometrioid adenocarcinoma (33%), clear cell carcinoma (18%), carcinosarcoma (4%), and undifferentiated carcinoma (3%). Median age was 66.3 years [56.7-76.0] and median BMI was 26.1 kg/m² [20.1-32.2]. Five patients in 67 (7.5%) had conversion to laparotomy. The average operating time was 288.5 minutes [208.9-368.1]. No intraoperative complication was noted, and 28.4% of patients had at least one postoperative complication. There was no perioperative death. The median hospital stay was 6.1 days [3.20-9.01] and the rehospitalization rate was 6% within the first 30 days. With a median follow-up was 23.5 months [4.6-42.4], the recurrence rate was 16.4%.

Conclusion

Robotic-assisted surgical management appears feasible for us due to the low conversion rate, the absence of intraoperative complication and the occurrence of minor postoperative complications.
Aims

To analyze the biopsy of sentinel lymph node (SLN) in intermediate and high risk endometrioid endometrial cancer (EC) as a method to detect nodal disease and to compare it with systematic pelvic and aortic lymphadenectomy.

Method

A series of 49 consecutive cases with diagnosis of intermediate or high risk endometrioid EC following the ESMO criteria.

We inject the indocyanine green tracer in the uterine fundus transcelvicaly and in cervix (3-9h) to cover aortic and pelvic lymphatic drainage after creation of pneumoperitoneum. Then, we identify and biopsy the fluorescent SLN with a laparoscopic optical (NIR/ICG system KARL STORZ®). Finally, we complete the aortic and pelvic lymphadenectomy.

The anatomophatological study is benefited by ultra standing of the SLN, using fine sections and the inmunohistochemistry.

Results

The overall detection rate of SLN was 95.9%, 89.8% in pelvic area and 63.3% in aortic area. In 3 cases the detection was exclusively aortic and in 16 exclusively pelvic.

We found 5 cases with metastatic lymph nodes, 4 of them the SLN was positive, nevertheless the other case was a false negative.

In the other 44 cases lymphadenectomy was negative, 38 of them with SLN negative, but we found micro-disease in 6 cases (12.2%).

Conclusion

Lymph node involvement in endometrioid EC is low, even in intermediate or high risk cases. Systematic lymphadenectomy in these patients may involve overtreatment. The SLN technique reduces the number of systematic lymphadenectomies. Moreover it permits an exhaustive histological. To minimize the rate of false negatives with a standardized technique is a challenge for the future.

Aims

The TransPORTEC consortium previously classified HR-EC into 4 molecular subtypes POLE, MSI, P53 mutated (P53m+), and no specific molecular profile (NSMP). We evaluated whether DDR biomarkers could further refine this HR-EC classification, in particular the poor prognosis NSMP and P53m+ subsets.

Method

DDR biomarkers including proteins involved in DNA damage (g-H2AX), homologous recombination (RAD51), positive or negative regulators of error-prone NHEJ (DNA-PK or FANCD2, respectively), and PARP were evaluated in 116 HR-EC by IHC using an H-score. CD8 and PD1 expression by IHC and mutation analyses were previously performed. Disease free survival (DFS) was calculated using Kaplan-Meier and Log-rank test.

Results

None of the DDR biomarkers alone were prognostic. However markers were informative within molecular subsets. Among the NSMP subset, gH2AX+ was significantly predictive of poor DFS (HR=2.56; p=0.026), and among P53m+, a DNA-PK+/FANCD2-profile (favouring error-prone NHEJ) predicted worst DFS (HR=4.95; p=0.009) resulting in 5 distinct HR-EC prognostic subgroups (DFS from best to worst: "POLE/ MSI" > "NSMP with no DNA damage" > "P53m+/NHEJ-" > "NSMP with high DNA damage" > "P53m+/NHEJ+"; p=0.0002). Actionable targets were also different among subsets. The P53m+/NHEJ- subgroup had significantly higher infiltration of PD1+ immune cells (p=0.003), segregating with POLE and MSI. The NSMP/gH2AX- had frequent PI3K pathway mutations and ER positivity. While the P53m+/NHEJ+ with the worst prognosis had high DNA damage and PARP expression providing a rationale for PARP inhibition.

Conclusion

The integration of DDR biomarkers further refined the TransPORTEC prognostic classification of HR-EC into 5 distinct subgroups and identified molecular subtype-specific therapeutic strategies.

WHY DID WE REFRAIN FROM ROBOT-ASSISTED LAPAROSCOPIC SURGERY IN ENDOMETRIAL CANCER PATIENTS?

G. Aune¹, S. Tinggaard, B. Hagen¹
¹St Olavs Hospital - Trondheim University Hospital, Department of Laboratory Medicine- Children's and Women's Health, Trondheim, Norway

Aims

To study why women with primary endometrial cancer underwent open laparotomy rather than robot-assisted laparoscopic surgery in the era of robotic surgery, and evaluate the surgical treatment.

Method

A retrospective study, including all women undergoing surgery for endometrial cancer from November 2012 through December 2015 at St.Olavs Hospital, a referral teaching hospital in Norway. Data were extracted from patient records.

Results

239 cases were identified. 137 (57%) underwent robot-assisted laparoscopic operation and 102 (43%) underwent open laparotomy. Suspected advanced disease was the most common reason for laparotomy (31%), followed by concomitant ovarian tumor (21%), large uterus (17%), and comorbidity (14%). Less frequent causes were previous pelvic/abdominal cancer (2%), planned concomitant gastrointestinal surgery (2%), lack of robotic capacity (2%), and previous abdominal surgery (1%). Six cases planned for robot-assisted surgery were converted to open operation, due to anesthesia complications or surgical challenges.

There was no difference in BMI or age between the laparotomy and robot-assisted laparoscopy group (median BMI 30 and 27, respectively, p=0.21, median age 67 years in both groups, p=0.32). The laparotomy group had more advanced stage disease (p=0.002). Lymph nodes were removed in 72% of laparotomy cases, and 93% of robotic cases (p<0.001). Number of nodes removed was significantly higher in the laparotomy group (median 12 vs 6 lymph nodes, p<0.001). The lymph node metastatic rate was 18% in the laparotomy group, compared to 12% in the robotic group (p=0.059).

Conclusion

Advanced stage disease was the main reason for laparotomy instead of robot-assisted laparoscopic operation.
A NOMOGRAM FOR DECISION MAKING OF COMPLETION SURGERY IN ENDOMETRIAL CANCER

S. Bozkurt¹, T. Toptas², H. Ayik Aydin³, T. Simsek³, Y. Yavuz⁴

¹Akdeniz University School of Medicine, Department of Biostatistics and Medical Informatics, Antalya, Turkey
²Antalya Research and Training Hospital, Department of Gynaecological Oncological Surgery, Antalya, Turkey
³Akdeniz University School of Medicine, Department of Gynaecological Oncological Surgery, Antalya, Turkey
⁴Ankara University School of Medicine, Department of Biostatistics, Ankara, Turkey

Aims

To develop a nomogram for decision making of completion surgery based on pathologic characteristics of the hysterectomy specimen in endometrial cancer (EC) patients treated with hysterectomy alone.

Method

Analyses were performed on the dataset of 336 patients. Age, grade, depth of myometrial invasion, lymphovascular space involvement, cervical involvement, positive peritoneal cytology, and histotype were assigned as potential covariates. To investigate associations between covariates and extrauterine disease, logistic regression analyses were performed. Several models were evaluated, and finally, three different models were developed. Accuracies of the models were internally validated in terms of their discrimination, calibration and overall performance. One of the models was selected, its clinical usefulness was quantified by decision curve analysis (DCA), and presented as a nomogram.

Results

Of the patients 67 (19.9%) had extrauterine disease. Performance values of the nomogram were as follows: area under the receiver operating characteristics curve, 0.870 (P<0.001); calibration slope β, 1.0; and Brier score, 0.101. Ten-fold cross-validation revealed a sensitivity of 50.7%, specificity of 95.5%, and positive predictive value of 73.9%. DCA revealed that a reasonable threshold probability for the presence of extrauterine disease that would indicate a completion surgery would be 2%. This cut-off value provided a net benefit of 18 true-positive results per 100 patients without an increase in the number of false-positive results. As compared with “treat all” strategy, it led to 10% fewer surgeries.
### Conclusion

Estimation of extrauterine disease and decision making for completion of surgery is possible with high predictive performance using a nomogram involving primary tumor characteristics.
TRANFORMATION OF ENDOMETRIOSIS INTO UTERINE CARCINSARCOMA IN POSTMENOPAUSAL WOMEN: A CASE REPORT

A. Babayeva1, J.A. Salau1, C. Giansiracusa1, Z. Kollmann2, Z. Halwani1
1Vivantes Humboldt Clinic, Gynecology and Obstetrics, Berlin, Germany
2Spital Zollikerberg, Frauen - Permanence Zürich, Zürich, Switzerland

Aims

Low-grade endometrial carcinosarcoma is very rare malignant tumor of the uterus with a poor prognosis.

Method

A 54 year old woman was referred to our Endometriosis center for interdisciplinary treatment of retroperitoneal tumor mass. Our patient underwent in 2004 abdominal hysterectomy and bilateral adnectomy by uterus myomatosus and fibroma of the left ovary, no malignancy. In December 2016 by upper abdominal pain, diagnostic surgery was performed in an outside institution. The obtained biopsy samples from vaginal stump were evaluated as fibromuscular tissue with elements of extragenital endometriosis. Afterwards, the old tissue from 2004 was reassessed and endometriosis focuses were exposed. The external CT images demonstrated 12 cm retroperitoneal tumor in upper abdomen with liver displacement and additionally, one solid tumor on left side of vaginal stump intraabdominal. Furthermore, we registered elevated serum markers of CA 125 539,4 kU/l. After these findings the explorative laparotomy and completion surgery was indicated.

Results

We have achieved macroscopic tumor clearance using multivisceral approach in right upper abdomen. After several inspection of samples, the final diagnosis was low-grade endometrial mixed Müllerian tumor. As treatment options we applied arimidex in off-label use for 3 months in combination with Vitamin D and bisphosphonate. One month later after treatment patient came with reduced tumor markers and tumor sizes in the vaginal stump from 7 to 2 cm in lower abdomen.

Conclusion

In this case we observed a 13 year transformation of endometriosis into neoplasms, emphasizing the necessity of improvement the tumor detectors such as biomarkers for the earlier recognition of carcinosarcomas.
THE EFFECTIVENESS OF DEBULKING SURGERY IN ADVANCED STAGE ENDOMETRIAL CANCER

I. Balescu\textsuperscript{1}, N. Bacalbasa\textsuperscript{2}
\textsuperscript{1}Ponderas Academic Hospital, Visceral Surgery, Bucharest, Romania
\textsuperscript{2}Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania

Aims

To demonstrate the effectiveness of debulking surgery for advanced stage endometrial cancer.

Method

We present a case series of three patients presenting disseminated lesions with endometrial origin in which the principles of debulking surgery were successfully applied.

Results

The mean age was 59 years and all patients presented disseminated lesions at the time of diagnostic. All patients were submitted to a total radical hysterectomy with bilateral adnexectomy, pelvic and para-aortic lymph node dissection. Other associated resections consisted in pelvic and bilateral peritonectomy in two cases, diaphragmatic peritonectomy in one case, total colectomy in two cases, sigmoidectomy in one case, atypical liver resection in one case and partial cystectomy in one case (Figures 1, 2) .

At one year follow up no sign of recurrent disease was found.

Conclusion

Debulking surgery for endometrial cancer is effective and might improve the long term outcomes.
ENDOMETRIAL CANCER

ESGO7-0786

TRANSVAGINAL ULTRASOUND EXAMINATION FOR PREOPERATIVE IDENTIFICATION OF HIGH-RISK ENDOMETRIAL CANCER: A PRELIMINARY EXPERIENCE.

C. Baima Poma¹, I. Cotrino¹, M. Ribotta², P. Zola³, E. Viora¹

¹A.O. Citta della Salute e della Scienza di Torino, Department of obstetric and gynecological ultrasound and prenatal diagnosis, Turin, Italy
²A.O. Citta della Salute e della Scienza di Torino, Department of histopathological anatomy, Turin, Italy
³A.O. Citta della Salute e della Scienza di Torino, Depart surgical sciences University, Turin, Italy

Aims

To evaluate the agreement between ultrasound evaluation performed by young examiners and definitive histology in identifying women with high risk of endometrial cancer.

Method

This was a single-center prospective observational cohort study from 2016 April to 2017 March comprising a consecutive series of women with a preoperative diagnosis of endometrial cancer with different histotypes. All women underwent transvaginal ultrasound examination by a two young examiners. According to the examiner's subjective impression, patients were considered high risk if myometrial infiltration was ≥ 50% and/or involvement of the cervix. According to definitive histological data women were classified as low risk (no myometrial infiltration, no cervical involvement) or high risk (myometrial infiltration ≥50% and/or cervical involvement). Sensitivity, specificity, PPV and NPV with 95% CIs, of transvaginal ultrasound for detecting stage >IB were calculated. Agreement between risk determined by transvaginal ultrasound and postoperative definitive histology was calculated.

Results

57 women were enrolled, 43 were included. Sensitivity, specificity, PPV and NPV of transvaginal ultrasound evaluating myometrial infiltration were 65.0% (95% CI, 44.0-85.9%), 60.8% (95% CI, 29.4-92.2%), 59% (95% CI, 49-69%) and 66.7% (95%CI, 57-67%), and cervical involvement were 60.0% (95% CI, 17-93%), 97.3% (95% CI, 95-99%), 75% (95% CI, 54-96%) and 94.8% (95%CI, 91.8-97.8%).

Conclusion

Preoperative transvaginal ultrasound may play an important role in identifying high-risk cases in young examiners’ hands, especially in detection of cervical involvement. The accuracy of ultrasound is reduced in cases of special histotypes (clear cell or mixed mullerian), miometrial pathology (adenomysis or myoma) or previous uterine surgery (D&C).
Aims

Correlate the size of metastatic sentinel node (SLN) with the risk of non-sentinel node (N-SLN) metastasis in endometrial cancer.

Method

We analyzed a series of 195 patients treated at AC Camargo Cancer Center from January 2013 to April 2017 that had SLN mapping with cervical injection of only blue dye (n=184) or indocyanine green (n=11). Eight-six (44.1%) patients had high-risk tumors (endometrioid grade 3, serous, clear cell, carcinosarcomas, deep myometrial invasion or lymphovascular space invasion). The SLNs were examined by immunohistochemistry when the hematoxylin-eosin was negative.

Results

The overall SLN detection rate was 85.6%, and bilateral of 60%. Median SLN detected was 2 per patient (range, 1-8). In low risk cases, there were only 2 (1.8%) patients with positive SLN – both with micrometastasis detected by immunohistochemistry (IHC). For high-risk group, there were 22 (25.6%) positive SLN cases. Five (5.8%) ITC, 7 (8.1%) micrometastasis, and 10 (11.6%) macrometastasis. 9/22 (40.9%) SLN metastasis was found only by IHC. Of the 24 patients with positive SLN, the median number of positive SLN was 1.5 (range, 1-8). Six (6/24, 25%) had positive N-SLN, with a median of 7 (range, 3-23) positive N-SLN. Regarding the size of SLN metastasis, presence of N-SLN were found in any (0/5) patient with ITC, 11% (1/9) with micrometastasis and in 50% (5/10) of patients with macrometastasis.

Conclusion

Our data suggest that size of metastasis in SLN correlates with the risk of N-SLN metastasis. Any patient with ITC in SLN had other metastatic lymph node.
ENDOMETRIAL CANCER

ESGO7-1158

SENTINEL NODE MAPPING AS AN ACCURATE TECHNIQUE FOR NODE STAGING IN ENDOMETRIAL CANCER: A BRAZILIAN CANCER CENTER EXPERIENCE

G. Baiocchi*, H. Mantoan², L. Kumaga², L. Badiglian-Filho², C. Faloppa², L. De Brot³, A. ¹

¹AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
²Gynecologic Oncology, Brazil
³Pathology, Brazil

Aims

To determine the detection rate, sensitivity and predictive negative value of SLN for low and high-risk endometrial cancer (endometrioid grade 3, serous, clear cell, carcinosarcomas, deep myometrial invasion or lymphovascular space invasion).

Method

We analyzed a series of 195 patients treated at AC Camargo Cancer Center from January 2013 to April 2017 that had SLN mapping with cervical injection of blue dye (n=184) or indocyanine green (n=11). Eight-six (44.1%) patients had high-risk and 109(55.9%) low-risk tumors.

Results

Sixty-two (31.8%) patients had pelvic lymph node dissection (LND), 65 (33.3%) pelvic+para-aortic LND, and 68(34.9%) had only SLN. The overall SLN detection rate was 85.6%, and bilateral of 60%. Median SLN detected was 2 per patient (range,1-8). In low risk cases, there were only 2 (1.8%) patients with positive SLN – both with micrometastasis detected by immunohistochemistry (IHC). For high-risk group, there were 22(25.6%) positive SLN cases. Five(5.8%) ITC, 7 (8.1%) micrometastasis, and 10 (11.6%) macrometastasis. 9/22(40.9%) SLN metastasis was found only by IHC. Only 2 patients had false negative SLN, with ipsilateral pelvic non-sentinel positive nodes. Of 164 patients with endometrioid histology, 17(11.3%) had positive SLN, and 8(47.1%) cases were found only after IHQ. We found an overall sensitivity was 92.3%, negative predictive value 98.6%, and false negative rate 7.6% (2/26).

Conclusion

Our data suggest SLN mapping as a safe and accurate technique for endometrial staging that increases metastatic nodal detection rates by 5.6% after IHC. In endometrioid tumors, 4.8% patients had nodal metastasis detected after IHC that clearly impacts the indication of adjuvant chemotherapy.
ENDOMETRIAL CANCER

DOES SENTINEL NODE MAPPING IMPACT THE PREVALENCE OF ISOLATED PARA-AORTIC NODAL METASTASES IN ENDOMETRIAL CANCER?

G. Baiocchi1, H. Mantoan2, L. Kumaga2, L. Badiglian-Filho2, C. Faloppa2, L. De Brot3, A. Da Costa4

1AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
2, Brazil
3 Pathology, Brazil
4 Sao Paulo, Brazil

Aims

To determine the impact of sentinel node (SLN) mapping in staging high-risk endometrial cancer (grade 3 endometrioid, serous, clear cell, carcinosarcomas, deep myometrial invasion, or angiolymphatic invasion).

Method

Eighty-three patients that had SLN mapping with blue dye cervical injection (SLN group) and pelvic ± para-aortic lymph node (LN) dissection from June 2007 to June 2015, were compared to 142 patients that received pelvic + para-aortic lymph node dissection (LND group) from June 2007 to June 2015. Patients with adnexal, peritoneal or suspicious LN metastasis were excluded.

Results

SLN group patients had more minimally invasive surgeries (71.1% vs. 3.5% years;p<0.001), and more presence of angiolymphatic invasion (42.1% vs. 14.8%;p<0.001). There was no difference between SLN and LND groups regarding deep myometrial invasion (55.4% vs. 63.4%;p=0.23), and presence of non-endometrioid histologies (34.9% vs. 29.6%). The overall detection rate for SLN group was 86.7% and bilateral in 61.4% of cases. Eight in 19 (41%) positive SLN were detected only after immunohistochemistry. SLN group had more pelvic LN (PLN) metastasis detected compared to LND group (25.3% vs. 12.7%; p=0.016). However no difference were found regarding para-aortic LN (PALN) metastasis between SLN and LND groups (8.6% vs. 5.6%; p=0.38). In LND group, 5 (3.5%) patients had PALN without PLN. Conversely, in SLN group, 1 (1.2%) patient had isolated PALN. Although included in the SLN group, this patient had no SLN detected.

Conclusion

Our data suggest that SLN mapping identified more PLN metastasis compared to only LN dissection. Furthermore, we found no isolated PALN metastasis when SLN was detected.

USE OF A NEW INSTRUMENT IN THE MANAGEMENT OF TOTAL LAPAROSCOPIC RADICAL HYSTERECTOMY (TLRH)

F. Barletta¹, G. Corrado², E. Vizza³
¹Azienda Ospedaliera San Giovanni Addolorata, Department of Gynecology, Rome, Italy
²Policlinico Gemelli Catholic University of Rome, Gynecologic Oncology unit, Rome, Italy
³IFO National Cancer Institute Regina Elena, Gynecologic Oncology, Rome, Italy

Aims

Evaluating safety and efficacy of a modified tenaculum called SNAIL (Simple Nebs Arising Incision Landmark) for gynecological oncologic surgery.

Method

This invention origins by a reusable instrument named Uterine Tenaculum Forceps, model Schroder of Martin catalogue. This tenaculum is modified adding four nebs 1-2 cm from the tips of the instrument, two for each main branch of the tenaculum. The nebs are 1 cm each and widen with a 90 degrees angle between them. They can be perpendicular to main axis of instrument or forming with latter 45-60 degrees angle bent forward. In order to preserve the pneumoperitoneum during colpotomy a simple iodine gauze with gloves are placed in vagina.

Results

We used SNAIL Tenaculum in 32 patients for early endometrial and cervical cancer. During the procedure the nebs were always under vision also in obese patients. The average length of circular vagina removed with the uterus was 21 mm (range 10-40). None intraoperative complication were registered.

Conclusion

Risk of perforation, lympho-vascular spaces involvement (LVSi) and positive peritoneal cytology by uterine manipulation is still debated. We found SNAIL tenaculum to be a safe and efficient tool for TLRH since it eliminates risks of perforation, LVSi and positivization of peritoneal cytology, maintaining same chances of uterine mobility. Also the nebs allow surgeon to choose length of vaginal wall to remove modulating, proximally or distally, the incision line. Last must be said SNAIL tenaculum combines the ease of use of a familiar instrument to gynecologists, with the lowest cost so far recorded.
TOTAL LAPAROSCOPIC HYSTERECTOMY VERSUS LAPAROSCOPIC-ASSISTED VAGINAL HYSTERECTOMY FOR THE MANAGEMENT OF ENDOMETRIAL CANCER

A. Urbute¹, E. Bartusevičienė², M. Gedgaudaitė², A. Bartusevičius²
¹Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania
²Lithuanian University of Health Sciences, Department of Obstetrics and Gynaecology, Kaunas, Lithuania

Aims

To analyse characteristics and outcomes of laparoscopic surgeries (laparoscopic-assisted vaginal hysterectomy (LAVH) and total laparoscopic hysterectomy (TLH)) due to a change of guidelines for treatment of endometrial cancer.

Method

A retrospective cohort study. The participants: women operated for endometrial cancer by laparoscopy in Lithuanian University of Health Sciences in 2012 and 2016. In 2012 there were 26 patients operated by TLH and 55 by LAVH, in 2016 - 79 operated by TLH and 16 by LAVH. Outcomes evaluated: duration of surgery, lymph node resection, hospital stay, intraoperative and postoperative complications. One-way ANOVA was performed to compare continuous variables and χ² tests to compare categorical variables, data was considered statistically significant if p<0.05.

Results

Significantly, in 2012 LAVH was performed more often than TLH (67.9% vs. 32.1%), vice versa in 2016 (16.7% vs. 83.3%). Hospital stay was different between years (average 8.4 and 5.8 days in 2012 and 2016 respectively, p=0.01), while duration of surgery and lymph node resection did not. The type of surgery had no significant effect on duration of surgery F(1,173)=1.548 (p=0.22), number of lymph nodes F(1,81)=0.159 (p=0.69) and hospital stay F(1,172)=0.357 (p=0.55) in both years. Intraoperative (2.8%) and postoperative (7.9%) complication rate did not depend on type of laparoscopy. Postoperative complication rate was higher in 2012 than 2016 (13.6% and 3.1%, p=0.01).

Conclusion

After laparoscopic approach in 2016 hospital stays were shorter and less postoperative complications occurred possibly due to improved surgical skills. The characteristics and safety of TLH and LAVH did not differ.
CHANGES OF THE THERAPEUTIC APPROACHES FOR ENDOMETRIAL CANCER PATIENTS IN GERMANY SINCE 2006

M.J. Battista¹, V. Schanz¹, M. Schmidt¹, S. Krajnak¹, T. Elger¹, A.S. Heimes¹, S. Maurer¹, E. Steiner², M. Eichbaum³, P. Mallmann⁴, A. Hasenburg¹

¹University Medical Center of the Johannes Gutenberg University of Mainz, Department of Obstetrics and Gynaecology, Mainz, Germany
²GP Rüsselsheim, Department of Obstetrics and Gynaecology, Rüsselsheim, Germany
³Horst-Schmidt-Kliniken Wiesbaden, Department of Obstetrics and Gynaecology, Wiesbaden, Germany
⁴University Medical Center Cologne, Department of Obstetrics and Gynaecology, Köln, Germany

Aims

The Arbeitsgemeinschaft Gynäkologische Onkologie has been describing the therapeutic approaches for endometrial cancer patients in Germany since 2006.

Method

In 2006, 2009, 2013 and 2015 a questionnaire was sent to all German gynecological departments. The results were compared to each other using the chi-square test.

Results

868 questionnaires were analyzed. 35.8%, 33.3%, 40.0% and 24.2% of the invited departments participated in 2006, 2009, 2013 and 2015, respectively. Since 2006 the pelvic and paraaortic lymphadenectomy have been less often performed in the low-risk stage pT1aG2 (38.6%, 22.9%, 16.3%, 10.0%, p<0.001 and 16.0%, 10.7%, 6.3%, 4.5%, p<0.001, respectively). However, the pelvic and paraaortic lymphadenectomy have been increasingly performed in the intermediate-risk stage pT1aG3 (88.0%, 93.9%, 98.0%, p<0.001 and 49.0%, 65.6%, 88.7%, 86.7%, p<0.001, respectively). During 2009 and 2015 vaginal brachytherapy has been rarely recommended in the low-risk stage FIGO IA G2 (16.0%, 13.3%, 14.0%, p=0.666, respectively). However, vaginal brachytherapy has been more often recommended in intermediate-risk stage FIGO IA G3 since 2009 (79.2%, 87.8%, 93.9%, p<0.001, respectively). During 2009 and 2015 external beam radiotherapy has been constantly recommended in stage FIGO II (53.5%, 49.2%, 56.6%, p=0.367, respectively) and in stage FIGO III (83.3%, 76.8%, 81.5%, p=0.194, respectively). Adjuvant chemotherapy has been increasingly offered since 2006 (48.8%, 63.7%, 90.4%, 97.3%, p<0.001, respectively). A combination of platinum and taxane was the preferred regime in 2015.

Conclusion

The detected changes in the therapeutic approaches of endometrial cancer patients in Germany reflect the alterations of the available literature during 2006 and 2015.
ENDOMETRIAL CANCER

PREOPERATIVE BIOPSY IS A POSSIBLE MISLEADING TOOL IN OMITTING LYMPH NODE ASSESSMENT IN ENDOMETRIAL CANCER

M. Beiner¹, H. Amichay Chariski¹, T. Perri¹, N. Lavee¹, S. Kalton¹, L. Helpman¹, B. Brandt¹, G. Ben-Baruch¹, J. Korach¹

¹Sheba Medical Center, Department of Gynecologic Oncology, Ramat Gan, Israel

Aims

The necessity of lymph node assessment in endometrial cancer has been a topic of controversy for many years. Some tend to omit lymph-nodes assessment in low risk cases relying on tumor grade on preoperative biopsy. However, when a discrepancy is found between the grade at preoperative biopsy and grade at final histology, the decision is challenged. Our objective was to determine the correspondence between preoperative grade and the hysterectomy specimen grade in patients with preoperative diagnosis of grade 1 (G1) Endometrioid endometrial cancer and to assess the rate of lymph-nodes metastasis in these patients.

Method

A retrospective cohort study of 577 patients treated for endometrial cancer at our Gynecologic-Oncology department between 1999 and 2013. As a policy we performed lymph-nodes dissection in all endometrial cancer cases.

Results

Of the 205 patients with G1 Endometrioid adenocarcinoma on preoperative biopsies, the surgical pathology report confirmed the diagnosis in 107 (52%), whereas 76 (37%) were upgraded to G2, 6 (2.9%) to G3 and 4 (1.9%) to Non-Endometrioid High-Grade tumors. Twelve (5.8%) patients had no residual malignancy. Ninety percent (185/205) of the pre-op G1 patients had lymph-nodes dissection, of them 10 (5.4%) had pelvic lymph-nodes metastases.

Conclusion

When deciding whether to assess lymph-nodes in Endometrioid adenocarcinoma based on pre-op grade, one should consider the high rate of upgrading on final histology and the considerable option to miss lymph-nodes metastasis.

CONTRIBUTION OF MAGNETIC RESONANCE IMAGING FOR PRE-OPERATIVE ASSESSMENT OF MYOMETRIAL AND CERVICAL INVASION AND PELVIC LYMPH NODE IN ENDOMETRIAL CARCINOMA

I. Ben Safta, O. Jaidane, H. Mansouri, S. Gadria, J. Ben Hassouna, K. Rahal

1Institut Salah azeiz of oncology, surgical oncology, TUNIS, Tunisia

Aims

To evaluate the accuracy of preoperative magnetic resonance imaging (MRI) to detect deep myometrial invasion, cervical extension and pelvic lymph node metastasis in patients with endometrial cancer.

Method

We retrospectively reviewed 42 cases of women with endometrial cancer, who underwent preoperative MRI assessment and surgical staging between January 2000 and December 2015. The MRI findings were then compared with the post-operative histopathological findings that served as reference standards.

Results

The sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of MRI for differentiation between superficial myometrial invasion and deep myometrial invasion were 86.6%, 40.9%, 50% and 81% respectively. The sensitivity, specificity, PPV and NPV were 60%, 96.2%, 90% and 81.25% for cervical invasion and 70%, 84.37%, 58.3 and 90% for pelvic lymph node metastasis, respectively. There were significant correlation between preoperative FIGO-MRI staging and FIGO-histological staging (p=0.047).

Conclusion

In patients with endometrial cancer, a preoperative MRI contributes to accurate staging, allowing planning for the scale of surgery and preoperative counseling.

FDG PET/CT AS PROGNOSTIC TOOL IN THE PREOPERATIVE STAGING OF ENDEMOTRIAL CANCER
A. Bergamini1, P. Mapelli2, F. Fallanca3, D. Ferrari4, E. Incerti2, F. Pella4, P.M.V. Rancoita5, E.G. Rossi4, M. Picchio6
1San Raffaele Hospital, Obstetric and Gynecology, Milan, Italy
2IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy
3IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy
4IRCCS San Raffaele Scientific Institute, Department of Obstetrics and Gynecology, Milan, Italy
5Vita-Salute San Raffaele University, University Centre of Statistics in the Biomedical Sciences, Milan, Italy
6IRCCS San Raffaele Scientific Institute, IRCCS San Raffaele Scientific Institute, Milan, Italy

Aims

To investigate the prognostic role of FDG PET/CT in the preoperative assessment of patients with endometrial carcinoma (EC)

Method

18F-FDG PET/CT was performed in 57 patients for EC preoperative staging. Maximum and mean standardized uptake values (SUVmax, mean), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of primary tumours, at different thresholds of 40%, 50%, 60% were compared with histopathological features. The diagnostic performance of PET parameters in discriminating low-risk disease from high-risk disease have been assessed.

Results

Categorized TLG40-50-60 were related to FIGO stage I versus FIGO Stage II-III-IV (P=0.003); the optimal cut-off values for risk stratification were 83.69, 61.81 and 41.32, respectively, with correspondent sensitivity and specificity of 60.00% and 71.43%. Categorized TLG40-50 were related to TNM stage with thresholds of 99.55 (P=0.03) and 77.58 (P=0.02), respectively. Categorized SUVmax, SUVmean40-50-60 and MTV40-50-60 were not related to FIGO stage. Categorized SUVmax and SUVmean40-50-60 could discriminate between endometrioid vs non endometrioid subtype with 14.35, 8.55, 9.8 and 10.9 threshold (P=0.01) for SUVmax and SUVmean50-60, P=0.0237 for SUVmean40). Correspondent sensitivity was 64.86% and 62.16% for SUVmax and SUVmean50-60 and 62.16% for SUVmean40; specificity was 70.00%. The mean OS rate was 79.77±3.34 and the mean DFS rate was 77.89±3.73. Tumour type was the only variable significantly associated with OS and TLG50 was the only variable significantly associated with DFS; specifically, TLG50>77.58 cc is associated with a higher risk of relapse according to logrank test.

Conclusion

TLG40-50-60 of primary EC can predict FIGO staging; TLG40-50 can predict pathological staging. These parameters, being able to discriminating between low and high risk disease, may be useful in the preoperative assessment of EC.

LONG-TERM COMPLICATIONS OF LYMPH NODE DISSECTION IN ENDOMETRIAL CANCER SURGERY

L. Volpi1, G. Sozzi1, V. Capozzi1, V. Cenì1, M. Pugliese1, C. Carrera1, A. Cianciolo1, G. Gambino1, M. Di Serio1, R. Berretta1

1Azienda Ospedaliero Universitaria, OB Gyn unit, Parma, Italy

Aims

To investigated the incidence and the potential causes of lymphadenectomy’s complications in primary surgery for endometrial cancer.

Method

Observational study in a tertiary care centre between January 2007 and March 2014. All women who underwent to pelvic and/or paraaortic lymphadenectomy for endometrial cancer were analyzed. Each patients were compared by age, comorbidity, cancer stage, BMI, surgical approach, number of resected pelvic and/or para-aortic lymph nodes and use of intraoperative devices.

Results

Of the 428 patients tested. 238 underwent to pelvic lymphadenectomy (55,6%), 36 (15,1%) of those underwent both pelvic and paraaortic lymphadenectomy. Among the 238 patients, a total of 38 (16%) developed lower-limb-lymphedema, while 10 of 238 (4,2%) lymphocele, 1 of 238 developed neurological complication due to nerve injury, none vessel injury.

The number of resected lymph nodes was found to be higher in patients with lymphedema and lymphoceles. To detect the independent developmental risk factors for lymphatic complications, we performed multivariate analysis with logistic regression for four variables (stage disease, intraoperative-haemostatic-devices, abdominal drains and number of dissected lymph nodes). Among these, we found a significant difference for only number of dissected lymph nodes.

Conclusion

lymphadenectomy continues to be an important part of the surgical staging for endometrial cancer as it can identify important prognostic information that may alter treatment decisions. Currently, it has been introduced the sentinel-lymph-node-mapping (SLNM) in endometrial cancer staging. This procedure upholds the effectiveness of standard lymphadenectomy allowing identifying node positive patients, minimizing the risk of lymphadenectomy-related morbidity.

THE PREDICTION OF MYOMETRIAL INFILTRATION BY TWO-DIMENSIONAL TRANSVAGINAL ULTRASONOGRAPHY IN PATIENTS WITH ENDOMETRIAL CARCINOMA.
V. Capozzi1, L. Volpi1, G. Sozzi1, V. Ceni1, M. Pugliese1, C. Carrera1, A. Cianciolo1, G. Gambino1, S. Cardinale1, M. Monica1, R. Berretta1, M. Rolla1
1Azienda Ospedaliero Universitaria, OB Gyn unit, Parma, Italy

Aims

to predict the myometrial infiltration in patients with diagnosed endometrial cancer with two-dimensional (2D) ultrasonography by a previously described technique.

Method

retrospective study that involved 298 patients with endometrial cancer stage I (FIGO 2009) who underwent surgery in our U.D. between January 2001 and December 2015. The miometrial infiltration has been assessed by 2D ultrasound following Karlsson's criteria: in a sagittal plane of the uterus a ratio between maximal anterior-posterior diameter of the endometrial lesion and the uterine anterior-posterior diameter over 50% classifies the endometrial lesion as deep infiltrating (M2); ratio less than 50% stands for a not infiltrating cancer (M1). The pathological data were used as the reference standard of the study.

Results

the ultrasound investigation based on Karlsson's criteria permitted to correctly predict miometrial infiltration in 251 cases (concordance of 84%, Cohen's K 0.65, p<0.001) of which 171 (57%) were M1 lesions, 80 (27%) were M2. 19 cases of deep infiltrating cancer were underestimated from the ultrasound examination, while 28 patients with no deep infiltrating lesions were classified as M2 with the US investigation. Statistical analysis evidenced a sensibility of the US method in predicting deep infiltrating lesion of 81%, with a specificity of 86%, positive predictive value of 74% and negative predictive value of 90%.

Conclusion

our results confirms the 2D ultrasonography as a valuable tool for the preoperative evaluation of myometrial infiltration in patients with endometrial carcinoma, allowing to correctly address high and low risk patients to the proper surgery treatment.

Department of Obstetrics and Gynecology- Catholic University of the Sacred Heart- Largo A. Gemelli- 8- 00168 Rome- Italy.,
Italy
3University of Insubria Varese, OB Gyn Unit, Varese, Italy

Aims

The purpose of this study was to analyze the correlation between tumor size (TS) and recurrence, in particular local recurrence,
in patients with endometrial cancer (EC), stratified according to the new ESMO-ESGO-ESTRO classification.

Method

Data of patients with histologically proven EC who received primary surgical treatment from November 1999 to November 2014,
were retrospectively retrieved from two institutions. Optimal TS cut-off was calculated using a Receiver Operating Characteristic
(ROC) curve. Site of recurrence as a function of TS and group of risk was calculated using the Chi-Square test. Local
recurrence-free survival (LRFS) and overall survival (OS) were calculated by Kaplan–Meier method.

Results

Data of 363 patients were analyzed. Among them 166 (45.7%) had low risk EC, 61 (16.8%) had intermediate risk EC, 37
(10.2%) had high-intermediate risk EC and 99 (27.3%) had high risk EC. A total of 47 women had (12.9%) recurrence: 13 of
them had local relapse and 34 had relapse at any other site. TS >25 mm emerged as the optimal threshold for a higher rate of
local recurrence (p=0.046, HR= 4.699, p= 0.032) and a lower 2-years LRFS (94% vs 100%, p=0.029) only in patients with low
risk EC. There was no statistically significant correlation between TS < or >25 mm and recurrence in the other risk groups.

Conclusion

Tumor size seems to be an independent prognostic factor of local recurrence in women with low-risk EC and could be a valuable
additional criterion to personalize the treatment approach to these patients.

CAN PREOPERATIVE MRI INFLUENCE SURGICAL MANAGEMENT OF ENDOMETRIAL HYPERPLASIA?
R. Bharathan¹, T. Ayakannu¹, M. Coutts¹, A. Papadopoulos¹, O. Devaja¹, S. Montalto¹
¹West Kent Oncology Centre- Maidstone Hospital, Department of Gynaecological Oncology, Maidstone, United Kingdom

Aims

Endometrial hyperplasia is a common entity. Management is guided by WHO classification. The diagnostic performance of pipelle and endometrial curettage techniques appear to be similar. The preoperative imaging is inaccurate even in women with higher degrees of hyperplasia-dysplasia.

Our study is designed to elucidate whether pre-operative magnetic resonance imaging (MRI) of the pelvis would influence the surgical management of women with atypical endometrial hyperplasia with or without stigmata of malignancy on histology.

Method

Patients who received definitive surgical treatment for atypical endometrial hyperplasia between 2006-2016 were included in this retrospective study.

Results

82 patients were analysed. Median age was 63 years. 16% of women were under 50 years. 80% women presented with post-menopausal bleeding (PMB). 14% presented with menstrual irregularities. Amongst those presenting with PMB, the median endometrial thickness was 12.5 mm. 43% were pipelle and 57% were curettage biopsies. In 69% of cases, the pre-operative diagnosis was confirmed on the hysterectomy specimen. When a cancer diagnosis was suspected (39/55), it was confirmed in 71% of cases. In an additional 13 cases a 'caveat of sampling error' was added to the report regarding the risk of cancer. 54 cases were confirmed as endometrial malignancy. Amongst this group 47 women had G1 (87%), 4 had G2 (7.4%) and 3 had G3 (5.6%) cancers. The stage subgroups were: stage 1A (74%), 1B (16.7%), 2 (5.6), 3 (3.7%).

Conclusion

Amongst 83 patients with a pre-operative diagnosis of atypical hyperplasia with suspicious features, a preoperative MRI scan may have influenced the surgical procedure in 26% of women.

PROGNOSIS OF THE PATIENTS TREATED FOR UTERINE CARCINOSARCOMA IN RURAL AND URBAN AREAS.
D.B. Anna¹, K. Magdalena², N.G. Anna³, B.Z. Elwira⁴, B. Barbara⁵
¹Medical University of Warsaw, 2nd Department of Obstetrics and Gynecology, Warsaw, Poland
²Maria Sklodowska - Curie Memorial Cancer Centre and Institute of Oncology, Department of Molecular Biology, Warsaw, Poland
³Jan Kochanowski University Faculty of Medicine and Health Science, Department of Pathology, Kielce, Poland
⁴Maria Sklodowska – Curie Memorial Cancer Centre and Institute of Oncology, Department of Pathology, Warsaw, Poland
⁵European Medicines Agency, Department of Statistics, London, United Kingdom

Aims

The aim of this article was analysis of prognosis for residents of rural and urban areas who suffered from uterine carcinosarcoma.

Method

Material for analysis was 51 women treated in Gynecological Oncology Department Oncological Center – Institute of Oncology in Warsaw between 2004 – 2010. There are rural and urban residents – 23 and 28, respectively. The average age of patients at diagnosis was 62 years. The youngest patient diagnosed with carcinosarcoma of the uterus was 47 years old and the oldest 78. All patients were treated by surgery followed by chemotherapy (41 pts) or radiotherapy (10 pts).

Results

Mean time from diagnosis to surgery was 4,2 weeks (range 3 to 7 weeks). Mean time of adjuvant chemotherapy was 18,6 weeks (range 16 – 21 weeks). Among 23 of rural residents, 10 died (43,5%) and in urban subgroup there were 14 deaths out of 28 women (50%). The mean time to progression among urban and rural residents were as follows: 66 and 81 weeks. The mean time to death was 145 and 187 weeks, respectively. Two out of all patients from rural area have died due to cardiac infarction and cerebral stroke.

Strong correlation in Pearson test was observed between tumor size and lymph node metastasis. Tumor diameter more than 4,5 cm is correlated with high number of node metastases (p=0,015).

Conclusion

The environment may influence the course of the disease and the efficacy of treatment, that is suggested by tendency to longer OS as well as PFS in rural residents.
THE LONG TERM SURVIVAL AFTER LAPAROSCOPIC TREATMENT OF ENDOMETRIAL CANCER

P. Sobieczewski1, M. Bidzinski2
1The Maria Sklodowska-Curie Memorial Cancer Center, Gynecologic Oncology, Warsaw, Poland
2The Maria Sklodowska-Curie Memorial Cancer Center- Institute of Oncology, Gynecologic Oncology, Warsaw, Poland

Aims

Laparoscopic surgery became a standard treatment in endometrial cancer however long term survival are rarely reported in the literature. The goal of our study was to analyse the long term survival after laparoscopic treatment in patients with endometrial cancer

Method

The analysed group consisted of 45 patients treated laparoscopically in our institution between 1994 and 2001. The routine follow-up in Oncologic Center continue up to 5 years. After this period all patients were contacted directly in 2016 and if it was not possible, their status was checked in Population Registry Office. Statistical analysis was performed with Kaplan-Meier method, the end point was overall survival.

Results

The analysed group consisted of 45 patients treated laparoscopically in our institution between 1994 and 2001. The median age was 54.6 years with median BMI 27.3. The distribution of FIGO stage: Ia 15 (33%), Ib 21 (46.5%), Ic 4 (9%), Ila 1 (2%), IIb 2 (4.5%), III 2 (4.5%). Grading: G1 15 (35%) G2 23 (54%) G3 4 (9%). Depth of invasion: <1/2: 29 (64%), >1/2: 16 (36%). The total complication rate was 23%, including urinary tract injury (4%), fever, hematoma. 18-year overall survival with 95%-CI: 0.842 (0.721, 0.964)

Conclusion

Laparoscopy according to ESGO guidelines (2015) may be recommended in the treatment of patients with endometrial cancer. The 18 year overall survival, as show our results, confirm the oncologic safety of this method in long term observation. Moreover the use of minimally invasive surgery completely eliminated some type of complications: wound dehiscence and postoperative hernia.
ICG-NIR FOR THE DETECTION OF SENTINEL LYMPH NODES IN EARLY STAGE CERVICAL AND ENDOMETRIAL CANCER

S. Rundle¹, N. Ratnavelu¹, N. Bizzarri¹, A. Fisher¹, R. Naik¹, V. Ghirardi¹, C. Ang¹, A. Kucukmetin¹
¹Northern Gynaecological Oncology Centre, Queen Elizabeth Hospital, Gateshead, United Kingdom

Aims

Determination of the regional lymph node status by SLN biopsy for cervical and endometrial cancer has the potential to reduce surgical morbidity without compromising oncological outcome. Established techniques for SLN mapping and biopsy use a combination of blue dye (BD) and radiolabelled nanocolloid (Tc-99m) as lymphatic tracers. Here we present results from a case series of fifty women for whom the indocyanine green-near infrared (ICG-NIR) technique was used for mapping sentinel lymph nodes.

Method

50 Women with early stage cervical and endometrial cancer underwent SLN mapping. Intra-cervical injection of ICG was used in all cases. For patients in whom retroperitoneal lymphadenectomy was indicated as part of their standard treatment, this was undertaken following SLN excision. SLNs and lymphadenectomy specimens were submitted for examination separately.

Results

The SLN detection rate was 90%. The bilateral SLN detection rate was 74%. There was one false negative result in a patient with endometrial cancer in whom the pelvic sentinel lymph nodes were negative, but a positive node was identified in the para-aortic lymphadenectomy specimen.

Conclusion

Sentinel lymph node biopsy using ICG-NIR has a detection rate which appears at least as good as standard techniques and is a valid technique for the confident identification of pelvic SLNs. Given the complex lymphatic pathways associated with the uterine corpus and the relative ease of use of ICG-NIR compared to BD/Tc-99m, it may be time to re-evaluate the role of non-cervical tracer injection in further increasing the diagnostic accuracy of SLN biopsy for early endometrial cancer.
ENDOMETRIAL CANCER

ESGO7-1293

PREDICTIVE VALUE OF CA125, HE4 AND ROMA INDEX IN ENDOMETRIAL CANCER. PRELIMINARY RESULTS.

N. Blontzos¹, C. Iavazzo¹, E. Galati¹, V. Vyllioti², E. Lamprou³, A. Miliaros⁴, N. Kalinoglou¹, G. Vorgias¹
¹Metaxa Memorial Cancer Hospital, Gynecologic Oncology, Pireaus, Greece
²Metaxa Memorial Cancer Hospital, Biochemical Laboratory, Pireaus, Greece
³Metaxa Memorial Cancer Hospital, Biopathology Laboratory, Pireaus, Greece
⁴Metaxa Memorial Cancer Hospital, Biostatistics, Pireaus, Greece

Aims

To assess the potential prognostic value of HE4, Ca-125 and ROMA index in the preoperative workout of patients with estimated stage I endometrial cancer.

Method

Thirty-five patients with endometrial cancer over the last six months were included. Preoperative Ca125 and HE4 were measured. Final histology was used as reference. We evaluated the correlation of Ca-125, HE4 and ROMA index with identified pathological variables (histological type, stage, cervical involvement, peritoneal cytology and lymph nodes metastasis). Two-sample t test with assumption of equal variances and ANOVA test were applied for comparisons. ROC curves were constructed, and the areas under the curve (AUC) with binomial exact 95% confidence intervals (95% CIs) were calculated as accuracy measures.

Results

Statistically significant high levels of Ca-125 were found in patients with non endometrioid histological type, cervical involvement and stage >IB (p=0.001, p=0.002 and p=0.013 respectively). Patients with stage≥IB had statistically elevated HE4 serum levels (p=0.046). Furthermore, ROMA index was significantly elevated in cases with cervical involvement, stage≥IB and non-endometrioid type (p=0.004, p=0.007, p=0.015 respectively). The constructed ROC curves to correlate ROMA index with stage≥IB indicated an AUC of 0.847. No statistical significant elevation of any of the tumor markers was observed concerning lymph nodes metastasis and cytology. Tumor upgrading between the histological report of D&C and hysterectomy was noticed in 4 patients, one of whom was found to have elevated HE4 levels.

Conclusion

Although the sample size is small and the results preliminary, it seems that the addition of HE4 and ROMA index improves diagnostic accuracy of endometrial cancer aggressiveness.

ESGO7-1298

DIFFERENTIAL DIAGNOSIS OF BENIGN VERSUS MALIGNANT ENDOMETRIAL TUMORS BASED ON RATIOS OF BLOOD COUNT. A PRELIMINARY STUDY

N. Blontzos1, C. Iavazzo1, E. Galati1, A. Maliaros2, N. Kalinoglou1, G. Vorgias1
1Metaxa Memorial Cancer Hospital, Gynecologic Oncology, Pireaus, Greece
2Metaxa Memorial Cancer Hospital, Biostatistics, Pireaus, Greece

Aims

A variety of biomarkers have been used in the preoperative workout of endometrial pathologies, involving Ca-125 and HE4. Our purpose is to evaluate whether the use of NLR (neutrophil-to-lymphocyte ratio), NMR (neutrophil-to-monocyte ratio), LMR (lymphocyte-to-monocyte ratio), NPR (neutrophil-to-platelets ratio), LPR (lymphocyte-to-platelets ratio), MPR (monocyte-to-platelet ratio) can add in the diagnostic accuracy of endometrial malignancy.

Method

Our study includes 120 patients treated for endometrial pathology during the last year. Final histological report was used as reference. Preoperative total blood count was used to calculate the mentioned above biomarkers. Receiver operating characteristic (ROC) curves were constructed, and the areas under the curve (AUCs) with binomial exact 95% confidence intervals (95% CIs) were calculated as accuracy measures. Best cut points were obtained by using the Youden’s Index for optimal sensitivity and specificity values determined by the ROC curves.

Results

The median age of the patients was 55.5 years ranging from 43 to 86 years. Malignancy was identified in 35/120 cases. ROC-AUC for NLR was 0.623, while the rest of the biomarkers were not found to be reliable for discrimination. Sensitivity of NLR was found 0.51 and specificity 0.71. The optimal cut off point was calculated to be 2.37.

![ROC Curve](image)

Figure 1. ROC AUC for 6 tumor markers between patients with malignant and benign endometrial conditions.

Conclusion

Preliminary statistical analysis showed that NLR constitutes a simple marker that improves the preoperative diagnostic accuracy of patients with endometrial pathologies. However, no colleration was found between the other ratios and endometrial cancer.
THE INFLUENCE OF FUCOIDAN TREATMENT ON UTERINE SARCOMA CELL LINES VIABILITY

M. Bobinski¹, K. Okła¹, J. Kotarski¹, P. Garcia Sanz², A. Wawruszak², M. Dmoszyńska-Graniczka³, M. Sobstyl¹, W. Bednarek¹
¹Medical University in Lublin, I Chair and Department of Oncological Gynaecology and Gynaecology, Lublin, Poland
²MD Anderson, Cancer Center Madrid, Madrid, Spain
³Medical University in Lublin, Department of Biochemistry and Molecular Biology, Lublin, Poland

Aims

Uterine sarcoma are malignant tumors, characterized by aggressive clinical course. Results of its treatment remain unsatisfactory. The need of new therapeutic agents and targets is widely postulated. Fucoidan is a group of sulfated heteropolysaccharide commonly found in brown seaweeds. Recent studies have demonstrated its various biological activities including anti-inflammatory, anticoagulant, and anti-cancer activities. It was proven to down-regulate the expression of VEGFR3. The aim of the study was to assess the expression of VEGFR3 in uterine leiomyosarcoma tissue and viability of uterine sarcomas cell lines treated with fucoidan.

Method

The expression of VEGFR3 was assessed in 50 uterine leiomyosarcoma tumor samples using immunochemical staining. Four uterine sarcoma cell lines: SK-UT 1, SK-UT 1B, MES-SA and ESS-1 were tested. HSF (human skin fibroblast) cell line was used as a control. All cell lines were treated with fucoidan, in concentration range 0.01-5 mg/ml. Cell viability was assessed using MTT test.

Results

High expression of VEGFR3 was detected in all of leiomyosarcoma tumors.

In MTT test IC₅₀ was achieved in all of sarcomas lines treated with fucoidan, except MES-SA. The IC₅₀ values were 0.8 mg/ml, 4.6 mg/ml, 3.6 mg/ml for SK-UT 1, SK-UT 1B, and ESS-1 respectively.

IC₅₀ was not achieved for MES-SA and HSF lines despite the dose escalation.

Conclusion

VEGFR3 is potential target for future therapy of uterine sarcomas. Fucoidan decreases cell viability in uterine sarcomas cell lines in dose dependent manner and has no impact on HSF in the same concentration range.

HOW TO IMPROVE SENTINEL LYMPH NODE MAPPING WITH INDOCYANINE GREEN (ICG) IN ENDOMETRIAL CANCER?
N. Body1, J. Grégoire1, M.C. Renaud1, A. Sébastianelli1, K. Grondin2, C. Morin2, M. Plante1
1Hôtel-Dieu de Québec, Gynecologic Oncology, Quebec, Canada
2Hôtel-Dieu de Québec, Pathology, Quebec, Canada

Aims
To determine the validity of sentinel lymph node (SLN) biopsy with ICG in endometrial cancer and to evaluate the factors associated with poor mapping or false negative.

Method
We reviewed all patients who underwent primary surgery for endometrial carcinoma with SLN mapping using ICG followed by pelvic lymphadenectomy, from February 2014 to December 2015. SLNs were ultrastaged on final pathology. Patients' demographics, surgical approach, FIGO stage, cervical involvement, lymphovascular space invasion, histologic type and grade were prospectively collected. Detection rate, sensitivity and negative predictive value (NPV) were calculated and univariate analysis was performed to evaluate factors associated with failed bilateral detection of SLNs.

Results
A total of 119 patients were included in the study. The overall and bilateral detection rate were 93% (111/119) and 74% (89/119). Sensitivity and NPV were 100% in patients with bilateral detection; 95% and 99% respectively in cases with at least unilateral detection. Advanced FIGO stage (II or IV) was the only factor related to failed bilateral detection (p=0.01). In 14 hemi-pelvis, the specimen labelled as SLN did not contain nodal tissue on final pathology (only lymphatic channels), which represented 37% of the “failed detection” cases. One false negative occurred in a patient with ipsilateral suspicious enlarged lymph nodes.

Conclusion
ICG is an excellent tracer for SLN mapping in endometrial cancer. Advanced FIGO stage was correlated to failed bilateral detection (p=0.01). Care should be taken to ensure that SLN specimen actually contains nodal tissue and not swollen lymphatic channels; suspicious lymph nodes should be removed regardless of the mapping.
EXPRESSION OF MATRICELLULAR PROTEINS: TENASCIN C, SPARC AND THROMBOSPONDIN-1 IN ENDOMETRIOID ENDOMETRIAL CANCER - PRELIMINARY RESULTS

M. Bogusiewicz1, A. Semczuk1, P. Miotła1, K. Futyma1, Ł. Nowakowski2, T. Rechberger1

1Medical University, 2nd Department of Gynecology, Lublin, Poland

Aims

Tenascin C (TNC), SPARC and thrombospondin-1 (TSP-1) are structurally unrelated matricellular proteins modulating cell-cell and cell-matrix interactions that play multiple role in tumorigenesis. The aim of the study was to assess their immunohistochemical expression in endometrioid endometrial cancer (EEC) and atypical endometrial hyperplasia (AEH).

Method

Material for the study were 43 samples of EEC: G1 (n=13), G3 (n=23), G3 (n=7) and 10 samples of AEH. Immunostaining was performed on paraffin-fixed sections with specific monoclonal antibodies using the avidin-biotin-peroxidase complex technique. Semi-quantitative assessment of expression: strong (S), moderate (M) and weak (W) was applied.

Results

A weak to strong expression of TNC, localized in epithelial cell membranes, was found in 60% of AEH samples but only in 2 (4.7%) cases of EEC. Stromal expression of SPARC was detected in all samples investigated. There was a tendency towards stronger SPARC expression in less differentiated cancers: G1 – S 23.1%/W 38.5%, G2 – S 34.7%/W 26.1%, G3 – S 57.1%/W14.2% with the lowest intensity in AEH – S 10%/W 50%. Likewise, stronger SPARC expression was associated with the depth of myometrial invasion: no invasion – S 14.3%/W 28.6%, <1/2 of the uterine wall – S 30.4%/W 30.4%, >1/2 of the uterine wall – 46.2%/W 15.4%. All but 3 EEC samples were negative for TSP-1.

Conclusion

Progression of AEH into EEC is characterized by the lost of TNC expression in epithelial cells. Invasiveness of EEC appears to be associated with stronger stromal SPARC expression. TSP-1 does not seem to play a role in the pathogenesis of EEC.
PRELIMINARY STUDY OF CORRELATION BETWEEN SERUM CA125 LEVELS AND INVASION DEPTH IN ENDOMETRIAL CARCINOMA

⁶Hospital Estadual Mario Covas, Gynecology / Oncogynecology, Santo André, Brazil
⁷Faculdade de Medicina do ABC, São Caetano do Sul, Brazil

Aims

Evaluate the clinical significance of preoperative sérum CA 125 levels in patients with Endometrial Carcinoma (EC)

Method

Retrospective study of all EC patients treated between 2015 and 2017 at the hospitals attended by Department of Obstetrics-Gynecology of Faculdade de Medicina do ABC. 85 patients were included in the present study, and their preoperative serum level of CA125 were evaluated in relation to various clinical and pathological variables and outcome.

Results

The preliminary results suggests a strong relation between serum CA 125 levels and miometral invasion depth in EC. The higher the serum CA 125 levels are, the more advanced the disease is and the greater are the chances of recurrence.

Conclusion

The present study suggests a significant meaning in measuring preoperative serum CA125. It can help in surgery planning and in the prognosis of patients with EC.

VALUE OF SENTINEL NODE BIOPSY IN NON-ENDOMETRIOID ENDOMETRIAL CARCINOMA
A. Bombín Arregui1, O. Vazquez Maiz1, O. Aristegi Guridi1, R. Ruiz Sautua1, M. Gorostidi Pulgar1, I. Jaunarena Marin1, K.E. Goiri Little1, J. Aguerrer Gogorza1, A. Lekuona Artola1
1OSI Donostialdea, Ginecology and Obstetrics, San Sebastian, Spain

Aims

Analyze the value of sentinel node biopsy in non-endometrioid endometrial carcinoma.

Method

Between 14th June 2014 and 31st October 2017, we operated 20 patients with non-endometrioid endometrial carcinoma (nEEC). In all of them, sentinel node biopsy was performed after injection of Green Indocianine tracer (ICG) in uterine fundus and cervix, followed by surgical staging. The sentinel nodes were processed by ultrastaging techniques.

Results

The overall detection rate was 80% (16 of 20), aortic 50%, one case with exclusive aortic SN, pelvic 75% and bilateral pelvic 35%.

6 cases (30%) presented lymph node macrometastasis (3 just in the aortic area and 3 in both areas); 1 patient SN was no detected, 3 were true positives and 2 presented microdisease in SN and macrodisease in no SN.

In the other 14 patients; in 3 cases no SN was found; 9 were true negative and in 2 cases, microdisease was found by ultrastaging in the SN with the rest of the lymph nodes negatives.

Conclusion

Patients with nEEC, the sentinel node detection rate is lower than our endometrioid EC series. The lymph node involvement is high, therefore the surgical staging is obligatory. SLN biopsy and ultrastaging increased the detection of lymph node involvement rate in 2 of 20 cases (10%).
SURVIVAL IMPACT OF RESTAGING BY INFRA RENAL PARA-AORTIC LYMPHADENECTOMY IN PATIENTS WITH INITIAL STAGE I ENDOMETRIAL CANCER

Y. Borghesi¹, F. Narducci¹, L. Bresson¹, E. Tresch², D. Hudry¹, E. Leblanc¹
¹Cancer Center Oscar Lambret, Gynecology Oncology, Lille, France
²Cancer Center Oscar Lambret, Biostatistics, Lille, France

Aims

A part of patients treated for a low or intermediate risk of recurrence endometrial cancer need a restaging by para-aortic lymphadenectomy (PAL) at the reception of final pathology in case of upstaging.

The objective of this study was to evaluate the Overall Survival (OS), the Specific Overall Survival (SOS) and the Relapse free Survival (RFS) at 3 years of this management.

Method

We included patients who need according to guidelines a second surgery by PAL treated from January 1, 2011, through September 31, 2015 for an initial low-intermediate risk of recurrence. Two groups were compared, the group "restaging" and the group "no restaging" composed by patients who had not restaging.

Results

31 patients were included in the group "restaging" and 22 in the group "no restaging" among 166 patients. There were no differences between the groups at the first surgery except for the age. Patients were older on average in the group "no restaging" (70.3 years ± 10.1 vs. 63.7 ± 4.6, p= 0.016). The 3-years SOS was higher in the group «restaging» 100% vs. 87.1% (95%CI, 56.1-96.8) (p=0.018). There were no difference in term of OS, RFS or in fonction of the localisation of metastasis (local vs. distant). The PAL were performed by laparoscopy in 27 cases whose 26 by extra-peritoneal laparoscopy and positive in 5 cases with 12.9% of grade 3 morbidity.

Conclusion

Our results confirm the importance of the restaging surgery to adapt the medical care in function of nodes status to increase the SOS.

COMPARISON OF MAYO AND MILWAUKEE RISK STRATIFICATION MODELS FOR PREDICTING LYMPH NODE METASTASIS IN ENDOMETRIAL CANCER

G. Boyraz1, F. Atalay2, A. Erturk1, C. Salman1, M. Gultekin1, N. Ozgul1, U. Alp3, K. Yuce1

1Hacettepe University, Department of Gynecologic Oncology, ANKARA, Turkey
2Uludag University, Pathology, Bursa, Turkey
3Hacettepe University, Department of Pathology, ANKARA, Turkey

Aims

To compare Mayo and Milwaukee risk stratification models for predicting lymphatic dissemination in patients with endometrioid cancer (EC).

Method

A total of 512 patients with stage I-III endometrioid EC who underwent staging surgery with systematic lymphadenectomy between 2004 and 2016 at Hacettepe University Hospital were identified. All slides of the cases were reviewed by the same gynecologic pathology subspecialist. After histological slide review, remaining 307 patients constituted our study group.

Results

Lymph node metastasis was detected in 28 (9.1%) subjects. Univariate analysis showed that primary tumor size, depth of myometrial invasion, lymphovascular space invasion (LVSI), cervical stromal and glandular involvement were associated with lymph node metastasis. Multivariate logistic regression analysis identified the independent risk factors associated with lymphatic involvement as LVSI (OR 4.59, 95% CI 1.66–12.68, p = 0.001), myometrial invasion (OR 4.01, 95% CI 1.17–13.76, p = 0.02) and cervical stromal invasion (OR 3.54, 95% CI 1.04–12.03, p= 0.043). The sensitivity, specificity, false negative and positive rates of Mayo and Milwaukee risk stratification models for predicting lymphatic dissemination among women endometrioid EC were 100%, 27.3%, 0%, 72.7%, and 89.3%, 61.3%, 10.7%, 38.7%, respectively.

Conclusion

Although Milwaukee risk model had a lower false-positive rate and can decrease the number of lymphadenectomies, false-negative rate of this new model was found as 10.7% in the present study. Furthermore, we found that Mayo model had a lower false negative rate and higher sensitivity. Therefore, Mayo model still looks more beneficial in order to predict lymph node metastasis in patients with endometrioid EC.
ASSESSMENT OF CURRENT PRACTICE OF SURGICAL STAGING OF LYMPH NODES IN ENDOMETRIAL CANCER.

S. Brugger¹, M. Rottmann², M. Pölcher¹
¹Rotkreuzklinikum München Frauenklinik, Gynäkologie, München, Germany
²Klinikum Großhadern, Tumorregister München, München, Germany

Aims

Objectives: Surgical staging of lymph nodes in endometrial cancer is controversial. In patients with uterine low risk factors (G1/G2, myometrial invasion <50%, no LVI) systematic lymph node dissection (LND) is not recommended. Patients with higher risk factors might benefit from LND. After implementation of sentinel lymph node dissection (SLND) at our hospital we tried to assess the current practice of surgical staging in our region.

Method

We analysed the current practice of lymph node assessment (LNA) in all patients with endometrial cancer registered at the Tumorregister München from 1998-2015 who have undergone surgery.

Results

8130 patients registered. In 5046 patients (62.1%), no lymph node assessment (LNA) was performed. In 3084 patients (37.9%), any lymph node assessment was performed (pelvic LND 40.9% (n= 1261), pelvic and paraaortic LND 46.4% (n=1431), SLND only 1.4% (n=44), not specified lymph node assessment 11.3% (n=348)). The number of LNA increased over time and the number of detected lymph node metastases increased continuously from 4.7 % in 1998 to 12.9 % in 2015. In 7203 patients, the tumor was confined to the uterus. In the low risk group (n=3614; 50.2%), 77.8% of the patients had no LNA. In the group of patients with intermediate/high intermediate and high risk factors (n=3589; 49.8%), LNA was performed in 47.8% compared to 52.2% without LNA.

Conclusion

The rate of patients without LNA is high, even in the group of patients with "higher than low risk"-features. Implementation of SLND might lead to a higher rate of LNA, however SLND is not common practice yet.
IDENTIFICATION OF MICRO-RNA EXPRESSION PROFILES RELATED TO RECURRENCE IN WOMEN WITH ESMO LOW RISK ENDOMETRIAL CANCER

G. Canlorbe¹, T. Cyril²
¹Pitié-Salpêtrière University Hospital- Assistance Publique des Hôpitaux de Paris, Department of Surgery and Oncological Gynaecology, Paris, France
²Creteil Intercommunal Hospital- Université Paris Est- Paris XII, Department of Obstetrics and Gynaecology, Créteil, France

Aims

Introduction: Actual European pathological classification of early-stage endometrial cancer (EC) may show insufficient accuracy to precisely stratify recurrence risk, leading to potential over or under treatment. Micro-RNAs are post-transcriptional regulators involved in carcinogenic mechanisms, with some micro-RNA patterns of expression associated with EC characteristics and prognosis. We previously demonstrated that downregulation of micro-RNA-184 was associated with lymph node involvement in low-risk EC (LREC).

Objectives: The aim of this study was to evaluate whether micro-RNA signature in tumor tissues from LREC women can be correlated with the occurrence of recurrences.

Method

Methods: MicroRNA expression was assessed by chip analysis and qRT-PCR in 7 formalin-fixed paraffin-embedded (FFPE) LREC primary tumors from women whose follow up showed recurrences (R+) and in 14 FFPE LREC primary tumors from women whose follow up did not show any recurrence (R-), matched for grade and age. Various statistical analyses, including enrichment analysis and a minimum p-value approach, were performed.

Results

Results: The expression levels of micro-RNAs-184, -497-5p, and -196b-3p were significantly lower in R+ compared to R- women. Women with a micro-RNA-184 fold change <0.083 were more likely to show recurrence (n=6; 66%) compared to those with a micro-RNA-184 fold change >0.083 (n=1; 8%), p = 0.016. Women with a micro-RNA-196 fold change < 0.56 were more likely to show recurrence (n=5; 100%) compared to those with a micro-RNA-196 fold change > 0.56 (n=2; 13%), p=0.001.

Conclusion

Conclusion: These findings confirm the great interest of micro-RNA-184 as a prognostic tool to improve the management of LREC women.

ESGO7-0643

FROZEN SECTION REVEALING THE ABSENCE OF LYMPHATIC TISSUE DURING SENTINEL LYMPH NODE BIOPSY IN ENDOMETRIAL CANCER STAGING.

J. Casarin1,2, F. Multinu1, A. Weaver1, M. McGree1, L. Tortorella1, W. Cliby1, S.C. Dowdy1, F. Ghezzi2, A. Mariani1, G. Glaser1
1Mayo Clinic, Gynecologic Oncology, Rochester- MN, USA
2University of Insubria, Obstetrics and Gynecology, Varese, Italy

Aims

To assess the role of frozen section (FS) to identify the absence of lymphatic tissue (“empty node” (EN)) during sentinel lymph node (SLN) biopsies for apparent early stage endometrial cancer (eEC) to avoid potential understaging in patients at high-risk of metastasis.

Method

All eEC patients undergoing SLN removal using cervical injection with Indocyanine Green from 06/01/2014 to 06/30/2016 were analyzed. FS was used to examine all SLNs removed. EN was defined as SLN specimen without evidence of lymphatic tissue. The association of tumor and patient’s characteristics with EN was evaluated. Trend analysis to compare the rate of EN over calendar quarters was performed using Cochrane-Armitage test.

Results

ENs were easily identified in 24/300 (8%) patients (23 cases unilateral and 1 case bilateral). No association between age, stage, histology, BMI, prior abdominopelvic surgery and presence of EN was observed. Rate of EN revealed at FS did not change over time (p=0.68 for trend) (Table1).

| Table1. Consecutive patients who underwent sentinel lymph node (SLN) biopsies with at least unilateral SLN removal for endometrial cancer staging using cervical injection of Indocyanine Green (ICG) at Mayo Clinic from June 1, 2014 to June 30, 2016. |
|---|---|
| **Descriptive analysis on 300 patients with SLN(s) removed** | **Bilateral SLN removed** (254(88.7%)) |
| | One-side SLN removed | 49 (16.3%) |
| **Empty Lymph Node (EN)** | **14 (6.0%)** |
| | Unilateral EN | 13 (7.7%) |
| | Bilateral EN | 1 (0.3%) |
| **Analysis of patients with Empty Lymph Node over time** | **1st 12 months** (10/122 (8.3%)) |
| | 2nd 12 months | 14/129 (10.8%) |
| **Trend analysis stratified by calendar year quarters** | **p=0.68** |

Data are reported as absolute number and percentage (%).

*Cochran-Armitage test for trend (after stratification by quarters, from 2014-03 to 2016-02).

Conclusion

The presence of EN during SLN biopsies is not a rare event. The easy identification of absence of lymphatic tissue at FS is useful to reveal intraoperative EN and avoid the need of reoperation for appropriate staging in patients undergoing SLN biopsy at high-risk of lymph node metastasis. Individual institutions should examine their own EN rates and determine if this would assist them in their SLN practices for eEC.

THE PREGNANCY OUTCOME AFTER FERTILITY-SPARING TREATMENT OF EARLY ENDOMETRIAL CANCER

S.H. Chae¹, J.H. Suh¹, S.H. Shim¹, S.J. Lee¹, J.Y. Lee¹, S.N. Kim¹, S.B. Kang¹
¹Konkuk university medical center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Incidence of endometrial cancer has been increasing among young women since 2000. It is difficult to make a decision between fertility sparing treatment and hysterectomy for early stage endometrial cancer patients in reproductive age. The aim of this study is to evaluate the fertility and pregnancy outcome of early stage endometrial cancer patients in reproductive age.

Method

Retrospective single center study was done from 1998 to 2017. Endometrial cancer patients with presumed FIGO stage 1 & 2 with grade 1 & 2 were included. Exclusion criteria were patients with age over 45, presumed FIGO stage over 3 and any stages with FIGO grade 3. Pregnant group and non-pregnant group of early stage endometrial cancer patients after fertility sparing treatment were compared.

Results

Total 117 endometrial cancer patients were enrolled in the study. Among 117 endometrial cancer patients, 48 patients wanted to be pregnant and 20 of them were successfully pregnant (41.6%). The number of endometrial curettage was not different between two groups. However, 18 patients (18%) had not got remission within 6 month and hysterectomy was done in these patients. The age factor was different between pregnant and non-pregnant endometrial cancer patients (34±3.9 vs 36±2.7, P ≤ .05). Moreover, basophil count was different between two groups (0.34±0.91 vs 0.69±0.43, P ≤ .05).

Conclusion

The pregnancy outcome was good after fertility sparing treatment in early stage endometrial cancer patients. Endometrial curettage does not affect the pregnancy outcome. Further study of large group should be done.
A CASE OF ENDOMETRIAL CANCER IN A PATIENT WITH FAMILIAL ADENOMATOUS POLYPOSIS

H.X. Chin¹, S.K. Lim Tan², I. Aggarwal¹
¹KK Women’s and Children’s Hospital, Gynaecological Oncology, Singapore, Singapore
²KK Women’s and Children’s Hospital, Department of Pathology and Laboratory Medicine, Singapore, Singapore

Aims

Lynch syndrome or hereditary non-polyposis colorectal cancer (HNPCC) is associated with colorectal and endometrial cancers, and accounts for the majority of inherited endometrial cancers. Comparatively, familial adenomatous polyposis (FAP), which is characterized by the presence of multiple colorectal adenomatous polyps, is associated with colorectal cancer but not known to have an association with endometrial cancer. We report a rare case of endometrial cancer diagnosed in a patient with FAP, and review the literature on similar cases, to highlight this rare entity.

Method

We report a rare case of endometrial cancer diagnosed in a patient with FAP, adenocarcinoma of the Ampulla of Vater and transverse colon. A review of the literature on similar cases was also performed.

Results

Endometrial cancer, although far less common than in Lynch syndrome, has been reported in cases of FAP. This may be a result of chance occurrence, improved survival of FAP patients with total colectomy, or may represent a rare and distinct genetic entity.

Conclusion

Inherited endometrial cancers may rarely be associated with FAP, as highlighted in this case report and review of the literature.
CIRCULATING CELL-FREE DNA IN ENDOMETRIAL CANCER.

L. Cicchillitti¹, G. Corrado², M. De Angelis³, E. Mancini⁴, E. Baiocco⁴, B. Chiofalo⁴, L. Patrizi⁴, A. Zampa⁴, G. Piaggio⁵, E. Vizza⁵

¹²³⁴⁵“Regina Elena” National Cancer Institute-, Department of Experimental Clinical Oncology- Gynecologic Oncology Unit, Rome, Italy
²Catholic University of Sacred Heart, Department of Obstetrics and Gynecology- Gynecologic Oncology Unit, Rome, Italy
³University of Rome “Tor Vergata”, Department of Biomedicine and Prevention- Obstetrics and Gynecology Unit, Rome, Italy
⁴“Regina Elena” National Cancer Institute, Department of Experimental Clinical Oncology- Gynecologic Oncology Unit, Rome, Italy
⁵“Regina Elena” National Cancer Institute-, Department of Research- Diagnosis and Innovative Technologies- Translational Research Area, Rome, Italy

Aims

To set up a simple test for circulating cell free DNA (cfDNA) quantification in endometrial cancer (EC) and correlate it with the individual metabolic syndrome factor and tumor aggressiveness to help clinical diagnosis and prognosis.

Method

The blood of cancer patients was obtained before surgery and before the beginning of any treatment. Information about patients was obtained by reviewing their medical charts.

Blood samples were collected in vacutainer tubes and leaved at room temperature to allow to clot. The clot was removed by centrifuging at 1,000–2,000 x g for 10 minutes in a refrigerated centrifuge and stored at –80°C.

For measurement of cfDNA levels SYBR Gold Nucleic Acid Gel Stain we followed the protocol described by Goldshtein et al (Ann Clin Biochem. 2009 Nov;46(Pt 6):488-94).

Results

Our data show that cfDNA levels are higher in G2 (n=30) and G3 (n=17) compared with G1 (n=12) EC sera, but this increase does not depend on cancer stage. Moreover, a significant increase on cfDNA amount was detected in sera from patients with BMI>30 compared with those with BMI<30, even if not related with EC grading. Interestingly, we observed a further and significant increase of cfDNA in hypertensive patients with G2-G3, but not with G1 EC.

Conclusion

cfDNA levels are indicative of EC occurrence and aggressiveness and further increase in hypertensive patients with high grade EC. Our data indicate that assessment of cfDNA levels in blood sera with direct SYBR gold assay may help in prediction of EC development and aggressiveness.

ELECTRONIC BRACHYTHERAPY AS ADJUVANT TREATMENT FOR ENDOMETRIAL CANCER: FIRST PRELIMINARY EXPERIENCE IN SWITZERLAND

S. Cima¹, P. Colleoni¹, M. Valli¹, M. Frapolli¹, S. Presilla², A. Richetti³

¹IOSI Oncology Institute of Southern Switzerland, Radiation Oncology, Bellinzona, Switzerland
²Ente Ospedaliero Cantonale, Medical Physics Unit, Bellinzona, Switzerland

Aims

To evaluate the feasibility and safety of high-dose rate electronic brachytherapy (EBT) with XOFT® Axxent System as monotherapy or after external beam radiation therapy (EBRT), in endometrial cancer patients.

Method

A total of 8 patients were treated from October 2016 to March 2017 in our Institute. The dose prescribed in monotherapy was 20 Gy in 4 fractions, the dose prescribed after EBRT was 15 Gy in 3 fractions. The doses were prescribed to a depth of 5 mm starting from the applicator surface and to the upper third of the vagina. The median EBRT dose was 45 Gy (range, 45-50.4 Gy). Adverse events and toxicity were collected using RTOG/EORTC score.

Results

The prescribed doses of EBT were successfully delivered in all patients. Of the 8 patients, one patient experienced Grade 2 gastrointestinal toxicity (12.5%); 2 patients experienced Grade 1 genitourinary toxicity (25%), no Grade 4 or 5 toxicity was registered. No Grade 2 or higher toxicities were registered in patients treated with EBT alone. The dosimetric parameters for organs at risk (OAR) are listed in Table 1.

Conclusion

XOFT® system provides a feasible and safety treatment option for adjuvant vaginal brachytherapy. Additional data is needed to further assess the clinical efficacy and late toxicity.
PAX2 AND BCL-2 EXPRESSION AS A PROGNOSTIC FACTOR IN ENDOMETRIAL ENDOMETRIOID ADENOCARCINOMA GRADE 1

M. Kirşavoğlu1, A. Çorakç1, Y. Doğan1
1Kocaeli University Faculty of Medicine, Gynecology and Obstetrics, Kocaeli, Turkey

Aims

Our aim is to detect the influence of bcl2 and PAX2 expression on the prognosis of endometrial endometrioid adenocarcinoma grade 1.

Method

All endometrial endometrioid adenocarcinoma grade 1 patients detected in Kocaeli University Medical Faculty Hospital between 2009-2012 were analysed. Fiftyseven endometrium carcinoma patients were included in the study and control group was composed of 34 patients reported as benign hyperplasia. Immunoreactivity was scored half quantitatively based on bcl2 and PAX2 staining. Staining intensity of gland epitelim was scored from 0 to 3. The extensity of the stain was evaluated also, if the tissue did not stain 0 score was given, 1-33% staining was scored as 1, 34-66% staining was scored as 2, 67-100% staining was scored as 3. Total scores were between 0 and 6. Immunohistochemical staining scores of the patients and control group were compared by MannWhitney U test. Bcl2 and PAX2 were compared with other prognostic factors including myometrial invasion, tumor size lymphovascular invasion and MELF (microcytic elongated fragmented pattern) using Mann Whitney U and Kruskal Wallis tests.

Results

Mean age of the patients was 58±8.5 (38-80). Bcl2 and PAX2 expression decreases significantly in endometrium carcinoma (p<0.01) but is not associated with myometrial invasion, tumor size and lymphovascular invasion (Tables). Bcl2 and PAX2 scores were higher in microcytic elongated fragmented pattern (p=0.05 and p=0.007 respectively).
Conclusion

Immunohistochemical evaluation of transcription factors can be useful for establishing prognosis and identification of patients that need adjuvant treatment. Bcl-2 and PAX2 can differentiate carcinoma from normal tissue but further studies are needed.

GENE PROMOTER METHYLATION IN THE DEVELOPMENT FROM NORMAL ENDOMETRIAL CANCER AND ITS RELATION TO K-RAS GENE MUTATION

K. Cornel1, K. Wouters2, K. van de Vijver3, A. van der Wurff4, M. van Engeland, R. Kruitwagen1, H. Pijnenborg5

1Maastricht University Medical Center +, Gynaecology & Obstetrics, Maastricht, The Netherlands
2Maastricht University Medical Center +, Pathology, Maastricht, The Netherlands
3Netherlands Cancer Institute, Diagnostic Oncology and Molecular Pathology, Amsterdam, The Netherlands
4Elisabeth Tweesteden Ziekenhuis, Pathology, Tilburg, The Netherlands
5Roadbed University Medical Center, Obstetrics and Gynecology, Nijmegen, The Netherlands

Aims

Up to 60% of untreated atypical hyperplastic endometrium will develop into endometrial carcinoma (EC), and for those who underwent a hysterectomy a coexisting EC is found in up to 20%. Gene promoter methylation might be related to the EC development.

The aim of this study is to determine changes in gene methylation profiles and K-Ras mutation in normal, atypical hyperplastic endometrium and EC.

Method

A retrospective study was conducted of patients diagnosed with hyperplasia based on endometrial sampling between 1996 and 2011. After hysterectomy promoter methylation was preformed for APC, hMLH1, O6-MGMT, P14, P16, RASSF1, RUNX3, SFRP1, CD01 and ER are related to final histological diagnosis. For each case K-Ras mutations were analysed.

Results

A total of 98 cases were analysed. For P16, promoter methylation was significantly increased from 10% in normal endometrium (n=1) to 7.7% in atypical hyperplasia (n=2) to 38% in EC (n=13). hMLH1 methylation gradually increased from 27.3% (n=3) in normal to 36.4% (n=12) in atypical hyperplasia to 38.0% (n=) in EC.

For O6-MGMT methylation it shows 8.3% (n=1), 18.2% (n=6) and 31.4% (n=16) respectively. K-Ras mutation was only observed in 12.1% (n=4) of atypical hyperplasia, and 19.6% (n=10) in EC. No relation between K-Ras mutations and gene promoter methylation was seen.

Conclusion

hMLH1 and O6-MGMT promoter methylation are early events and already seen in atypical endometrial hyperplasia, whereas P16 promoter methylation occurs later and is especially seen in EC. K-Ras mutations are more frequently seen in EC than in atypical hyperplasia.

PROJECT ALYSE: ASSESSING THE RISK OF LAPAROSCOPIC AORTIC LYMPHADENECTOMY USING SAGITTAL ABDOMINAL DIAMETER IN ENDOMETRIAL CANCER

A. Correa-París, V. Gorraiz Ochoa, A. Fernandez Oliva, L. Gomila Villalonga, B. Diaz-Feijoo, J.L. Sanchez Iglesias, A. Gil-Moreno

1Institut Catala de Salut, Atencio Primaria Barcelona Ciutat - ASSIR, Barcelona, Spain
2Hospital Vall d’Hebron, Obstetrics & Gynecology Dept., Barcelona, Spain
3Hospital Vall d’Hebron, Gynecologic Oncology Unit- Obstetrics & Gynecology Dept., Barcelona, Spain

Aims

to evaluate the usefulness of Sagittal Abdominal Diameter (SAD)-measured in a preoperative MRI, and other factors to assess the risk of surgical complications of laparoscopic para-aortic lymphadenectomy (L-PAL) for endometrial cancer staging.

Method

multivariate analysis of a cohort of patients with endometrial cancer randomized to transperitoneal or extraperitoneal technique (within another randomized controlled trial, the STELLA trial). A logistic regression analysis and ROC curves were performed. A composite outcome to assess risk was defined by: hospitalization >3 days, need for blood transfusion, hematocrit drop >12%, surgical time >90th percentile (>330min), L-PAL time >90th percentile (>130min), complication during L-PAL or surgical complication grade >Dindo III, L-PAL uncompleted or converted. Covariates analyzed were: SAD, BMI, Charlson’s age-adjusted comorbidity (AAC), cardiovascular disease, diabetes, previous surgeries.

Results

a total of 47 patients were included. The descriptive analysis is summarized in the following table. In the ROC curve we found an accuracy (AUC)=0.76 when using the SAD-AAC interaction (p=0.01). Interestingly, when applying the model only to the group of patients who underwent the transperitoneal approach AUC was 0.80 (p=0.08), whereas for the extraperitoneal group AUC=0.72 (p=0.11). Furthermore, when the model was restricted to the “conventional-laparoscopy, transperitoneal” group AUC=0.90 (p=0.09). In comparison, using the same model replacing SAD with BMI, AUC=0.63 (p=0.07).

<table>
<thead>
<tr>
<th>median(range)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operative time-(min)</td>
</tr>
<tr>
<td>L-PAL time-(min)</td>
</tr>
<tr>
<td>Hematocrit change-(%)</td>
</tr>
<tr>
<td>Hospital stay-(days)</td>
</tr>
<tr>
<td>AAC</td>
</tr>
<tr>
<td>SAD-(mm)</td>
</tr>
</tbody>
</table>
Conclusion

SAD and AAC, but not BMI, could be useful to assess the risk of L-PAL, an optimal cutoff value must be determined to help chose the best surgical approach.

ESGO7-0127

ENDOMETRIAL CANCER PATIENTS LEVEL OF HE4 AND MMP2
A. Cymbaluk-Płoska, A. Chudecka-Glaz, E. Pius-Sadowska, A. Sompolska-Rzechuła, B. Machaliński, A. Surowiec, J. Menkiszak

1Pomeranian Medical University, Department of Gynecological Surgery and Gynecological Oncology of Adults and Adolescents, Szczecin, Poland
2Pomeranian Medical University, General Pathology Department, Szczecin, Poland
3West Pomeranian University of Technology, Department of Statistics, Szczecin, Poland

Aims
Diagnostic potential of the serum levels of HE4 and MMP2 in patients with endometrial cancer and benign endometrial diseases. To assess the relationship between the serum levels of HE4 and MMP2 and the typical prognostic factors in endometrial cancer patients.

Method
Included in the study was a group of 112 patients presenting with bleeding abnormalities at the Pomeranian Medical University in years 2012-2016. Serum HE4 concentrations were measured using the Elecsys ECLIA assay from Roche. MMP2 concentrations were quantified in the serum using multiplex immunoassays (Luminex Corporation, Austin, TX, USA).

Results
The diagnostic potential of HE4 and MMP2 in differentiation of high (FIGO III i IV) vs. low (FIGO I and II) clinical stage of tumor and prediction of cellular differentiation grade (G1 vs. G3) on the basis of the analysis of the area under the curve is respectively 0.86 and 0.82 for HE4 and 0.82 and 0.74 for MMP2. The HE4 marker was significantly more specific than MMP2 in every study group and amounted to: 93% vs. 86% in all patients included in the analysis, 94% vs. 84% in pre-menopausal patients, and 84% vs. 79% in post-menopausal patients.

Conclusion
HE4 and MMP2 are characterized by high specificity and may be useful as biomarkers in the diagnostics of endometrial cancer. When determined preoperatively, HE4 is correlated with the prognostic factors of endometrial cancer and may be helpful in the planning of individual treatment of endometrial cancer patients.
A CASE OF EXTRA-UTERINE SPREAD IN NONINVASIVE SEROUS PAPILLARY ENDOMETRIAL CARCINOMA ARISING FROM A POLYP

M. Puljiz¹, D. Danolic¹, I. Alvir¹, I. Mamic¹, D. Tomica², L. Susnjar¹, K. Cindric³, V. Stepanić³, M. Peric-Balja³

³University Hospital for Tumors- University Hospital Centre Sestre Milosrdnice, Department of Clinical Pathology, Zagreb, Croatia
⁴Clinical Hospital Centre Split, Department of Gynecology and Obstetrics, Split, Croatia
⁵Clinical Hospital Merkur, Department of Gynecology and Obstetrics, Zagreb, Croatia

Aims

To report a case of noninvasive serous papillary endometrial carcinoma with para-aortic lymph node metastases.

Method

A 61 years-old nulliparous woman, with history of breast carcinoma, was admitted to our department for postmenopausal bleeding. Transvaginal ultrasonography was performed and an endometrial thickness of 6 mm was found. She underwent hysteroscopy that showed small endometrial polyp arising from the anterior uterine wall. The endometrial polyp was resected and pathological examination revealed noninvasive serous papillary carcinoma arising from the polyp. The immunohistochemical staining analysis showed negative estrogen and progesterone receptors and strong p53 overexpression. She underwent hysterectomy, bilateral salpingo-oophorectomy, omentectomy and pelvic and para-aortic lymphadenectomy.

Results

The pathological finding revealed atrophic endometrium without lymphovascular space invasion and no omental or pelvic lymph node metastasis. Residual tumor was not found in the endometrium. Para-aortic lymph node metastases were present in 3 of 17 lymph nodes. Six cycles of adjuvant chemotherapy with carboplatin and paclitaxel were given. Patient is receiving radiation therapy.

Conclusion

The present case emphasizes the aggressive behavior of uterine serous papillary carcinoma, along with the need for complete surgical staging including para-aortic lymphadenectomy. Extra-uterine disease spread may frequently occur even with noninvasive disease. The performance of pelvic lymphadenectomy alone represents an incomplete surgical effort resulting in failure to identify patients who may benefit from adjuvant therapy.
FREQUENT HOMOLOGOUS RECOMBINATION DEFICIENCY IN HIGH-GRADE ENDOMETRIAL CANCER PROVIDES OPPORTUNITIES FOR NOVEL THERAPEUTIC STRATEGIES.

Aims

High grade endometrial cancer (EC) has a poor prognosis. By assessing the incidence and molecular basis of homologous recombination deficiency (HRD) in EC, we aimed to determine whether EC patients may benefit from treatments that target homologous recombination deficiency.

Method

Fresh tumour tissue of 28 ECs was prospectively collected in the LUMC between 2015-2017 (16 endometrioid (EEC) and 12 non-endometrioid endometrial cancers (NEEC). For functional analysis, the ability of replicating tumour cells to form RAD51-foci after ionizing radiation was used as a functional read out for HR-proficiency. Molecular analysis was done by copy number aberration analysis (CNA, genomic instability score, GIS) and sequencing of known HR-genes (BRCA1, BRCA2, ATM, PALB2, BRI1P1, RAD51D, RAD51C, BARD1, CHEK2). Immunohistochemical staining was performed to determine p53-status and mismatch-repair deficiency (MMRd). Independent validation was performed on TCGA-EC data (BRCA-like CNA-profile).

Results

Functional HR-analysis showed impairment of HR in 39% (n=11) of the 28 ECs. HRD was more frequently observed in NEECs (9/12, 75%) compared to EEC (2/16, 13%, p<0.01). 3 (27%) HRD cases were MMRd and 7 (64%) cases displayed a p53-mutant staining pattern. GIS derived from aCGH data showed concordant outcomes with RAD51-assay in 82%. In three HRD-EC we identified gene mutations that might explain the phenotype (two BRCA1, one BRI1P1). TCGA-data showed a BRCA-like profile in 42% (81/192) of NEEC and 8% (33/404) of EEC.

Conclusion

A significant proportion of EC, mainly NEEC, are defective for homologous recombination. Assessment of HR efficacy in EC might allow identification of patients that could benefit from treatments targeting HRD.

PROGESTERONE THERAPY FOR ENDOMETRIAL CANCER PROTECTION IN OBESE WOMEN: THE PROTEC TRIAL
A.E. Derbyshire1,2, M.L. Mackintosh1,2, R.J. McVey3, J. Bolton3, P.W. Pemberton4, M. Needham5, H.C. Kitchener6, E.J. Crosbie1,6
1Central Manchester University Hospital NHS Foundation Trust, Obstetrics and Gynaecology, Manchester, United Kingdom
2Manchester Academic Health Science Centre, Women and Children, Manchester, United Kingdom
3Central Manchester University Hospital NHS Foundation Trust, Histopathology, Manchester, United Kingdom
4Central Manchester University Hospital NHS Foundation Trust, Clinical Biochemistry, Manchester, United Kingdom
5Salford Royal Hospitals NHS Foundation Trust, Sleep Apnoea Service, Manchester, United Kingdom
6University of Manchester, Division of Molecular and Clinical Cancer Sciences- Faculty of Biology- Medicine and Health, Manchester, United Kingdom

Aims

Obesity is strongly associated with endometrial cancer (EC). The levonorgestrel intrauterine system (LNG-IUS) reduces the risk of EC and its precursor lesion, atypical hyperplasia (AH). We assessed the feasibility, acceptability and endometrial impact of the LNG-IUS for primary prevention of EC in obese women.

Method

Morbidly obese women (BMI>40kg/m²) with histologically normal endometrium were recruited to a clinical trial of the LNG-IUS for endometrial protection. Sequential blood and endometrial samples were obtained before and after LNG-IUS insertion. Quality of life and menstrual function questionnaires were completed. Endometrial samples underwent histological assessment and biomarkers of endometrial proliferation (Ki-67, pAKT) and hormone receptor status (ER, PR, AR) quantified by immunohistochemistry. Circulating biomarkers of insulin resistance and reproductive function were measured. Follow up for six months after LNG-IUS insertion will be completed in August 2017.

Results

In total, 25 women received an LNG-IUS. Their median age and BMI were 54 years (IQR 52, 57) and 46.7kg/m² (IQR 43.6, 50.8) respectively. Three women were ineligible due to EC/AH on their baseline biopsy. The LNG-IUS had a positive overall effect on bleeding patterns and quality of life. The LNG-IUS was associated with morphological, Ki-67 and PR expression changes in the endometrium but circulating biomarkers of proliferation and reproductive function were unchanged.

Conclusion

The incidence of occult endometrial neoplasia was high in morbidly obese women screened for participation (9%). The LNG-IUS was well tolerated and all completed patients chose to keep it for ongoing endometrial protection. Use of the LNG-IUS for this indication appears feasible.
Aims

The aim of study is to determine Survivin, Bcl-2, Bad, Bax and Caspase-9 gene expressions after metformin (M) and medroxyprogesterone acetate (MPA) treatment on endometrial hyperplasia rat model.

Method

Three groups created (E, E+P, E+M). We have applied 4mg/kg 17β Estradiol hemihydrates (E) for 20 days after oophorectomy operation to all groups. In the tenth day of E treatment 50 mg/kg metformin added for E+M group and 1mg/day MPA for E+Progesterone (P) group. Only 4mg/kg 17β estradiol hemihydrates was used for 20 days in group E. Hysterectomies were performed at 20. day of treatment. RNA isolation was performed from tissues for genetic analysis. cDNA was obtained using the reverse transcriptase enzyme. Real time PCR used for detected Survivin, Bcl-2, Caspase-9, Bad and Bax gene mRNA expressions. Endometrial histopathological samples were stained with hematoxylin eosin.

Results

Metformin and progesterone have significant and similar effect on endometrial hyperplasia. Survivin, Bcl-2, Caspase-9, Bad and Bax gene expressions were not statistical significant between the groups (p>0.05). Bcl-2/Bax ratio was significantly decreased in MPA and M group compared to the control group (E) (p: 0.020).

Conclusion

We conclude that metformin and progesterone have significant and similar effect on endometrial hyperplasia. These agents stimulate the apoptotic pathway of the endometrial cells and prevent the tissue from endometrial cancer.
ENDOMETRIAL CANCER

ESGO7-0425

PREDICTION OF ENDOMETRIAL CANCERS STAGE1A BY THE RISK OF INVASIVE ENDOMETRIAL CANCER SCORE - INVREC-SCORE

M. Dueholm¹, L. Kjeld Pedersen², G. Oertoft³
¹Aarhus University Hospital, Obstetrics and Gynecology, Aarhus N, Denmark
²Randers Central Hospital, Obstetrics and gynecology, Randers, Denmark
³Rigshospitalet, Obstetrics and Gynecology, Copenhagen, Denmark

Aims

To predict high risk or more than stage 1a endometrial cancer(EC) tumors by transvaginal ultrasound(TVS) with the use of the invREC-score system.

Method

Endometrial pattern in 239 consecutive women with EC were evaluated by residencies supervised by trained sonographers using the TVS REC-score system. Findings were related to histopathology at hysterectomy. Multivariate logistic regression was used to obtain most optimal parameters for the invREC-score.

Results

Endometrial tumors were as follows: Stage1a:135; high risk tumors: 64; LVI: 43. A total of 126 women had more than stage 1a tumors or high risk tumors.

Doppler parameters, endometrial thickness(ET) and age predicted high risk tumors or stage more than stage1a. Endometrium was scored according to the (invREC-score ) system by adding scores for: Age (65+ =score 1); ET(10-14=score 1); ET(15-19=score 1); ET(20-24=score 1); ET(25+ score=1); vascularity, but not a single/double dominant vessel (present =score 1); multiple vessels(present=score 1); large vessels(present=score 1); and splashed/densely packed vessels(present=score 1).

A high invREC score predicted: high risk tumors AUC: 0.68; presence of advanced stage more than stage1a AUC: 0.76; LVI AUC: 0.74; highrisk or more than stage1a tumors AUC: 0.75.

At a cut point of ≥6 and ≥7 respectively invREC-score had sensitivity(SE) 68% and 59% specificity(SP) 73% and 84% for identification of stage more than stage 1a tumors, and correctly classified 73% of all women

Conclusion

The invREC-score system could be used for selection of sentinel node. Thereby sentinel node is avoided in 84% of stage1a women. Combined with endometrial sampling and intraoperative gross examination additional lymphnode removal may be needed in only 13%.
Aims

Adherence to guidelines is an important indicator for quality of care. Compliance to adjuvant therapy guidelines for endometrial cancer patients was evaluated in the Netherlands, in a population-based cohort, over a period of 10 years.

Method

From the Netherlands Cancer Registry (NCR), data from all patients diagnosed with endometrial cancer between 2005 and 2014, without residual tumor after surgical treatment, were extracted. Patients were stratified into risk groups according to FIGO stage, grade, tumor type and age. Compliance to adjuvant therapy guidelines was assessed for each risk group. Variation in compliance in time and impact of compliance on survival was assessed.

Results

Data from 13568 patients were extracted from the NCR. Patients were stratified into low/low-intermediate (52%), high-intermediate (21%) and high (20%) risk groups. Overall compliance to guidelines was 85%. Compliance was 98% in patients with low/low-intermediate risk (no adjuvant therapy indicated), 78% in the high-intermediate risk (radiotherapy indicated) and 61% in patients with high risk (external beam radiotherapy with/without chemotherapy indicated). In high risk patients compliance decreased from 64% in 2005-2009 to 57% in 2010-2014. Patients that were treated according to guidelines had favorable survival outcomes compared to patients that were treated otherwise.

Conclusion

While compliance to adjuvant therapy guidelines is excellent in patients with low and low-intermediate risk, there is room for improvement in high risk endometrial cancer patients. Eagerly awaited results of ongoing randomized clinical trials may provide more definitive guidance regarding adjuvant therapy for high risk endometrial cancer patients.

SENTINEL NODE MAPPING USING INDOCYANINE GREEN AND NEAR-INFRARED FLUORESCENCE IMAGING TECHNOLOGY FOR UTERINE MALIGNANCIES: FIRST YEAR EXPERIENCE WITH THE DA VINCI XI SYSTEM

M.L. Eloranta¹, K. Louhiranta², H. Kärkkäinen¹, H. Salinen¹, K. Hämäläinen², M. Anttila¹

¹Kuopio University Hospital, Department of Obstetrics and Gynecology, Kuopio, Finland
²Kuopio University Hospital, Department of Pathology and Forensic Medicine, Kuopio, Finland

Aims

Lymphadenectomy (LND) is essential when evaluating the stage and need for adjuvant treatment in endometrial cancer. However, its therapeutic value is still open. In cervical cancer, the role of LND in treatment selection is more established. In the surgical treatment of both cancers, the sentinel lymph node (SLN) procedure is gaining more interest. The aim of this study was to evaluate indocyanine green (ICG) and near-infrared (NIR) fluorescence mapping in endometrial and cervical cancer.

Method

This is a cohort study of patients with clinical stage I endometrial (n=58) and cervical (n=10) cancer undergoing robotic surgery (da Vinci Xi, Intuitive Surgery, Sunnyvale, CA, USA) in Kuopio University Hospital between March 2016 and 2017. ICG tracer was injected in the cervix at the 3 and 9 o’clock positions submucosally and stromally.

Results

SLN was detected bilaterally in 60.3% (41/68), and at least unilaterally in 92.6% (63/68) of cases. After 27 cases, at least unilateral SLN was detected reflecting the learning curve. In 17.6% of the patients, SLN harbored metastasis. Four patients (5.9%) had false-negative SLN. The SLN was the only metastatic node in six patients (8.8%). Of the patients, 17 had nodal metastases, and 12 of them had the metastasis in the SLN yielding a sensitivity of 81% (95% CI 58.09-94.55%) to detect node-positive disease and a negative predictive value of 90.2% (95% CI 79.2-95.74%).

Conclusion

SLN detection using ICG and da Vinci NIR technology proved to be easily taken into clinical practice and accurate. Our results correlate with previous results.
LOCAL EXCISION WITH ADJUVANT IRRADIATION FOR THE TREATMENT OF LOCAL RECURRENCES ENDOMETRIAL CANCER AFTER PRIMARY RADICAL HYSTERECTOMY – THE SERIES OF 41 PATIENTS

W. Falęcki¹, G. Panek¹
¹Medical University of Warsaw, I Dep. Obstetrics and Gynaecology, Warsaw, Poland

Aims

The aim of the study was to evaluate the effectiveness of combined surgery and brachytherapy for the local recurrences of endometrial cancer after primary surgery.

Method

41 patients with microscopy proven local recurrences of endometrial cancer were treated in years 2010-2015. The treatment of recurrences consisted of adjuvant irradiation of the pelvis (mean dose 46Gy) plus intracavitary brachytherapy HDR with dose 20-25 Gy at 0.5 cm below the surface of the mucosa. Follow-up ranged from 12-60 months (median 18 months). Survival curve was calculated with Kaplan-Meier method. The long-rank test was used to evaluate the influence of the following prognostic factors on survival: clinical stage (Ia, Ib), histological type, grading, time from the completion of primary treatment to the diagnosis of recurrence, and localisation of the relapsing tumor.

Results

The probability of survival of 3 and 5 years was 0.33 and 0.21 respectively. Both analyses prognostic factors – time to the diagnosis and localisation of the recurrence had a statistically significant influence of survival. The risk of death from the disease was significantly higher with extravaginal spread of the tumor and time delay of less than 1 year after completion of primary treatment (p<0.05).

Conclusion

The results of treatment, confirmed a very serious prognosis in this particular group of patients, with the use of presently available methods of treatment. Better methods of early detection of relapses and more effective treatment may contribute to the better survival of these high risk patients.
A 34 year-old nulliparous woman was referred to our center due to infertility with a history of irregular menses. She had had a gastric bypass surgery due to obesity at 30 years. On physical examination, Body Mass Index was 25 Kg/m2.

Method

At Ultrasound examination showed up a thickened endometrium (25mm). A hysteroscopic exam was then decided and revealed an endometrial polyp with increased atypical vessels on its surface, the remaining endometrium showed a normal proliferative endometrial pattern. Complete hysteroscopic polypectomy was performed; pathological examination of the surgical specimen confirmed an endometrial endometrioid carcinoma (EC) grade 1.

Myometrium invasion or any extra uterine lesions were not identified at Ultrasound Examination and Magnetic Resonance Imaging. Pre-treatment serum CA-125 was negative.

Results

Given her decision to pursue fertility-sparing treatment, was treated with Megestrol Acetate 160 mg/day for 6 months. After that, hysteroscopy and endometrial biopsy were performed, which resulted negative showing complete remission of EC.

Patient became pregnant by in vitro fertilization. She delivered by elective cesarean at 33.1 weeks due to lymphedema for malabsorptive syndrome and inferior vena cava compression syndrome, getting a live born baby. The placenta showed no disease at histology. Four months after delivery, laparoscopic hysterectomy with bilateral salpingectomy was performed. Definitive histology was negative for malignancy. At one-year follow-up, no recurrence was found. Conclusion

The conservative approach of early endometrial cancer with high-dose progesterone therapy can be considered acceptable management in premenopausal women who wish to preserve their fertility. However, close follow-up is required and hysterectomy is the definitive treatment.
Aim of this study was to rate the misdiagnosis between preoperative endometrial biopsy, intra-operative frozen section and final pathology in endometrial cancers. Secondary objective was to evaluate whether the failure in preoperative recognition of non-endometrioid endometrial cancers (NE-EC) impacts the surgical planning and the oncological outcomes.

Method

A multicenter retrospective study was conducted in patients with histological diagnosis of endometrial cancer who underwent surgical staging between 2011 and 2016. The concordance rate and the Kappa Cohen coefficient were calculated to assess the correlation between endometrial biopsy or frozen section and final pathology concerning the histological type.

Results

295 patients were enrolled, 226 were endometrioid carcinomas and 61 non-endometrioid at final pathology. The concordance rate between pre-operative and final pathology for NE-EC and the Kappa Cohen coefficient were 83.33% and 0.6203 (IC 95% 0.5004-0.7402), respectively. 24 out of 61 (39.34%) NE-EC were preoperatively misdiagnosed. The frozen section was performed in 86 patients (29.15%). The concordance rate between frozen section and final pathology for NE-EC was 80% and the Kappa Cohen coefficient was 0.391 (IC 95% 0.267-0.456). In patients with non-corresponding and corresponding histology, the surgical procedures were similar, and the 5-year overall survival and the disease free survival were not statistically different, (73% vs. 63.8%; p=0.9) and (32% vs. 65%; p=0.18) respectively.

Conclusion

Pre-operative and intra-operative histotype assessment do not reliably forecast final pathology in endometrial cancers and therefore may not be the optimal determinant for surgical and therapeutic planning. In our study, the failure to identify preoperatively NE-EC did not affect oncological outcomes.

14Katholieke Universiteit, Department of Electrical Engineering- ESAT-SCD, Leuven, Belgium
15University Hospital Leuven, Department of Obstetrics and Gynecology, Leuven, Belgium
16Katholieke Universiteit, Department of Development and Regeneration, Leuven, Belgium

Aims

To describe the sonographic features of endometrial cancer in relation to stage, grade, and histotype using the IETA terminology.

Method

Prospective multicenter study on 1714 women with endometrial cancer undergoing a standardized transvaginal grayscale and Doppler ultrasound examination by an experienced ultrasound examiner using a high-end ultrasound system. Clinical and sonographic data were entered into a web-based protocol. Sonographic characteristics according to IETA were compared with outcome of hysterectomy, i.e. tumor stage, grade, and histotype.

Results

After excluding 176 women (no or delayed hysterectomy, final diagnosis other than endometrial cancer, or incomplete data), 1538 women were included in our statistical analysis. Mean age was 65 years (SD, 10.5), and mean BMI 30 (SD 7.1), 1378 (89.7%) women were postmenopausal, and 1296 (84.2%) reported abnormal vaginal bleeding. Grayscale and color Doppler features changed with increasing grade and stage. High-risk tumors (stage 1A, grade 3 or non-endometrioid or > stage 1B) were less likely to have regular endometrial myometrial border (difference of -23%, 95% CI -27 to -18%), whilst they were larger (mean endometriatal thickness; difference of +9mm, 95% CI +8 to +11mm), more frequently had non-uniform echogenicity (difference of -10%, 95% CI -15 to -5%), the multiple, multifocal vessel pattern (difference of +21%, 95% CI +16 to +26%), and a moderate or high color score (difference of +22%, 95% CI +18 to +27%), than low-risk tumors.

Conclusion

Grayscale and color Doppler ultrasound features of endometrial tumors vary by grade and stage. This knowledge may improve preoperative ultrasound discrimination between low and high-risk cancer.
CLINICAL SIGNIFICANCE OF CLASSIFICATION BETWEEN G1 AND G2, IN UTERINE BODY ENDOMETRIOID ADENOCARCINOMA

S. Furukawa¹, H. Iwase¹, S. Endo¹, Y. Tazo¹, H. Sato¹, T. Takada¹, M. Arai¹, T. Onda¹
¹Kitasato University School of Medicine, Obstetrics and Gynecology, Sagamihara, Japan

Aims

Although uterine body endometrioid adenocarcinoma (EMA) is usually classified into three grades by the degree of differentiation; high (G1), intermediate (G2), and low (G3), recommended management for G2 is the same as G1 in both Japanese and ESGO Guidelines. The aim of this study is to evaluate the necessity to distinguish G2 from G1 in EMA.

Method

We retrospectively reviewed medical records of 365 patients with EMA (G1: 281, G2: 84) treated at our hospital from 2005 to 2013. Clinicopathological features and prognosis were analyzed.

Results

Median age of G1/G2 patients was 55/59 years-old, and stage distribution was 235/15/30/1 and 55/10/17/2 in stage I/II/III/IV (FIGO 2008), respectively. G2 patients had higher risk for recurrence (high risk in Japanese Guideline or high/advanced/metastatic in ESGO Guideline) (34.5% vs. 16.4%, p=0.0006), and thus underwent adjuvant treatment more frequently (58.3% vs. 35.9%, p=0.0004) compared to G1. The median follow-up period of all patients was 61 months. Overall survival (OS) in G2 was significantly worse than G1 (p=0.0086, 5Y-OS: 89.9% vs. 97.1%). Among the pathological risk factors, significant differences in frequency between G2 and G1 were observed in deep muscular invasion (>1/2), lymphovascular space invasion, cervical involvement, and lymph node metastasis. On multivariate analysis, positive peritoneal cytology and to be high-risk for recurrence were the only independent predictors of unfavorable OS.

Conclusion

Although G2 had poor prognosis compared to G1, the grade itself may not be the cause of worse prognosis. We could not find the reason to distinguish G2 from G1 in management.
ENDOMETRIAL CANCER

ESGO7-1058

ACCURACY OF 2D AND 3D ULTRASOUND IMAGING IN THE ANATOMICAL EVALUATION OF TUMOR INVASION IN ENDOMETRIAL CANCER

L. Fusio¹, V. Facelli², L. Ottino³, L. Marianitä, G. De Rosa⁴, G. Menato³, A. Ferrerō³
¹ ASO Mauriziano, Gynecology Obstetrics, Torino, Italy
² ASO Mauriziano, Gynecology and Obstetrics, Torino, Italy
³ ASO Mauriziano, Gynecology and Obstetrics, Torino, Italy
⁴ ASO Mauriziano, ASO Mauriziano, Torino, Italy

Aims

Prognosis in early stages endometrial cancer depends on histological type and grading, depth of myometrial invasion, cervical involvement and lymph-node metastases. Prognostic factors are acquired by surgical staging with hysterectomy and bilateral salpingo-oophorectomy. Pelvic and para-aortic lymphadenectomy are recommended for patients at risk for lymphatic dissemination on the basis of intraoperative findings, in particular the depth of myometrial invasion. Performing a lymphadenectomy has specific risks such as lymphedema, lymphocele or urinary complications. Thus the need of performing lymphadenectomy only when strictly necessary.

To evaluate if the use of a standardized diagnostic protocol adopting 2D and 3D ultrasound imaging could improve the accuracy of intraoperative frozen section of the uterine sampling detecting the depth of myometrial invasion

Method

2D ultrasound and frozen section performance was prospectively evaluated on 50 consecutive patients diagnosed with endometrial cancer (tumor dimension, depth of myometrial invasion and tumor free margin) Then 2D - 3D US examination performed by a gynecologic oncologist with expertise in ultrasounds was applied in a protocol designed to guide the anatomopathologist to the best cut on frozen section. This procedure aimed to improve the sensitivity and specificity of the pre and intraoperative examination

Results

A preoperative standardised protocol adopting 2D-3D US giving accurate information on anatomical localization of the tumour to anatomopathologist results in improving the performance of the intraoperative frozen section (sensitivity from 67% to 100%, specificity 93% to 100%, PPV from 83% to 100%, VPN from 83% to 100%)

Conclusion

This leads to a better management of patients with endometrial cancer.
ENDOMETRIAL CANCER

ESGO7-1297

ENDOMETRIAL CANCER: IS THERE A BETTER WAY TO EVALUATE MYOMETRIAL INVASION WITH TVUS 2D?

L. Fusot, L. Ottino2, V. Liberale2, L. Mariani2, A. Ferrero2, G. Menato2, N. Biglia2
1ASO Mauriziano, Gynecology Obstetrics, Torino, Italy

Aims

to compare the diagnostic performance of four different TVUS 2D methods to study the myometrial invasion in endometrial cancer.

Method

This prospective single Institution study was performed on 42 endometrial cancer patients between Jan/2015 and Dec/2016. Myometrial invasion (<50% vs > or = 50%) was estimated in each patient, using four TVUS 2D different methods: IETA d/D, subjective assessment, endometrial thickness (considered positive if > or = 18 mm) and myometrial-endometrial junction (considered positive if interrupted or not defined). The concordance between the TVUS 2D and pathological findings has been calculated and reported as sensitivity, specificity, PPV, NPV and k Cohen’s.

Results

Median age was 66 years, 38 patients had EC, 4 had NEC; 13/42 patients had myometrial invasion > or = 50% at histopathology. The results are shown in Table 1.

Table 1: sensitivity, specificity, PPV, NPV and k Cohen’s of four different TVUS 2D methods

ENDOMETRIAL CARCINOMA IN A SINGLE HORN OF A BICORNUATE UTERUS: A CASE REPORT

K.M. Gaballa¹, C. cicero², V. Gallotta², G. Zannoni³, G. Scambia²

¹Oncology Center Mansoura University, Surgical oncology, Mansoura, Egypt
²Largo Agostino Gemelli, Gynecologic Oncology, Rome, Italy
³Largo Agostino Gemelli, Human Pathology, Rome, Italy

Aims

In the presence of bicornuate uterus, a bilateral endometrial biopsy should be performed in order to reduce the risk of delayed or missed diagnosis.

The possibility of existence of a separate uterine cavity should always be considered when endometrial cancer is clinically suspected but pathology fails to confirm the diagnosis.

Method

we discuss the diagnosis and the management of endometrial carcinoma in a single horn of bicornuate uterus in a 64 years old woman as a case report

Results

The gross examination of the uterus revealed a bicornuate uterus with a greater horn of 12x9x8 cm and a smaller horn of 10x3 cm (Figure 2). The cavity of the greater horn showed a neoplastic growth of 10 cm with infiltration of about 1,8 cm of the myometrium from whole thickness of thickness of 1.9 cm. while the other horn was free of tumor tissue.

The microscopic examination of the uterus revealed G2 endometrioid adenocarcinoma of the endometrium of the greater horn with infiltration of more than 50% of the myometrium.

Conclusion

The management of a case of bicornuate unicollis uterus with endometrial carcinoma in only one horn is the same as patients with endometrial cancer in single uterus and depends mainly on stage and histological grade of the tumor.

The possibility of existence of a separate uterine cavity should always be considered when endometrial cancer is clinically suspected but pathology fails to confirm the diagnosis. This points out the importance of a careful physical examination and radiographic evaluation in such cases.
Aims

The aim of study is to estimate the accuracy of hysteroscopy in predicting different endometrial histopathology.

Method

The study included 207 women aged 21 to 79 years (mean aged 41.06) with or without abnormal uterine bleeding. They underwent diagnostic hysteroscopy and endometrial biopsy. Endometrial polyps and hyperplasia were considered abnormal hysteroscopic findings. Sensitivity, specificity, and negative (NPV) and positive (PPV) predictive values of hysteroscopy were defined to assess hysteroscopic accuracy in estimating pathologic conditions. The hysteroscopy diagnosis was compared with histology at the end of the study.

Results

Histologically endometrial polyps were found in 170 (82%), and hyperplasia in 34 (16%) patients. Hysteroscopy showed sensitivity – 92.42%, specificity – 33.33%, NPV – 16.67%, and PPV – 96.83% in predicting abnormal histopathology of endometrium. Highest accuracy was in diagnosing endometrial polyps, with sensitivity, specificity, NPV, and PPV of 98.8%, 90.24%, 94.87%, and 97.62%, respectively; the worst result was in estimating hyperplasia, with respective figures of 59.38%, 98.86%, 93.01%, and 90.48%. All failures of hysteroscopic assessment resulted from poor visualization of the uterine cavity or from underestimation or overestimation of irregularly shaped endometrium.

Conclusion

Hysteroscopy is recommended for diagnosis and treatment of focal lesions like polyps or uterine fibroid. But endometrial sampling is mandatory in all hysteroscopies showing unevenly shaped and thick endometrial mucosa or an anatomically distorted uterine cavity, and when intrauterine visualization is less than optimal.
ENDOMETRIAL CANCER

ESGO7-0341

MALIGNANT POTENTIAL OF ENDOMETRIAL POLYPS IN PREMENOPAUSAL AND POSTMENOPAUSAL WOMEN

A. Ganovska¹, S. Kovachev¹

¹Military Medical Academy, Department of Gynecology, Sofia, Bulgaria

Aims

The aim of this study is to evaluate the risk of premalignant and malignant changes in endometrial polyps with or without symptoms.

Method

The study is single-center retrospective (years 2014–2016) and enrolled 355 women with histologically diagnosed endometrial polyp. The patients are aged 20 to 80 years (mean age 45.16). All patients included in the study underwent diagnostic hysteroscopy and subsequent endometrial biopsy or dilation and curettage.

Results

Endometrial polyps with premalignant and malignant amendments were distributed as follows: atypical hyperplasia – 8 (2.25%); complex hyperplasia – 27 (7.6%), simple hyperplasia – 113 (31.83%) and endometrial carcinoma – 12 (3.4%). The average age of patients in group with premalignant changes in the endometrial polyps was 43.18 years, and that in the group with malignant changes was 60.8. Ten (10/83.33%) women with endometrial carcinoma were in menopausal status and in 9 (90%) of them there were symptoms like abnormal uterine bleeding.

Conclusion

The age and menopausal status are risk factors which increases the risk of malignant changes in endometrial polyps.
SENTINEL LYMPH NODE BIOPSY WITH DUAL LABELING TECHNIQUE IN SURGICAL MANAGEMENT OF EARLY-STAGE ENDOMETRIAL CARCINOMAS

V. García Pineda¹, A. Zapico Goñi², A. Couso González², M.D. Rodríguez Garnica¹, P. Valenzuela Ruiz², J.M. Menéndez Fuster¹

¹Infanta Cristina University Hospital, Obstetrics and Gynecology, Madrid, Spain
²Príncipe de Asturias University Hospital, Obstetrics and Gynecology, Madrid, Spain

Aims

The aim of our study is to analyze the technique of sentinel lymph node (SLN) biopsy for node status evaluation in the management of early stage endometrial carcinoma in order to avoid unnecessary full lymphadenectomy and tailoring adjuvant therapy.

Method

An observational prospective single-center study was carried out between January 2015 and March 2017. Dual labeling mapping was performed in patients with early endometrial cancer diagnosis: lymph node mapping with lymphoscintigraphy after Tc99 cervical injection the day before surgery and isosulfan blue injected cervically on the day of surgery. SLN detection was performed intraoperatively with gammaprobe and direct visual inspection of blue dye. Intraoperative histological examination of myometrial invasion and SLNs was made and pelvic ± para-aortic lymphadenectomy was carried out according surgical indication. We made statistical analysis of detection rate and negative predictive value (NPV) of SLN biopsy.

Results

30 patients underwent surgery with total SLN rate detection of 90% (27 patients) and bilateral rate detection of 43,3% (13 patients). The mean number of SLN per patient was 2.47±1.6 and the most common location was external iliac vessels, 48,15% (13 patients), just one case (3,3%) was isolated in para-aortic area. 96,3% SLNs were negative for malignancy, with a NPV of 100%, only one case was positive. Finally, 90% of carcinomas were endometrioid types and 10% were serous papillary type with lymphovascular invasion in 6,7% of cases.

Conclusion

Sentinel lymph node biopsy seems to be a feasible alternative to systematic lymphadenectomy given its high NPV and detection rate.

FERTILITY-PRESERVING MANAGEMENT OF EARLY STAGE ENDOMETRIAL CANCER: ONCOLOGICAL AND REPRODUCTIVE OUTCOME

R. Gatsinga¹, R.P. Namuduri², Y.K. Lim², I. Aggarwa², W.L. Wong², K.L.P. Yam²
¹Duke-NUS Medical School, School of medicine, Singapore, Singapore
²KK Women and Children’s Hospital, Gynaecological Oncology, Singapore, Singapore

Aims

Assess efficacy of progestins as fertility-sparing treatment of early endometrial cancer and to evaluate the oncological and reproductive outcome in a South East Asian population.

Method

This is a retrospective cohort study in a large tertiary institution in Singapore. We identified women below 40 years, with clinically presumed stage IA grade 1 and selected grade 2 endometrial cancer (The two patients were keen to try fertility preservation treatment and were adequately counseled) who were offered progestin therapy for fertility-sparing management at our center between 2010 and 2015. We retrieved their medical record and ran analyses for association of patient characteristics with treatment outcome.

Results

Forty-three patients with grade 1 tumors and two patients with grade 2 tumors were identified. Fourteen were either lost to follow up, sought treatment elsewhere, or requested for definitive treatment. Thirty-one were included in the analysis. Twenty-one (67%) achieved complete remission at median time of 5 months (2-25). Nine patients (29%) did not respond to treatment and underwent hysterectomy (median time: 9 months). Both patients with grade 2 tumors achieved remission. The overall probability of remission increases steeply for the first 9 months, then plateaus and gradually increases after 15 months. Three patients had subsequent pregnancies. Ten patients (45%) patients recurred at a median time of 17 months (6-64) after remission. Morbidly high BMI was associated with increased recurrence risk (p<0.05).

Conclusion

With aggressive monitoring, high dose progestin appears to be a safe therapy for early endometrial adenocarcinoma in women 40 years old or younger wishing to preserve fertility.
A COMPARATIVE STUDY OF TWO FOLLOW-UP STRATEGIES FOLLOWING TREATMENT OF ENDOMETRIAL CANCER BETWEEN AN ITALIAN AND A UK CENTRE

V. Ghirardi1, N. Bizzarri1, R.L. O'Donnell1, S. Rundle1, I.C. Kotsopoulos1, P. Korompelis1, A. Kucukmetin1, A. Fisher1, C. Ang1, N. Ratnavelu1, H. Manderville1, K. Roberts1, S. Costantini2, M. Valenzano Menada3, R. Naik1

1Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom
2IRCCS AOU San Martino – IST- University of Genoa,
Academic Unit of Obstetrics and Gynecology-Department of Neurosciences-Rehabilitation-Ophthalmology-Genetics-Maternal and Child Health DiNOGMI, Genoa, Italy

Aims

To date there are no studies demonstrating survival advantage in endometrial cancer (EC) with intensity of follow-up (FU). The objective of this study was to compare PFS and OS in EC patients treated and followed-up in two European tertiary centers, each with markedly different FU protocols.

Method

This retrospective study included consecutive patients treated for EC 2005 to 2010, with 5-years of FU. FU in the Italian group (Genoa) included examination, vault cytology, CA125, CT and ultrasound scans at predefined intervals regardless of symptoms. In the UK group (Gateshead), FU included examination at decreasing time intervals with symptom-directed imaging.

Results

907 patients were surgically treated for EC 2005-2010. There were 61(10.9%) recurrences in the UK group and 24(8.0%) in the Italian group. In the UK group, 45(73.8%) recurrences were symptomatic with confirmation on examination in 14(22.9%) cases and radiologically in 31(50.8%). 16 cases were asymptomatic, of which 4(25.0%) were detected on examination and 12(75.0%) as an incidental finding on unrelated imaging. In the Italian group, 6(25.0%) cases were symptomatic. Of the 18(75.0%) asymptomatic cases, 2(11.1%) were detected following examination, and 7(38.9%) with pre-planned imaging. There was no survival advantage observed in the patients diagnosed using intensive FU in comparison to the less intense UK based FU.

Conclusion

This observational study suggests that early diagnosis of asymptomatic recurrence has no significant survival advantage. Structured FU interview and clinical assessment is likely to trigger appropriate and timely imaging. Initial evaluation suggests that there are significant health service costs associated with intensive FU.
ENDOMETRIAL CANCER

ESGO7-1361

ACCURACY OF PREOPERATIVE ASSESSMENT BY CT SCAN IN HIGH GRADE NON ENDOMETRIOID ENDOMETRIAL CANCERS

R. Giannice¹, S. Manek², H. Soleymani³, P. Guarnerio³, R. Garruto Campanile¹, S. Dhar³, G. Valenti¹, M. Morotti¹, M.I. Sereni¹, R. Tozzi³

¹Churchill Hospital- Oxford University Hospitals NHS Foundation Trust, Gynecologic Oncology, Oxford, United Kingdom
²Churchill Hospital- Oxford University Hospitals NHS Foundation Trust, Anatomy, Oxford, United Kingdom
³Asst Santi Paolo E Carlo, Obstetrics and Gynaecology, Milan, Italy

Aims

To analyse accuracy of the preoperative CT scan assessment in patients with high grade non endometrioid endometrial malignancy.

Method

From a prospective collected database, we retrieved clinical and histological data on patients undergone full surgical staging (hysterectomy, bilateral salpingo-oophorectomy, pelvic lymphadenectomy and infracolic omentectomy) between 2010 and 2016. Patients were included in the study if they had high grade endometrial serous and clear cell cancer and endometrial carcinosarcoma. Outcomes were accuracy, sensibility and specificity of preoperative CT scan for omental and nodal involvement.

Results

In the study period, among 55 patients with high grade non endometrioid malignancies of the endometrium 25 (45%) were serous, 12 (22%) were clear cell and 18 (33%) were carcinosarcoma histotypes. Patients and surgical characteristics are details in table 1 and 2. Surgical staging by CT scan assessment in table 3. Based on the final histology, 17 patients out of 55 (31%) were upstaged. One patient (1.8%) was found with microscopic (<2mm) omental implants among CT scan stage I cases. Ten patients (18%) were found with metastasis into the lymph-nodes. Accuracy of CT scan on nodal status was 80% while on omental status was 94%.

Conclusion

In patients with high grade non endometrioid malignancies of the endometrium CT scan shows a high accuracy on omental assessment and a low accuracy is confirmed on nodal status. The rate of omental disease is very low in patients with preoperative CT scan stage I and therefore omentectomy seems unnecessary. To the contrary, pelvic lymphadenectomy has a significant role.

6Institut Català d'Oncologia-Hospital Duran i Reynals. IDIBELL, Medical Oncology, L'Hospitalet de Llobregat-Barcelona, Spain
7Institut Català d'Oncologia. IDIBELL. CIBERESP, Unit of Biomarkers and Susceptibility- Cancer Prevention and Control Program, L'Hospitalet de Llobregat-Barcelona, Spain
8Institut Català d’Oncologia. IDIBELL, Clinical investigation Unit, L’Hospitalet de Llobregat-Barcelona, Spain
9Institut Català d’Oncologia-Hospital Duran i Reynals. IDIBELL, Radiation Oncology, L’Hospitalet de Llobregat-Barcelona, Spain

Aims

To evaluate the outcome of high risk EC treated with CCT and its correlation with a surrogated molecular classification.

Method

Forty-nine patients (pts) treated from 2011 to 2016 were included in a prospective database. Pts were treated with cisplatin with pelvic external beam radiotherapy (RT), plus brachytherapy; followed by paclitaxel and carboplatin. The molecular classification into the 4 TCGA groups (POLE mut, MSI, CN-low, CN-high/serous-like) was performed in 38 pts using a surrogate classification: POLE mutations (detected by Sanger), and immunohistochemistry for p53 and MMR (as surrogate markers for TP53 mutations and MSI).

Results

Pts median age was 67yo; Endometrioid pathology in 59%, serous 20%; up to 73% grade 3; and FIGO Stage III in 82%. With a median follow-up of 39 months, 30% of pts experienced metastatic relapse. 3-year overall survival (OS) was 80%, and 3-year progression free survival was 74%.

Pts were molecularly classified as: 0% POLE mut, 13% CN-low, 37% MSI and 50% CN-high. CN-low present an 3-y OS of 100%, MSI of 82% and CN-high of 67%. No statistically significant differences were found (low number of events and pts). It is remarkable the survival difference between endometrioid and serous tumors in the CN-high group (86% vs 50%, respectively).

Conclusion

CCT followed by CT is an effective adjuvant therapy in high risk EC pts with an acceptable toxicity. Molecular prognostic classification has shown a big proportion of patients in MSI and CN-high groups, with known worse prognosis. Morphologic differentiation between endometrioid and serous carcinomas in CN-high hold prognostic implications.

ROBOT-ASSISTED MANAGEMENT OF APPARENT EARLY-STAGE ENDOMETRIAL CANCER: THE BELGIAN EXPERIENCE

J. Pinckers¹, C. Ver Eecke², K. Tran³, P. Van Trappen⁴, F. Peeters⁵, E. Despierre³, I. Vergote², F. Goffin¹

¹Hôpital de la Citadelle, Department of Obstetrics and Gynecology, Liege, Belgium
²University Hospitals Leuven, Department of Obstetrics and Gynecology, Leuven, Belgium
³Onze-Lieve-Vrouweziekenhuis, Department of Obstetrics and Gynecology, Aalst, Belgium
⁴AZ Sint-Jan Hospital, Department of Obstetrics and, Bruges, Belgium
⁵AZ Klina, Department of Obstetrics and Gynecology, Brasschaat, Belgium

Aims

We report the Belgian experience of endometrial cancer management with robotic-assisted laparoscopy.

Method

A retrospective, multicenter, descriptive study including patients with presumed early stage endometrial cancer surgically treated by robot-assisted laparoscopy between 2007 and 2016. All patients were treated according to local policies and had a total hysterectomy with bilateral salpingo-oophorectomy with or without lymph node dissection. Operative and postoperative variables were measured to assess the feasibility and safety of the procedure. Follow-up data and oncological outcomes were collected.

Results

Four hundred sixty-five patients were included. The median age was 68 years and the median BMI was 30 kg/m2. Histology types were endometrioid (78%), serous (11%), carcinosarcoma (3%), mixed (6%) and mucinous (1%). Nodal staging was performed in 274 patients (58%). The median nodal counts were 21 for pelvic and 10 for para-aortic areas. The median estimated blood loss was 75 ml. Median operative times were 170 min (skin to skin) and 122 min (console time). We report 3 conversions to laparotomy (0.6%). Sixteen % of the patients developed at least one post-operative complication graded according to Clavien (Clavien I-II: 17%, Clavien III: 4.7%, Clavien IV-V: 0.8%). There was one perioperative death (necrotizing fasciitis). The median hospital stay was 3 days. After a median follow-up of 21 months, the disease-free survival was 88.8%.

Conclusion

This large series supports the feasibility and safety of robotic surgery in apparent early stage endometrial cancer patients. The low complication and conversion rates associated with the favorable oncological outcomes support its use in this indication.
Aims

To evaluate in routine practice ESMO-ESGO-ESTRO guidelines which recommended a second staging surgery (SSS) to perform a para-aortic (+/- pelvic) lymphadenectomy in case of high risk endometrial cancer operated by only a radical hysterectomy.

Method

At Gustave Roussy, from 2010 to 2014, 55 patients had a hysterectomy with a diagnosis of high risk endometrial cancer.

Results

Median age and BMI were respectively 63 years (53-74) and 26 kg/m² (23-30). Performance status was 0 (n=37), 1 (n=16), 2 (n=2). Twenty-four patients had a SSS with a number’s median of para-aortic nodes of 18 (12-14). Six (25%) patients had at least one metastatic node and received radiotherapy with extension field in para-aortic area and adjuvant chemotherapy. We used systematically a laparoscopic approach (extraperitoneal approach in 87%). One patient required a conversion by laparotomy for a vascular injury. No major postoperative morbidity occurred. Twenty-one patients didn’t have a second staging surgery for the following reasons: age> 70 years (n=7), comorbidities (n=3), initial surgery’s delay (n=1), previous abdominal surgery (n=4), poor medical status (n=2), patient’s choice (n=1), combined reasons (n=10). Adjuvant treatment consisted on radiotherapy (n=44), brachytherapy (n=48) and chemotherapy (n=19). Among the 24 patients with a SSS, 23 (96%) received the complete adjuvant treatment whilst 8 patients (26%) of the 31 patients without SSS stopped the adjuvant treatment due a toxicity (P=.03).

Conclusion

Due to change of management, SSS via a laparoscopic approach should be considered in high risk endometrial cancer in light of age, comorbidities, BMI, medical status and previous abdominal surgery.
ENDOMETRIAL CANCER

ESGO7-0376

ADJUVANT CHEMOTHERAPY MAY NOT BE NECESSARY FOR LOW-INTERMEDIATE RISK ENDOMETRIAL CANCER

Y. Habu, A. Mitsuhashi, A. Matsuoka, K. Nishikimi, S. Tate, H. Usui, M. Shozu

Chiba University, Department of Reproductive Medicine, Chiba, Japan

Aims

Adjuvant chemotherapy has been recommended for patients with intermediate-risk endometrial cancer (EC) according to the Japan Society of Gynecologic Oncology guidelines; however, this is controversial. The purpose of this study was to investigate the necessity of chemotherapy in patients with intermediate-risk EC in Japan.

Method

We performed a retrospective analysis of 546 EC patients surgically staged from 1A to 3C. Patients with intermediate risk were divided into low-intermediate risk (LIR) and high-intermediate risk (HIR) groups, as indicated in the table. Adjuvant chemotherapy was administered to the HIR and high-risk groups. The independent prognostic risk factors were investigated using multivariate analysis and the relapse rates between the LIR and low-risk groups were compared.

Results

Five (2.2%) out of 228 patients in the low-risk group, 8 (9.1%) out of 88 patients in the intermediate-risk group, and 60 (26.8%) out of 230 patients in the high-risk group relapsed. Lymph node metastasis, tissue type (type 2), muscle invasion (≥1/2), and positive cytology of ascites were revealed as independent prognostic factors. Two (5.9%) out of 34 patients in the LIR group and 6 (11.1%) out of 54 patients in the HIR group relapsed. There was no significant difference in relapse rates between the LIR and low-risk groups.

Conclusion

LIR EC patients may not require adjuvant chemotherapy.

LOW GRADE ENDOMETRIAL STROMAL SARCOMA : REVIEW OF 10 CASES
S. Haddad¹, I. Zemni¹, N. Boujelbene², M. Rezgani¹, M. Bouhani¹, M. Slimene¹, J. Ben Hassouna¹, K. Ben Mrad², M. Hechiche¹, K. Ben Rahal¹
¹Salah Azaiez Institute, Surgery, Tunis, Tunisia
²Salah Azaiez Institute, Anatomy and Pathology, Tunis, Tunisia

Aims

Endometrial stromal sarcoma (ESS) is a rare malignant tumor of the endometrium, occurring among premenopausal women. We conducted a retrospective study in order to evaluate the clinical behavior and management outcome of low-grade endometrial stromal sarcoma (LGESS).

Method

From October 2000, to March 2013, 10 patients with histologically proven LGESS in the department of surgical oncology of Salah Azaiez institution, Tunis-Tunisia, were included in this analysis. Demographics, pathology, treatment, time to recurrence, salvage therapy and survival information were reviewed retrospectively.

Results

The median age was 43 years. The most common presenting symptoms were pelvic pain and abnormal vaginal bleeding. Diagnosis was made through curettage in only one patient. Two patients were diagnosed after simple hysterectomy that took place in another department and they were sent to our institution for recurrent disease. Four patients were diagnosed at FIGO stage I. All the patient underwent surgical treatment. Adjuvant therapy was administrated in five cases. The median follow-up period was 48 months. Three patients had disease recurrence.

Conclusion

Surgical treatment not preserving ovarian function is mandatory to decrease the risk of recurrence compared with treatment sparing the ovaries.

CANCER OF THE ENDOMETER UTERUS LOCALLY ADVANCED EXPERIMENT OF MEDICAL ONCOLOGY ALGIERS

F. Hadjarab¹, A. Taibi², K. BOUZID¹
¹center pierre marie curie algiers, medical oncology, algiers, Algeria

Aims

the goal of this work for watch that the effective head end in the cancer of the endometer, remains the surgery and the radiotherapy the chemotherapy used in the advanced stages but its effectiveness is poor

Method

we used the data of the files of our patients, attacks of cancer of the endometer, we use the parameters (old, standard histological, stage, treatment received initially)

We bring back a series of 39 patients treated for cancer of endometer during period (2011-2016)

The number of patients diagnosed with a cancer of the endometer during this period is of 54 but only 39 files could exploited either 72%, the median age is 57 years (28-79), and majority was at the stage IVB 48% (19/39)

Results

The majority of our patients profited from a surgical treatment, Colpo-hysterectomy extended to the distal parameter with pelvic and lomboaortic lymphadenectomy soit 79%

The histological type most frequent is the adenocarcinominist epidermoïde, 51% (20/39). With a majority of Rank 2.

The radiotherapy has was indicated only at 28%, The patients treated by chemotherapy 41% (16/39), with Paclitaxel + Carboplatine

A complete answer to the treatments atonly 30% of the patients is (12/39).

41%(16/39), alive patients in remission, the average of survival : 25 months.

Conclusion

Our study shows that the cancer of the endometer uterus is diagnosed at a late stage, the surgical assumption of responsibility is satisfactory, the multidisciplinary access of the treatment enable us to have an acceptable average survival however an earlier diagnosis would make it possible to improve survival.

CHARACTERIZATION OF TUMOR INFILTRATING LYMPHOCYTES IN ENDOMETRIAL CANCER

J. Barrou¹, E. Lambaudie¹, C. Degos², J. Thomassin Piana³, G. Houvenaeghel¹, M. Heinemann¹, D. Olive²
¹Institut paoli calmettes, Surgical oncology- Immunology and cancer laboratory, Marseille, France
²Institut paoli calmettes, Immunology and cancer laboratory, Marseille, France
³Institut paoli calmettes, Anatomopathology, Marseille, France

Aims

There is a host immune response to the tumor cells by tumor infiltrating lymphocytes (TILs). These cells infiltrate many solid tumors like in melanoma or lung cancer, with different prognosis impact and development of new therapies. The aim of this study was to describe the TILs in endometrial cancer (EC) from a quantitative and functional point of view.

Method

We studied a prospective cohort of patients with endometrial cancer. All FIGO stage and histological type were included. Tumoral and normal endometrium was sampled from surgical hysterectomy, prior to any treatment. A peripheral blood was also obtained for each patient and mononuclear cells were extracted (PBMC). All samples were analyzed in flow cytometry.

Results

The CD45+ cells infiltrate significantly higher tumor tissue than in normal endometrium (p=0.0195). The tumor immune microenvironment presents more Treg cells (p=0.002), but less Natural Killer (NK) cells (p<0.001) than normal endometrium. In comparison to PBMC from the same patients, TILs have a different activation profile with higher PD1, TIM3 and OX40 surface expression.

Conclusion

Our study highlights more TILs in EC than in normal endometrial tissue. In term of functional activity, the immune response of TILs against tumor cells appears to decrease. An inversion of the TILs function, by immunotherapy, could be a new treatment for EC.

ANALYSIS OF ENDOMETRIAL CELLS OBTAINED BY VAGINAL TAMPONS DURING ANNUAL GYNAECOLOGICAL SURVEILLANCE IN WOMEN WITH LYNCH SYNDROME

J. Helder-Woolderink¹, G. de Bock², B. van Hemel³, H. Hollema³, N. Werner³, M. Mourits⁴

¹Martini Hospital, Obstetrics and Gynaecology, Groningen, The Netherlands
²University Medical Center Groningen, Epidemiology, Groningen, The Netherlands
³University Medical Center Groningen, Pathology, Groningen, The Netherlands
⁴University Medical Center Groningen, Gynecologic Oncology, Groningen, The Netherlands

Aims

Endometrial sampling is a common approach to screen women with Lynch syndrome (LS) for endometrial cancer. As this is an invasive and painful procedure, the aim of our study was to search for a less invasive alternative.

Objective: To analyse if endometrial sampling collected by a vaginal tampon in women with LS is of good quality and comparable to endometrial sampling as obtained by invasive endometrial sampling, during annual surveillance.

Method

In this prospective feasibility study, 25 women with LS or first degree relatives (FDR) who underwent repetitive annual gynaecological surveillance, including endometrial sampling, in the University Medical Center Groningen and in the Martini Hospital Groningen from January 2017 until now were included. Women were asked to insert a vaginal tampon 2-4 hours before surveillance. After removing the tampon, standard gynaecological surveillance including endometrial sampling was performed. Both samples were send to the Pathology department and evaluated independently by two pathologists. The quality of the endometrial sampling obtained by the tampon and by endometrial sampling were compared.

Results

At this moment, the preliminary pathology results of 13 women are available; we expect to have all the results of 25 women within three months. In the 13 collected procedures, all samples obtained with tampons were of good quality, although none contained endometrial cells.

Conclusion

Collection of endometrial cells using tampons in women with LS might not be possible, as these asymptomatic women are not shedding endometrial cells.
DIFFERENTIATING LOW-GRADE ENDOMETRIAL STROMAL SARCOMA AND UNDIFFERENTIATED ENDOMETRIAL SARCOMA BY USING MAGNETIC RESONANCE IMAGING

⁴Chang Gung Memorial Hospital and Chang Gung University- Linkou Medical Center, Clinical Trial Center, Taoyuan City, Taiwan R.O.C.

Aims

Endometrial stromal sarcoma (ESS) is a rare uterine malignancy, with distinct prognosis between different subtypes. This study aimed to analyze the diagnostic value of magnetic resonance imaging (MRI) in staging and differentiating low-grade ESS (LGESS) from undifferentiated endometrial sarcoma (UES).

Method

We retrospectively reviewed 18 ESS patients who had pre-operative pelvic MRI in our institute from 2000 to 2016, including eight low-grade ESS (LGESS) and ten UES. Two radiologists independently evaluated imaging characteristics based on T1-, T2-, diffusion-weighted and contrast enhanced MRI. Statistic analysis included Chi-square and Mann-Whitney tests.

Results

T2 hypointense bands, marginal nodules, intratumoral nodules and worm-like intramyometrial nodules were found in both LGESS and UES. UES demonstrated significantly more extensive necrosis and feather like enhancement, as compared with LGESS (P < 0.05). MRI yielded good radiologic-pathologic correlation in terms of tumor size, necrosis, hemorrhage and extrauterine involvement (P < 0.05). Both LGESS and UES demonstrated diffusion restriction, but no statistic difference of apparent diffusion coefficients (ADC) value existed between the two subtypes.

Conclusion

Extensive necrosis and feather like enhancement on MRI aided in differentiating LGESS from UES.

SEARCH FOR RISK FACTORS FOR RECURRENCE IN INITIALLY LOW RISK ENDOMETRIAL CANCER: SOMATIC MUTATIONS AND HISTOPATHOLOGICAL CHANGES

S. Imboden¹, K. Taghavi², T. Rau², A. Papadia¹, S. Mohr¹, F. Siegenthaler¹, C. Simillon³, B. McKinnon¹, M. Mueller¹

¹University Hospital Bern, Obstetrics and Gynecology, Bern, Switzerland
²University Bern, Institute of Pathology, Bern, Switzerland
³University Bern, DFKE, Bern, Switzerland

Aims

State of art for identifying patients at risk for recurrence is with the FIGO Staging and histopathological classifications. Evidence indicates that genetic mutations are involved in the development of endometrial cancer (EMCA) with approximately 90%. Whether any of these mutations are specifically related to recurrence of endometrial carcinomas is however not yet clear.

Method

The internal database of the University Hospital of Bern from 2002 to 2014 was reviewed retrospectively for patients with recurrent EMCA that was initially diagnosed as low risk. The histopathology was re-evaluated to confirm the low risk nature of the tumor and LVI, lower uterine segment involvement (LUI) and microcystic, elongated, and fragmented (MELF) were analyzed. Then laser capture microdissection was performed for DNA extraction. Somatic mutational assessment was performed using the qBiomarker Somatic Mutation PCR Array, endometrial cancer plate (Qiagen), which includes 84 sequence mutations.

Results

The combined presence of LVI and LUI indicates a highly significant risk for recurrence in a group of initially low-risk EMCA cases. The most common mutations occur in the CTNNB1, PTEN and the PIK3CA genes. These mutations are more present in tumor tissue with histopathological changes such as MELF and LVI. Only in one patient the same mutation were present in the primary tumor and recurrence.

Conclusion

LVI combined with LUI risk factors for recurrence in low risk EMCA. Mutations in CTNNB1, PTEN and PIK3CA could be detected, no correlation with the recurrence could be identified. However, they seem to be in correlation with histopathological changes.

EFFICACY OF ADJUVANT TREATMENT FOR STAGE IIIC ENDOMETRIAL CANCER: A SINGLE-INSTITUTION RETROSPECTIVE STUDY
H. Iwase¹, S. Furukawa¹, S. Endo¹, Y. Tazo¹, H. Sato¹, T. Takada¹, M. Arai¹, T. Onda¹
¹Kitasato University School of Medicine, Obstetrics and Gynecology, Sagamihara, Japan

Aims

Although chemotherapy has become generally used as an adjuvant treatment for stage IIIC endometrial cancer in Japan, the efficacy is not yet well evaluated. The aim of this study is to reveal the clinicopathological features of the patients with positive lymph nodes (LN+) and the efficacy of adjuvant treatment.

Method

Medical records of 349 patients with stage I to III endometrial cancer who underwent primary surgery with regional lymph nodes dissection at our hospital between 2005 and 2013 were retrospectively reviewed. Clinicopathological factors and prognosis of these patients, especially 50 LN+ patients, were analyzed.

Results

Median age was 58 years and number of stage IIIC1/IIIC2 patient was 33/17, respectively. Average number of removed pelvic and para-aortic lymph nodes was 19.4(2-44) and 7.5(1-26), respectively. Average number of positive nodes was 4.1(1-25). Forty-nine patients received adjuvant chemotherapy and 29 patients recurred. Sixteen patients recurred within one year from the completion of primary treatment. The major recurrence sites were regional LNs (N=17) and distant sites (N=15) (including multisite recurrence). Five-year overall survival (OS) was very poor in LN+ (48.8%) and the prognosis became worse as the number of LN+ is increased. Overall Survival was significantly worse in patients with positive cytology (p=0.0413, 5y-OS: 28.1% vs 55.6%) and with high risk factor for recurrence other than LN+ (p=0.0070, 5y-OS: 36.9% vs 90%).

Conclusion

Irrespective of adjuvant treatment, LN+ patients had poor prognosis. More effective adjuvant treatment may be necessary, especially for patients with positive cytology and/or high risk factor other than LN+.

ENDOTHELIAL PROGENITOR CELLS (EPCS) AND CIRCULATING ENDOTHELIAL CELLS (CECS) IN PERIPHERAL BLOOD OF WOMEN WITH ENDOMETRIAL CANCER

A. Czekański¹,², M. Paprocka¹, A. Kantor¹, A. Bielawska-Poh³, P. Lepka¹,², M. Jędryka¹,²
¹Lower Silesian Cancer Center, Oncological Gynaecology, Wrocław, Poland
²Wroclaw Medical University, Oncology, Wrocław, Poland
³Polish Academy of Sciences, Institute of Immunology and Experimental Therapy, Wrocław, Poland

Aims

To analyze the number of endothelial progenitor cells (EPCs) and circulating endothelial cells (CECs) – as potential new markers of neoangiogenesis – in peripheral blood from endometrial carcinoma patients regarding the stage and grade of the malignancy.

Method

We studied 30 patients with endometrial cancer compared to control group of 28 women with non malignant diseases. The blood samples were taken perioperatively and labeled with monoclonal antibodies: anti CD31, anti CD45 for CECs and anti CD34, anti VEGFR2/KDR for EPCs. After incubation with fluorescent CytoCount beads all samples were calculated by flow cytometry. Analysis was supported by CellQuest software with the use of debris gates.

Results

The CECs numbers (CD31⁺, CD45⁻) were similar in both groups but EPCs numbers (CD34⁺, VEGFR2/KDR⁺) in the peripheral blood of women with endometrial carcinoma were significantly augmented as compared with those of control healthy women (Fig. 1). When patients were divided, according the grading, into G1 and G2 groups it appeared that augmented EPC numbers may be demonstrated only in G1 stage patients (Fig.2). When patients were divided, according to the stage into FIGO I and FIGO II groups difference in EPC number was found in patients with FIGO I (Fig.3).

Conclusion

We demonstrated that the general number of EPCs is significantly increased in peripheral blood from women with endometrial cancer what may be related with tumor neoangiogenesis. However we could not show such result referring to CECs and the correlation with tumor stage and grade. Further studies could clarify the subject.
THE EFFECT OF PATIENT-INITIATED FOLLOW-UP ON FEAR OF RECURRENCE AND HEALTH CARE USE: A RANDOMIZED TRIAL IN EARLY-STAGE ENDOMETRIAL CANCER

M.M. Jeppesen¹, P.T. Jensen¹, D. Gilså², R. dePont Christensen³, M.M. Jensen⁴, O. Mogensen⁵

¹Odense University Hospital, Department of obstetrics and gynecology, Odense, Denmark
²University of Southern Denmark, The national research center of cancer rehabilitation- Research unit of general practice, Odense, Denmark
³University of Southern Denmark, Research unit of general practice, Odense, Denmark
⁴Aalborg University Hospital, Department of obstetrics and gynecology, Odense, Denmark
⁵Karolinska University Hospital and University of Southern Denmark, Department of obstetrics and gynecology, Stockholm, Sweden

Aims

To compare hospital-based follow-up with patient-initiated follow-up with regard to fear of recurrence (FCR) and health care use.

Method

Women treated for FIGO stage I low-intermediate risk endometrial cancer were included in this pragmatic randomized trial from four Danish departments of gynecology between 2013-2016. Participants allocated to the intervention had no schedule of follow-up visits, but were instructed in alarm symptoms that required examination and had direct access to the department of gynecology. FCR was measured using the Fear of Cancer Recurrence Inventory at 1, 3, 6 and 10 months follow-up. Difference in change in FCR was compared between the two groups using linear regression analysis. Number of cancer-related visits to general practitioner, private practicing gynecologist, and telephone contacts, and examinations at the department of gynecology were compared using Mann-Whitney U test.

Results

In total, 212 (69.1 %) women were randomized, and complete datasets were obtained for 156 (73.6 %) women. FCR improved in both groups from baseline to 10 months follow-up, though significantly more in the control group (difference 5.9, 95% CI: [-10.9; 0.9]). No differences in use of general practitioner, private practicing gynecologist, and telephone contacts were found between the two groups. Women in the intervention had significantly fewer examinations at the department of gynecology compared to the control group (19 vs. 139 visits, p < 0.01).

Conclusion

Hospital-based follow-up alleviates FCR more effectively than patient-initiated follow-up, though the estimated difference may not be of clinical importance. Patient-initiated follow-up is a relevant cost-reducing alternative to traditional follow-up.

PELVIC LYMPHADENECTOMY IN THE MANAGEMENT OF ENDOMETRIAL CANCER: A SERVICE REVIEW OF WALES' LARGEST TERTIARY CENTRE

R. Jones¹, M. Awad², E. Drews¹, E. Rzyska², R. Howells¹, K. Lim¹, A. Sharma¹
¹University hospital of Wales, Gynaecological Oncology, Cardiff, United Kingdom
²University hospital of Wales, Obstetrics & Gynaecology, Cardiff, United Kingdom

Aims

The 2015 Cochrane review which concluded the role of Pelvic lymphadenectomy (PLA) in intermediate & high risk early stage endometrial cancer (EC) is unclear means PLA in the management of endometrial cancer remains controversial. Standard practice includes external beam radiotherapy (EBRT) +/- brachytherapy (BT) in these cases. The South East Wales Gynaecological Oncology Centre (SEWGOC) guidelines include PLA for high risk EC, avoiding EBRT if nodes negative. Our aim was to undertake a service evaluation of PLA in high risk EC patients and whether EBRT was avoided in node negative patients.

Method

We conducted a retrospective review of patients referred to the SEWGOC whose treatment included surgery from 01/04/2013-31/03/2015 with SEWGOC guidelines on patient selection for PLA as the standard.

Results

292 patients had surgery for EC, 123 had PLA indicated, 113 underwent PLA. 2 year disease free survival was 76% with 2 year mortality 15%.

Post-operatively 77 patients had ≤ stage 2 disease and 36 ≥ stage 3 disease. Following PLA, 16 patients were up-staged & 9 were down-staged altering their management accordingly.

After PLA, 68 patients were intermediate/high risk of recurrence; 7 received EBRT & BT, 59 BT alone & 2 were not fit for adjuvant therapy. In the follow-up period there were no recurrences in the EBRT & BT group, 6 in the BT group & 1 in the patients who were unfit for adjuvant treatment group.

Conclusion

Adherence to the local SEWGOC guidelines is high and 90% of patients avoided EBRT as a result of having PLA.

CLINICOPATHOLOGIC CHARACTERISTICS OF DOUBLE PRIMARY ENDOMETRIAL AND COLORECTAL CANCERS IN SINGLE INSTITUTION

W.D. Joo¹, H.J. Lee², M.C. Choi¹, S.G. Jung¹, H. Park¹, T. Kim², C. Lee¹, J.H. Lee¹, S.H. Song¹

¹CHA Bundang Medical Center, Division of Gynecologic Oncology, Seongnam, Republic of Korea
²CHA Bundang Medical Center, Department of Obstetrics and Gynecology, Seongnam, Republic of Korea
³CHA Bundang Medical Center, Department of Pathology, Seongnam, Republic of Korea

Aims

To investigate clinicopathologic and genetic correlation between double primary endometrial and colorectal cancer related to Lynch syndrome in Korea, and to analyze the germline mutation in the DNA MMR genes of endometrial cancer.

Method

Thirteen patients who were pathologically proven endometrial and colorectal cancer between January 2005 and November 2016 in a single institution were enrolled. The medical records of these patients were retrospectively analyzed.

Results

Patients diagnosed with endometrial cancer precedent to colorectal cancer were 62%, and median interval between diagnosis of endometrial cancer and colorectal cancer was 5.3 years. Endometrioid adenocarcinoma was reported in 77% endometrial cancer patients and Non-endometrioid types were 3 cases. Endometrial and colorectal cancer was found at low uterine segment and right side colon in 3 and 2, respectively. The incidence of defined Lynch syndrome by clinical criteria based on family history(4/13) or MSI and IHC(6/13) was 77%. Three of them underwent genetic testing, and all revealed positive for pathologic germline mutation. Also, possible founder mutations in the DNA MMR genes of endometrial cancer in Korea were assessed among 21 germline mutation information from the present study and previous studies reviews. c.1757_1758insC mutation in MLH1 was found three times.

Conclusion

The present study suggests the clinicopathologic data for appropriate diagnosis for double primary cancer patients associated Lynch syndrome, and supports that double primary endometrial and colorectal cancer patients should be needed close genetic approach for Lynch syndrome. Moreover, possible founder mutations in Korean endometrial cancer patients were identified.
VENOUS THROMBOEMBOLIC COMPLICATIONS IN PATIENTS WITH CANCER CORPUS UTERI

6Aalborg University Hospital, Institute of Pathology, Aalborg, Denmark
7Aalborg University, Department of Health Science and Technology, Aalborg, Denmark
8Aalborg University Hospital, Department of Cardiology and Epidemiology/Biostatistics, Aalborg, Denmark

Aims

To estimate the risk of venous thromboembolism (VTE) in uterine cancer considering possible risk factors. We aim to clarify if minimally invasive surgery (MIS) is correlated with a lower risk of VTE compared to open surgery which thromboprophylactic recommendations are mainly based on.

Method

In a registry based nationwide cohort study data on patients with uterine cancer was retrieved from the nationwide Danish Gynaecological Cancer Database (DGCD). Data on VTE was extracted from the Danish National Patient Register. The National Population Register and the National Causes of Death Register hold information on vital status, date of birth and death including cause of death. Time to VTE was examined with cox proportional hazard models.

Results

We identified 7,067 patients with uterine cancer in DGCD diagnosed in the period 2005-2014.

Focusing on patients undergoing surgical treatment for uterine cancer (n=6330) we found a 30-day VTE incidence of 0.49% with open surgery (23/4651) and 0.48% (8/1679) with MIS (P=0.918). In a multivariable cox regression model we identified advanced disease and previous VTE as significant predictors of 30-day VTE risk. The 30-day hazard ratio for VTE following MIS did not show any significant difference compared to open surgery (HR 0.92, CI 0.41-2.05, P= 0.833).

Conclusion

The 30-day incidence of venous thromboembolism after surgery for uterine cancer was low overall (0.49%) and there was no difference in hazard ratios between MIS and open surgery.

The MSKCC Nomogram is More Accurate in the Prediction of Overall Survival in a German Endometrial Cancer Patient Population Than the FIGO Staging System.

A. Huss¹, A. Hasenburg², M. Oehler³, M. Klar¹
¹University Clinic of Freiburg, Obstetrics and Gynecology, Freiburg, Germany
²University Clinic of Mainz, Obstetrics and Gynaecology, Mainz, Germany
³University of Adelaide, Gynaecological Oncology, Adelaide, Australia

Aims

Nomograms have shown better discrimination and calibration values to predict overall survival (OS) compared to conventional staging systems for a number of tumours. We tested the Memorial Sloan Kettering Cancer Center (MSKCC) nomogram for the prediction of OS in endometrial cancer (EC) patients in our patient cancer population.

Method

493 (322 type I and 171 type II) EC patients who received primary surgical treatment at the Universitaetsfrauenklinik Freiburg between 1991 and 2011 were included and a dataset of 50 covariates was created. Cox regression analyses were performed to identify independent predictors of survival. Predicted survival was calculated using the nomogram calculator on https://www.mskcc.org/nomograms. Receiver operating characteristic (ROC) curves were created for the FIGO 1988, FIGO 2009 staging classification and for the MSKCC 1, 3 and 5 year-survival prediction models. The calculated area under the curve (AUC) values of predicted versus actual OS were compared.

Results

After a mean follow-up time of 100 months, 232 patients were reported dead (47 %). Independent predictors of survival in our population of EC patients were FIGO stage (1988 and 2009), positive cytology and positive resection margins (p < .01). The AUC values of the ROC curves were 0.66 (FIGO 1988), 0.64 (FIGO 2009), 0.79 (predicted 1-year OS), 0.79 (predicted 3-year OS) and 0.8 (predicted 5-year OS).

Conclusion

In this external validation, the FIGO classification showed a moderate and the MSKCC models showed a good accuracy in predicting OS in endometrial cancer patients. The MSKCC nomogram may be useful for a better patient stratification in clinical trials.

L1CAM AS RISK FACTOR FOR RECURRENCE IN STAGE I ENDOMETRIAL CANCER PATIENTS

J. Klat¹, A. Mladenka¹, O. Simetka¹, J. Dvorackova²
¹University hospital Ostrava, Ob/Gyn, Ostrava, Czech Republic
²University Hospital Ostrava, Dept. of Pathology, Ostrava, Czech Republic

Aims

Endometrial cancer is the most common gynecologic cancer in developed countries and the second most common gynecologic cancer worldwide. From clinical and epidemiological studies, a dualistic classification of endometrial cancers was proposed, namely type I and type II tumors, which have different patterns of molecular alterations that underlie their pathogenesis and clinical outcome. In general, prognosis of early-stage type I endometrial cancer is excellent, with a 10-year overall survival rate exceeding 80%. L1 cell adhesion molecule (L1CAM) expression has been implicated as risk factor for disease recurrence and risk of death in endometrial cancer type I.

Method

We conducted a retrospective single center study to determine expression of L1CAM by immunohistochemistry in 273 FIGO stage I endometrial cancer patients. All tumor specimens were endometroid adenocarcinoma.

Results

Total number of 273 patients with endometroid adenocarcinomas were included in the study. 84 women (30.8%) were rated as L1CAM-positive and 189 women (69.2%) were related a L1CAM-negative. Of these L1CAM-positive cancer patients 11.9 % recurred during follow-up compared with 4.23 % L1CAM-negative cancers (p-value = 0.03632).

Conclusion

L1CAM has been shown to be strong prognostic factor in FIGO stage I endometrial adenocarcinoma for disease recurrence.
ENDOMETRIAL CANCER

ESGO7-1229

ENDOMETRIAL STROMAL NODULE IN A WOMAN WITH ABNORMAL UTERINE BLEEDING AND ABDOMINAL PAIN: A CASE REPORT

E. Klonos

1Aristotle University of Thessaloniki.,
First Department of Obstetrics & Gynecology "Papageorgiou" General Hospital of Thessaloniki, Thessaloniki, Greece

Aims

The endometrial stromal nodule constitutes a particularly rare tumor in pre- or postmenopausal women, who have undergone hysterectomy, due to intense symptoms, namely the abdominal pain and abnormal uterine bleeding. A case of a patient with endometrial stromal nodule is presented, emphasizing on the therapeutic strategy and the dilemmas regarding the management and her follow-up.

Method

The immunoprofile of endometrial stromal nodule practically matches that of an endometrial stromal sarcoma. [3,4,5] However, the need for precise identification and diagnosis is critical, since outcomes in patients with stromal sarcomas are significantly worse, compared to the often-excellent outcomes in patients presenting with stromal nodule.[18,19] This fact is evident when looking at the survival statistics; there is a 90% five year survival rate for stages I and II while the corresponding figures for stages III and IV, significantly decrease, reaching 50%.

Results

The diagnosis of endometrial stromal nodule is an exotic but realistic pathology for the female patient who presents with severe vaginal bleeding and abdominal pain. The therapeutic strategy is surgical. The most critical point, is the histopathology diagnosis, which has its pitfalls

Conclusion

Following surgery and diagnosis, a frequent follow-up including imaging assessments, is necessary. It is clear that patients diagnosed with endometrial stromal nodule have an excellent prognosis.
NOVEL ALGORITHM FOR DIAGNOSIS OF ENDOMETRIAL CANCER

T. Knific1, J. Osredkar2, Š. Smrkolj3, I. Tonin3, K. Vouk1, A. Blejec4, S. Frković Grazio5, T. Lanišnik Rižner1

1Institute of Biochemistry, Faculty of Medicine - University of Ljubljana, Ljubljana, Slovenia
2Clinical Institute of Clinical Chemistry and Biochemistry, University Medical Centre, Ljubljana, Slovenia
3Division of Obstetrics and Gynecology, University Medical Centre, Ljubljana, Slovenia
4National Institute of Biology, Department of Organisms and Ecosystems Research, Ljubljana, Slovenia
5Department of Pathology - Division of Obstetrics and Gynecology, University Medical Centre, Ljubljana, Slovenia

Aims

To evaluate the diagnostic and prognostic potential of preoperative serum levels of CA-125 and HE4 in endometrial cancer patients and control group of patients.

Method

Prospective case-control study of 133 women that underwent surgical treatment at the University Medical Centre Ljubljana (64 endometrial cancer patients, 69 control patients with prolapsed uterus or myoma). Serum levels of CA-125 and HE4 were determined with electrochemiluminescent specific assays.

Results

Concentrations of CA-125 and HE4 were significantly increased in case compared to control groups with p values of $2.67 \times 10^{-4}$ and $1.36 \times 10^{-7}$, respectively. With logistic regression analysis we built a diagnostic model that combines CA-125, HE4 and BMI with an AUC of 0.804, sensitivity of 66.7% and specificity of 84.6%. Serum levels of HE4 significantly differed when patients were stratified according to presence/ absence of deep myometrial invasion ($p = 0.001$, $AUC = 0.776$) or lymphovascular invasion ($p = 0.003$, $AUC = 0.810$). According to ESMO-ESGO-ESTRO guidelines we evaluated the prognostic value of CA-125 and HE4 in patients with grade 1 and 2 endometrioid endometrial cancer in whom lymphadenectomy can be omitted. HE4 significantly differed when these patients were stratified according to deep myometrial invasion (yes/ no) ($p = 3.39 \times 10^{-4}$). The median values of HE4 were higher in patients with lymphovascular invasion ($p = 0.06$) but this difference was not significant.

Conclusion

A model including preoperative levels of CA-125, HE4 and BMI has good diagnostic characteristics, while serum levels of HE4 have prognostic potential to stratify patients according to myometrial and lymphovascular invasion.
Aims

Since 66.8 % of patients with leiomyosarcoma (LMS) receive an inadequate surgery, the development of a preoperative LMS-risk-score is an imperative.

Method

We calculated the LMS-risk in presumed LM by a logistic regression model for a binary response variable based on clinical findings from 670 LM and 231 LM\textsubscript{S} from the German Clinical Competence Centre for Genital Sarcomas and Mixed Tumours and cooperating departments.

Results

Table 1. LMS-risk-points calculated by a logistic regression model

The AUC in the Receiver−Operating−Characteristic Curve was 0.962, giving an excellent result.

Conclusion
Based on just six clinical criteria an easy-to-use preoperative LMS-risk-score for prevention of inadequate LMS-surgery was established and should be used prior of LM-surgery. Our score provides a personalized decision working tool.
ENDOMETRIAL CANCER

ESGO7-0223

IMPACT OF CONSERVATIVE MANAGEMENTS IN YOUNG WOMEN WITH GRADE 2 OR 3 ENDOMETRIAL ADENOCARCINOMA CONFINED TO ENDOMETRIUM

C. Gonthier1, A. Tefoux-Bourdet1, M. Koskas1
1Hopital Bichat-Claude Bernard- Gynecology, Gynecology Obstetric, Paris, France

Aims

To evaluate the impact of ovarian and/or uterine preservation in young patients with grade 2 or 3 endometrial adenocarcinoma confined to endometrium.

Method

A population-based analysis was conducted. The SEER’17 Database was used to identify women younger than 45 years of age with grade 2 or 3 endometrial adenocarcinoma confined to endometrium from 1983 to 2012. A cohort of 1106 women was included: 849 underwent hysterectomy with bilateral adnexectomy, 96 underwent hysterectomy with ovarian preservation and 49 underwent uterine preservation. The demographics and survival rates according to the type of treatment administered were compared.

Results

The five-year overall survival probabilities were 94.8% (95%CI [92.8-96.2], 93.8% (95%CI [85.8-97.4]), and 78.2% (95%CI [62.1-88.1]) for patients who underwent hysterectomy with bilateral adnexectomy, ovarian preservation and uterine preservation, respectively (p<0.001).

The five-year cancer-related survival probabilities were 99.3% (95%CI [98.6-99.9], 98.9% (95%CI [96.9-99.9]), and 86.2% (95%CI [75.7-98.2]) for patients who underwent hysterectomy with bilateral adnexectomy, ovarian preservation and uterine preservation, respectively (p<0.001).

Patients who received uterine conservation had lower disease-specific (aHR=15.8 95%CI [5.5-45.2]) and overall survival probabilities (aHR=6.6 95%CI [3.3-13.4]) than did patients who underwent hysterectomy with or without oophorectomy. Ovarian conservation was not associated with decreased disease-specific (aHR=1.45 95%CI [0.31-6.71]) or overall survival (aHR=0.58 95% IC [0.17-1.90]).

Conclusion

Ovarian preservation has no impact on survival probability in patients with grade 2 or 3 endometrial cancer confined to endometrium. On the contrary, physicians and patients should be aware of the worse prognosis associated with uterine preservation.
EVALUATION AND SELECTION OF QUALITY INDICATORS FOR THE MANAGEMENT OF ENDOMETRIAL CANCER
M. Koskas¹, L. Chenoz¹, J. Phelippeau¹
¹Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France

Aims
To evaluate 36 quality indicators (QI) for monitoring the quality of care of uterine cancer to be implemented in the EFFECT (EFFectiveness of Endometrial Cancer Treatment) project.

Method
The 36 QI were evaluated in the first ten patients diagnosed with endometrial cancer and managed in fourteen French hospitals in 2011. To assess the status of each QI, a questionnaire detailing the 36 QI was sent to each hospital, and the information was cross-checked with information from the multidisciplinary staff meeting, surgical and pathological reports. The QI were evaluated in terms of measurability and improvability. The remaining QI were evaluated with a multiple correspondence analysis (MCA) to highlight the interrelationships between qualitative variables describing a population.

Results
Thirteen of the 14 institutions responded to the survey for a total of 130 patients. Twenty-five of the 36 QI affected less than 80% of the patients. Thirteen QI were found not to be improvable because they reached >95% of the theoretical target. Finally, five QI concerning more than 80% of the patients were found to be improvable. The MCA finally identified three dimensions—outcome, safety and perioperative management—that included the five QI.

Conclusion
In the present study, five of the 36 QI suggested by the EFFECT project appear to be sufficient to report on the quality of endometrial cancer management. Further studies are needed to correlate the information provided by those five questions and the relevant outcomes reflecting quality of care in endometrial cancer.
ENDOMETRIAL CANCER

ADHERENCE TO GUIDELINES FOR FOLLOW UP OF PATIENTS OPERATED ON FOR ENDOMETRIAL CANCER: ANALYSIS OF THE FRENCH HEALTH INSURANCE DATABASE
M. Koskas¹, J. Phelippeau¹, R. Rouzier²
¹Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France
²René huguenin, Gynecology, Saint Cloud, France

Aims

The objectives of our study were to examine adherence to follow up guidelines in patients operated on for EC and to identify associated explanatory variables.

Method

Patients operated on for EC between January 2005 and December 2014 were identified among the Echantillon Généraliste des Bénéficiaires (EGB), a 1/97th random sampling of the French population covered by the national healthcare insurance system. Patients with associated cancer or EC recurrence were excluded. Adherence to guidelines was defined by fewer than two complementary examinations performed during the two postoperative years among vaginal smear, CA 125 dosage and imaging. The research for explanatory variables used a multilevel model.

Results

314 women who underwent surgery were included. A gap between recommendations and practices was found in 48.1% of patients. This gap was more frequent in patients operated on before 2011, in private institutions or in institutions performing less than 20 hysterectomies for EC per year, and among patients with Long Duration Disease declaration for EC.

Conclusion

The gap between recommendations and practices for follow-up in EC represents almost half of the cases. Updating the recommendations in 2010 may have improved compliance with the recommendations. However, improvements are still needed.
COMPLICATIONS AND EXTRA HOSPITAL DRUG CONSUMPTION AFTER LAPAROSCOPY COMPARED WITH
LAPAROTOMY FOR ENDOMETRIAL CANCER STAGING: THE FRENCH REGISTRY ANALYSIS

M. Koskas¹, J. Phelippeau¹
¹Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France

Aims

The aim of this study was to compare laparoscopic and laparotomic staging considering complications and extra hospital drug consumption.

Method

Data concerning 405 patients operated on for EC between 2005 and 2014 were abstracted from the Echantillon Généraliste des Bénéficiaires (EGB) database, a 1/97th random sample of the French population covered by the national healthcare insurance system. End points were hospital length stay, complications rate and extra hospital drug consumption of anticoagulant and antibiotics during the first post-operative month.

Results

335 (82.7%) patients underwent laparotomy and 70 (17.3%) patients underwent laparoscopy. The proportion of laparoscopy increased from 2005 to 2014 (9.3% before 2010 and 20.2% after). Patients from the two groups were comparable for age and comorbidity. Women who underwent laparoscopy had lymphadenectomy (p=0.05) and external adjuvant radiation (p=0.01) more frequently. Laparoscopy was associated with a shorter length of hospital stay (5.8 days vs. 8.8 days, p<0.01) and a non-significant lower complication rate (14.3% vs. 21.8%, p=0.2). Laparoscopy was not associated with decreased antibiotics and anticoagulants consumption.

Conclusion

Over the last decade, laparoscopy has been used more frequently for the surgical staging of patients with EC but remains underused in France. Laparoscopy is associated with a shorter length of hospital stay. However, laparoscopy has no measurable impact on antibiotics or anticoagulants extra hospital consumption.

LAPAROSCOPIC SURGERY FOR LOW, INTERMEDIATE AND HIGH-RISK ENDOMETRIAL CANCER: A RETROSPECTIVE ANALYSIS OF LONG-TERM OUTCOMES

M.A. VARDAR\textsuperscript{1}, U. KUCUKGOZ GULEC\textsuperscript{1}, A.B. GUZEL\textsuperscript{1}, D. GUMURDULU\textsuperscript{2}, G. SEYDAOGLU\textsuperscript{3}, G. KHATIB\textsuperscript{1}

\textsuperscript{1}Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
\textsuperscript{2}Cukurova University School of Medicine, Pathology, Adana, Turkey
\textsuperscript{3}Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

The aim of the present study was to compare the long-term outcomes of laparoscopic and laparotomic surgeries and to evaluate the results according to low, intermediate, and high-risk groups of endometrial cancer.

Method

Data of endometrial cancers were collected retrospectively from a single gynecologic oncology department between the January 2005 and January 2016. Patients were divided into 2 groups as laparotomic surgery (group 1, n=515) and laparoscopic surgery (group 2, n=286) groups. Patients' demographics, clinical characteristics such as stage, grade, histopathologic type, lymphovascular space invasion (LVSI), myometrial invasion, lymph node involvement, and risk groups, peri- and post-operative outcomes, and survival outcomes were compared between the groups.

Results

The demographic characteristics of both groups were similar except age. Shorter hospital stay and fewer complications were observed in group 2. The overall survival (OS) was similar in the low and intermediate risk groups but higher in the high-risk patients for laparoscopy compared to laparotomy. The covariate analysis revealed that the death and recurrence risks were approximately twice higher in the laparotomy group than in the laparoscopy group (OR: 1.9, 95%CI: 1.2-3.1 for overall survival; OR: 2.95%CI: 1.2-3.3 for disease-free survival). Age, stage, histopathological type, and operation type were determined as independent prognostic factors in the multivariate analysis for both of DFS and OS.

Conclusion

The results of our study support the well known positive aspects of laparoscopy as well as safe and effective use in cases of intermediate and high risk endometrial cancer.
IS IT REALLY UTERINE GRADE 3 ENDOMETRIOID ADENOCARCINOMA AND CARCINOSARCOMA CLINICALLY SIMILAR?

U. Kucukgoz Gulec¹, S. Paydas², A.B. Guzel¹, G. Khatib¹, D. Gumurdulu³, M.A. Vardar¹
¹Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
²Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
³Cukurova University School of Medicine, Pathology, Adana, Turkey

Aims

Was to compare the clinical characteristics and outcomes of the cases with uterine high grade (grade 3) endometrioid adenocarcinoma (HGEAC) and uterine carcinosarcoma (CS).

Method

A total of 141 patients recruited from the Gynecologic Oncology Unit of Cukurova University, Faculty of Medicine were included in this study; 61 cases with uterine HGEAC (group 1) and 80 cases with CS (group 2) followed between January 1996-2016. Clinical and pathological characteristics including age, stage, initial symptom, operation type, myometrial invasion, lymphovascular invasion, lymph node invasion, adjuvant therapy and survival were compared between the groups.

Results

There are no statistically significant differences between the groups according to age, nulliparty, menopausal status, medical history of patients, family history of cancer, complication rate. PPALND was performed 85% of the group 2 and 67% of the group 1 (p<0.001). Stage, myometrial invasion degree, lymph node metastasis were similar between the groups. Lymphovascular space invasion was more present in group 1 than group 2 (p=0.032). But positive cytology was more common in group 2 (p=0.008). Adjuvant RT was given more in group 1 (p<0.001) and KT was applied more in group 2 than 1 (p=0.008). There is no difference between the group according to DFS (p=0.316) but OS was found better in group 1 (p=0.02).

Conclusion

Patients in both groups had similar stage. KT was used more frequently in patients with carcinosarcoma, RT was used more in patients with HGEAC for the main adjuvant therapy modality. The survival was found better in patients with HGEAC.
The Effect of Preoperative Hematological Parameters to Prognosis in Cases with Endometrium Cancer

I. Temur1, U. Kucukgoz Gulec1, A.B. Guzel1, S. Paydas2, G. Khatib1, M.A. Vardar1

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
2Cukurova University School of Medicine, Medical Oncology, Adana, Turkey

Aims

We investigated that if the preoperative rate of neutrophile to lymphocyte (NLR), mean thrombocyte volume (MPV), rate of platelet to lymphocyte (PLR), monocyte count, rate of mean thrombocyte volume to thrombocyte count (MPV/PR) are related with prognosis in endometrium cancer or not.

Method

We evaluated 763 patient with endometrium cancer who operated and followed at Cukurova University Faculty of Medicine Obstetric and Gynecology Department. We evaluated clinical and pathological parameters like preoperative hematological parameters, histopathological type, cervical involvement, degree of myometrial invasion, lymph node metastasis, surgical stage, characteristics of operation in a retrospective way. The effects of these factors to prognosis analysed by Kaplan Meier and Cox regression analysis.

Results

Five year survival chance was %86. Mean OS was significant for NLR value (p=0.017); but there was not statistically significance for monocyte count (p=0.670), for MPVPR (P=0.122) and MPV (P=0.452). The patients with high NLR had short survival. NLR was associated with stage, metastatic lymph node, myometrial invasion, cervical invasion, lymphovascular invasion, adnexial involvement, positive cytology and status. PLR was associated with stage, metastatic lymph node, myometrial invasion, cervical invasion, lymphovascular invasion, adnexial involvement. Monocyte count was associated with stage, metastatic lymph node, grade and status. MPV/PR was associated with stage and metastatic lymph node.

Conclusion

We detected that age, co-morbidity, histopathological type, stage, grade, lymphovascular invasion, NLR were prognostic factors in endometrium cancer. Age, stage, co-morbidity, cervical invasion were independent prognostic factors for endometrial cancer in multivariant analysis.

CLINICAL AND PROGNOSTIC EFFECTS OF OBESITY ON ENDOMETRIAL CANCER

A.B. GUZEL1, U. KUCUKGOZ GULEC1, M. SUCU1, G. KHATIB1, M.A. VARDAR1

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey

Aims

To determine the association of body mass index (BMI) on operative outcomes, clinicopathologic characteristics and prognosis in endometrial cancer.

Method

Three hundred ninety two patients with endometrial carcinoma who were operated and followed up in our clinic were evaluated according to the BMI groups. Patients' demographics, clinical characteristics such as stage, grade, histopathologic type, lymphovascular space invasion (LVSI), myometrial invasion, lymph node involvement, and risk groups, peri- and post-operative outcomes, and survival outcomes were compared according to BMI stratifications.

Results

BMI groups were <30 (n=104, 26.5%), 30–34 (n=85, 21.7%), 35–39 (n=96, 24.5%), and≥40 (n=107, 27.3%). Laparotomy was performed to 186 cases, and laparoscopy to 206 cases. The medians of age, comorbidity status, surgical type (laparotomy or laparoscopy) were not different among the groups (p=0.057, 0.065, 0.263, respectively). The medians of operation time (p=0.224), postoperative hospitalization time (p=0.212), estimated blood loss (p=0.077), drop in hb level (p=0.387) were similar. High BMI increased intra- and postoperative complication rates (p=0.049). Stage (p=0.481), grade (p=0.756), myometrial invasion (p=0.190), risk groups (low, moderate and high: p=0.638), nodal involvement (p=0.334) and histologic type (p=0.919) were not differed according to groups of BMI. Median of overall survival and disease free survival were found similar (p=0.551, 0.534, respectively).

Conclusion

We demonstrated that BMI did not alter the patient's clinicopathologic characteristics and did not affect the prognosis negatively but increased the operative complications.
PROGRAMMED DEATH (PD-1), PROGRAMMED DEATH-LIGAND 1 (PD-L1) EXPRESSION IN UTERINE CARCINOSARCOMAS

U. Kucukgoz Gulec¹, E. Bagir², S. Paydas², G. Seydaoglu³, A.B. Guzel¹, M.A. Vardar¹
¹Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
²Cukurova University School of Medicine, Pathology, Adana, Turkey
³Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
⁴Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

Programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) are new targets in cancer immunotherapy. PD-1 protein is an immune checkpoint expressed in many tumors. The aim of this study is to evaluate the clinical and prognostic importance of PD-1 and/ or PD-L1 in uterine carcinosarcomas (UCS).

Method

Formalin fixed, paraffin-embedded tissue samples from 59 cases with UCS were analyzed in this study. Immunohistochemical staining was performed to detect the PD-1 and PD-L1 expressions in tumor tissue and microenvironment, separately.

Results

PD-1 expression in tumor tissue and microenvironment was detected in 15 (25 %) and 18 (30 %) cases, respectively. PD-L1 expression in tumor tissue and microenvironment was detected in 15 (25 %) and 12 cases (20 %), respectively. It has been found that expression of PD-L1 in tumor was associated with longer survival although PD-1 expressions were not found to be related with survival. Median survival in cases with and without PD-L1 expression were 38 and 15 months, respectively (p=0.019). Lymphovascular space invasion (LVSI) (p=0.014), myometrial invasion (p=0.008) and PD-L1 expression were found prognostic factors. Cox regression analysis showed that expression of PD-L1 was found to be an independent risk factor for prognosis (OR 3.9; 95 % CI 1.4–11.0).

Conclusion

Targeting PD-1 and/or PD-L1 meaningful due to the 25 % expression of each in UCS, and we found an important association between PD-L1 expression and prognosis in UCS. Programmed death pathway is involved in UCS development/biology and larger studies will be more informative for targeted treatment and/or checkpoint blocking therapies.

³Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
⁴Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

The aim of this study was to evaluate the clinical and prognostic importance of PD-1 and/or PD-L1 in grade 3 endometrioid adenocancer (EAC).

Method

Formalin fixed, paraffin-embedded tissue samples from 53 cases with grade 3 EAC were analyzed in this study. Immunohistochemical staining was performed to detect the PD-1 and PD-L1 expressions in tumor tissue and microenvironment, separately.

Results

PD-1 expression in tumor tissue and microenvironment was detected in 18 (34%) and 22 (42%) cases, respectively. PD-L1 expression in tumor tissue and microenvironment was detected in 12 (23%) and 18 cases (34%), respectively. It has been found that expression of PD-1 in tumor and PD-L1 expression in tumor and microenvironment were associated with shorter survival although PD-1 expressions in microenvironment was not found to be related with survival. Median survival in cases with and without PD-1 expression were 55 and 30 months, respectively (p=0.025). Median survival in cases with and without PD-L1 expression were 50 and 27 months, respectively (p=0.001). Lymphovascular space invasion (LVSI) (p=0.033), myometrial invasion (p=0.043), PD-1 expression and PD-L1 expression were found to be prognostic factors. Cox regression analysis showed that expression of PD-1 and PD-L1 were found to be an independent risk factors for prognosis (OR 3.0; 95% CI 1.3–7.1 - OR 3.3; 95% CI 1.3–8.4, respectively).

Conclusion

PD-1 and/or PD-L1 expressions were meaningful due to the 34% and 23%, respectively in grade 3 EAC. Our study results demonstrated an important association between PD-1, PD-L1 expressions and prognosis in grade 3 EAC.
Aims

Programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) are new targets in cancer immunotherapy. PD-1 protein is an immune checkpoint expressed in many tumors. The aim of this study is to evaluate the clinical and prognostic importance of PD-1 and/or PD-L1 in type 2 endometrial cancer.

Method

Formalin fixed, paraffin-embedded tissue samples from 67 cases with type 2 endometrial cancer were analyzed in this study. Serous adenocancer (n=21, 31%), clear cell (n=14, 21%) and mixed type adenocancer (n=32, 48%) were consisted the study cohort. Immunohistochemical staining was performed to detect the PD-1 and PD-L1 expressions in tumor tissue and microenvironment, separately.

Results

PD-1 expression in tumor tissue and microenvironment was detected in 26 (39 %) and 34 (51 %) cases, respectively. PD-L1 expression in tumor tissue and microenvironment was detected in 11 (16 %) and 19 cases (28 %), respectively. It has been found that expression of PD-1 and PD-L1 in tumor was associated with shorter survival although PD-1 and PD-L1 in microenvironment expressions were not found to be related with survival. Median survival in cases with and without PD-1 expression were 48 and 21 months, respectively (p=0.004). Median survival in cases with and without PD-L1 expression were 48 and 15 months, respectively (p=0.0001).

Conclusion

This study demonstrated an important association between PD-1 and PD-L1 expression and prognosis in type 2 endometrial cancers. Larger studies will be more informative for targeted treatment and/or checkpoint blocking therapies in type 2 endometrial cancer.

ESGO7-0777

A CASE OF SUCCESSFUL DELIVERY AFTER UTERUS-CONSERVING TREATMENT FOR EARLY STAGE ENDOMETRIAL CANCER: HYSTEROSCOPIC RESECTION WITH BILATERAL TUBAL LIGATION

J.Y. Kwack¹, Y.S. Kwon¹, H.J. Roh¹, S.H. Lee¹
¹Ulsan University Hospital, Obstetrics and Gynecology, Ulsan, Republic of Korea

Aims

Conventional treatment of early stage endometrial cancer is total abdominal hysterectomy and bilateral salpingo-oophorectomy with lymph node assessment. However, in young patients who desire future fertility, conservative management could be considered. The aim of study is to present successful cases of conservative surgical treatment of women with early endometrial cancer who desire to have fertility.

Method

A 32-year-old nulligravid woman had stage IA endometrial cancer which was a 1.5 cm sized lesion confined to the left fundal side of the uterus. The patient underwent laparoscopic tubal ligation with clips. In the peritoneal cavity, there was no lesion suspicious for extrauterine disease. After that, hysteroscopic resection was performed using a Storz (Tuttlingen, Germany) 26F unipolar resectoscope with a 24F loop electrode. A resectoscopic approach was performed three times until a clear resection margin had been confirmed by a pathologist. The surrounding endometrium including myometrium were resected. The other side of the endometrial tissue was saved for preserving the implantation capacity. Then, a levonorgestrel-releasing uterine device (LNG-IUS, Mirena®, Bayer, Germany) was inserted into the uterus. The intrauterine device was kept in place for 1 year and then removed.

Results

Six months after removal of LNG-IUS, follow-up biopsy showed no evidence of malignancy. The patient got pregnant by in vitro fertilization, and she delivered a male, 3140g at 39wks of gestation without complication such as uterine rupture or placenta accreta.

Conclusion

Hysteroscopic resection followed by insertion of a progesterone-releasing intrauterine device can be the option for early endometrial cancer patients who want to preserve their fertility.

14CHU Tenon, Gynecologic department, Rennes, France

Aims

BACKGROUND: The standard of care of endometrial cancer involves complex procedures such as pelvic and para-aortic lymphadenectomy and omentectomy, particularly for high-risk endometrial cancer. Few data are available about these complex surgical procedures and adjuvant therapy in elderly women. We aim to examine treatment and survival of elderly women diagnosed with high-risk endometrial cancer.

Method

STUDY DESIGN: We performed a case-control study of women diagnosed between 2001 and 2012 with high-risk endometrial cancers. Women older than 70 years (n=198) were compared with patients <70 years (n=198) after matching on high-risk for recurrence and LVSI status.

Results

RESULTS: Elderly patients had lymphadenectomies less frequently compared with younger patients (76% vs 96%, p<0.001) and no adjuvant treatment more frequently (17% vs 8%, p=0.005) due to less chemotherapy being administered (23% vs 46%, p<0.001). The 3-year DFS, CSS and OS of patients ≥ 70 years was 52% (43-61), 81% (74-88) and 61% (53-70), respectively. These were significantly lower than the 3-year DFS, CSS, and OS of younger patients, which was 75% (68-82) (p<0.001), 92% (87-96) (p<0.008) and 75% (69-82) (p=0.018), respectively. Cox proportional hazard models found that elderly women had 57% increased risk of recurrence (hazard ratio 1.57, 95% CI 1.04-2.39) compared with younger patients.

Conclusion

CONCLUSION: Although we found an independently significant lower DFS in elderly patients with high-risk endometrial cancer when compared with young patients, elderly women are less likely to be treated with lymphadenectomy and chemotherapy. Specific guidelines for management of elderly patients with high-risk endometrial cancer are required to improve their prognosis.
IMPACT OF GYNECOLOGIC SCREENING IN LYNCH SYNDROME

M. Gosset¹, L. Rossi¹, C. Cornou², C. Ngo², M. Delomenie², C. Nos², F. Lecuru², A.S. Bats²

¹ Hôpital Européen Georges Pompidou, Chirurgie Gynécologique Cancérologique et du Sein, Paris, France
² Hôpital Européen Georges Pompidou, Chirurgie Cancérologique Gynécologique et du Sein, Paris, France

Aims

Lifetime risk of developing endometrial cancer in Lynch syndrome is higher than in the general population and gynecologic screen appears interesting, although unproven until now. The aim of our study was to determine the diagnostic value of gynecologic screening for the diagnostic of endometrial cancer in patients with Lynch syndrome.

Method

We conducted a prospective study in patients with Lynch syndrome and identified mutation from 1998 to 2016 at the European Georges-Pompidou Hospital in Paris. All patients had an annual screening including clinical examination, pelvic ultrasound, endometrial biopsy, and hysteroscopy. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each test and of the global screening strategy were described.

Results

One hundred and ninety one patients, with 620 surveillance visits, were included in the study. The median age of patients was 51 years. Identified mutation were MLH1 (49.4%), MSH2 (48.4%), MSH6 (23.17%), and PMS2 (4.7%). Sensitivity, specificity, PPV, and NPV of pelvic ultrasound were respectively 84.6%, 92.8%, 40.7%, and 99.0%. For endometrial biopsy, they were respectively 89.5%, 99.8%, 94.4%, and 99.5%, and for hysteroscopy, they were 84.6%, 99.7%, 88.9% and 98.8% in all cases. Sensitivity of the global screening strategy was 100%. Five cases of endometrial cancers (ECs) were diagnosed through the screening. One case of EC was associated with an ovarian cancer (endometrioid carcinoma), which was detected by pelvic ultrasound.

Conclusion

A screening strategy including pelvic ultrasonound, endometrial biopsy, and hysteroscopy appears efficient for the diagnosis of gynecologic cancers in Lynch syndrome.
Aims

Our study aimed to assess the accuracy of pre-operative grading and histology of endometrial cancer by Pipelle endometrial sampling and dilatation and curettage (D&C).

Method

Patients with endometrial cancer treated by hysterectomy in the Prince of Wales Hospital in Hong Kong from January 2007 to December 2016 were identified retrospectively and those with pre-operative Pipelle endometrial sampling or D&C were included. Patients' records were reviewed for demographic and pathology findings. The accuracy of pre-operative grading and histology are compared with final histology.

Results

A total of 414 patients with pre-operative Pipelle endometrial sampling and 79 patients with D&C were included. The accuracy of pre-operative histology assessment is higher for D&C than Pipelle (94.9% VS 86.2%, p=0.049). The accuracy of grading with Pipelle and D&C are comparable (65.7% VS 66.2%, p=1.0). The strength of agreement for grade 1, 2 and 3 tumors are moderate, fair and moderate respectively (Table 2). The accuracy of pre-operative grading is higher for grade 1 tumors (79.5%) than grade 2/3 tumors (45.5%) (p=0.00). Myometrial invasion of <50% and lymph node negativity are related to higher accuracy of pre-operative grading (p=0.01, p=0.04) (Table 3). Cervical invasion, lymphovascular space invasion and age did not affect accuracy of pre-operative grading (Table 3).

Conclusion

Pre-operative histology assessment is better with D&C than Pipelle. Pre-operative grading with Pipelle and D&C is comparable. The accuracy is higher for grade 1 than grade 2/3 tumors. However, the accuracy and strength of agreement to final pathology is only fair to moderate.
PROGNOSTIC FACTORS FOR DISEASE RECURRENT IN EARLY ENDOMETRIAL CANCER

S.H. Lee1, P. Jung-Woo1, H. Myoungseok1, C. Yeon Jean1, K. Su Jin1
1Dong-A University Hospital, Obstetrics and Gynecology, Busan, Republic of Korea

Aims

The purpose of this study is to evaluate the clinicopathologic factors of early (International Federation of Gynecology and Obstetrics (FIGO) I-II stage) endometrioid endometrial adenocarcinoma (EMCA) in single institution and to identify factors affecting recurrence and prognosis.

Method

A single-center retrospective study of FIGO stage IA-IIB 102 EMCA patients who underwent comprehensive surgical staging from June 1995 to August 2016 was conducted. Non-endometrioid type and double primary cancer were excluded. We selected several clinicopathologic factors including age, CA-125, depth of myometrial invasion (DMI), tumor grade, lymphovascular space invasion (LVSI), and status of estrogen receptor/progesterone receptor (ER/PR). Univariate and multivariate Cox proportional hazard model and Kaplan-Meier estimates were used for analyzing all clinicopathologic factors related to the risk of disease recurrence.

Results

The median age was 55.05 years (range, 35 to 81 year). And the median follow-up time was 35 month (range, 2 to 155). Fifteen patients (10.78%) showed disease recurrence. Three patients, distant and 12 patients, locoregional metastasis were included. In univariate analysis, tumor grade (P=0.0045) and LVSI (P=0.0374) were associated with disease recurrence. Mutivariate analysis demonstrated an association between any type of recurrence and LVSI (hazard ratio [HR], 6.308; 95% confidence interval [CI], 1.851-11.484).

Conclusion

LVSI is highly associated with disease recurrence in early EMCA. As such, the presence of LVSI may indicate the need for adjuvant systemic therapy in patients with early stage disease.

SURGICAL OUTCOME OF FLUORESCENT IMAGE GUIDED SENTINEL LYMPH NODE (SLN) DISSECTION WITH INDOCYANINE GREEN (ICG) IN ENDOMETRIAL CANCER PATIENTS

S.W. Kim1, Y.N. Kim1, Y.J. Lee1, S.H. Park1, Y.S. Chung1, K.J. Eoh1, J.Y. Lee1, E.J. Nam1, S. Kim1, Y.T. Kim1

1Yonsei University College of Medicine, Women's Cancer Center- Yonsei Cancer Center, Seoul, Republic of Korea

Aims

The purpose of this study was to review the current performance of sentinel lymph node biopsy (SLNB) in terms of success rate, bilateral detection rate, location, and number of nodes per level. Through subgroup analyses of node positive patients, the clinical pre-operative risk factors that warrant full lymphadenectomy are outlined.

Method

We performed a retrospective review of 112 endometrial cancer patients who underwent laparoscopic or robotic lymphadenectomy after fluorescent SLNB with ICG from May 2014 to March 2017.

Results

SLN detection rate was 94.6% (106/112 patients) and bilateral detection rate was 74.6% (88/112 patients). The median number of harvested SLN was 5 (ranging from 1 to 24) and harvested total lymph node was 20 (ranging from 1 to 94). SLN metastasis was found in 6.25% (7/112 patients). Out of seven patients who were positive for SLN metastasis (3 with SLN only, 4 with both SLN and non-SLN metastasis). One patient 0.94% (1/106) had isolated non-SLN metastasis in para-aortic lymph node. This patient had serous carcinoma, r/o carcinosarcoma with >5cm tumor size and suspicious para-aortic lymph node on PET-CT. There was no pelvic non-SLN metastasis. Percentage of metastatic node of all harvested node was 1.86% (12/645) for SLN and 0.73% (16/2220) of non-SLN. Sensitivity for SLN detection was 87.5% and negative predictive value was 99.1%.

Conclusion

SLN detection with ICG was feasible and useful for its high specificity and negative predictive value. However, in high risk endometrial cancer patients, full lymphadenectomy should be done.

AN UNUSUAL PRESENTATION OF CARCINOSARCOMA AND PERIPHERAL TYPE PRIMITIVE NEUROECTODERMAL TUMOUR OF THE UTERUS AND A REVIEW OF LITERATURE

X.Y. Ho¹, J. Wang¹, S.H. Chew², S. Lim-Tan², Y.K. Lim¹
¹KK Women's & Children's Hospital, Gynaecologic Oncology, singapore, Singapore
²KK Women's & Children's Hospital, Pathology and Laboratory Medicine, singapore, Singapore

Aims

Primitive neuroectodermal tumours (PNETs) are uncommon tumours that usually occur in bone and soft tissue. They have been found in the female genital tract, with primary ovarian PNETs being the most common, followed by uterine PNETs. However, a mixed pathology of carcinosarcoma and PNET is extremely rare with only a few cases described in medical literature.

We present an unusual case of a 59 year old lady who was found to have a mixed pathology of carcinosarcoma and PNET of uterine origin. In this report, we discuss about the clinical presentation as well as the pathological diagnosis. We will also discuss briefly about the management of this uncommon case.

²KK Women's and Children's Hospital, Medical Oncology, Singapore, Singapore
³KK Women's and Children's Hospital, Gynaecological Oncology, Singapore, Singapore
⁴KK Women's and Children's Hospital, Radiation Oncology, Singapore, Singapore

Aims

Adjuvant chemotherapy followed by radiotherapy (RT) was offered as standard treatment at KKH for Stage 3 uterine cancer since 2005. We aim to analyse the survival outcomes in this group of patients comparing with the historical group of patients who received RT only.

Method

This study is a retrospective analysis of all patients in KKH diagnosed with Stage 3 endometrioid adenocarcinoma of the uterus from Year 2000 to 2010. SPSS program was used to analyse the data.

Results

A total of 121 patients had histology of endometrioid adenocarcinoma (EAC) only. Out of these patients, 48 patients received chemotherapy and RT whereas 55 patients received RT alone. The mean age of patients was 54 with no significant difference. The median duration of follow up was 56 months. The 2 groups were well balanced for age, stage of disease (3A, 3B, 3C), residual disease, depth of invasion, lymphovascular invasion and tumour size. Nearly all of our patients (99.3%) were surgically staged. The mean overall survival, cancer specific survival, disease free survival were 129 months, 137 months and 126 months respectively. The median was not reached. There was no significant difference for overall survival, cancer specific survival and disease free survival for the 2 groups of patients.

Conclusion

In our local population, patients with advanced endometrioid adenocarcinoma of the uterus who have full surgical staging have no difference in overall survival, cancer specific survival and disease free survival whether they receive chemotherapy and radiotherapy or radiotherapy only post operatively.

THE OUTCOMES OF FERTILITY SPARING TREATMENT FOR EARLY STAGE WELL-DIFFERENTIATION ENDOMETRIAL ENDOMETRIOID ADENOCARCINOMA

H. Lin¹, Y.C. Ou¹, C.H. Wu¹, S.C. Liu¹, H.C. Fu¹

¹Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.

Aims

The purpose of present study is to evaluate the outcomes of oral progestin treatment in women diagnosed with early stage grade 1 endometrial endometrioid cancer (G1EEC), who wish to preserve their fertility, in a single institute.

Method

We reviewed the medical records of patients that had been treated using oral progestin between 2010 and 2016. Women with disease limited to endometrium and no evidence of metastasis on pelvic magnetic resonance imaging scans were included. Endometrial biopsies were taken at follow-up periods.

Results

We identified 24 young women with G1EEC. The median age was 33 years old (range, 23 to 42), and the median treatment duration was 9 months (range, 3 to 24). Eighteen patients (75.0%) achieved complete remission (CR; median time to CR was 6 months; range, 3 to 12), only 1 patient (5.6%) with CR had recurrence at 40 months. Five patients with CR had subsequent levonorgestrel intrauterine device insertion due to no fertility desired yet. A total of 8 patients finally received surgery (4 non-responders, 2 after childbearing, 1 recurrence, 1 after ART failure). Eight of 16 CR patients attempted conception and 4 (50%) became pregnant with 5 live births. The proportion achieving pregnancy in our study cohort was 16.7% (4 of 24). Till now, all patients are alive with a median follow-up period of 37 months (range, 12 to 81).

Conclusion

We demonstrated high efficacy of fertility-sparing treatment with oral progestin. Low recurrent rate may be related to prolonged use of levonorgestrel intrauterine device. Further studies are necessary for clarification.
IMPORTANCE OF ULTRASOUND MARKERS IN THE RISK ASSESSMENT OF LYMPH NODE INVOLVEMENT IN ENDOMETRIAL CANCER

M. Liro¹, M. Sniadecki², S. Wojtylak³, E. Wycinka³, S. Sawicki¹, D. Wydra¹
¹Medical University of Gdansk, Gynecology- Gynecologic Oncology and Gynecologic Endocrinology, Gdansk, Poland
²Medical University of Gdansk, Patomorphology, Gdansk, Poland
³University of Gdansk- Faculty of Management, Statistics, Sopot, Poland

Aims

To evaluate ultrasonographic tumor and invasion markers (myometrial invasion [uMI; ≥ 0.5 myometrium], tumor area [AREA, cm²], tumor volume [SPE-VOL, cm³], tumor free distance [uTFD, mm]) and endomyometrial irregularity [EMIR] as predictors of lymph nodes involvement (LNI) in epithelial endometrial cancer (EC).

Method

One hundred and sixteen consecutive EC patients were included into this prospective study between January 2011 and November 2012. 2D transvaginal ultrasound and surgical treatment according to Mayo Clinic algorithm was applied in all patients. The study group and 86 G1-G2 endometrioid low risk (LR) as well as G3 endometrioid and serous type (high risk, HR) subgroups underwent separate statistical analyses regarding accuracy of ultrasound markers in predicting LNI. P value of <0.05 was statistically significant.

Results

LNI was found in 20/116 (17%) patients. In univariate analysis, only uMI, EMIR and uTFD were significant variables with accuracy of 70.7% (p<0.003), 67.2% (p<0.001) and 63.8% (p<0.02) in predicting LNI, respectively. The model combining ≥ 2 any of the factors did not increase accuracy. For LR tumors significant variables were uMI and EMIR with accuracy of 74.4% (p<0.001) and 70.9% (p<0.02), whereas for HR no of the factors were significant in univariate analysis.

Conclusion

uMI and EMIR may be useful predictive ultrasound markers, especially in LR tumors. The preoperative histology defining HR EC prevails over informative value of ultrasound. It would be of interest whether histologic counterparts of ultrasound factors (i.e. depth of invasion, type of growth) are of independent predictive or prognostic value in LR and HR tumors.
ENDOMETRIAL CANCER

ESGO7-0609

BRCA AND GENETIC BREAST/OVARIAN CANCER (GBOC) SUSCEPTIBILITY GENE MUTATIONS IN TYPE II ENDOMETRIAL CANCER – IMPLICATIONS FOR PROPHYLACTIC HYSTERECTOMY

B. Long¹, J. Lilyquist², A. Weaver³, C. Hu⁴, R. Gnanaolivu⁵, K.Y. Lee⁶, S.N. Hart⁷, J. Bakkum-Gamez¹, F. Couch⁴, S.C. Dowdy⁴
¹Mayo Clinic, Division of Gynecologic Oncology, Rochester- MN, USA
²Mayo Clinic, Division of Epidemiology, Rochester- MN, USA
³Mayo Clinic, Department of Biostatistics, Rochester- MN, USA
⁴Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester- MN, USA
⁵Mayo Clinic, Department of Biomedical Statistics and Informatics, Rochester- MN, USA

Aims

To determine the incidence of germline BRCA and genetic/familial high-risk breast and/or ovarian (GBOC) mutations in endometrial cancer (EC) subtypes.

Method

Germline DNA was extracted from whole blood collected from consenting patients undergoing primary surgery for EC between 5/2005-11/2016. DNA samples were evaluated by sequencing of products from a Qiaseq targeted multiplex PCR panel including 37 known or suspected cancer predisposition genes. Variants were classified as pathogenic/likely pathogenic based on allele frequency (<0.003), effects on protein function, and ClinVar assertions. Comparisons were evaluated using Fisher’s exact test.

Results

Germline panel testing was performed on 1177 cases of EC; 852 (72.4%) were type I, and 325 (27.6%) were type II EC, including 136 uterine serous cancers (USC, 11.6%). The incidence of BRCA1/2 mutations was low in both type I EC and USC (0.35% (3/852) vs. 0.74% (1/136); p=0.45). BRCA1 mutations were present in none of the type I EC vs. 3 patients (0.9%) with type II EC (p=0.02). Lynch Syndrome (LS) mutations were identified in 2.1% of type I and 1.8% of type II EC (p=1.00), including 1.5% in USC. Non-LS GBOC mutations were present in 3.3% of type I and 4.0% of type II EC (p=0.59), as well as 5.1% of patients with USC.

Conclusion

BRCA mutations were rare in this cohort of unselected patients with USC. However, BRCA1 mutations were significantly more common in patients with type II compared to type I EC. The role of hysterectomy in risk reducing surgery for patients with HBOC mutations remains unclear.

²Hospital Montepríncipe, Gynecology and Obstetrics. EGOM, Boadilla del Monte, Spain
³Hospital Montepríncipe, Pathological Anatomy Service, Boadilla del Monte, Spain
⁴Hospital Montepríncipe, Gynecology and Obstetrics. Resident Medical Intern, Boadilla del Monte, Spain

Aims

Undifferentiated endometrial sarcoma (UES) is a very rare subtype of uterine sarcoma with an aggressive behavior. We would like to present the treatment and the clinical evolution of two patients.

Method

Descriptive, retrospective study about UES in the last year at our hospital.

Results

The first patient was 42 years old. She approaches the gynecology department at our hospital because of hypermenorhea two months ago. Ultrasound and Magnetic Resonance (MR) showed a myoma of 10 cm. She had anemia due to hysterectomy and bilateral salpingectomy by laparotomy was decided. The histology results confirmed UES (image 1a). The extension study reported lung metastases. The patient received two cycles of Gemcitabine-Docetaxel and radiotherapy. Two months later the diagnosis she died. The second patient was 49 years old. In August she was derived for acute metrorrhagia to the hospital. At the revision impress myoma through the Ultrasound and MR showed a myoma of 9 cm and multiple nodular images in vagina. Hemodynamic instability, it was decided to perform total hysterectomy and bilateral anexectomy by laparotomy. The histology results confirmed UES (image 1b). The extension study reported multiples metastases in lymph nodes and bones. Treatment with Carboplatin-Taxol and radiotherapy. In October the patient died.

Conclusion

UES has devastating consequence in a short period of time. There is not yet consensus on the treatment of this disease.
ENDOMETRIAL CANCER

ESGO7-0068

MRI IN THE PREOPERATIVE EVALUATION OF WOMEN WITH ENDOMETRIAL CANCER IN CHUH

E. López González¹, C. Forero Díaz¹, J.A. Rojas Luna¹, F. Larre Meneses¹

¹Complejo Hospitalario Universitario de Huelva Juan Ramón Jimenez, Ginecology, Huelva, Spain

Aims

The presence and/or depth of myometrial invasion of endometrial adenoma carcinoma has important prognostic and therapeutic implications. So our task is to assess the accuracy of MRI (Magnetic resonance Imaging) in determining the presence and depth of myometrial invasion.

Method

Retrospective study of 145 patients diagnosed with adenocarcinoma of the endometrium since 2010 to 2016. The results were compared with those obtained after total hysterectomy and bilateral salpingo-oophorectomy.

Results

MRI was made and was able to discriminate the degree of invasion (superficial or deep) in 72.4% of them. According to the criteria of greater or equal to 50% involvement to the myometrial wall invasion as the representation of depth and less than 50% as superficial invasion.

Conclusion

Based on the results, it conlute that MRI appears to be an excellent technique to determine the invasion of the myometrium and can play an important role in the preoperative planning a thorough of the invasion of the myometrium, but in our population the vaginal ultrasound could be considered as a useful alternative to determinate the invasion grade. This was planning to future studies in our Hospital.
ENDOMETRIAL CANCER

ESGO7-0069

ENDOMETRIAL CANCER PATHOLOGY OF ENDOMETRIAL CANCER IN OUR AREA: CHUH

E. López González¹, C. Forero Díaz¹, J.A. Rojas Luna¹, F. Larre Meneses¹
¹Complejo Hospitalario Universitario de Huelva Juan Ramón Jimenez, Ginecology, Huelva, Spain

Aims

Evaluate the different histologic subtypes of endometrial cancer diagnosed in Hospital Juan Ramón Jimenez’s Hospital in the last six years since 2010.

Method

Retrospective study of pathological anatomy in women diagnosed endometrial cancer since 2010.

Macroscopically, endometrial cancer can develop in uterus with normal or small size, in menopause women with atrophic uterus or in premenopause women with normal or higher uterus.

Microscopically, there are different histological subtypes: endometrioid adenocarcinoma, serous papillary adenocarcinoma, clear cells adenocarcinoma, mucinous adenocarcinoma, scads adenocarcinoma, mixed cancer, undifferentiated cancer and endometrioid adenocarcinoma with scads differentiation.

Results

Of the 208 cases of endometrial cancer, it is observed in the majority of cases (145 cases = 69%) corresponds to the subtype histology endometrioid carcinoma; 15 corresponds to STUMP (= 7.2%), 9 cases (= 4.3%) corresponds to serous papillary; 5 cases (2.4%) clear cell subtype and 18 cases with sarcomatous component (8.6%).

Conclusion

It has been shown that endometrioid subtype is the most common and is related to the hiperestronismo and endometrial hyperplasia. The aggressiveness of endometrioid carcinoma is variable and is related to their degree of differentiation. Endometrial cancers in which has not been shown hiperestronismo and relationship with or that are developed from a hyperplastic endometrium, have a poor prognosis.
ENDOMETRIAL CANCER

ESGO7-0071

PRIMARY DIFFUSE LARGE B-CELL LYMPHOMA OF THE ENDOMETRIUM.

E. López González¹, C. Forero Díaz¹, J.A. Rojas Luna¹, F. Larre Meneses¹
¹Complejo Hospitalario Universitario de Huelva Juan Ramón Jimenez, Ginecology, Huelva, Spain

Aims

To know the incidence of non-Hodkking lymphoma in the uterine tissue to can get an early diagnosis and multidisciplinary management. large-cell diffuse B-cell non-Hodkkin's lymphoma (LNHDGB) of the uterine is a rare entity.

Method

Bibliographic review through the PubMed database.

Results

Case: A 42-years-old woman presented a refractory metrorrhagia with anemia. Cervical cytology was negative. No endometrial pathology evaluable ultrasonographically. Anatomopathological study was performed through endometrial aspiration, due to the lack of response to hormonal treatment. Result: LNHDGB infiltrated endometrial with Ki-67 greater than 80% . Result of Abdominal-pelvic CT: lymphadenopathy distributed from the gastroesplenic ligament, gastrohepatic to retroperitoneal region. The patient was treated with three courses of Rituximab(R) + CHOP (Cyclophosphamid, Doxorubicin, Vincristin and Prednisolon). After completion of chemotherapy the patient underwent abdominal hysterectomy with bilateral salpingectomy. Histology revealed complete remission .

Conclusion

The 25% of the lymphomas have an extraganglionic origin, and reach 40% in diffuse large cell lymphomas, although only 1% develops at the gynecological level. The ovary is the most frequent location and only 1 out of 175 extraganglionic lymphomas in women originate in the uterus or vagina. The average age of presentation is in the fifth decade of life. The most common histology is LNHDGB. The reason why patients usually consult is abnormal vaginal bleeding. The treatment for the disease used include a treatment with chemotherapy and radiotherapy, and there is a good response in the early stages of the disease. Endometrial biopsy is a reliable and easy method, which provides essential information.
THE LAPAROSCOPIC APPROACH IN ENDOMETRIAL CARCINOMA OF THE CORPUS UTERI: SHORT- AND MEDIUM-TERM RESULTS

E. López González, C. Forero Díaz, J.A. Rojas Luna, F. Larre Meneses

Complejo Hospitalario Universitario de Huelva Juan Ramón Jimenez, Ginecology, Huelva, Spain

Aims

To evaluate the effectiveness of the laparoscopic approach in cases of endometrial carcinoma.

Method

Retrospective observational study using the records of endometrial carcinoma cases diagnosed in our hospital between January 2010 and December 2016 and treated with laparoscopic surgery.

Results

In the analyzed period, 208 were diagnosed; 145 endometrioid adenocarcinomas (69%). The mean age of the patients at the time of diagnosis was 63 years (range: 30-87) of 208 patients rejected the intervention. 193 were initially treated by surgery and all of them the laparoscopic approach was used as the first option but in 19 (10.7%) was necessary to convert a laparotomy pathway. In 106 (55%) of the surgical procedures a pelvic lymphadenectomy was performed: all of them laparoscopically. In addition, paraaortic lymphadenectomy was performed in 101 cases. We obtained a mean of 12 lymph pelvic nodes (range: 8-16) and 10.2 aortic nodes (7-13) per patient. Only in one case, there was intraoperative complications that consisted of an bladder lesion that was repaired in the same surgical act. During the immediate postoperative period, one patient presented a lymphedema in the left lower limb. Of the 208 women diagnosed with endometrial carcinoma, 4 had died during the follow-up period, 5 had relapsed, while the remaining 199 (95.67%) continued to live, free of Disease, at the time of the study.

Conclusion

The laparoscopic approach of endometrioid endometrial adenocarcinoma surgery is feasible, safe, and has success rates similar to the classic abdominal pathway and less morbidity.
VALUE OF FOLLOW-UP PROCEDURES IN ENDOMETRIAL CANCER PATIENTS: A STUDY OF RELAPSES IN OUR INSTITUTION

Aims

The aim of this retrospective study was to examine the recurrence rates and patterns in patients with endometrial cancer in our hospital and evaluate the usefulness of routine follow-up procedures for the detection of recurrent disease following treatment of endometrial carcinoma.

Method

We conducted a retrospective descriptive study including all patients with a diagnosis of recurrent endometrial cancer treated at the Department of Gynecologic Oncology from the University Hospital of the Canary Islands between 2000 and 2014.

Results

The mean age of these patients at the time of treatment of their initial tumor was 67.72 years.

The most common site of recurrence was vaginal vault (28.4) followed by lymph nodes in 19 cases (23.45%) and carcinomatosis (23.45%). The distant metastases occurred in 20 cases (24.69%) and in fourteen patients there were more than one site of recurrence.

The recurrences were diagnosed in 66.7% and 80.2% within 2 and 3 years after primary treatment, respectively.

41% of patients had symptomatic recurrent disease (33 cases).

Half of the patients were diagnosed by pelvic examination (51%), the remaining 49% of relapses were found by elevated tumors markers (28/81 cases, 34.56%), by imaging procedures (7/81 cases, 8.64%) and only 5 cases by Papsmears (6.17%).

Conclusion

In our study, the vast majority of relapses occurred in the first three years of follow-up (80.2%). The results show that routine vaginal cytology was only beneficial in 6.2% of recurrences, so it can be concluded that surveillance by vaginal cytology is ineffective for the detection of relapses of endometrial cancer.
Predictive Factors of Recurrence in Endometrial Cancer: Proposal for a New Morphological Model.

M. Mitidieri1, V. Elena1, M. Ribotta2, P. Danna1, C. Macchi1, D. De Ruvo1, D. Ferraioli1, P. Zola1
1AOU Città della Scienza e della Salute di Torino, Dept of Surgical Science University of Turin, Turin, Italy
2AOU Città della Scienza e della Salute di Torino, Dept of Pathology, Turin, Italy

Aims

Identify morphological and immunohistochemical features as predictive markers of recurrence in endometrial endometrioid cancer (EEC).

Method

Retrospective study of a single-center clinical series of 72 patients treated for EEC at the Department of Gynecologic Oncology of the University of Turin, between the 1st of January 2012 to 31st of December 2014. The histological specimens have been revalued in blind by a pathologist to define: FIGO stage, histological grading, number of mitosis (at 40HPF and 10HPF), Ki-67% expression and morphological features. In addition the tumor aggressiveness and its recurrence has been analyzed in relation to the proliferation boost: this was defined as the percentage of the cells in mitosis during the interphase.

Results

The analysis revealed a strong association between the Ki-67% expression (p= 0.015) and disease free survival (DFS). Proliferation boost results to be the best marker of recurrence (p= 0.007) with OR 1.93 (95% CI 1.86-1.99; p = 0.013). The only two morphological variables that showed a correlation with the recurrence are the LVSI (p= 0.032) and the pattern of infiltration (p= 0.012). At multivariate analysis the FIGO stage and the proliferation boost result independent predictors of DFS with OR 4.04 (95% CI 1.41-11.59; p= 0.009) and OR 5.01 (95% CI 1.42-17.75; p= 0.012) respectively.

Conclusion

The integration of FIGO stage and proliferation boost is feasible and could be used as predictive factor of recurrence in EEC.

SAFETY AND FEASIBILITY OF ROBOTIC SURGERY FOR ENDOOMETRIAL CANCER: EXPERIENCE FROM A TERTIARY CANCER CENTRE IN INDIA

A. Maheshwari

Tata Memorial Hospital, Gynecologic Oncology, Mumbai, India

Aims

Robotic surgery has become the preferred surgical approach in the management of endometrial cancer in many developed countries. However, the same is not true for less developed countries where open surgery still continues to be standard of care. At our institute Xi Robotic system was installed in September 2014. The current study presents our early experience with robotic surgery in endometrial cancer.

Method

The study is retrospective analysis of prospective data of endometrial cancer patients underwent robotic hysterecomy from October 2014 to December 2016.

Results

A total of 58 patients underwent robotic surgery. The median age was 59 years (range 31-75). The median BMI was 30 (Range 20 - 42). The median docking time and procedure time was 12 min and150 min, respectively. All surgeries were completed robotically except one, which required laparotomy for advanced disease found intraoperatively. The median blood loss was 100 ml. Surgical procedures performed were – RH + BSO with bilateral pelvic lymphadenectomy in 52 %, RH + BSO + Sentinel node in 29%, RH + BSO + pelvic and retroperitoneal node dissection in 3.5 % and RH + BSO in 14%. Seventeen patients underwent sentinel node biopsy with Indocyanine green (ICG) dye, bilateral sentinel nodes were detected in all. The post operative period was uneventful except one re-exploration on first post operative day for undiagnosed needle injury to ileum. At a median follow up of 16 months 2-year recurrence free survival was 85%.

Conclusion

Robotic surgery for endometrial cancer is safe, feasible and carries low peri-operative morbidity.

RISK FACTORS FOR DIFFICULTIES IN OFFICE ENDOMETRIAL CYTOLOGICAL SAMPLING

1Attikon University Hospital, Ob/Gyn, Athens, Greece
2Medical School- National and Kapodistrian University of Athens- Greece, Assisted Reproduction Unit- Third Department of Obstetrics and Gynecology- General Hospital “Attikon”, Athens, Greece
3Medical School- National and Kapodistrian University of Athens- Greece, Department of Cytopathology- General Hospital “Attikon”, Athens, Greece
4Medical School- National and Kapodistrian University of Athens- Greece, Unit of Gynecological Oncology- Third Department of Obstetrics and Gynecology- General Hospital “Attikon”, Athens, Greece
5Medical School- National and Kapodistrian University of Athens- Greece, Department of Hygiene- Epidemiology and Medical Statistics, Athens, Greece

Aims

Endometrial cytology is useful for the diagnosis of endometrial cancer. This study aims to evaluate factors associated with difficulties in endometrial cytology sampling.

Method

204 women that underwent endometrial cytological sampling with the Endogyn curette (Biogyn S.N.C., Mirandola, Italy) were included in the study. Difficulty (strenuousness) in obtaining the sample was graded into a five-level scale-score. Various risk factors were examined in association with the strenuousness score; multivariate ordinal logistic regression analysis was conducted. Statistical analysis was performed with Stata/SE statistical software (Stata Corp., College Station, TX, USA).

Results

Postmenopausal status (adjusted OR=2.91, 95%CI: 1.72-4.92, p<0.001) and previous invasive/surgical procedures in the cervix (adjusted OR=2.23, 95%CI: 1.20-4.15, p=0.011) were independently associated with higher difficulty score. On the other hand, participants’ phase of the menstrual cycle, endometrial thickness, obesity, current hormone use and the reproductive history of women were not significantly associated with the difficulty in conducting the procedure.

Conclusion

Difficulties during endometrial sampling are observed in postmenopausal women, as well as in women with previous surgical procedures in the cervix.

HIGH GRADE ENDOMETRIAL STROMAL SARCOMA ASSOCIATED WITH YWHAE-FAM22 REARRANGEMENT – TWO CASE REPORTS.

Z. Marchocki¹, C. O’Riain², W. Kamran³, F. Abu Saadeh⁴
¹St. James’s Hospital, Department of Gynaecologic Oncology, Dublin, Ireland
²St. James’s Hospital, Histopathology Department, Dublin, Ireland

Aims

Endometrial stromal sarcoma (ESS) is the second most common malignant uterine mesenchymal tumour and accounts for around 0.2% of all uterine malignancies.

Method

We present two cases of high grade endometrial stromal sarcoma associated with YWHAE-FAM22 rearrangement harboring t(10, 17) (q22, p13).

Results

First patient was a 39 year old nulliparous women who underwent transcervical polypectomy for heavy irregular vaginal bleeding on background history of stage IV endometriosis. Histology showed high grade ESS. Subsequent completion surgery revealed residual low grade ESS, FIGO stage IB and extensive endometriosis. She recovered well post operatively and required no adjuvant therapy. She is well with no signs of recurrence 36 month after primary diagnosis.

Second patient was 57 year old, P3 morbidly obese women who underwent diagnostic hysteroscopy and curettage for abnormal uterine bleeding. Histology was suspicious for sarcoma. She was subsequently admitted with significant vaginal bleeding requiring emergency uterine artery embolization. Total abdominal hysterectomy with bilateral salpingo-oophorectomy was performed which revealed high grade ESS, at least FIGO stage IB. Decision for adjuvant pelvic radiotherapy was made. CT abdomen and pelvis performed 3 months following surgery revealed disease recurrence with new pelvic and retroperitoneal lymphadenopathy.

Conclusion

YWHAE-FAM22 ESS have been described in the literature as a clinically aggressive subtypes of ESS. Our second case certainly reflects that theory. Positive outcome of the first case could be potentially explained by the fact that high grade ESS was limited only to the endometrial polyp.
MESONEPHRIC LIKE ENDOMETRIOID UTERINE CARCINOMA – A CASE REPORT.

Z. Marchocki¹, F. Abu Saadeh¹
¹St. James’s Hospital, Department of Gynaecologic Oncology, Dublin, Ireland

Aims

Mesonephric adenocarcinomas are rare female genital tract neoplasms occurring most commonly in the cervix and occasionally in the vagina and uterus. It is assumed they originate from remnants of mesonephric (Wolffian) ducts that run parallel to the Mullerian ducts in the embryonic period.

Method

We present a case of 39 year old women with stage IV mesonephric like endometrioid uterine carcinoma.

Results

She presented initially with irregular vaginal bleeding and histological diagnosis of atypical endometrial hyperplasia was confirmed. She returned few months later with abdominal pain. Laparoscopy at that time revealed metastatic malignancy to peritoneum, omentum and ovaries. She subsequently underwent staging laparotomy. Histology showed metastatic uterine adenocarcinoma with glandular, solid and slit-like formations. There were no tubular formations with luminal eosinophilic material. Immunohistochemistry showed positive staining with EMA, vimentin, PAX8, TTF1, focal immunoreactivity with cytokeratins, p16, Ca125 and calretinin. PS3 exhibited “wild type” and hormone receptors (ER and PR) were weakly positive. WT1, inhibin, CD10, GATA3 and androgen receptor were negative. She is currently well at her 6th cycle of adjuvant carboplatin and paclitaxel based chemotherapy. Based on current knowledge it can be speculated whether this case represent true mesonephric adenocarcinoma of the uterine corpus or unusual variant of endometrioid adenocarcinoma.

Conclusion

Similar cases present significant pathological challenge since a mesonephric adenocarcinoma typically exhibits a mixture of different morphologic patterns with multiple immunohistochemical markers which can be often confused with different histological subtypes. Future studies are necessary in order to classify this tumours appropriately and guide the treatment.

PROOF OF CONCEPT: CAN THE INTELLIGENT SURGICAL KNIFE DIAGNOSE ENDOMETRIAL CANCER?
D. Marcus¹, A. Savage¹, D. Phelps¹, Z. Bodai¹, F. Rosini¹, H. Kudo¹, Z. Takats¹, S. Ghaem-Maghami¹
¹Imperial College London, Cancer and Surgery, London, United Kingdom

Aims

The aim of this study was to establish whether the intelligent surgical knife (‘iKnife’) could distinguish between normal and malignant endometrial tissue based on differences in their lipidomic profiles.

Furthermore, we intend to use this reference dataset to create a multivariate statistical model to enable real-time tissue recognition in the gynaecology clinic; thus providing rapid point-of-care diagnosis.

Method

A Waters G2-XS Xevo Q-Tof mass spectrometer (MS) was used in this study in conjunction with a modified handheld diathermy (collectively coined the ‘iKnife’). The resultant surgical aerosol containing ionic species were then analysed with this technology; producing spectra that are background subtracted, lock mass corrected and in the phospholipid range. Principal component analysis (PCA) and linear discriminant analysis (LDA) were then performed to find the variance in spectral signatures between benign and malignant endometrial tissues. A leave one patient out cross validation was used to obtain sensitivity and specificity values.

Results

Seventy-two frozen uterine samples (23 normal and 49 malignant endometrial tissue samples) were analysed using the technique above.

The iKnife differentiated between normal and malignant endometrial tissues on the basis of differences in their unique phospholipid spectral signatures. A leave one patient out cross validation was performed; which revealed a sensitivity and specificity of 78% and 86% respectively.

Conclusion

This pilot study is the first to use the iKnife as a tool to differentiate between normal and malignant endometrial tissue. These results are promising, and suggest that the iKnife could be used as an adjunct in clinic to provide a point-of-care diagnosis.
SENTINEL NODE MAPPING IN ENDOMETRIAL CANCER: A SINGLE CENTER EXPERIENCE OVER 200 CASES OF HYSTEROSCOPIC INJECTION OF TRACERS

F. Martinelli1, A. Ditto1, G. Bogani1, M. Signorelli1, V. Chiappa1, C. Scaffa1, D. Recalcati1, S. Perotto1, L. Montanelli1, C. Borghi1, D. Lorusso1, F. Raspagliesi1
1Fondazione IRCCS Istituto Nazionale dei Tumori, Gynecologic Oncology, Milano, Italy

Aims

To analyze detection-rate (DR) and diagnostic-accuracy (A) of sentinel-nodes (SLNs) mapping following hysteroscopic-injection of tracer. To compare DR and A between tracers used: ICG and Tc99m.

Method

Retrospective evaluation of Prospectively collected data of Consecutive patients with endometrial cancer underwent SLNs mapping following hysteroscopic-peritumoral-injection of tracer+/−full surgical-staging. Evaluation of DR (overall-bilateral-aortic) and A among the entire cohort and comparison between tracers.

Results

202 procedures were performed. Mean age: 60 years (28-82); mean BMI: 26.8 Kg/m2 (15-47). In 133 cases (65.8%) hysterectomy and mapping procedure were performed laparoscopically. The overall-DR of the technique was 93.2% (179/192) (10 cases excluded: 9 equipment failure; 1 vagal reaction). Bilateral pelvic mapping was found in 59.7% of cases (107/179) and was more frequent in the ICG group (72.8% vs 53.3%; p: 0.012). In 50.8% of cases (91/179) SLNs mapped both to pelvic and aortic nodes, and in 5 cases (2.8%) only in the aortic area. Mean number of detected SLNs was 3.7 (1-8).

22 patients (12.3%) had nodal involvement: 10 (45.5%) macrometastases; 5 (22.7%) micrometastases; 7 (31.8%) ITCs. In 6 cases (27.3%) only aortic nodes were positive; in 5 cases (22.7%) both pelvic and aortic nodes and in 11 cases (50%) only pelvic area was involved.

Three false negative results were found, all in the Tc99m group. All had isolated aortic metastases with negative pelvic nodes.

Overall-sensitivity was 86.4% and overall-negative-predictive-value (NPV) was 98.1%.

No differences in terms of overall-DR, overall-sensitivity and overall-NPV were found between the two tracers. (Table)

</table>

Conclusion

Hysteroscopic-injection of tracer for SLNs mapping in endometrial cancer is as accurate as cervical injection with a higher DR in the aortic area. ICG improved bilateral DR. Further investigation is warranted on this topic.

MULTIPOSITIONAL EVALUATION OF CLEAR-CELL ENDO METRIAL CANCER

T. Litvinova¹, A. Okeano², I. Kosenko³, O. Matylevich⁴, M. Khoroshun⁴
¹Belarusian State Medical University, Oncology Department, Minsk, Belarus
²N.N.Alexandrov National Cancer Center, Cancer Control Department, Minsk, Belarus
³N.N.Alexandrov National Cancer Center, Gynecologic Oncology Department, Minsk, Belarus
⁴Brest Regional Oncology Center, Gynecologic Oncology Department, Brest, Belarus

Aims

The trends in some epidemiological indices of clear-cell endometrial cancer (CCEC) and the efficacy of treatment were evaluated.

Method

Annual incidence and mortality values and 5-year survival rates were analyzed in 350 patients treated according to the National standards in period 2005-2015. The 5-year survival rates were compared with the same indices in 128 patients receiving non-standard therapy.

Results

The proportion of stage I CCEC patients increased by 12.7%, stage IV by 8.6%. The incidence grew from 0.6‰ to 0.8‰. Mortality in the period under study varied from 0.1‰ to 0.3‰, being 0.2‰ in most of the cases. The 5-year survival rate in the 350 patients was 65.7%, being 85.4% for stage I CCEC, 69.7% for stage II, 43.0% for stage III, and 23.6% for stage IV. In 128 patients treated with non-standard techniques, this rate was 59.2%, being 85.0% for stage I, 56.5% for stage II, 26.6% for stage III, 0.0% for stage IV. None of stage IV patients survived for 5 year, the 3-year survival rate being 10.4%.

Conclusion

Over the recent years, CCEC incidence growth from 0.6‰ to 0.8‰ was noted in Belarus, with no change in mortality rates. The employment of the National standards made it possible to increase the 5-year survival rate for stage II CCEC by 13.6%, for stage III by 16.4%, for stage IV by 23.6%, with no change in its value for stage I which was 85.4% and 85.0% in those years.

PROTEOMIC PROFILING OF ENDOMETRIOID ENDOMETRIAL CANCER REVEALS DIFFERENTIAL EXPRESSION OF HORMONE RECEPTORS AND MAPK SIGNALING PROTEINS IN OBESE VERSUS NON-OBESE PATIENTS

K.K. Mauland¹, Z. Ju², I.L. Tangen¹, A. Berg¹, L. Bjørge³, S.N. Westin³, C. Krakstad¹, J. Trovik³, G.B. Mills⁵, H.M. Werner³

¹University of Bergen, Department of Clinical Science, Bergen, Norway
²The University of Texas M.D. Anderson Cancer Center, Department of Bioinformatics and Computational Biology, Houston- TX, USA
³Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway
⁴The University of Texas M.D. Anderson Cancer Center, Department of Gynecologic Oncology and Reproductive Medicine, Houston- TX, USA
⁵The University of Texas M.D. Anderson Cancer Center, Department of Systems Biology, Houston- TX, USA

Aims

Endometrial cancer development is strongly linked to obesity, but knowledge regarding the influence of excess weight on endometrial tumor signaling pathways remains scarce.

Method

We examined obesity-related protein expression patterns with reverse phase protein array (RPPA) in well-annotated patient samples using one training (n=272) and two test cohorts (n=68; n=178) of patients treated for endometrioid endometrial cancer. Gene expression profiling and immunohistochemistry were used for cross-platform validation.

Results

Body mass index (BMI) was significantly correlated with progesterone receptor (PR) expression and a hormone receptor protein signature, across all cohorts. BMI was negatively correlated with receptor tyrosine kinase- and mitogen-activated protein kinase (MAPK) pathway activation, particularly phospho-MAPK (T202 Y204) level (p-MAPK). Using stepwise selection modelling, a BMI-associated protein signature, including phospho-estrogen receptor (ER)a (S118) (p-ERa) and p-MAPK, was identified. In the subset of FIGO stage 1, grade 1-2 tumors, obese patients (BMI≥30) had significantly better disease-specific survival compared to non-obese patients (p=0.042). Non-obese patients had higher p-MAPK levels, whereas obese patients had higher p-ERa levels and enrichment of gene signatures related to estrogen signaling, inflammation, immune signaling and hypoxia. In subgroup analysis of non-obese patients with stage 1 tumors, low PI3K-activation was associated with reduced survival (p=0.002).

Conclusion

Increasing BMI is associated with increased PR and p-ERa levels as well as reduced MAPK signaling, both in all patients and in subsets with predicted excellent prognosis. The MAPK-pathway represents a potential target for therapy in non-obese patients with low stage and low grade tumors.
ENDOMETRIAL CANCER

ESGO7-0280

HIGH VISCERAL FAT PERCENTAGE IS ASSOCIATED WITH POOR OUTCOME IN ENDOMETRIAL CANCER
K.K. Mauland¹, Ø. Eng², S. Ytre-Hauge³, I.L. Tangen¹, A. Berg¹, C. Krakstad¹, J. Trovik⁴, E.A. Hoivik¹, H.M. Werner⁴, G. Melgrén², I.S. Haldorsen³
¹University of Bergen, Department of Clinical Science, Bergen, Norway
²Haukeland University Hospital, Hormone Laboratory, Bergen, Norway
³Haukeland University Hospital, Department of Radiology, Bergen, Norway
⁴Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway

Aims

Despite evidence of increased endometrial cancer (EC) risk in obese women, the impact of obesity and fat distribution pattern on clinical and histological phenotype is poorly understood. We therefore evaluated abdominal fat volumes and fat distribution quantified by computed tomography (CT), in relation to tumor characteristics and outcome.

Method

227 EC patients with preoperative contrast-enhanced abdominal CT scans and comprehensive clinicopathological data were included. Total abdominal fat volume (TAV), subcutaneous abdominal fat volume (SAV) and visceral abdominal fat volume (VAV) were quantified, and visceral fat percentage calculated (VAV%=[VAV/TAV]x100). Waist circumference (WC) and liver density (LD) were measured, and body mass index (BMI) calculated. Data for estrogen, progesterone and androgen receptor (ER/PR/AR) expression by immunohistochemistry were available for 149 tumors, and global gene expression data for 105 tumors.

Results

High BMI, TAV, SAV and WC, and low LD, were associated with markers of less aggressive disease, including low-grade endometrioid tumors and PR and AR positivity (all ps<0.03). High VAV% was associated with high age (p<0.001) and aneuploidy (p=0.01), and independently predicted reduced disease-specific survival (HR 1.05, 95% CI 1.00-1.11, p=0.041). Tumors from patients with low VAV% showed enrichment of gene sets related to immune activation and inflammation.

Conclusion

High abdominal fat volumes and markers of obesity are associated with less aggressive endometrial cancer. High VAV% independently predicts reduced EC survival. Tumors arising in patients with low VAV% show enrichment of immune and inflammation related gene sets, suggesting that the global metabolic setting may be important for tumor immune response.
ENDOMETRIAL CANCER

PIPELINE BIOPSY: THE KEY TO REDUCING CANCER WAITING TIMES?
A. McAvoy¹, A. Currie¹
¹Craigavon Area Hospital, Obstetrics and gynaecology, Craigavon, United Kingdom

Aims

Aim: During the year 2015 cancer waiting times across the UK have fallen below established targets of 85% of patients completed treatment from initial referral red flag referral. The purpose of the review was to highlight the reduced waiting times experienced when a pipeline biopsy was performed in patients with suspected endometrial cancer.

Method

Methods: A retrospective review was performed of all endometrial cancer patients (n=60) in Craigavon area hospital in 2015. From this group patients who had pipeline performed at initial hospital consultation (n=30) were compared with those who had hysteroscopy as the diagnostic tool(n=30). The total waiting time from initial referral to definitive treatment were then compared to assess for reduction in waiting time.

Results

Results: Average referral to appointment time =13.4 days which hits the target as set out by NICE guidelines. The average referral to surgery time for the pipeline group was 61.94 days in pipeline group vs 106 days in the hysteroscopy group.

Conclusion

Conclusion: Average reduction in waiting time for definitive treatment was 64.04 days. This meant that having a pipeline biopsy at initial consultation reduced the waiting time for definitive treatment by 43%.
CLINICOPATHOLOGICAL FEATURES OF UTERINE ENDOMETRIAL CANCER IN YOUNG WOMEN UNDER 40 YEARS

M. Miwa¹, H. Yoshida¹, M. Hanaoka¹, D. Ichikawa¹, D. Shintani¹, Y. Yano¹, A. Ogasawara¹, A. Yabuno¹, T. Nishikawa¹, Y. Ikeda¹, K. Hasegawa¹, K. Fujiwara¹, M. Yano², M. Yasuda²

¹Saitama Medical University International Medical Center, Gynecologic Oncology, Hidaka, Japan
²Saitama Medical University International Medical Center, Pathology, Hidaka, Japan

Aims

To verify the feature of young uterine endometrial cancer patients who were diagnosed at age of less than 40 years; clinical course, histopathological data, family cancer history and more.

Method

From 2007 to 2016, we reviewed 47 patients of uterine endometrial carcinoma under 40 years; clinically and histopathologically. As a second study, we separated patients to two groups. One is Lynch suspected group; patients who has family cancer history of Lynch related cancer within first degree relatives. Second group is Sporadic group; patients without family cancer history of “Lynch suspected group”, and reviewed both group’s feature retrospectively.

Results

Median age was 36, BMI was 28.3. 40 of 47 patients were stage I, and 41 of 47 patients were Endometrioid carcinoma. 7 patients had synchronous ovarian cancer. 7 of 47 patients met criteria of Lynch suspected group, but no patients met Amsterdam criteria II. There were no specific findings between two groups, both Lynch suspected group and Sporadic group.

Conclusion

In young endometrial cancer patients, ratio of early stage and histology of endometrioid carcinoma was high. 15% patients had family cancer history which is related to Lynch syndrome. This suggest that it is important to treat young endometrial cancer patients with consideration of hereditary tumor. Prospective analysis of more patients will be needed.
Aims

The new, revised WHO classification of endometrial hyperplasia has greater benefit to clinical management that is why it is preferred by gynecologic oncologists. Correct assessment of precancerous lesions in peri or postmenopausal women with abnormal uterine bleeding means to avoid under or over treatment of these patients, so to identify the true neoplasia is the most important for the clinical practice.

The main objective for the nonsurgical management in EIN is to induce and maintain disease regression. Unfortunately, hormonal treatment is not so well standardized regarding optimal route, dose, duration for administrating of progestins, nor for the follow-up and endometrial surveillance in these women.

A significant proportion of patients diagnosed with endometrioid intraepithelial neoplasia -EIN have a coexisting invasive cancer or have a high risk of developing cancer. Also, in patients diagnosed with EH by endometrial sample, after surgery the diagnosis was EIN, so surgical treatment should be established correctly.

Method

In our study were included all the patients diagnosed with endometrial hyperplasia in our institution in the last two years after having an endometrial sampling with or without a hysteroscopy.

Results

All our patients diagnosed with EIN who underwent hysterectomy had an associated well differentiated endometrioid adenocarcinoma of endometrium.

Conclusion

Because of the risk of concurrent endometrial cancer or because of the risk of progression to cancer, we consider total hysterectomy with bilateral salpingoophorectomy appropriate for all women diagnosed with EIN. Women with benign EH or those diagnosed with EIN who wish to preserve their fertility can be managed conservatively.
ENDOMETRIAL CANCER

ESGO7-0351

ANALYSIS OF THE RISK FACTORS FOR THE OVERALL SURVIVAL IN PATIENTS WITH ENDOMETRIAL CANCER
J. Molero Vílchez1,2, E. Martínez Lamela3,4, S. Sancho García2, E. Bancalari Rojnic3, R. Fuentes Mateos7
1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, MADRID, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Ntra. Sra. del Rosario Hospital, Gynecology Oncology, Madrid, Spain
5Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain
6Jimenez Ayala Institute, Pathology, Madrid, Spain
7Advance Tecnicas Cancer Center, Medical Oncology, Madrid, Spain

Aims
To evaluate the influence of the risk factors on the survival in patients treated for endometrial cancer (EC)

Method
Retrospective review. Staging surgery/debulking was performed in 169 patients between April 2004 and April 2017. A total hysterectomy and double salpingo-oophorectomy was performed with sentinel node in 12 cases, with pelvic lymphadenectomy in 69 cases and with pelvic and para-aortic lymphadenectomy in 52 cases. A laparoscopic technique was performed in 101 patients. Pelvic exenteration was performed in 2 cases. 90 patients received adjuvant treatment with chemotherapoy-radiotherapy. The factors that affect survival were assessed using Kaplan-Meier survival curves and a multivariate analysis.

Results
Mean age was 64.3 years. Mean Surgical time was 195.2 minutes, and mean blood loss was 1132 ml. Mean removed nodes was 20 pelvic nodes (10-55) and 18.1 para-aortic nodes (7-51). The global survival of the studied group was 94.5% at 3 years and 93.1% at 5 years. There were significant differences according to myometrial infiltration (95.2% vs. 84.9% at 3 years, 93.8% vs. 68.6% at 5 years; log rank p=0.034), FIGO stage (Log rank p=0.00) and preoperative Ca125 levels (89.4% vs. 53.2% when Ca125 > 35; log rank 0.030). There weren't significant differences on the survival depending on the surgical technique (LPS vs LPM) (p=0.727), histological differentiation degree (p=0.180), tumor size (p=0.271), infiltration lymphovascular (p=0.140), positive nodes (p=0.436) and histological type (p=0.083).

Conclusion
In this serie the risk factors in the overall survival of patients with EC, was the stage at diagnosis, preoperative Ca125 levels and myometrial infiltration.
THE ROLE OF COMPREHENSIVE SURGICAL STAGING IN SEROUS ENDOMETRIAL CANCER: A PROSPECTIVE EXPERIENCE

³University of Ferrara- Sant’Anna University Hospital- Ferrara, Department of Obstetrics and Gynecology, Ferrara, Italy

Aims

To evaluate the role of comprehensive surgical staging in serous endometrial carcinoma.

Method

Data of consecutive patients diagnosed with serous carcinoma of the endometrium undergoing surgery between 2000 and 2016 at Fondazione IRCCS Istituto Nazionale Tumori of Milan (Italy) were prospectively collected and reviewed. Disease-free and overall survival outcomes were evaluated using Kaplan-Meier and Cox proportional hazard models.

Results

Overall, 101 patients were included. Forty-nine (48.5%) patients had gross peritoneal disease and they had cytoreductive procedures. Among the 52 (51.5%) patients with apparent uterine confined disease 22 (42.3%) patients were upstaged. Five (9.6%) patients had microscopic disease located in the adnexal regions; while, seven (13.4%) and 10 (19.2%) were upstaged due to the presence of microscopic peritoneal and retroperitoneal disease, respectively. Considering factors predicting disease-free and overall survival, we observed that presence of extra-uterine disease significantly impact on patients’ outcomes (p<0.05). Deep of myometrial invasion (HR: 2.00 (95%CI: 1.16, 3.46); p=0.013), LVSI (HR: 1.99 (95%CI: 0.95, 4.14); p=0.065), and peritoneal disease (HR: 2.09 (95%CI: 1.06, 4.12); p=0.032) were associated with disease-free survival at univariate analysis. Via multivariate analysis, only peritoneal disease influenced disease-free survival (HR: 2.25 (95%CI: 1.11, 4.55); p=0.023). Similarly, peritoneal disease was the only factor predicting for overall survival (HR: 3.28 (95%CI: 1.75, 6.17); p<0.001).

Conclusion

In apparent early stage serous endometrial cancer, peritoneal and retroperitoneal staging allow to identify patients with disease harboring outside the uterus. Owing to the high prevalence of extra-uterine disease in apparent early stage serous endometrial carcinoma, comprehensive staging should be mandatory.

VALUE OF SENTINEL LYMPH NODE (SLN) MAPPING AND BIOPSY USING COMBINED INTRACERVICAL RADIOTRACERS AND BLUE DYE INJECTIONS FOR ENDOMETRIAL CANCER
A. Moridi1, F. Farzaneh1, Z. Azizmohammadi2, M.S. Hosseini1
1Shahid Beheshti University of Medical Sciences, Preventative Gynecology Research Center, Tehran, Iran
2Shahid Beheshti University of Medical Sciences, Nuclear Medicine Department, Tehran, Iran

Aims

This study was conducted to evaluate SLN mapping of early stage endometrial cancer with blue dye in conjunction with a radioactive tracer.

Method

In this prospective cross-sectional study, patients with stage I and II endometrial cancer who were candidates for systemic lymph node dissection during surgery were enrolled, some underwent lymph node mapping and SLN biopsy using combined intra cervical radiotracer and blue dye injections and some applying only an intra cervical radiotracer. SLNs and other lymph nodes were sent for pathological assessment. Sensitivity, specificity, the positive predictive value, and the negative predictive value were calculated as predictive values for the radiotracer and blue dye.

Results

Pre-operative lymph node mapping showed SLN in 29 out of 30 patients. Intra operations in 29/30 patients, SLNs were harvested by gamma probe; in 13 out of 19 patients SLNs were detected by blue dye. The median number of SLNs per patient was 3 and the total number of SLNs detected was 81. Four patients had positive pelvic lymph nodes. All of the positive nodes were SLNs. Using this technique (radiotracer and blue dye) an overall detection rate of 96.7%, an NPV of 100%, a sensitivity of 100% and a specificity of 3.85% were achieved.

Conclusion

Results of SLN research for endometrial cancer are promising and make feasible the possibility of avoiding unnecessary aggressive surgical procedures in near future by advances in SLN mapping.

OUTCOMES OF CONSERVATIVE THERAPY FOR ADENOCARCINOMA AND ATYPICAL ENDOMETRIAL HYPERPLASIA OF THE ENDOMETRIUM IN YOUNG WOMEN: A SINGLE INSTITUTION EXPERIENCE WITH 14 CASES

M. Munmany1, L. Fernandez1, P. Fusté1, R. Nonell1, M. Del Pino1, B. Gil1, J. Pahissa1, A. Torné1

1Hospital Clinic de Barcelona, ICGON Department of Gynecology. Oncology Unit, Barcelona, Spain

Aims

To evaluate treatment efficacy and fertility outcomes in women with complex atypical hyperplasia (CAH) or grade one endometrial cancer (G1EC) treated with high-dose oral progestin for fertility preservation at our Hospital (2007 to 2015).

Method

A total of 14 patients were identified, 6 with CAH and 8 with G1EC. Complete response (CR) was defined as the absence of carcinoma/hyperplasia on endometrial sampling.

Results

The age at presentation ranged from 30 to 40 years (median, 38y). All patients were nulliparous, and 10/14 had a history of infertility while four of them of abnormal uterine bleeding. Mean Body Mass Index was 28±6Kg/m2. Patients received 500mg of medroxyprogesterone acetate (6/14) or 160mg of megestrol acetate (8/14) orally daily. Transvaginal ultrasound and endometrial biopsy were performed at 6 months of treatment. CR rate was 87% (7/8) in the CAH and 50% (3/6) in the G1EC group. Among those with CR, two patients recurred at 12 and 16 months. Nine out of fourteen (64%) underwent fertility treatment with the following outcomes: 3/9 (33%) no pregnancy, 2/9 (18%) at least one live infant and 1/9 (11%) spontaneous abortion. While 3/9 were undergoing assisted reproductive techniques during abstract elaboration. None achieved a live birth without intervention. Ten out of fourteen (71%) underwent hysterectomy; 5/14 for persistent and 2/14 for recurrent disease and 3/14 after attempting pregnancy, none were upstaged. One patient was lost during follow-up.

Conclusion

Oral progestin is an effective temporizing fertility-sparing treatment for women with CAH/G1EC. Fertility specialist is recommended due to the low live birth rate without intervention. Hysterectomy is recommended after childbearing due to a high recurrence rate.

APRONECTOMY FOR GYNAECOLOGICAL CANCER SURGERY: A CASE SERIES
B. Ghosh¹, E. Myriokefalitaki¹, C. Robotin¹, M. Datta¹, B. Worsnop¹, B. Winter-Roach¹, M. Smith¹, S. Richard¹
¹The Christie NHS FT UK, gynaecological oncology, Manchester, United Kingdom

Aims

To investigate surgical outcomes of apronectomy combined with laparotomy in gynaecological oncology, as a technique to gain access to the abdomen, especially for morbidly obese women.

Method

Retrospective case series of all patients with gynaecological cancer, who had apronectomy combined with laparotomy at The Christie, between 1/9/2007 and 31/8/2016. Data collection included patient demographics (age, BMI, body weight, performance status, co-morbidity and anaesthetic scoring) level and complexity of surgery, histopathological features (stage, type, grade) and surgical outcomes (peri and post-operative morbidity, mortality, length of hospital stay, readmission).

Results

We identified 77 consecutive cases. Median age was 58.7 years old (range 31-84 y.o) with a mean BMI of 45.5 and a mean body weight of 116.2 kg. 30% had a BMI>50. 34% were diabetic and 58% had cardiovascular disease. 82% had at least a moderate risk in the adult co-morbidity evaluation score (ACE) and 30% had an ECOG performance status of 2 or higher. Mean hospital stay was 6.9 days (range 4-23 days). Post-operative complications included wound infection in 32% of patients, 7% of UTI and chest infections, and only 1.2% of Clavien-Dindo level 3a complication. There were no deaths within 30 days post op. There were 2.4% readmissions for wound healing problems.

Conclusion

Apronectomy in this high risk cohort of patients is a safe procedure with acceptable morbidity although longer than average hospital stay.

14oscar lambret cancer center, anesthesiology, lille, France
15paoli calmette cancer center, anesthesiology, marseille, France
16paoli calmette cancer center, surgery in gynecologic oncology, marseille, France

Aims

In gynecologic oncology, mini-invasive surgery by laparoscopy decreases incidence of severe morbidity compared to open surgery. The robotic-assisted laparoscopy (RL) was approved by FDA in gynecology in 2005. ROBOGYN (NCT01247779) is the first multicentric randomized trial comparing severe perioperative morbidity after RL versus conventional laparoscopy (CL).

Method

Patients with a gynecologic cancer eligible for mini-invasive surgery were recruited in 13 French centers between December-2010 and December-2015. Severe perioperative morbidity was defined as Oslo grade>=II for per-operative complications, Clavien-Dindo grade>=II in the first 30 days, or NCI-CTCAE-4.03 grade>=3 up to 6 months after surgery, evaluated on the per-protocol dataset. Overall 374 evaluable patients were required to detect 10%-decrease of severe morbidity (15%-versus-5%) with a 90%-power (two-sided α=5%). Balanced randomization was stratified by center.

Results

383 patients with uterine (54%), cervical (43%) and ovarian cancer (3%) were recruited. Median age=58, BMI=25.9, WHO-0 in 83%. Per-protocol analysis includes 369 patients: 176 underwent RL, 193 CL. 208 and 92 patients had total and radical hysterectomy, respectively. A pelvic and/or iliac lymphadenectomy was performed in 186 patients, para-aortic lymphadenectomy in 71. Ten patients in each arm had a laparocversion (p=0.83). RL was associated with a significantly longer operating time (median, 205 vs 162min, p<0.001), and higher blood loss (estimated volume, median, 100 vs 50ml, p=0.005).

Severe perioperative morbidity was reported in 48/176 for RL (27%) and 40/192 for CL (21%) (p=0.15, 1 missing data).

Conclusion

We did not observe any reduction of severe perioperative morbidity with robot-assisted laparoscopy compared to conventional laparoscopy in patients with gynecologic cancer.
MULLERIAN MIXED TUMOR: ADENSARCOMA REPORT OF A CASE.

L. Navia Ortuño1, R.M. Raúl1

1Instituto Nacional de Cancerología, Ciudad de México, Ciudad de México, Mexico

Aims

Mullerian adenosarcoma is a rare biphasic malignant mesenchymal tumor composed of a benign glandular component and a malignant stromal component, but usually of low grade. The age range of onset is very wide, ranging from 10 to 90 years, although it is more frequent in postmenopausal women.

Given the rarity of adenosarcomas, we presents a case of adenoarcomas with sarcomatous overgrowth.

Method

Report of a Case

Results

Female 18 years old, with no relevant clinical history. Began with clinical manifestations transvaginal bleeding, initially in abundant amount, went to gynecologist, received hormonal treatment for 6 months without response, performed PET CT: hypermetabolic uterine lesion at right diaphragmatic, retroperitoneal and pelvic diaphragmatic level Left, mesentery, and free fluid in the peritoneal cavity. Hysteroscopy with biopsy, histopathological report: Endometrial adenosarcoma with stromal overgrowth and heterologous component of rhabdomyosarcoma. Immunohistochemistry: Myogenin: + zonal. Desmin: + zonal CD10: + zonal in negative areas of Myogenin. RE: + focal. Clinical stage IVB.

Received systemic treatment with Carboplatin and paclitaxel for 5 cycles, assessing response with PET CT with Partial Response.

Then, it was decided to perform endometrial interval cytoreductive laparotomy, findings with the presence of subserosal, ileum, parietal peritoneum, pelvic and aortic lymphatic implants.

Intercurred with abdominal pain of great intensity predominance in right hypochondrium. TAC: Heterogeneous lesion of hypodense predominance, with areas of greater density, with dimensions of 16x8cm in topography of the hepatic capsule segment VI, conditions important displacement of adjacent structures. Free liquid in pelvic cavity. The biopsy with histopathological report of fusco cell sarcoma

Conclusion

Case of Adenosarcomas with sarcomatous overgrowth.
ENDOMETRIAL CANCER

EXPRESSION OF FOCAL ADHESION-ASSOCIATED PROTEINS IN ENDOMETRIAL CANCER FOR INDICATOR OF METASTATIC POTENTIAL

L. Nicholson¹, L. Anderson², S. Saidi³, J. Carter³, L. Lindsay¹, C. Murphy¹

¹University of Sydney, Anatomy and Histology, Sydney, Australia
²Royal Prince Alfred Hospital, Pathology, Sydney, Australia
³Chris O'Brien Lifehouse, Gynecological Oncology, Sydney, Australia

Aims

To investigate the expression of focal adhesion-associated proteins in human endometrial cancer samples (endometrium and myometrium) and relate to the level of metastasis of the samples to determine if proteins have metastatic indicator potential. Expression of the same proteins were looked at in the rat during blastocyst implantation and early pregnancy, as the uterine luminal epithelium during this type exhibits similar adhesion-loss to cancer metastasis.

Method

Human samples were obtained through a human ethics approved collaboration with local hospitals, from patients with type 1 or 2 endometrial cancer. Uterine epithelial cells were obtained from rats during different stages of early pregnancy, when focal-adhesions were intact and then when they are lost. Western blotting, immunohistochemistry and qPCR were then used to determine protein expression and localization.

Results

Focal adhesion-associated proteins, such as lasp-1 and palladin isoforms, showed expression in the varying types of endometrial cancer consistent with literature of different cancer types. There was an increase of those proteins associated with cell adhesion loss in types with more metastatic potential (type 2). Additionally, there is a significant loss of alpha-parvin once uterine epithelial adhesion loss has occurred during rat early pregnancy, and an increase in phosphorylated alpha-parvin, palladin 140 kDA isoform and lasp-1 during adhesion loss of early pregnancy.

Conclusion

Preliminary results in human endometrial cancer samples suggests the use of some focal adhesion-associated proteins as an indicator for cell movement. This is supported by the same changes in protein expression during controlled adhesion loss in rat uterine luminal epithelial cells during early pregnancy.

TYPE I VS. II ENDOMETRIAL CANCER: DIFFERENTIAL IMPACT OF COMORBIDITY
M. Noer\textsuperscript{1}, S.L. Antonsen\textsuperscript{1}, B. Ottesen\textsuperscript{1}, I.J. Christensen\textsuperscript{2}, C. Hagdall\textsuperscript{1}
\textsuperscript{1}Rigshospitalet, Department of Gynecology, København Ø, Denmark
\textsuperscript{2}Herlev University Hospital, Department of Pathology, Herlev, Denmark

Aims

Two distinct types of endometrial carcinoma (EC) with different etiology, tumor characteristics and prognosis are recognized. We investigated if the prognostic impact of comorbidity varies between these two types of EC. Further, we studied if the recently developed ovarian cancer comorbidity index (OCCI) is useful for prediction of prognosis in EC.

Method

This nationwide cohort study was based on data from 5369 type I and 1219 type II EC patients diagnosed in Denmark in 2005-15. Patients were assigned a comorbidity index score according to the Charlson comorbidity index (CCI) and the OCCI. Kaplan Meier survival statistics and adjusted multivariate Cox regression analyses were used to investigate the differential association between comorbidity and overall survival in type I and II EC.

Results

The distribution of comorbidities varied between the two EC types and a consistent negative association between increasing level of comorbidity and survival was observed for both types. Cox regression analyses revealed a significant interaction between stage and comorbidity indicating that the impact of comorbidity varied with stage. In contrast, the interaction between comorbidity and EC type was not significant. Both the CCI and the OCCI were useful measurements of comorbidity but the CCI obtained a better statistical fit in the multivariate model.

Conclusion

This study demonstrates that comorbidity is an important prognostic factor in type I as well as in type II EC though the overall prognosis differs significantly between the two types of EC. The prognostic impact of comorbidity varies with stage but not with type of EC.
PREOPERATIVE CT AND MR IMAGING TO DETECT LYMPH NODE (LN) METASTASIS AND DEEP MYOMETRIAL INFILTRATION IN ENDOMETRIAL CANCER (EC) PATIENTS

N.J. Nordskar¹, A. Ogarkov², M. Valla³, E. Araya¹, G. Aune¹, A.K. Engebretsen¹, J. Kippervik¹, M. Ravlo¹, M. Sundset¹, S. Tingulstad¹, B. Hagen¹

¹St Olavs University Hospital, Section of Gynecologic Oncology- Dept. of Obstetrics and Gynecology, Trondheim, Norway
²St Olavs University Hospital, Department of Imaging, Trondheim, Norway
³St Olavs University Hospital, Department of Pathology, Trondheim, Norway

Aims

In a prospective study of sentinel lymph node (SLN) mapping (1) all patients underwent preoperative imaging with CT (thorax + abdomen) and MR (pelvis). The aim was to evaluate the diagnostic performance of the preoperative imaging.

Method

Consecutive patients with apparently early stage EC were included and underwent robot-assisted laparoscopic HBSO with ICG fluorescence SLN mapping including extended pathology (serial sectioning and immunohistochemistry) on H-E negative SLNs. The result of preoperative CT and MR imaging combined was compared to the histopathologic LN metastasis status and myometrial infiltration depth in the uterine surgical specimen.

Results

Among the 108 patients included in the study 17 (16 %) had LN metastasis. Only 8 had a corresponding true positive imaging result (sensitivity 47 %, PPV 57 %), and among those 92 LN negative patients 6 had a false positive imaging result (specificity 93 %, NPV 91 %). 48 patients (44 %) had > 50 % myometrial infiltration depth on histology, 25 of whom were correctly identified on preoperative imaging. The PPV and NPV were 76 % and 70 %, respectively.

Conclusion

Due to inaccuracy, CT and MR preoperative imaging alone is not sufficient for rational treatment planning.

RISK OF ENDOMETRIAL CANCER IN POSTMENOPAUSAL WOMEN UNDERGOING DIAGNOSTIC HYSTEROSCOPY: ROLE OF AUB AND ENDOMETRIAL THICKNESS

M. Noventa1, A. Vitagliano1, P.S. Litta1, S. Borgato1, V. Bertoldo1, S. Tosatto1, M. Palumo1, A.S. Laganà2, S.G. Vitale2, S. Gizzo1, B. Kobal3, K. Jakopic3, A. Lukanovic1, C. Saccardi1

1University of Padua, Department of Woman and Child Health, Padua, Italy
2University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
3University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubljana, Slovenia

Aims

to investigate the predictive value of endometrial thickness on the risk of endometrial cancer in postmenopausal women according to the presence or absence of AUB history. Secondly, to estimate the weight of BMI, hormone replacement therapy, hypertension and diabetes mellitus on the risk of cancer.

Method

We conducted a prospective, observational study from June 2012 to June 2014 on a cohort of postmenopausal patients undergoing diagnostic hysteroscopy with endometrial biopsy. Patients were included if a recent endometrial thickness measurement was available. For each patient we collected general features and history.

Results

435 patients were included in the study: 329 asymptomatic with endometrial thickness ≥ 4 mm (ET_Group), 106 with AUB (AUB_Goup), of which 58 with endometrial thickness ≥ 4 mm (AUB_Subgroup1) and 48 with ET < 4 mm (AUB_Subgroup2). We found higher prevalence of cancer in AUBGroup in comparison to ET_Group (15.2% vs 3.7%; p<0.001) and in AUB_Subgroup1 than AUB_Subgroup2 (20.7% vs 8.5%; p<0.001). Sensitivity and specificity of endometrial thickness for cancer detection in AUB patients resulted 75% and 48.3%. In ET_Group we found a correlation between endometrial thickness and BMI with cancer risk. The best cut-off of endometrial thickness for cancer diagnosis was 11 mm (100% sensitivity and 80% specificity).

Conclusion

In asymptomatic women hysteroscopy should be indicated exclusively when endometrial thickness is ≥ 11 mm, especially in case of overweight. In women with AUB the risk of cancer is considerably high even if endometrial thickness is < 4 mm, therefore diagnostic hysteroscopy is always recommanded in these patients.
ENDOMETRIAL CANCER

ESGO7-1326

ENDOMETRIAL SURVEILLANCE IN TAMOXIFEN USERS: ROLE, TIMING AND ACCURACY OF HYSTEROSCOPIC INVESTIGATION: OBSERVATIONAL LONGITUDINAL COHORT STUDY

A. Vitagliano¹, M. Noventa¹, S. Gizzo¹, P.S. Litta¹, S. Borgato¹, V. Bertoldo¹, S. Tosatto¹, M. Palumbo¹, A.S. Laganà², S.G. Vitali², B. Koba³, M. Jakimovska³, S. Kostoski³, C. Saccardi³

¹University of Padua, Department of Woman and Child Health, Padua, Italy
²University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
³University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubljana, Slovenia

Aims

To determine the role of endometrial hysteroscopy in relation to the ultrasound, clinical and histological features of the endometrium during tamoxifen(TAM) use.

Method

We performed an observational longitudinal cohort study (2007–2012) that investigated the endometrium of 151 TAM users with hysteroscopy and histology. For all patients, ultrasound endometrial thickness(ET), gynecological history, years of adjuvant treatment and indications for hysteroscopy were recorded.

Results

Hysteroscopic findings showed that 100% of patients referred for simple follow-up had no evidence of endometrial disease. A strong correlation was found between history of abnormal uterine bleeding (with or without endometrial thickening) and hysteroscopic suspicion of endometrial atypia, confirmed by histology. Hysteroscopy had 83.3% sensitivity, 99% specificity, 83.3% positive-predictive-value(PPV) and 99% negative-predictive-value(NPV) in detecting endometrial atypia. No correlation was found between ET>5mm without bleeding and histological atypia. Similarly, the duration of treatment was not related to ET and histological atypia. Endometrial stromal hyperplasia was detected by histology in 70.5% of patients with ET between 5 and 10mm. In contrast, no atypia was detected when ET was <5mm. Ultrasound performed using a 5mm cut-off threshold for ET showed 100% sensitivity, 15% specificity, 4% PPV and 100% NPV in detecting endometrial atypia, while a 10mm cut-off threshold resulted in 84% sensitivity, 69% specificity, 10% PPV and 99% NPV.

Conclusion

Low-risk TAM users do not require different endometrial surveillance than general population. Hysteroscopy could play a fundamental role in determining the endometrial status of patients before the initiation of TAM treatment and in assessing the endometrial status of patients when bleeding occurs.
LAPAROSCOPIC SENTINEL NODE DETECTION IN ENDOMETRIAL CANCER AFTER INJECTION OF INDOCYANINE GREEN. PRELIMINARY REPORT FROM LJUBLJANA MEDICAL CENTER.

K. Jakopic¹, M. Noventa², B. Cvjetičanin¹, M. Barbič¹, L. Meglič¹, B. Kobal²
¹University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubljana, Slovenia
²University of Padua, Department of Woman and Child Health, Padua, Italy

Aims

To report the preliminary results concerning feasibility, safety and detection rate (DR) of sentinel lymph nodes (SLNs) detection in type-I endometrial cancer (EC) patients, after injection of indocyanine green (ICG) according to the internal protocol of Ljubljana Medical Center.

Method

Observational prospective study involving patients with apparent early stage endometrial cancer scheduled for surgical staging and SLN-mapping. The mapping technique according to our internal protocol consist in the peri-cervical injection of 0.5mg/mL of ICG followed by visualization of pelvic cavity through a laparoscope equipped with a near infrared (NIR)-camera.

Results

We performed a total of 42 procedures. The detection rate of SNLs was 90.5%(38/42). Of These 5 patents underwent complete pelvic-lymphadenectomy based on surgeon decision. The unilateral SNLs DR was 85.7%(36/42), the bilateral was 76.2%(32/42). In 6 cases we did not detect SNLs and patients underwent complete pelvic-lymphadenectomy. All SNLs were negative. Interestingly the only positive node detected was not a SNL and was included in the 5 patients who underwent complete lymphadenectomy on the basis of surgeon decision. Ultrastaging was not performed. The median operative time was 96 minutes (35 -160 min), blood loss 207 ml (50 – 300 ml). We did not reported serious intra-operative/post-operative complications.

Conclusion

Laparoscopy SNLs technique with ICG showed in our preliminary report a high degree of DR in apparently early stage endometrial cancer patients. Even if the DR and accuracy is not 100%, SNLs technique has the potential to reduce morbidity of complete lymphadenectomy. Probably the routine use of ultrastaging technique may reduce the gap increasing diagnostic accuracy.

IMPACT OF LYMPHOVASCULAR SPACE INVOLVEMENT ON THE PROGNOSIS OF ENDOMETRIAL CARCINOMA

M.D.L.R. Oliver Pérez1, A. Tejerizo García1, C. Villalain1, C. Martínez Biosques1, G. Lopez González1, C. Barcena1, C. Almansa González1, J.S. Jiménez López1

1Hospital 12 de octubre, Gynaecology Oncology, Madrid, Spain

Aims

To evaluate whether LVSI is an independent prognostic factor in endometrial cancer.

Method

It is an observational retrospective cohort study. A total of 327 patients were included and were stratified by the presence (study group) vs. absence (control group) of LVSI. LVSI positivity was established as the presence of tumoral cells in a space completely surrounded by endothelial cells.

Results

36.7% of included patients had LVSI. Presence of LVSI was significantly associated with non-endometrial histological type, deep miometrial infiltration (OR 50.2; p<0.001) and cervical stroma invasion (OR 6.1; p<0.001). In endometrioid tumors, LVSI was significantly associated with tumor grade 2 (OR 2.4; p=0.011) and 3 (OR 7.4; p<0.001), lower third of the uterus invasion (OR 5.2; p<0.001) and tumoral size bigger or equal to 20 mm (OR 2.6; p=0.02). LVSI was significantly associated with higher risk of pelvic and paraaortic node invasion (OR 4.4; p=0.004). The association was independent from histological subtype, tumor grade, depth of myometrial invasion and cervical stromal invasion. The study group presented significantly higher distant recurrence rates than the control group (88.9% vs. 61.5%, p=0.007). In the univariate analysis, LVSI was a risk factor for DFS (Hazard Ratio, HR 1.65; p=0.031), distant DFS (HR 2.46; p=0.001) and OS (HR 1.71; p=0.032). In multivariate analysis, LVSI was not an independent risk factor for DFSR (HR 1.05; p=0.856), distant DFSR (HR 1.44; p=0.236) and OS (HR 1.02 p=0.940).

Conclusion

LVSI is not an independent prognostic factor.
ENDOMETRIAL CANCER

ESGO7-0259

CRUDE LYMPH VASCULAR INVASION (LVSI) IS PROGNOSTIC FOR SURVIVALS AND RECURRENCES IN THE MAINLY NON-RADIATED DANISH ENDOMETRIAL CANCER POPULATION. A DANISH ENDOMETRIAL CANCER DATABASE STUDY

G. Ortoft¹, C. Hogdall¹, L. Lausten-Thomsen², M. Dueholm³
¹Copenhagen University Hospital, Department of Gynecology, Copenhagen Ø, Denmark
²Roskilde Hospital, Department of Urology, Roskilde, Denmark
³Aarhus University Hospital, Department of Gynecology, Aarhus, Denmark

Aims

LVSI is a strong independent prognostic factor for survivals and recurrences in early stage endometrial cancer. We examine the effect of LVSI on overall (OS), cancer-specific (CSS) and recurrence-free (RFS) survivals in the Danish population of 4521 endometrial cancer patients, only rarely given radiation.

Method

28.9% had lymph node resection (LN-resection). LVSI-status was reported to the database for 1946 cases and another 1521 were found in the pathology reports, leaving 1054 (23.3%) unknown. Therefore, three groups were examined by Kaplan-Meier and COX-analysis; LVSI-positive, LVSI-negative, LVSI-unknown

Results

3467 cases had known LVSI-status and of these 20.4% were LVSI-positive. For stage I, 11.3 % were LVSI-positive and this increased with risk-group (low-risk: 5.7%, intermediate-risk: 20.5%, high-risk: 23.6%). For LVSI-negative/LVSI-positive/LVSI-unknown the 5-years-OS were 85.9%/56.0%/77.7%, CSS: 93.8%/63.9%/86.5% and RFS: 89.2%/55.3%/80.4% and for stage I: OS: 87.8%/72.3%/86.5%, CSS: 95.7%/82.8%/95.5% and RFS: 91.4%/74.2%/91.0%.

In univariate analysis LVSI significantly increased the risk of dying by 4.02, whereas a metastatic lymph node increased the risk by 3.15.

In multivariate analysis LVSI was an independent prognostic factor for survivals and recurrences in all patients, in non-LN-resected, LN-resected and in lymph node metastatic patients. For non-LN-resected stage I, LVSI was an independent prognostic factor for all three risk groups, but in LN-negative LVSI was only a prognostic factor in intermediate-risk not in the low- or high-risk. Conclusion

LVSI is a strong independent prognostic factor for OS, CSS and RFS. For lymph node negative stage I, LVSI was a strong independent prognostic factor for survivals and recurrences for intermediate risk, but not for low- or high-risk.

RETROSPECTIVE ANALYSIS OF RADICAL RADIOTHERAPY FOR ENDOMETRIAL CANCER
N. Oshima¹, R. Nakamura¹, A. Furusawa¹, M. Toba², K. Wakana¹, N. Miyasaka¹
¹Tokyo Medical and Dental University, Obstetrics and Gynecology, Tokyo, Japan
²Tokyo Medical and Dental University, Quality Management Center, Tokyo, Japan

Aims

The first choice for the treatment of endometrial cancer is surgical therapy, but radical radiotherapy may be selected for cases with difficulty because of comorbidities. In this study, we examined the characteristics of patients undergoing radical radiotherapy for endometrial cancer.

Method

From 2005 to 2015, we retrospectively examined the backgrounds, treatment complications, and therapeutic effects of patients undergoing radical radiotherapy as the initial treatment for endometrial cancer at our hospital.

Results

Among the 223 cases undergoing initial treatment for endometrial cancer at our hospital, 5 (2.1%) underwent radical radiotherapy because surgical therapy was judged to be difficult because of comorbidities. Age was 30–86 years (median, 81 years), and many were elderly patients. Performance status (PS) was poor. The disease was classified as stage IA in three patients, IB in one, and II in one, and as endometrioid adenocarcinoma grade 1 or 2. The major comorbidities were cardiovascular disorders in two cases, breathing disorder in one, cerebrovascular disorder in one, and anaphylactic shock due to anesthetic reagent in one. The treatment comprised external irradiation plus intraluminal brachytherapy in two patients, external irradiation in two, and intraluminal brachytherapy in one. All treatments were completed without high adverse events, and the tumor disappeared after treatment in all patients.

Conclusion

Only patients who posed difficulties in surgery because of comorbidities were selected for radical radiotherapy. Despite a small number of studies, radical radiotherapy has been suggested to display few adverse events and a high curative effect. Further studies are warranted for long-term and late adverse events.

2D ULTRASOUND THRESHOLD PREDICTIVE OF FOCAL LESIONS REQUIRING ADVANCED HYSTEROSONIC TECHNIQUES IN CASES PRESENTED WITH POSTMENOPAUSAL BLEEDING OR INCIDENTAL ASYMPTOMATIC THICKENED POSTMENOPAUSAL ENDOMETRIUM

F. Gardner¹, C. Bell², O. Ali³
¹Queen Alexandra Hospital, OG, Portsmouth, United Kingdom
²West Cumberland hospital, OG, Whitehaven, United Kingdom

Aims

to evaluate the frequency of detecting focal endometrial lesions requiring advanced hysteroscopic technique in PMB by 2D pelvic ultrasound. It assesses the value of Myosure in the outpatient setting compared to the Gynaecare scope.

Method
234 outpatient hysteroscopies done by one experienced operator from March 2014 to March 2017 for PMB and asymptomatic thickened endometrium were analysed for the frequency of finding cancer or precancer against various endometrial thresholds. The cases were analyzed whether done by Gynaecare scope (178/234) vs. Myosure (56/234) comparing outcome measures.

Results
The incidence of cancer was 11/234 (4.7%). The hysteroscopies to pick one cancer or precancer is approximately 6:1. The presence of focal lesion (polyps, fibroid, elevation, abnormally thickened endometrium) raises as the thickness of the endometrium increased; 8% at < 4mm thickness with no cancer and 9.5% at the zone of 4-5mm with one case of precancer (hyperplasia), and 24.2% at the zone of 5-6mm with 50% risk of cancer or precancer. From the thickness of > 6mm the risk of focal lesion is >40% with 39-53% risk of cancer or precancer.

Adverse events happened in 38/234(16.2%) and severe complication in 7/234(2.99%). with no difference in both groups. Only 1.7% were unsatisfied with the experience and satisfaction rate was comparable in both groups with less pain during the procedure and shorter duration in the Myosure group.

Conclusion
The threshold to hysteroscopy in PMB can be set at ET >5mm with a role for pipelle under that. The likelihood to need Myosure treatment is > 40% when endometrium is >6mm.

PREDICTION OF MYOMETRIAL INVASION IN PATIENTS WITH ENDOMETRIAL CARCINOMA: COMPARISON OF TOLUIDINE BLUE STAINING AND GROSS VISUAL INSPECTION.

M. DEDE¹, M. Ozturk², R. PA³, S. Bodur³, M. Yenen⁴

¹University of Health Sciences Gülhane Medical Faculty, Obstetrics and Gynecology, Ankara, Turkey
²University of Health Sciences Dr. Sadi Konuk SUAM, Obstetrics and Gynecology, İstanbul, Turkey
³University of Health Sciences Gülhane Medical Faculty, Obstetrics and Gynecology, Ankara, Turkey
⁴University of Health Sciences Gülhane Medical Faculty, Obstetrics and gynecology, Ankara, Turkey

Aims

This study evaluated the accuracy of toluidine blue staining frozen endometrium and myometrium (TBSEM) on postoperative detection of myometrial invasion by endometrial cancer. We also evaluated the results of gross visual inspection (GVI) of surgical specimens compared with histopathological diagnosis.

Method

Thirteen women underwent postoperative TBSEM and GVI. Myometrial tumor invasion was evaluated histologically and classified as absent (depth a), superficial (depth b: < or = 50% invasion), or deep (depth c: > 50% invasion).

Results

The accuracy TBSEM and GVI were shown to be not reliable for postoperative evaluation of deep myometrial invasion.

Conclusion

The high accuracy of TBSEM methods for endometrium but not for myometrium.
ENDOMETRIAL CANCER

DEDIFFERENTIATED ENDOMETRIOID ADENOCARCINOMA: REPORT OF AN HIGHLY AGGRESSIVE LETHAL CASE AND REVIEW OF LITERATURE.
1San Martino Hospital, Obstetrics & Gynecology, Genova, Italy
2San Martino Hospital, General surgery, Genova, Italy
3San Martino Hospital, Pathology, Genova, Italy
4San Martino Hospital, Oncology, Genova, Italy

Aims

Dedifferentiated endometrioid adenocarcinoma (DEAC) has been recently described as a rare uterine malignancy containing both undifferentiated carcinoma and differentiated endometrioid adenocarcinoma (usually FIGO G1-2). The aim of this study is to report a case of an aggressive DEAC in a young patient and to perform a review of the literature.

Method

We collected clinical data and imaging from our medical records. We performed a review of literature on Medline/PubMed/Embase.

Results

A 42-year-old woman was admitted to our department complaining of abdominal pain. TV-US scan showed: normal uterus, two 10-cm complex pelvic masses, free fluid and suspicious peritoneal nodules. The MRI-scan confirmed a peritoneal carcinomatosis. CA125: 1211 U/mL. The patient underwent laparotomy and debulking surgery including hysterectomy, bilateral salpingo-oophorectomy, pelvic and diaphragmatic peritonectomy, resection of caecum+anastomosis, sigmoid colon and rectum with left hemicolecotomy, infragastric omentectomy, removal of multiple peritoneal nodules, and one liver nodule, ileal resection and end colostomy. Residual disease was macroscopically absent. The histology report revealed a DEAC pT3a/Nx/M1, FIGO IVB (liver metastasis), G4. 11 days after the surgery the patient presented increasing abdominal pain and a CT-scan showed disease recurrence. In the 15th postoperative day she was transferred to medical oncology department to assess the possibility of starting adjuvant chemotherapy, but she died on postoperative day 18th. We performed a review that includes 10 reports for a total of 104 patients.

Conclusion

In conclusion DEAC is a rare and aggressive tumor, sometimes misdiagnosed. A prompt and appropriate diagnosis is important to provide a correct and quick treatment including adjuvant therapy.
SEROUS ENDOMETRIAL INTRAEPITHELIAL CARCINOMA ARISING ON A SUBMUCOSAL LEIOMYOMATOUS POLyps. REPORT OF THE SECOND CASE IN THE LITERATURE

Aims

We report a case of serous endometrial intraepithelial carcinoma (SEIC) arising on a submucosal leiomyomatous polyp, the second in the English literature.

Method

A 59-year-old female patient was referred to our department because of ascites. The patient presented with abdominal distention and anorexia. Her past medical history included thyroidectomy 17 years ago, ectopic pregnancy at the age of 29 plus 2 cesarean sections. Clinical examination revealed normal external genitalia and mild cervical atrophy. Abdominal computed tomography (CT) scan revealed ascitis, multiple nodular lesions on the peritoneal surfaces and the omentum and a normal size uterus with heterogenous texture of the endometrium and myometrium. Ca 125 was normal. Cytological examination of the peritoneal fluid was positive for low grade adenocarcinoma. The patient underwent a total abdominal hysterectomy, bilateral salpingo-oophorectomy and omentectomy. Macroscopically, the uterus appeared normal.

Results

On microscopic examination there was a 13mm submucosal leiomyoma projecting in the endometrial cavity. The surface epithelium above it as well as the underlying glands were involved by SEIC. Immunohistochemical study was positive for P-16 and P-53. Ki-67 was positive in 70% of tumor cells. Immunohistochemical study of deeper sections revealed a 2.5mm area of confluent glands suggesting early invasion. The peritoneum was infiltrated by high grade serous carcinoma.

Conclusion

The diagnosis of SEIC with associated minimal uterine serous carcinoma and high grade peritoneal serous carcinoma was made. To the best of our knowledge this is the second case of SEIC associated with leiomyatous polyps in the English literature.
ENDOMETRIAL CANCER

ESGO7-0759

DIAGNOSTIC ACCURACY BETWEEN PREOPERATIVE IMAGING AND SENTINEL LYMPH NODE BIOPSY DURING ROBOTIC OR LAPAROSCOPIC SURGERY IN ENDOMETRIAL AND CERVICAL CANCER LYMPH NODE METASTASIS

G.W. Lee1, S.W. Lee1, J.Y. Park1, D.Y. Kim1, D.S. Suh1, J.H. Kim1, Y.M. Kim1, Y.T. Kim1, J.H. Nam1

1Asan medical center, obstetrics and gynecology, Seoul, Republic of Korea

Aims

Appropriateness assessment of Sentinel Lymph Node Biopsy application in endometrial and cervical cancer.

Method

Performed a retrospective review of patients with cervical cancer and endometrial cancer who diagnosed and treated at a single institute. All cases underwent preoperative PET/CT or MRI followed by definitive robotic (da Vinci®) or laparoscopic surgical therapy including SLNB with Indocyanine green (ICG) fluorescence detection using Firefly® and NIR/ICG.

Results

The 89 patients underwent intraoperative sentinel nodes mapping. Deposition of ICG into at least one lymph node was observed in 100% of studied cases. Most common detected lymph metastasis locations in SLNB were obturator area 50%(9/18). And 35.6% obturator lymph node metastasis was found in all lymph node metastasis. Tumor size was not related with SLNB positive. Sensitivity, specificity, positive predictive value and negative predictive value were evaluated among preoperative PET/CT, preoperative MRI and sentinel lymph node frozen biopsy. In three variables (PET/CT, MRI, SLNB), Overall detection sensitivity were 50.0%, 31.3%, 81.3%. Specificity were 98.0%, 94.0%, 99.3%. Positive predictive value were 72.7%, 35.7%, 92.9%. Negative predictive value were 94.8%, 92.8%, 98.0%. False positive rate were 2.0%, 6.0%, 0.7%. False negative rate was 50.0%, 68.7%, 18.7%.

Conclusion

Individualized treatment to reduce therapy-associated morbidity is an important consideration in the surgical treatment. SLNB with ICG mapping is more accurate method than conventional imaging tools. SLNB has gained more acceptance and may offer an alternative to complete pelvic lymphadenectomy in the future.

FEASIBILITY OF LAPAROSCOPIC INDOCYANINE GREEN (ICG)-GUIDED SENTINEL NODE BIOPSY IN OPEN ENDOMETRIAL CANCER SURGERY

M. Peiretti\(^1\), A. Buda\(^2\), G. Candotti\(^1\), F. Congiu\(^1\), G. Di Martino\(^2\), P. Di Lorenzo\(^2\), L. Locatelli\(^2\), E. Malune\(^1\), M. Onnis\(^1\), A. Proto\(^1\), V. Mais\(^1\)

\(^1\)University of Cagliari, Division Of Obstetrics and Gynecology, Cagliari, Italy
\(^2\)Department of Obstetrics and Gynecology - Monza, San Gerardo Hospital-Unit of Gynecology Oncology Surgery, Monza, Italy

Aims

Regional lymph nodes are the most important prognostic factor in endometrial cancer (EC). Sentinel lymph node (SLN) biopsy has proven a safe and feasible procedure in EC. The aim of this preliminary retrospective study was to assess the feasibility of Indocyanine Green (ICG) sentinel node sampling using laparoscopic camera during open endometrial cancer surgery.

Method

Retrospective study. Twelve women with endometrial cancer, that did not fit for the complete laparoscopic staging, underwent SLN mapping using the IMAGE1 camera during open surgery.

Results

Median age was 67 years (range 47-86). The median BMI was 30 (range 19.7-58.2). Mean operative time 185 minutes and hospital stay 5 days. The overall detection rate of SLN mapping was 95%. Bilateral detection was 91%. No post-operative short or long complication were observed.

Conclusion

Real-time NIR technology supported by the IMAGE1 S is a reliable system and represents a promising method for SLN mapping in those selected cases with EC and severe surgical risks, during open traditionally approach. The use of Laparoscopy IGC in Open Surgery seems to be a feasible and useful tool for the detection of sentinel node biopsy in endometrial cancer patients with intraoperative and/or postoperative high morbidity risk and it represents a valid alternative to robotic surgery, particularly in countries and centers where the robotic platform is not available.

THE ROLE OF ADJUVANT CHEMOTHERAPY IN ENDOMETRIAL CANCER – THE EXPERIENCE OF A CENTER
F. Ferreira Pereira¹, M. Henriques Abreu¹, I. Pimentel¹, J. Savva Bordalo¹, M. Ferreira¹, R. Couto¹, S. Sousa¹, L. Salgado², L. Carvalho³, A. Petiz⁴, D. Pereira¹
¹Instituto Português de Oncologia do Porto, Medical Oncology, Porto, Portugal
²Instituto Português de Oncologia do Porto, Radiation Oncology, Porto, Portugal
³Instituto Português de Oncologia do Porto, Radiation Oncology, Porto, Portugal
⁴Instituto Português de Oncologia do Porto, Gynecologic Oncology, Porto, Portugal

Aims

Endometrial Cancer(EC) is the most frequent gynaecological cancer in developed countries. Nowadays, the indications for and the real impact of adjuvant systemic treatment(AST) remain uncertain. This study aimed to analyze the real-life impact of AST in EC patients based on two endpoints: disease-free(DFS) and overall survival(OS).

Method

Retrospective revision of a EC patients'cohort treated with adjuvant chemotherapy(CT) (taxane/platinum) and radiotherapy(RT) ± brachytherapy(BT) in a tertiary cancer center between 2005-2016 (250patients, medium follow-up 51months). Significance was achieved when p<0.05.

Results

Median age at diagnosis was 63 years(37-83). Most cases was of endometrioid type (62/250; 24.8%), serous (56/250; 22.4%) and carcinosarcoma (38/250; 15.2%) and were detected in an initial stage(FIGO I/II: 132/250; 52.8%). Poor prognostic factors: lymphovascular invasion(LVI), high grade and incomplete surgical stage were described in 105/240(43.8%); 176/245 (71.8%) and 57/250 (22.8%); respectively. Near 73%(182/250) were submitted to CT+RT+BT: in an alternation scheme(166/250, 66.4%) or a sequential one(14/250, 5.6%). Relapsed was detected in 65/250(26%) with a median DFS of 19 months(3-74). Distant metastasis was the presentation at recurrence in 41/65(63.1%) and the majority of patients underwent palliative CT (37/65, 56.9%). In multivariate analysis, the independent risk factors for recurrence were FIGO stage(p<0.001) and LVI(p 0.007). 2-year OS was 88.4% and 5-year was 76.4%. The only independent prognostic factor was FIGO stage(p<0.001).

Conclusion

FIGO stage and LVI seems to be important factors for relapse and the first one also for death. More studies are needed to understand if theses factors could define a subgroup of EC patients that do not need such aggressive adjuvant approaches.
USE OF MRI IN ENDOMETRIAL CARCINOMA STAGING

M. Pérez de Puig¹, M. Esteve¹, D. Al-Dali¹, G. Salinas¹, F. Ojeda¹
¹Fundación Hospital Asil Granollers, Obstetrics and Gynaecology, Granollers, Spain

Aims

The purpose of this review is to evaluate the utility of magnetic resonance imaging (MRI) in endometrial carcinoma (EC) staging regarding to local myometrial invasion.

Method

A retrospective study of all cases of endometrial carcinoma operated in our hospital from 1st January 2013 to 31st December 2016 who had undergone a MRI prior to their surgery were reviewed. MRI myometrial infiltration was compared to final surgical stage registered in Pathology reports (Stage Ia versus stage Ib or higher).

The International Federation of Gynecology and Obstetrics (FIGO) classification was used for the staging of EC.

Results

Data from 82 patients diagnosed with endometrial carcinoma were analysed; only 69 (84.14%) had undergone MRI studies before surgery. The histologies were as follows: 69 endometrioid carcinoma (77.53%); 10 papillary serous carcinoma (11.23%); 1 clear cell carcinoma (1.12%), and 2 carcinosarcoma (2.25%). The average age was 68.65 years.

Concordance between predicted stage by MRI and stage after surgery was found in 40 of 69 patients (57.97%). The 29 (42.03%) cases with no MRI concordance were analysed: 12 (41.38%) were understaged, and 17 (58.62%) overstaged by MRI.

These results did not reveal significant differences between tumor stage predicted by MRI and definitive surgical stage (\(p>0.05\)).

Conclusion

The MRI is a widespread imaging tool used to diagnose and evaluate disease extent, helps treatment planning and postoperative evaluation and follow up. As in our study, MRI works as a good predictive tool. Nevertheless, surgical staging is still the only way accepted for endometrial cancer staging.
ENDOMETRIAL CANCER

ESGO7-0884

DEPTH OF MYOMETRIAL INVASION AS A PREDICTOR OF LYMPH NODE METASTASIS
M. Esteve, M. Pérez de Puig, D. Al-Dali, N. Sarasa, F. Ojeda
1Fundació Hospital Asil de Granollers, Obstetrics and Gynecology, Granollers, Spain

Aims

Evaluate the association between myometrial invasion and incidence of lymph node metastasis in endometrial cancer.

Method

Patients diagnosed with endometrial carcinoma that underwent oncological surgery in our Hospital from 1st January 2013 to 31st December 2016 were included. Pelvic and/or paraaortic lymphadenectomy was performed.

Myometrial invasion and lymph node metastasis were analyzed as expressed in Pathology report after surgery. Myometrial invasion was classified as <50% and ≥50%.

Statistical analysis was made with SPSS, using Chi-squared Distribution.

Results

Data from 79 patients were evaluated during this period. The average age was 68.85.

Positive lymph node invasion was found in the 7% (6/79) of the patients, from which 83% (5/6) were reported with >50% myometrial invasion. In the non lymph node invasion group (73/79), the 72% (52/73) of the patients had <50% myometrial invasion.

The statistical analysis revealed a significant association between percentage of myometrial invasion and presence of lymph node metastasis (p<0.05), with and OR=12.38 IC 95% (1.36-112.41).

Conclusion

As literature supports and confirmed in our study, myometrial invasion is a good predictor of possible lymph node metastasis (greater percentage of metastasis in greater invasive carcinomas). Lymphadenectomy is a great cause of morbidity in patients undergoing oncologic surgery, so seems necessary to balance the desire to prevent unnecessary lymphadenectomy and the need of extension diagnose, and this kind of predictors might help taking the decision.
IS TUMOR SIZE A GOOD PREDICTOR OF MYOMETRIAL INFILTRATION IN ENDOMETRIAL CARCINOMA?

M. Pérez de Puig', M. Esteve', D. Al-Dali, J. Palau', A. Reus', F. Ojeda'

1Fundación Hospital Asil Granollers, Obstetrics and Gynaecology, Granollers, Spain

Aims

Evaluate the association between tumor size and myometrial infiltration in endometrial carcinoma, expecting less grade of invasion in smaller tumors.

Method

Patients diagnosed with endometrial carcinoma that underwent oncological surgery in our Hospital from 1st January 2013 to 31st December 2016 were included.

Tumor size and myometrial infiltration were analyzed as expressed in Pathology report. Myometrial invasion was classified as <50% and ≥50%. Tumor size was divided using 2cm as cut point.

Statistical analysis was made with SPSS, using Chi-squared distribution.

Results

79 patients were evaluated, with an average age of 68.85.

Expected infiltration concordance with tumor size, according to literature, was found in 38/79 patients of the total (48.10%). The 52.6% of them (20/38) were tumors less than 2cm which invasion reported was <50%. The other 47.4% (18/38) turned out to be tumors >2cm with >50% myometrial invasion. No concordance was found in the other 41/79 patients.

We were not able to prove statistically significant association between tumor size and myometrial invasion in this study.

Histological diagnose was also evaluated. The histologies were as follows: 69 endometrioid (77.53%); 10 papillary serous (11.23%); 1 clear cell (1.12%), and 2 carcinosarcoma (2.25%). Higher percentage of myometrial invasion was found in non-endometrioid histological subtypes, regardless of tumoral size.

Conclusion

Tumor size has been related to risk of myometrial invasion >50%. In this study, association was not proved with data evaluated. Histological type seems to be determinant in carcinoma invasion, which could be assessed in further studies.
ENDOMETRIAL CANCER

ESGO7-0891

PROGNOSTIC FACTORS IN ENDOMETRIAL CARCINOMA TYPE-I AND TYPE-II

M. Esteve¹, M. Pérez de Puig¹, D. Al-Dali¹, A. Pereda¹, M. Girvent¹, F. Ojeda¹
¹Fundació Hospital Asil de Granollers, Obstetrics and Gynecology, Granollers, Spain

Aims

Evaluate the surgical prognostic factors of different histological subtypes in endometrial cancer.

Method

Patients diagnosed with endometrial carcinoma that underwent oncological surgery in our hospital from 1st January 2013 to 31st December 2016 were included.

This is a descriptive study, where histological subtypes type-I (endometrioid) and type-II (serous papillary and clear cells) are analyzed, valuing the percentages of myometrial invasion and lymph node metastasis in each cases.

Results

The histologies were 69 Type-I or endometrioid type (77.53%), and 13 Type-II or non-endometrioid type (15.85%): 10 serous papillary (11.23%); 1 clear cell (1.12%), and 2 carcinosarcoma (2.25%). The average age was 68.85.

Myometrial invasion >50% was found in the 46.15% (6/13) of Type-II group, while in patients with Type-I was only 28.98% (20/69). Myometrial invasion <50% was found in the 71.01% (49/69) of patients included in Type-I group, and in the 53.84% (7/13) of patients in the Type-II group.

Regarding lymph node metastasis, there was 30.77% (4/13) of patients with positive lymph node metastasis in Type-II group, while only 2.89% (2/69) were affected by lymph node metastasis in Type-I group.

Conclusion

The main predictors of lymph node and distant metastasis are the depth of myometrial invasion and the degree of tumor differentiation.

Regarding the different histological types of endometrial carcinoma, type-I carcinomas tend to be well differentiated forms of carcinoma, and their prognostic is better, with a higher rate of cure. Type-II carcinomas, on the other hand, generally correspond to more aggressive forms, with a higher percentage of lymph node metastasis and a deeper myometrial invasion, as revealed in our study.
ENDOMETRIAL CANCER

ESGO7-0617

DOES TUMOR DIAMETER AFFECT SIGNIFICANTLY SURVIVAL OUTCOMES IN STAGE I ENDOMETRIOID ENDOMETRIAL CANCER? A PROSPECTIVE COHORT STUDY.
S. Petousis¹, C. Margioula-Siarkou¹, P. Christidis¹, N. Sparangis¹, G. Karavas¹, A. Papanikolaou², A. Athanasiadis¹, I. Kalogiannidis¹
¹Aristotle University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Thessaloniki, Greece
²Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynaecology, Thessaloniki, Greece

Aims

To study the prognostic value of tumor diameter ≥ 2cm on survival outcomes in patients with surgically staged I endometrioid endometrial cancer.

Method

A prospective study was conducted during 1996-2016 enrolling patients with endometrioid endometrial cancer treated in the 3rd Department of Obstetrics and Gynaecology. Epidemiological, histopathological and survival outcome of patients were prospectively recorded in a computerized database. Primary outcome of the study was to assess the prognostic impact of tumor diameter ≥ 2cm on overall survival and recurrence of disease. This was separately studied for low-risk cases (grade 1 or 2 invading<50% of myometrium) and intermediate or high-risk cases (grade 3 and grade 1 or 2 invading ≥ 50% of myometrium). Cox regression analysis was used to examine potential impact of tumor diameter on survival parameters.

Results

There were 183 cases of surgically staged I endometrial cancer treated during the period of the study. Mean age of patients was 62.5 ± 10.4 years. Regarding low-risk cases (N=112), tumor diameter was not significantly correlated with risk for recurrence and overall survival (P=.44 and P=.49). Similarly, no significant impact of tumor diameter ≥ 2cm was indicated on risk for recurrence and overall survival in intermediate or high-risk patients as well (P=.61 and P=.62).

Conclusion

Tumor diameter ≥ 2cm may not to be an independent prognostic factor affecting overall survival and risk for recurrence.
PELVIC VS. PELVIC AND PARAORTIC LYMPHADENECTOMY FOR INTERMEDIATE AND HIGH-RISK ENDOMETRIAL CANCER: SYSTEMATIC REVIEW AND META-ANALYSIS.

S. PETOUSIS¹, P. CHRISTIDIS¹, C. MARGIOULA-SIARKOU¹, A. PAPANIKOLAOU², A. RODOLAKIS³, A. ATHANASIADIS¹, I. KALOGIANNIDIS¹

¹Aristotle University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Thessaloniki, Greece
²Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynaecology, Thessaloniki, Greece
³National and Kapodistrian University of Athens, 1st Department of Obstetrics and Gynecology, Athens, Greece

Aims

To compare overall survival and disease-free survival between intermediate and high-risk endometrial carcinomas treated with pelvic and paraaortic vs. only pelvic lymphadenectomy.

Method

A computerized datasearch was performed in Pubmed and Scopus databases. Terms used for search were “endometrial cancer” or “endometrial carcinoma” or “endometrial adenocarcinoma” AND “para-aortic lymph*” or “paraaortic lymph*”. In the present analysis we included studies having as primary endpoint to compare survival outcomes of intermediate and high-risk endometrial carcinomas treated with pelvic and paraortic (PVAL) vs. only pelvic lymphadenectomy (PVL). Non-english studies, animal studies, studies involving only low-risk cases and studies restricted to cases of certain surgical stage were excluded. Prospective or retrospective character of study was not set as exclusion criterion. Primary outcomes were overall survival (OS) and disease-free survival (DFS).

Results

Out of 460 studies identified after computerized datasearch with key-phrases, there were 378 remaining after duplicates removed, 112 assessed for eligibility and finally 5 studies included in the meta-analysis. Quality of studies was assessed as low. A total of 1,489 cases were included, of which 633 concerned cases treated with PVAL and 856 treated with PVL. Overall survival was significantly increased in the group of PVAL vs. PVL (RR: 1.175 with 95% CI: 1.096-1.256, P<.001). Similarly, the group of PVAL presented an 11.9% increase in DFS compared with PVL (RR: 1.119 with 95% CI: 1.053-1.171, P<.001).

Conclusion

Pelvic and paraaortic lymphadenectomy is associated with improved overall survival and disease-free survival compared with only pelvic lymphadenectomy. Further prospective RCTs should be performed in order to improve quality of evidence.

AN UNUSUAL CASE OF DUAL SITE LATE RECURRENT FOLLOWING SURGERY FOR LOW-RISK ENDOMETROID CARCINOMA: A REPORT OF A CASE

S. Phadnis¹, M. Powell², A. Hameeduddin³, N. Singh⁴, E. Brockbank¹
¹Barts Health NHS Trust, Gynaecological Oncology, London, United Kingdom
²Barts Health NHS Trust, Clinical Oncology, London, United Kingdom
³Barts Health NHS Trust, Radiology, London, United Kingdom
⁴Barts Health NHS Trust, Pathology, London, United Kingdom

Aims

We report an unusual case of late dual site recurrence from an initial early stage endometroid carcinoma and discuss the dilemma of diagnosis and management.

Method

Case report

Results

A 55-year-old postmenopausal woman had total laparoscopic hysterectomy and bilateral salpingoopherectomy for stage 1A grade 1 endometroid endometrial carcinoma. No adjuvant treatment was offered. Five years later, she presented with upper abdominal pain. Abnormal liver function test prompted US of liver and referral to a Hepatologist. A triple-phase liver computed tomography (CT) scan suggested a lesion in the right liver dome. Positron Emission Tomography (PET) scan revealed metabolically active lesion along the right dome of the liver and extrinsic to rectosigmoid junction. Biopsy of the liver lesion under ultrasound guidance was performed which confirmed metastatic adenocarcinoma consistent with recurrence of endometrial carcinoma. Colonscopic biopsy did not identify malignancy, but in view of the PET scan it was presumed to be most likely dual site recurrence of the previous endometrial cancer. She underwent a laparotomy with rectosigmoid resection with division of large bowel 10 cm above and below the visible tumour, primary colorectal anastomosis with defunctioning ileostomy and non-anatomical liver resection from the right dome of the liver. Pathology confirmed presence of stage 2 metastatic endometroid carcinoma in both the rectosigmoid and liver resection specimens. She was reviewed by the clinical oncology team and is receiving 6 cycles of adjuvant chemotherapy.

Conclusion

We report unusual case of late recurrence of low risk endometrial cancer at two sites, which was managed with complete surgical resection.

4University Hospital Hradec Kralove, Third Department of Medicine-Gerontology and Metabolic Care, Hradec Kralove, Czech Republic
5Palacky University Olomouc, Department of Oncology, Olomouc, Czech Republic

Aims

The aim of this study was to compare preoperative TFF3, AIP and S100-A11 serum levels in patients with endometrial cancer, endometrial hyperplasia and in healthy female controls, to investigate an association with tumor grade, stage and nodal status. Furthermore, we analyzed an association between TFF3, S100-A11, AIP-1 and biomarkers of inflammatory response, oxidative stress and nutritional balance.

Method

In total 98 consecutive patients with endometrial cancer who underwent hysterectomy with bilateral salpingoophorectomy, pelvic and paraaortic lymphadenectomy were included in the study. The control group was comprised of 24 patients who had elective total hysterectomy for nonmalignant disorder. Furthermore, preoperative blood samples were taken in 43 patients diagnosed with endometrial hyperplasia at hysteroscopy. Ninety one patients with negative hysteroscopic findings represented a control group.

Results

TFF3 serum levels were significantly higher in endometrial cancer patients when compared to controls. S100-A11, and AIF-1 levels were higher in endometrial hyperplasia patients than in controls, and also significantly higher in endometrial cancer than in endometrial hyperplasia patients. The serum concentrations of TFF3, S100-A11, but not AIF-1 were associated with tumor stage and lymph node status. TFF3 exhibited positive correlation with age, IL-6, vitamin D, kynurenine, urinary neopterin/creatinine ratio and kynurenine/tryptophan ratio. S100-A11, as well as AIF-1 correlated positively with IL-6 and TFF3.

Conclusion

TFF3, S100-A11 and AIF-1 represent potential biomarkers in patients with endometrial cancer. TFF3 and S100-A11 increase with tumor stage and lymph node involvement, reflecting higher tumor mass that is also associated with increased concentration of biomarkers of immune dysfunction.

IMPLEMENTATION OF SENTINEL LYMPH NODE MAPPING WITH INDOCYANINE GREEN FLUORESCENT DYE IN ENDOMETRIAL CANCER IN CLINICAL PRACTICE: OUR PRELIMINARY RESULTS

A. Novelli1,2, A. Puppo3, M. Ceccaroni3, E. Piovano1, M.M. Ianieri3,4, G. Scambia2
1Regina Montis Regalis Hospital, Obstetrics and Gynecology Unit, Mondovi CN, Italy
2Catholic University of the Sacred Heart, Department of Women and Child Health - Division of Gynecologic Oncology, Rome, Italy
3Sacred Heart Hospital, Department of Obstetrics and Gynecology- International School of Surgical Anatomy, Negrar VR, Italy
4Gabriele D’Annunzio University, Department of Medical and Oral Sciences and Biotechnologies, Chieti-Pescara, Italy

Aims

We report our initial experience with laparoscopic Indocyanine-Green (ICG) Sentinel Lymph Node (SLN) mapping in endometrial cancer (EC) in terms of feasibility and diagnostic accuracy, focusing on low (LR), intermediate (IR), high-intermediate and high risk (HIR/HR) groups, according to ESMO/ESGO/ESTRO classification.

Method

All patients diagnosed with apparently uterine-confined EC between September 2016 and April 2017 in Mondovi and Negrar Hospitals underwent laparoscopic ICG-SLN mapping (according to SLN Memorial-Sloan-Kettering-Cancer-Center algorithm) via cervical injection, SLN biopsy and subsequent appropriate surgical treatment according to the risk group. Detection rate, sensitivity and negative predictive value (NPV) were prospectively analyzed and risk groups were taken into account.

Results

48 patients were included (preoperative 17LR-19IR-12HIR/HR): SLN was detected in 45/48 (93.7%), without complications; overall and bilateral detection rate were 91.6% and 75%, respectively. The median number of removed lymph nodes was 2(0-4)-23-21, for SLNs, pelvic non-SLNs and para-aortic non-SLNs, respectively. Metastatic SLNs were 6/45 (13.3%): 4 macrometastasis, 1 micrometastasis and 1 isolated tumor cells; in 4/6 of them SLN was the only positive node. Two patients had false negative (FN) SLN (1 metastatic pelvic non-SLN and 1 metastatic para-aortic non-SLN); FN rate was 4.4% (2/45); sensitivity was 75% (6/8); all SLNs in LR patients were negative; for pre-operative IR-HIR/HR NPV was 90%. Post-operative groups were: 21LR-10IR-17HIR/HR.

Conclusion

In our preliminary experience the ICG-SLN technique in EC was feasible, safe and cheap, with good detection rate and low FN rate. The pre-operative IR group seems very interesting, because of its frequent reassignment to another risk group on final pathology.

ADVANTAGES OF LAPAROSCOPIC SURGERY VERSUS OPEN SURGERY IN ENDOMETRIAL CANCER - 3 YEAR SINGLE INSTITUTION DATA

A. Pletnev1, S. Taranenko1, S. Mavričev1
1N.N. Alexandrov National Cancer Center of Belarus, Gynecologic Oncology Department, Minsk, Belarus

Aims

Laparoscopic surgery is being used in gynecologic oncology for total hysterectomy, bilateral salpingo-oophorectomy and lymph node dissection for endometrial cancer (EC). The purpose of this study is to compare the feasibility and complications among women undergoing open and laparoscopic hysterectomy for endometrial cancer

Method

We carried out a single center retrospective study using Belarus cancer register database between 2013 and 2016 on all women diagnosed with uterine cancer, classifying women in groups as either laparoscopically or open surgery treated.

Results

Laparoscopic surgery has more advantages versus open surgery in Endometrial Cancer Patients. The total for 3 years 378 laparoscopic and 1724 open hysterectomies were performed, including 56 operations with laparoscopic pelvic lymphadenectomy and 432 with open pelvic lymphadenectomy surgeries. The average duration of laparoscopic operation – 73 min. (40-180 min.), the average volume of blood loss – 51,9 ml (15-330 ml) were registered. Conversion to open surgery was in 4 cases; bladder injury – in 2, trauma of a sigmoid colon – in 1, bleeding – in 1 case. The average duration of open surgery – 74 min (50-174 min), average blood loss – 75,4 ml (20-950ml). Duration of lymphorrhea in laparoscopic operations was 3,4 days vs 6,3 days in open surgery. Laparoscopic surgery has benefits over open surgery in patients with morbid obesity with BMI more than 35 kg/m2 in surgical wound complications (1 vs 15) and thromboembolic complications (0 vs 5 cases).

Conclusion

Laparoscopy for EC retains its advantages over open surgery, especially in case of obesity patients.
ETHNIC DIFFERENCES IN THE MUTATIONAL LANDSCAPE OF ENDOMETRIAL CANCER

K. Polymeros¹, D. Guttery¹, S. Macip², E. Moss¹
¹University of Leicester, Cancer Studies, Leicester, United Kingdom
²University of Leicester, Molecular and Cell Biology, Leicester, United Kingdom

Aims

Background: Endometrial cancer (EC) is the commonest gynaecological malignancy in the UK and the incidence in Leicester is particularly high. Our previous work has shown that British South Asian (BSA) and White British (WB) women are diagnosed with a similar distribution of Type I/II cancers but BSA women are significantly younger in age compared to WB women.

Objectives: To determine whether BSA and WB women diagnosed with EC harbour different mutational profiles.

Method

DNA was extracted from formalin-fixed, paraffin embedded (FFPE) tissue from 32 patients. Ion Torrent targeted next generation sequencing (tNGS) was performed using a bespoke tNGS panel interrogating 10 commonly mutated genes in EC.

Results

A total of 99 mutations were found in this cohort (3.1/patient). The most commonly mutated genes were PIK3CA and PTEN with 53% and 47% of patients, respectively. None of the BSA patients carried a POLE mutation compared to 23% of the WB patients (p=0.15). ARID1A mutations were also less frequent in BSA patients (10% versus 36%, p=0.21).

Conclusion

ARID1A and POLE mutations were more frequent in WB versus BSA patients. Although the trend did not reach significance, it raises interesting clinical questions since it is known that POLE mutations are associated with better prognosis. It has been suggested that ARID1A mutations are associated with mutations in the PI3K pathway. Since many targeted therapies are focused on this frequently mutated pathway, a possible implication is that BSA patients may not respond as well to these newer agents. Analysis in a larger cohort is ongoing.

THE PARAMETRIAL AND PELVIC LYMPH NODES INVOLVEMENT IN SURGICAL-PATHOLOGIC STAGE II ENDOMETRIAL CARCINOMA

R. Puente¹, E. Schneider¹, R. Miranda²

¹Universidad Austral de Chile, Institute of Obstetrics and Gynecology, Valdivia, Chile
²Universidad Austral de Chile, Institute of Histology and Pathology, Valdivia, Chile

Aims

To know if the invasion of cervical stroma by endometrial cancer is associated to an increased percentage of parametrial and pelvic lymph nodes involvement in patients surgically staged II (FIGO 2008).

Method

In 150 patients with endometrial carcinoma, all with endometrioid histology submitted to radical hysterectomy type A or B with bilateral salpingoophorectomy and systematic pelvic lymphadenectomy we had 22 patients (14.6%) with pathologic study in strict stage II. The pathologic study included the pelvic lymph nodes and parametrial status.

Results

In the group of 22 patients stage II endometrioid adenocarcinomas we had an average of 35 pelvic lymph nodes (range 11-41), with 2 patients with positive pelvic lymph nodes (9.0%). No patient had positive parametrial involvement at pathologic study.

Conclusion

According to this study, in surgical-pathologic endometrial endometrioid adenocarcinoma stage II, the risk of positive pelvic lymph nodes is 9%, without involvement of parametria.

ENDOMETRIAL CANCER TISSUE HAS A UNIQUE PHOSPHOLIPID SIGNATURE IDENTIFIABLE USING DESORPTION ELECTROSPRAY IONISATION (DESI) IMAGING

O. Raglan¹,², L. Doria³, R. Soares³, F. Rosini³, T. Farrokh-Eslamlou¹, J. McKenzie³, Z. Takats³, M. Kyrgiou¹,²
¹Institute of Reproductive and Developmental Biology, Surgery and Cancer- Imperial College London, London, United Kingdom
²Imperial College Healthcare NHS Trust, Imperial College, London, United Kingdom
³Imperial College London, Computational and Systems Medicine- Department of Surgery and Cancer, London, United Kingdom

Aims

Endometrial cancer (EC) is the fourth most common gynaecological cancer in Europe. Strongly associated with obesity, incidence of endometrial cancer is rising. DESI-MSI (Desorption Electrospray Ionisation-Mass Spectrometry Imaging) is one mass spectrometry imaging technique that allows direct correlation between biochemical changes within a tissue and histological features, providing topographically localised biochemical information.

Method

Fresh frozen endometrial samples (benign, cancer) were analysed using DESI-MSI. Peaks of interest were identified from mass spectra, matched with histopathological tissue annotations and clinical data, which was combined to generate a reference database from which principal component analyses (PCA) and maximum margin criterion (MMC) were performed highlighting the biochemical differences between the sample groups analysed.

Results

59 fresh frozen sections were analysed using DESI-MSI, of which 47 (79.7%) were endometrial tumour tissues and 12 (20.3%) were benign. Clear distinction of the different tissue types (tumour-associated stroma versus tumour) was identified within each sample. Benign endometrial samples and endometrial cancer samples produced unique spectra which enabled clear separation in PCA-cross validated MMC analyses. Cross-validation resulted in 91.5% sensitivity and 98.0% specificity for the correct classification of EC. Phosphatidylinositol, PI (34-0), was more abundant in tumour tissue, and phosphatidylglycerol, PG (44:1), more abundant in benign tissue.

Conclusion

DESI-MSI can discriminate benign endometrial versus tumour tissue by identifying unique lipodomic profiles. Our analysis contributes to knowledge of lipid metabolism in cancer and can identify potential lipid markers. These markers can be useful in identifying patients at risk in whom signalling pathways involved in carcinogenesis are overexpressed.

ESGO7-1307

EVALUATING THE ACCURACY OF THE SENTINEL NODE MAPPING ALGORITHM IN ENDOMETRIAL CANCER USING INDOCYANINE GREEN DYE AND ROBOTIC PLATFORM

R. Agarwal

Kochi, India

Aims

To Evaluate the accuracy of SLN mapping algorithm in endometrial cancer when using Indocyanine green (ICG) dye and Robotic Assisted Infrared Imaging.

Method

Single institution prospective study carried out from July 2015 till October 2016. Patients with histology proven endometrial cancer undergoing robotic staging surgery were included. The Sentinel node mapping was done using intracervical ICG dye injection and robotic assisted Near infrared imaging. Algorithm published by Berlin et al and adopted by NCCN was followed. Careful inspection was made to identify and remove the sentinel node, any enlarged non sentinel nodes. Complete lymphadenectomy was done when sentinel nodes could not be identified.

Results

72 patients with endometrial cancer underwent surgery during this period out of which 64 underwent robotic staging surgery including sentinel node mapping. Sentinel node was detected in 60 patients (93.8%). 7 patients (11%) had positive nodes in histopathology, out of which 5 patients had positive sentinel node and in 2 patients enlarged non sentinel nodes were positive. Just by using sentinel node technique, those two patients would have been missed. But by following the algorithm, all patients with positive nodes could be identified.

Conclusion

The SLN mapping technique in endometrial cancer should be used only as a part of the complete algorithm for accurately detecting positive nodes.

Aims

Surgical staging, treatment and prognosis of uterine corpus malignancies are highly dependent on disease severity and spread, factors that can be intraoperatively assessed by frozen section (FS). We aimed to determine the accuracy of FS in surgical staging and agreement with permanent section (PS); to evaluate the association between adverse prognostic intraoperative findings with final histopathology.

Method

Retrospective chart analysis from January 2007 to March 2017 of all uterine corpus malignancies diagnosed in a tertiary university hospital. Kappa (K) statistics and proportions of agreement (PA) with 95% confidence intervals were applied. Exclusion criteria were absence of FS, clinically advanced disease, coexisting second malignancy.

Results

A total of 205 cases were identified. Regarding myometrial depth invasion, substantial agreement between FS and PS was found (K= 0.63), which was higher for tumours confined to the inner half of myometrium (PA= 0.92) and lower for serosa invasion (PA= 0.33). The sensitivity and specificity for involvement of the outer half was 74% and 99%. For cervical stromal involvement, a sensitivity and specificity of 65% and 99% was found. Regarding adverse prognostic oncological factors: the rate of adjacent organ invasion was higher in mesenchymal tumours (50%); lymph node involvement was more frequent in serous (45%) and mixed cell adenocarcinoma (40%), followed by mullerian mixed tumours (33%). Positive ascitic fluid was more frequent in mixed (50%) and miscellaneous (33%) categories.

Conclusion

Particularly in low risk disease and epithelial tumours, comprehensive surgical staging with FS seems beneficial. For locally aggressive tumours, preoperative imagiological staging might have a promising role.

Aims

Preoperative oncological uterine stratification based on endometrial sampling (ES) influences surgical planning and radically. The aim was to evaluate the histopathological agreement between ES, frozen section (FS) and permanent section (PS).

Method

Retrospective longitudinal study of all uterine corpus malignancies diagnosis/suspicion in a tertiary university centre from January 2007 to March 2017. Kappa (K) statistics and proportions of agreement (PA) with 95% confidence intervals (CI) were applied to evaluate agreement between pre, intra and postoperative histology, regarding histologic type, subtype and grade.

Results

A total of 215 cases of uterine corpus malignancies were included, from which 104 performed both ES and FS, 171 ES and PS and 113 FS and PS. Among those with final histopathological exam, 84% were epithelial, 9% mesenchymal, 5% miscellaneous and 1% benign and mixed tumours. Concerning the histologic type, the PA between ES and FS was 70% for total agreement and 8% for partial agreement. The majority of discordant cases were due to endometrioid tumours, revealed as complex atypical hyperplasia in ES. A PA of 72% was achieved for total or partial agreement between ES and PS. Regarding agreement between FS and PS a good agreement was found, with a PA of 88% for total or partial concordance. Agreement in tumour grade was moderate between the three groups (K= 0.47, 0.43, 0.43).

Conclusion

A higher agreement was found between FS and PS, compared to ES. Discordance was greater among high risk epithelial, mixed and mesenchymal tumors, suggesting a more challenging diagnosis.
ENDOMETRIAL CANCER

ESGO7-0865

COMBINING CA-125 AND COMPUTED TOMOGRAPHY IMPROVES SELECTION OF ADVANCED STAGE ENDOMETRIAL CARCINOMA

B. Israel\(^1\), C. Reijnen\(^1\), N.C. Visser\(^2\), J. Kasius\(^1\), J.J. Hermans\(^3\), L.F.A.G. Massuger\(^1\), J.M.A. Pijnenborg\(^1\)

\(^1\)RadboudUMC, Obstetrics & Gynaecology, Nijmegen, The Netherlands
\(^2\)RadboudUMC, Pathology, Nijmegen, The Netherlands
\(^3\)RadboudUMC, Radiology and Nuclear Medicine, Nijmegen, The Netherlands

Aims

To investigate the predictive value of preoperative CA-125 and computed tomography (CT) for advanced FIGO stage in the work-up for endometrial carcinoma (EC).

Method

The PIpelle Prospective ENDOmetrial carcinoma (PIPENDO) study cohort comprised all consecutive patients treated for endometrial carcinoma at nine hospitals in the Netherlands between September 2011 and December 2013. Patient characteristics, preoperative CA-125 and CT-scan results, histology, and follow-up data were collected. CT-scan results were classified as: suspected or unsuspected for extra-uterine disease, or inconclusive. Serum levels of CA-125 > 35 Ku/L were considered as elevated. Primary outcome was advanced FIGO III-IV stage, determined for low-(grade 1-2), and high (grade 3) tumor grade.

Results

A total of 432 EC patients were included; 25.9% with high-grade, and 74.1% with low-grade EC. Overall, 29.0% of the patients had an elevated CA-125, and 14.1% of the patients were suspected for extra-uterine disease based on CT-scan. Elevated CA-125 had a positive predictive value for advanced stage in of 8.8% in low-grade EC, compared to 47.5% in high-grade EC. Abnormal CT-scan had a positive predictive value for advanced stage of 30.0% in low grade EC, compared to 53.3% in high grade EC. Combined elevated CA-125 and abnormal CT-scan resulted in a positive predictive value of 28.6% in low-grade EC and 66.7% in high grade EC.

Conclusion

Combining CA-125 and CT-scan increases the positive predictive value for advanced FIGO stage in high-grade EC.
ENDOMETRIAL CANCER

ESGO7-0810

CLINICAL DECISION-MAKING BASED ON PREOPERATIVE ENDOMETRIAL SAMPLING IN ENDOMETRIAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Reijnen¹, N. Visser², L. Massuger¹, I. Nagtegaal², J. Bulter², J. Pijnenborg¹

¹Radboud University Medical Center Nijmegen, Obstetrics and Gynecology, Nijmegen, The Netherlands
²Radboud University Medical Center Nijmegen, Pathology, Nijmegen, The Netherlands

Aims

To determine the agreement between preoperative endometrial sampling and final diagnosis for tumor grade and subtype.

Method

MEDLINE, EMBASE, ClinicalTrials.gov and the Cochrane library were searched from inception to January 1, 2017, for studies that compared tumor grade and histological subtype in preoperative endometrial samples and hysterectomy specimen. In eligible studies the index test included office endometrial biopsy, hysteroscopic biopsy or dilatation & curettage; the reference standard had to be hysterectomy. Outcome measures included tumor grade, histological subtype or both.

Results

Two independent reviewers assessed the eligibility of the studies. Risk of bias was assessed (QUADAS-2). A total of 45 studies (12,459 patients) met the inclusion criteria. Pooled agreement rate for tumor grade was 0.67 (95% confidence interval [CI] 0.60-0.75) and Cohen’s k was 0.45 (95% CI 0.34-0.55). Agreement between hysteroscopic biopsy and final diagnosis was higher (0.89, 95% CI 0.80 – 0.98) than for office endometrial biopsy (0.73, 95% CI 0.60 – 0.86) and dilation and curettage (0.70, 95% CI 0.60 – 0.79). Lowest agreement rate was found for grade 2 endometrial carcinomas (0.61, 95% CI 0.53-0.69). Downgrading was found in 25% and upgrading was found in 21% of the endometrial samples. Agreement for histological subtypes was 0.95 (95% CI 0.94 – 0.97) and 0.81 (95% CI 0.74 – 0.92) for the preoperative endometrioid and non-endometrioid carcinomas respectively.

Conclusion

The moderate agreement between preoperative endometrial sampling and final diagnosis should be taken into account when selecting the most appropriate surgical treatment procedure.
ADENOCARCINOMA ENDOMETRIOIDE AND ADENOMIOSIS

M. Riera Blasco, B. Ruperez Perez, I. Moysset Agustí, C. Homs Mir, C. Vidal Ventura, V. Adame Alcudia

1CAP TORRASSA, Gynaecological Department, Hospitalet de Llobregat, Spain
2Consorci Sanitari Integral, Anatomia Patologica, Barcelona, Spain

Aims

A 42-year-old patient who turned to the gynaecologist with dysmenorrhea and hypermenorrhea of six months of evolution with a history of laparoscopy due to endometriosis. The patient is treated for three months with gestagens in the second phase of the cycle without response to treatment and with IUD of levonorgestrel with which we obtained amenorrhea during six months but later the expulsion takes place.

Method

Bx endometrium and cytology normal.
Transvaginal ultrasound: it reports two myomas, one submucosal intramural of 23 x 14 mm, another cornual myoma of 19 x 17 mm, proliferative endometrium, normal ovaries and free Douglas. Hysteroscopy: it confirms the diagnosis of submucous myoma of 23 x 14 mm.

Results

Pathologic anatomy:

Myometrium: Fragments of endometrioid adenocarcinoma on adenomyosis with presence of lymphatic tumor permeation.

Adenomyosis

Proliferative endometrium. Postoperative MR:

17mm adenopathy in right internal iliac chain. In a second time is realized: Cervical excision, bilateral anexectomy and lymphadenectomy. Pathological anatomy: residual endometroid adenocarcinoma that affects endocervix and lateral margin extension. Right pelvic attachments and lymph nodes: microinvasive implants in hilum and next to the ovary.

Lymph node metastasis (0/22).

Left pelvic attachments and lymph nodes: ovary without alterations. Lymph node metastasis (3/13) one with capsular rupture.

Peritoneum Bx: Endometrioid adenocarcinoma micrinoinvasar implant

Conclusion

It is important in these cases not to delay the surgery and to opt for surgical techniques that allow the correct study of uterus and ovaries avoiding the morcelation (fragmentation) this will allow us to make a better assessment of the margins affected and the size of the tumor.
ENDOMETRIAL CANCER

ESGO7-0263

CLINICOPATHOLOGIC CHARACTERISTICS OF ENDOMETRIAL CARCINOMA METASTATIC TO THE OVARY COMPARED TO ENDOMETRIAL CARCINOMA WITH SYNCHRONOUS OVARIAN CARCINOMA

N. Gomez-Hidalgo¹, R. Soslow¹, B. Weigelt¹, V. Sioulas¹, A. Aloisi¹, N. Abu-Rustum¹, J. Mueller¹, V. Makkii¹, M. Leitao¹
¹Memorial Sloan Kettering Cancer Center, Department of Surgery, New York, USA

Aims

To characterize the clinicopathologic characteristics and outcomes of sporadic synchronous endometrial and ovarian cancers (SEOC) patients compared to endometrial carcinoma with metastasis to the ovaries.

Method

Cases with carcinoma in the endometrium and ovary who underwent primary surgery at our institution between 06/1993 and 09/2014 were identified. Pathology reports were reviewed to determine the pathologist’s assessment of whether the ovarian carcinomas were likely synchronous or metastatic. Stage IV were excluded.

Results

76 cases were identified. 19 were SEOCs and 57 cases were classified as endometrial carcinoma with ovarian metastasis (ECOM). Median age was 52 (range: 32-71) and 63 (range: 43-89) years, respectively (p=0.4). Non-endometrioid histology was seen in only 21% of SEOC as compared to 58% in ECOM (P=0.006). No myoinvasion was noted in 32% SEOC compared to only 9% ECOM (P=0.01). Endometriosis was noted in 58% SEOC compared to 4% ECOM (p<0.0001). Median follow-up time was 44.2 mo (range: 0.4-201.4) for the entire cohort. The 4-year progression-free survival (PFS) was 82% (SE+/9.5) for SEOC and 51.6% (SE+/7) for ECOM group (p=0.06). 4-year overall survival (OS) was 94.7% (SE+/5.1) for SEOC and 69.8% (SE+/6.2) for ECOM (p=0.046). 4-years PFS for endometrioid histology only cases was 84% (SE+/10.6) for SEOC vs 77.8% (SE+/8.87) for ECOM (p=0.97). 4-years OS for endometrioid histology was 93.3% (SE+/8.4) for SEOC vs 81.9% (SE+/8.2) ECOM (p=0.3).

Conclusion

SEOC was associated with more favorable endometrial factors and endometriosis, these are likely dissemination by retrograde flux. SEOC was associated with better survival outcomes but not when analyzing endometrioid histology alone.

ENDOMETRIAL CANCER RISK IN BRCA MUTATION CARRIERS: A PROSPECTIVE DATABASE STUDY
E. Crosbie1,2, N. Ryan1,3, A. Wallace4, F. Lalloo4, E. Woodward4, R. Clayton2, R. Edmondson1,2, D. Evans3,4
1Faculty of Biology - Medicine and Health, Division of Molecular and Clinical Cancer Sciences, Manchester, United Kingdom
2Central Manchester University Hospitals NHS Foundation Trust - Manchester Academic Health Science Centre - Manchester - U K, Department of Obstetrics and Gynaecology, Manchester, United Kingdom
3School of Biological Sciences - University of Manchester - St Mary’s Hospital - Manchester - U K, Division of Evolution and Genomic Medicine, Manchester, United Kingdom
4Central Manchester University Hospitals NHS Foundation Trust - Manchester Academic Health Science Centre - Manchester - U K, Manchester Centre for Genomic Medicine, Manchester, United Kingdom

Aims

The risk of endometrial cancer (EC) in BRCA mutation carriers is unclear. Whether risk-reducing surgery should include hysterectomy (TH) at the time of bilateral salpingo-oophorectomy (BSO) is controversial.

Method

We analysed our prospectively maintained clinical database of BRCA mutation carriers >20 years of age. Expected EC rate was calculated using national data standardised by age, year and geographical region from date of BRCA1/2 test report (true prospective group) and from 01/01/1980-31/12/2015 (full dataset). Women were censored at time of death, hysterectomy or date of last follow up. Observed EC cases were verified with the national cancer registry.

Results

There were 2156 women (BRCA1 n=1107, BRCA2 n=1049) and over 51,185 total women years at risk (median: 23.5yrs). Median age at last follow up was 51yrs (IQR 42, 60). In total, 160 underwent risk-reducing TH-BSO (median 42.5yrs, IQR 38, 48) and a further 447 underwent BSO without TH (median age 45yrs, IQR 40, 52) and were followed up for a median 6.2 years. Fourteen women were diagnosed with EC; two had high-grade serous pathology. None were recorded in the BSO group. We found no evidence for an increased risk of EC overall (E: 9.8, O: 14; OR: 1.42 95% CI: 0.78-2.39, p=0.24), nor in the prospective group from mutation report (E: 3.64, O: 2; OR: 0.55 95% CI 0.07-1.98) where there were only two endometrioid cancers in 8724.5 years follow-up

Conclusion

We found no evidence for an increased risk of EC amongst BRCA mutation carriers, although the cohort is still young.
ENDOMETRIAL CANCER

IMPACT OF TUMOR GRADE ON PROGNOSIS IN TYPE 1 ENDOMETRIUM CANCER

A. Gül¹, G. Sahin¹, S. Akar¹, T.T. Ilhan², C. Celik¹, E. ÇINTESUN³
¹SELCUK UNIVERSITY, gynecologic oncology, KONYA, Turkey
²Mersin Research and Training Hospital, gynecologic oncology, Mersin, Turkey
³SELCUK UNIVERSITY, gynecology, KONYA, Turkey

Aims

The aim of this study was to evaluate the relationship between prognosis and tumor grade of patients with type 1 endometrial cancer.

Method

165 patients with type 1 endometrial cancer who underwent operation in the Department of Obstetrics and Gynecology of Selçuk University between 2009-2016 were included in this study. Histological grade of the tumor was determined from pathologic reports. The patient's last clinical status, recurrence dates, and death dates were determined from medical records. The relationship between the histological grade and the disease recurrence life table was established and the Wilcoxon test was used to compare the survival curves.

Results

The mean age of the patient was 58.5 years. 87 patients were classified stage 1A, 38 patients stage 1B, 10 patients stage 2, 5 patients stage 3A, 3 patient stage 3B, 19 patients stage 3C and 3 patients stage 4 were detected. The mean follow-up time was 45.4 months. 127 patients were Grade 1, 30 patients were Grade 2 and 8 patients were Grade 3. Recurrence was detected in 10 patients and there was no death during the follow-up. The mean duration of relapse was 55.1 months. 4 of the patient with recurrence were grade 1 and 6 were grade 2. Life table analysis showed a statistically significant increase in recurrent Grade 2 patients (p = 0.045).

Conclusion

The recurrence risk was detected higher in grade 2 patients than grade 1 and grade 3 patients in this study. Further studies with more patients are needed to confirm this study.

SERUM ISCHEMIA MODIFIED ALBUMIN AND ENDOMETRIAL CANCER; PROSPECTIVE CASE-CONTROL STUDY
H. Şahin1, S. Ayhan2, M.E. Sari1, S. Yaman1, İ. Yaçın1, T. Candar3, M. Öz1, T. Güngör1
1Zekai Tahir Burak Women Health Care Education and Research Hospital, Gynecologic Oncology, ANKARA, Turkey
2Yenimahalle Training and Research Hospital- University of Yıldırım Bayezid, Obstetrics and Gynecology, Ankara, Turkey
3Dr. Ridvan Ege Training and Research Hospital- Ufuk University, Department of Biochemistry, Ankara, Turkey

Aims

To investigate the importance of ischemia modified albumin (IMA) in the diagnosis and evaluation of endometrioid type endometrial carcinoma

Method

Serum IMA levels of patients with and without endometrioid type endometrial cancer were measured by the calorimetric assay technique and their absorbance units were compared.

Results

A total of 120 women consisting of 56 endometrial cancer patients and 64 patients as the control group, were included in the study. The median ages were 58 and 56, respectively. Age, gravida, body mass index, serum albumin levels were not different between the groups (p > 0.05). In the endometrial cancer group, the median serum IMA level was 0.667 and range was 0.57 (0.313-0.883), while in the control group the median serum IMA level was 0.639 and range was 0.754 (0.178-0.932). There was no significant difference between the two groups (p = 0.433). IMA levels were similar when myometrial invasion, lymphovascular involvement, grade, tumour size and stage were evaluated (p > 0.05).

Conclusion

Although IMA was predominantly used as a cardiac marker only, it was found to be significantly higher in a limited number of patient studies with some types of cancer. The IMA level does not appear to be an additional predictor of preoperative diagnosis and evaluation of endometrioid type endometrial cancer.
CLUSTERIN IMMUNOEXPRESSION IS ASSOCIATED WITH EARLY STAGE ENDOMETRIAL CARCINOMAS

K. Sait1

1King Abdulaziz University Hospital, gynecology oncology unit, Jeddah, Saudi Arabia

Aims

Clusterin has anti-apoptotic, regeneration and migration stimulating effects on tumor cells. This study investigates the relation between clusterin expression and the clinicopathological parameters in endometrial carcinomas.

Method

Seventy one cases of previously diagnosed endometrial carcinoma (including 59 endometrioid adenocarcinoma, 9 serous adenocarcinoma, 1 clear cell adenocarcinoma, and 2 malignant mixed Mullerian tumor) and 30 tissue samples of non-cancerous endometrium (including 16 proliferative endometrium, 10 secretory endometrium and 4 endometrial polyps) were employed for clusterin detection using tissue microarrays and immunostaining.

Results

A total number of 23 (32.4%) cases were positive for clusterin immunostaining. Brown granular cytoplasmic expression of clusterin was detected in 33.9% of endometrioid adenocarcinomas, 22.2% papillary serous endometrial carcinomas. Three (10%) control cases showed granular cytoplasmic expression. Positive clusterin immunostaining was found more frequent in well differentiated and stage I endometrial carcinomas, showing significant statistical association (p-value = 0.036 and p-value = 0.002 respectively). Significant difference in clusterin expression was observed between tumor cases and control group (P-Value = 0.019), i.e., endometrial carcinoma cases are more than four times likely to show positive clusterin immunostaining (odds ratio 4.313 with 95% confidence interval 1.184–15.701). This study did not find relation between clusterin expression and disease recurrence, survival or any of the other clinicopathological parameters in endometrial tumors. The results of our study confirms the diagnostic values of clusterin in supporting the diagnosis of endometrioid carcinoma.

Conclusion

When clusterin is expressed in endometrial tumors, it is associated with lower stage. The correlation of clusterin with tumor stage suggests involvement of this molecule in endometrial tumor progression.

ROBOT-ASSISTED LAPAROSCOPY VERSUS LAPAROTOMY FOR INFRA-RENAL PARAAORTIC LYMPHADENECTOMY IN WOMEN WITH HIGH-RISK ENDOMETRIAL CANCER: A RANDOMIZED CONTROLLED TRIAL (RASHEC)

S. Salehi1, E. Ávall-Lundqvist2, B. Legerstam1, J.W. Carlson2, H. Falconer1

1Karolinska Institutet/Karolinska University Hospital, Department of Women's and Children's Health/Division of Obstetrics and Gynecology, Stockholm, Sweden
2Linköping University, Department of Oncology and Department of Clinical Experimental Medicine, Linköping, Sweden
3Karolinska Institutet/Karolinska University Hospital, Department of Oncology and Pathology/Department of Pathology and Cytology, Stockholm, Sweden

Aims

To investigate if robot-assisted laparoscopic surgery (RALS) was non-inferior to laparotomy (LT) in harvesting infrarenal paraaortic lymph nodes in patients with presumed stage I-II high-risk endometrial cancer.

Method

Patients with histologically proven endometrial cancer, presumed stage I-II with high-risk tumor features, were randomized to hysterectomy, bilateral salpingo-oophorectomy, pelvic and paraaortic lymphadenectomy by either RALS or LT. Primary outcome was paraaortic lymph node count. Secondary outcomes were perioperative events, postoperative complications and total health care cost.

Results

Overall 120 patients were randomized and 96 patients were included in the per protocol analysis. Demographic, clinical and tumor characteristics were evenly distributed between groups. Mean (±SD) paraaortic lymph node count was 20.9 (±9.6) for RALS and 22 (±11, p=0.45) for LT. The difference of means was within the non-inferiority margin (-1.6, 95% CI -5.78, 2.57). Mean pelvic node count was lower after RALS (28±10 vs. 22±8, p<0.001). There was no difference in perioperative complications or readmissions between the groups. Operation time was longer (p<0.001) but total blood loss less (<0.001) and hospital stay shorter (<0.001) in RALS group than LT group. Health care costs for RALS was significantly lower (mean difference $1,568 USD/€1,225 Euro, p<0.05).

Conclusion

Our results demonstrate non-inferiority in paraaortic lymph node count, comparable complication rates, shorter hospital length and lower total cost for robot-assisted laparoscopic surgery over laparotomy. Generalizability of the latter finding requires a high-volume setting and high surgical proficiency. In women with high-risk endometrial cancer confined to the uterus, RALS is a valid treatment modality.

THE UTERINE CHORIOCARCINOMA IN POSTMENOPAUSAL WOMEN: SPECIFICITIES OF DIAGNOSIS AND TREATMENT

M.S. Rhim¹, H. Salhi², M. Rezgani², A. Didouni¹, O. Jaidane², I. Zemni², J. Ben Hassouna², T. Dhiab², M. Hechiche², A. Haddad¹, K. Rahal², R. Faleh¹

¹Maternity Center, Department of Gynaecology and Obstetrics, Monastir, Tunisia
²Salah Azaiz Institute, Surgical Oncology Department, Tunis, Tunisia

Aims

Choriocarcinoma is a gestational trophoblastic tumor that mainly affects women of childbearing age. Cases of choriocarcinoma in postmenopausal women are exceptional.

Method

Through an observation and literature review, we propose to study the specific diagnosis and treatment features of this tumor in menopausal women.

Results

We report the observation of a pure uterine choriocarcinoma, which occurred in post-menopause. The diagnosis was made on the analysis of surgical specimens confirmed by measurement of hCG. Chemotherapy was started after a total hysterectomy and bilateral salpingo-oophorectomy first. The improvement was dramatic after 3 courses of chemotherapy and the patient is in complete remission after five years of monitoring.

Conclusion

The primitive forms of pure choriocarcinoma in postmenopausal women are exceptional. Their etiology is poorly understood and their treatment based on chemotherapy.

²Turkish Gynecologic Oncology Group, Gynecologic Oncology, İstanbul, Turkey
³Turkish Gynecologic Oncology Group, Gynecologic Oncology, İzmir, Turkey
⁴Turkish Gynecologic Oncology Group, Gynecologic Oncology, Antalya, Turkey

Aims

To assess the prognosis of surgically-staged non-invasive clear cell carcinoma (UCCC), and to determine the role of adjuvant therapy.

Method

A multicenter, retrospective department database review was performed to identify patients with UCCC who underwent surgical treatment between 1997 and 2016 at 8 Gynecologic Oncology centers. Demographic, clinicopathological, and survival data were collected.

Results

A total of 232 women with UCCC were identified. Of these, 53 (22.8%) had surgically-staged non-invasive UCCC (UCCC with no myometrial invasion). Twelve patients (22.6%) were upstaged at surgical assessment, including a 5.6% rate of lymphatic dissemination (3/53). Of those, 1 had stage IIIA, 1 had stage IIIC₁, 1 had stage IIIC₂, and 9 had stage IVB disease. Of the 9 women with stage IVB disease, 5 had isolated omental involvement indicating omentum as the most common metastatic site. UCCC limited only to the endometrium with no extra-uterine disease was confirmed in 41 women (73.3%) after surgical staging. Of those, 13 women (32%) were observed without adjuvant treatment whereas 28 patients (68%) underwent adjuvant therapy. The 5-year disease-free survival rates for patients with and without adjuvant treatment were 100% vs. 74.1%, respectively (p=0.06).

Conclusion

Extra-uterine disease may occur in the absence of myometrial invasion, therefore comprehensive surgical staging including omentectomy should be the standard of care for women with UCCC regardless of the depth of myometrial invasion. Larger cohorts are needed in order to clarify the necessity of adjuvant treatment for women with UCCC truly confined to the endometrium.

A FEASIBILITY STUDY OF SENTINEL LYMPH NODE MAPPING BY CERVICAL INJECTION OF A TRACER IN JAPANESE WOMEN WITH EARLY STAGE ENDOMETRIAL CANCER

Y. Todo\textsuperscript{1}, H. Kato\textsuperscript{1}, S. Takeshita\textsuperscript{1}, M. Yamazaki\textsuperscript{1}

\textsuperscript{1}Hokkaido cancer center, gynecologic oncology, sapporo, Japan

Aims

The aim of this study was to investigate the feasibility of sentinel lymph node mapping characterized by a cervical tracer injection in endometrial cancer.

Method

This retrospective study was carried out using data for 57 patients with endometrial carcinoma who had undergone intraoperative sentinel lymph node mapping and subsequent surgical staging. Technetium colloid and/or indocyanine green was injected into the uterine cervix and a gamma-detecting probe and/or photodynamic eye camera system was used intraoperatively to locate hot spots.

Results

Of the 57 patients, 52 (91.2\%) had FIGO Stage I disease. Successful unilateral or bilateral mapping occurred in 54 patients (94.7\%) and 46 (80.7\%), respectively. The median number of sentinel lymph nodes detected was two (range, 0–5). Following sentinel lymph node mapping, 41 patients (71.9\%) underwent pelvic lymphadenectomy alone and 16 (28.1\%) full lymphadenectomy. The median number of lymph nodes resected was 17 (range, 8–110). Sentinel lymph nodes were involved in four patients (7.0\%), two with macrometastases and two with low-volume metastases. The sensitivity and negative predictive value for detecting lymph node metastasis were both 100\%.

Conclusion

Sentinel lymph node mapping with the use of cervical tracer injection is highly feasible in Japanese women with early stage endometrial cancer.

EVALUATING THE LONG TERM PROGNOSTIC FACTOR AND THE ROLE OF CYTOREDUCTION IN THE OVERALL POPULATION OF PATIENTS WITH CLINICAL AND SURGICAL STAGE IV ENDOMETRIAL CARCINOMA

Y. Shimizu¹, H. Kajiyama¹, S. Suzuki¹, N. Yoshikawa¹, K. Nakamura¹, M. Yoshihara¹, S. Tamauchi¹, K. Yoshida¹, F. Kikkawa¹
¹Department of Obstetrics and Gynecology, Nagoya University Graduate School of Medicine, Nagoya City, Japan
²Department of Obstetrics and Gynecology, Aichi Cancer Center, Nagoya City, Japan

Aims

This study aimed to evaluate the long term prognostic factor and the role of cytoreduction in the overall population of patients with clinical and surgical stage IV endometrial carcinoma.

Method

All patients with Stage IV endometrial carcinoma treated in Aichi Cancer Center between 1982 and 2016 were retrospectively analyzed.

Results

The median age was 59 years (range 31 to 79); the most common histologic subtypes were 52 (61.1%) with endometrioid carcinoma, 11 (12.9%) with serous carcinoma, and 10 (11.9%) with carcinosarcoma. Median overall survival time (MST) of all cases were 12 months (range 0 to 189). The presence of metastasis beside peritoneal dissemination was analyzed and differed statistically (with (n=42) vs without (n=43), MST 12,14 months p=0.0456). Patients were divided into three groups according to their initial treatment: primary surgery following chemotherapy, primary chemotherapy following surgery and chemotherapy alone were 48(56%), 20(24%) and 16(19%) cases retrospectively. Among patients underwent surgery, no postoperative intra-abdominal residual tumor (NRD) or <=1cm, >1cm were 13, 24 and 31 retrospectively. Postoperative intra-abdominal residual tumor significantly differed statistically in MST (NRD, <=1cm, >1cm groups, MST 63, 14, 13 months p<0.001). No other characteristics showed statistical difference. Twelve cases (14.1%) showed more than 5 years survival in which 11 were treated with surgery and 7 with no residual tumor after surgery.

Conclusion

From our result completely debulking abdominal disease regardless of primary treatment appears to be most important determinants of long term survival in patients with Stage IV endometrial carcinoma. Though there are few cases dying in a short time which makes essential to regard the management of treatment.
LYMPHOCELE AFTER PELVIC LYMPHADENECTOMY FOR PATIENTS WITH ENDOMETRIAL CANCER

T. Rogovskaya¹, A. Sidoruk¹, ², N. Mikaya¹, N. Bondarev¹, ³, E. Ulrikh¹, Y. Gavrish², I. Berlev¹, ², A. Urmancheeva¹, ⁴
¹Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia
²North-Western State Medical University named after I.I Mechnikov, Gynaecological department, Saint-Petersburg, Russia
³Pavlov First Saint Petersburg State Medical University, Oncological department, Saint-Petersburg, Russia
⁴North-Western State Medical University named after I.I Mechnikov, Oncological department, Saint-Petersburg, Russia

Aims

To identify the incidence of lymphocele after pelvic lymphadenectomy in patients after laparoscopic and open abdominal surgery for endometrial cancer.

Method

648 endometrial cancer patients underwent hysterectomy and bilateral pelvic lymphadenectomy with laparoscopic and open approach in N.N. Petrov Research Institute of Oncology from 2010 to 2016. The median age of patients at surgery was 59.8 (25–88) years. Median BMI was 32.7 (18.31-60.97) kg/m2. A total of 327 patients after laparoscopic surgery were compared to 321 patients after open surgery group. In both groups the majority of patients were at stage IA and IB (89.3% in the laparoscopic group and 69.7% in the laparotomic group). Metastases in pelvic lymph nodes were detected in 4.89% and 10.9% of patients respectively. Ultrasound examination of the pelvis for all patients after surgery was performed.

Results

The overall incidence of lymphoceles was 320/648 (49.4%); 141/320 (44.06%) after laparoscopy and 179/320 (55.9%) after open surgery (p=0.01). Symptomatic lymphoceles were found in 15 (4.6%) and 21 (6.5%) patients after laparoscopic and open surgery respectively. The mean size (largest diameter) of lymphoceles was 43.7 mm (1–155 mm). There was a significant size difference between asymptomatic (mean size 39.9 mm; 1–114 mm) and symptomatic lymphoceles (mean size 82.3 mm; 32–155 mm) [p=0.02].

Conclusion

The incidence of lymphocele after lymphadenectomy for endometrial cancer is high (49.4%). Most of them are asymptomatic (88.9%). Laparoscopic approach in endometrial cancer surgery is associated with a lower occurrence of both asymptomatic and symptomatic lymphoceles compared to open surgery.

CLINICAL FEATURES OF ENDOMETRIAL CANCER IN PATIENTS OVER THE AGE OF 70

Y.E. Gavrish¹, A. Baltrucova¹, T. Rogovskaya², A. Sidoruk¹,², E. Ulrikh², I. Berlev¹,²

¹North-Western State Medical University named after I.I. Mechnikov, Gynaecological department, Saint-Petersburg, Russia
²Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia

Aims

To study clinical features of endometrial cancer in patients elder 70 years

Method

All patients (316) were divided into two groups: I group - patients aged ≥ 70 (n=157), average age 75.2, II group - patients < 70 (n = 159), average age 59.5 (2009-2016)

Results

I stage of the disease was observed in 66.25% patients ≥ 70 years vs 86.79% in patients < 70 years (p<0.05). The II stage was registered more often - in the group ≥ 70 years (15.29% vs 6.29%, p<0.05). The III stage of endometrial cancer also more often became apparent in the group ≥ 70 (15.91% vs 6.29%, p<0.05). The IV stage is revealed in 2.55% of patients of the I group and in 0.63% of patients of the II group (p>0.05). In both age groups the endometrioid adenocarcinoma prevailed. G1 carcinoma was less often observed in patients ≥70 (17.8% vs 37.1% in the II group, p<0.05). G2 and G3 endometrioid adenocarcinomas occurred in 49.7% and 10.8% respectively in the I group against 47.8% and 6.92% in the II group (p>0.05). The serous endometrial carcinoma prevailed, it became apparent in the senior age group authentically more often and was of 15.9% against 4.4% in the II group (p<0.05).

Conclusion

Among patients ≥ 70 years the tendency to increase in specific weight of advanced stages of endometrial cancer is noted, the highly differentiated endometrioid adenocarcinoma occurs less often, and among the non-endometrioid forms of a tumor the serous endometrial carcinoma which is characterized by the unfavourable prognosis prevails.

HYPOXIA AND HYPERGLYCAEMIA ARE ASSOCIATED WITH METFORMIN RESISTANCE IN ENDOMETRIAL CANCER

V. Sivalingam1, A. Latif2, S. Kitson1, R. McVey2, H. Kitchener1, I. Stratford4, E.J. Crosbie1

1Division of Molecular and Clinical Cancer Sciences, School of Medical Sciences, Manchester, United Kingdom
2Division of Pharmacy and Optometry, School of Health Sciences, Manchester, United Kingdom
3Department of Histopathology, Central Manchester University Hospitals Foundation Trust, Manchester, United Kingdom
4Division of Pharmacy and Optometry, School of Health Science, Manchester, United Kingdom

Aims

Obesity and insulin resistance are key drivers in the pathogenesis of endometrial cancer (EC). Metformin reduces tumour proliferation in vitro and following short-term pre-surgical administration in patients with EC. We hypothesised that metformin’s anti-tumour activity is driven by effects on mitochondrial function and affected by glucose and oxygen concentrations.

Method

Ishikawa and HEC1A EC cell lines were used in cell viability, flow cytometry and mitochondrial assays to test the cytostatic and mitochondrial function effects of metformin at varying glucose (0.5-25mM) and oxygen (1%-21%) concentrations. In patients, baseline serum glucose and insulin levels were measured before treatment with metformin in a pre-surgical study. Baseline tumour hypoxia (HIF-1α, CA-9) and change in mitochondrial mass (TOMM-20) was measured by immunohistochemistry in endometrial tumours.

Results

In vitro, metformin’s dose-dependent cytostatic effects (p<0.01) were reduced by high glucose and hypoxia (p<0.05-0.001). These conditions suppressed basal and mitochondrial respiration in mitochondrial assays (p=0.017). In vitro, metformin increased mitochondrial mass (p<0.0001) but decreased mitochondrial function (p<0.001) at low glucose concentrations (p<0.01), while treatment in patients was associated with increased mitochondrial mass (p=0.03). There was no association with baseline glucose or insulin levels but metformin response was reduced in hypoxic tumours (p=0.03).

Conclusion

Supraphysiological concentrations of metformin are required for cytostatic effects in high glucose culture conditions. Metformin response is reduced in low oxygen concentrations, both in vitro and in patients. Metformin targets mitochondrial function, however in high glucose, a switch to glycolysis may contribute to metformin resistance. Understanding these metabolic adaptations can help identify patients likely to benefit from metformin.

RADIATION-RELATED TOXICITIES AND OUTCOMES IN ENDOMETRIAL CANCER: ARE OBESE WOMEN AT A DISADVANTAGE?

A. Smits1, J. McGrane2, A. Lopes3, E. Kent4, R. Bekkers2, L. Massuger5, N. Simpson2, K. Galaal6

1Radboudumc, Gynaecology, Nijmegen, The Netherlands
2Royal Cornwall Hospital Trust, Oncology, Truro, United Kingdom
3Retired, Gynaecology, Truro, United Kingdom
4Royal Cornwall Hospital Trust, Gynaecology, Truro, United Kingdom
5Radboud UMC, Gynaecology, Nijmegen, The Netherlands

Aims

To assess the impact of body mass index (BMI) on radiotherapy toxicities in endometrial cancer patients.

Method

This was a retrospective cohort study of women diagnosed with endometrial cancer between January 2006 and December 2014 at the Royal Cornwall Hospital Trust. Women who received radiotherapy as part of treatment, including EBRT and/or vaginal brachytherapy were included. Radiation-related toxicities were graded according to the Radiation Therapy Oncology Group (RTOG) guidelines. Toxicity outcomes were compared across BMI groups; non-obese (BMI <30 kg/m²) and obese (BMI ≥30 kg/m²), according to radiotherapy treatment received (EBRT, brachytherapy or a combination).

Results

A total of 159 women received radiotherapy of which 110 could be included. Sixty-three women had a BMI <30 kg/m² and 47 women were obese. Obese women had poorer ECOG performance status (P=0.021) and more comorbidities (P<0.001) compared to the non-obese group. Total (any) toxicity rates were 60.3%, 72.7% and 52.0% for respectively; EBRT and brachytherapy (N=63), single mode EBRT (N=22) and brachytherapy (N=25). BMI was not associated with the incidence of acute and late radiation toxicities in the different radiotherapy groups. Nor were there differences in individual complications between the BMI groups.

Conclusion

When comparing obese to non-obese women, obesity does not negatively impact the incidence of radiation toxicities in endometrial cancer. However, toxicities remain an important challenge as they are common and negatively influence the quality of life (QoL) of survivors. Future studies need to further explore the role of BMI and possible interventions to improve toxicities and QoL.

EFFICACY OF ENDOMETRIAL CANCER FOLLOW-UP: AN EXPERIENCE FROM A TERTIARY CARE HOSPITAL IN ITALY

I. Turrini1, F. Sorbi1, A. De Magnis1, D. Pavone1, G. Fantappiè1, F. Petraglia1, I. Noci1, M. Fambrini1

1University of Florence, Department of Experimental and Clinical Biomedical Sciences - Division of Obstetrics and Gynecology, Florence, Italy

Aims

To review the experience of a tertiary university hospital on endometrial cancer follow-up in a 10 year period.

Method

We retrospective review our institutional experience of follow up between September 2006 and September 2016 for patients treated for endometrial carcinoma and critically analyzed how to improve the clinical practice and the quality of life, reducing the public spending. Patients have been examined with a frequency of 4-5 months for the first 2 years, 6-8 months between third and fifth year, every 12 months between fifth and tenth year.

Results

367 patients were enrolled. The recurrence rate was 8.18% with the highest recurrence rate in stage IIIC (36.4%). Only six patients (20%) showed symptoms before the diagnosis with no difference in recurrence free survival between asymptomatic and symptomatic patients. Among the asymptomatic endometrium recurrences, the diagnosis was made with imaging clinical examinations in the 87.5% of cases. Vaginal cytology did not detect any disease recurrence in case of central asymptomatic endometrium recurrences. There were no relapses after the fifth year of follow-up

Conclusion

Considering the necessity of a spending reduction for the National Health System, we recommend a more careful modulation of the number of examinations and of required tests based on risk factors and on the patient’s prognostic. In accordance with literature, the use of vaginal cytology in endometrial cancer follow-up should be reduced. The absence of recurrence after the fifth year of follow-up might suggest to reduce the length of follow-up programme.

STATISTICAL ANALYSIS OF HOSPITAL STAY OF PATIENTS WITH MALIGNANT TUMORS OF THE UTERUS AND OBESITY

R. Stoyanov1, G. Chakalova1

1University Hospital of Oncology, Clinic of gynecology, Sofia, Bulgaria

Aims

Obesity is a major public health problem, and it is observed in cases of endometrial cancer.

Method

A hospital stay of 262 women (non-obese - 55 patients and obese - 207 patients) with malignant tumors of the uterus in terms of BMI and its influence on the preoperative and postoperative stay operated in the clinic of Gynecology (01.01.2013 – 31.07.2016) University Hospital of Oncology in Sofia was conducted. As control group 331 patients with cervical and ovary cancer (non-obese - 161 patients and obese - 170 patients) were used. The Kruskal-Wallis Test and the Mann-Whitney Test were used for statistical analysis of the results. The null hypothesis is rejected at a P-value of less than 0.005.

Results

Statistically there were found out significant differences between BMI and postoperative stay in patients with malignant tumors of the uterus. No statistically significant differences between the categories of BMI and postoperative stay in patients with cervical cancer and ovarian cancer has been observed.

Conclusion

Our results indicate that there is a relationship between postoperative hospital stay and BMI in patients with malignant tumors of the uterus and prolonged stay in patients with a higher BMI. Regarding patients with gynecological cancer correlation between complications and obesity has not been established.
THE INFLUENCE OF SOME CLINICAL FACTORS ON SURVIVAL OF ENDOMETRIAL STROMAL SARCOMA PATIENTS.

V. Sukhin¹, O. Sukhina², V. Kolomatskaja³, N. Fedorenko¹
¹Grigoriev Institute of medical radiology, Oncogynecology, Kharkov, Ukraine
²Grigoriev Institute of medical radiology, Radiation therapy, Kharkov, Ukraine
³Grigoriev Institute of medical radiology, Clinical oncology, Kharkov, Ukraine

Aims

analyse clinical cases of uterine sarcoma patients, who were diagnosed for the first time and underwent treatment between January 1997 and December 2016 in the clinic of «Grigoriev Institute for Medical Radiology of NAMS of Ukraine».

Method

There was evaluated the treatment results of 42 uterine endometrial stromal sarcoma patients stage IA-IVB (T1-3NxM0-1). All the patients underwent surgery, radiotherapy and/or chemotherapy. The treatment efficacy was assessed by the incidence-rate, recurrence-rate, disease-free and overall survival, site of recurrence and metastasis.

Results

the progression index was 22.2 ± 1.0 % at stage I, 50.1 ± 1.7 % at stage II, 66.7 ± 1.7 % at III stage, and 62.5 ± 1.8 % at stage IV, with the period of observation up to 60 months. The recurrence-rate after combined or complex treatment in ESS patients stage I-IV was 42.9 ± 7.6 %. Loco-regional recurrence was detected in 16.7 ± 5.8 % of patients, distant metastases – in 26.2 ± 6.8 %.

Conclusion

The progressive disease in term before 6 months was noted in 80 % of patients with stage II and IV. The 5-year non-progressive survival, without taking into consideration the stage of disease, was 57.1 %. The treatment regimen has no influence on relapse-rate in ESS patients.

POST-PREGNANCY OUTCOMES OF YOUNG PATIENTS WITH ENDOMETRIAL CANCER OR ATYPICAL ENDOMETRIAL HYPERPLASIA WHO RECEIVED FERTILITY-PRESERVING HORMONAL THERAPY USING MEDROXYPROGESTERONE ACETATE.

N. Susumu¹, W. Yamagami², T. Hirano², T. Makabe², K. Saka², T. Chiyyoda², H. Nomura², F. Kataoka², E. Saitoh¹, A. Hirasawa², E. Tominaga², K. Banno², D. Aoki²

¹International University of Health and Welfare Mita Hospital, Gynecology, Tokyo, Japan
²Keio University School of Medicine, Obstetrics and Gynecology, Tokyo, Japan

Aims

We aimed to clarify retrospectively, the post-pregnancy outcomes of young patients with endometrioid adenocarcinoma (EC) or atypical endometrial hyperplasia (AEH) who received fertility-preserving hormonal therapy using medroxyprogesterone acetate (MPA).

Method

We reviewed 248 patients with AEH (102), EC Grade1 (142), EC Grade2 (4), who were determined to have neither myometrial invasion nor extrauterine metastasis. After 4 months oral administration of MPA (400-600mg/day), D&C was performed. An additional 2 months medication and D&C were repeated when positive residual disease. At intrauterine recurrence, we repeated MPA therapy for patients meeting the same eligibility for initial therapy. We analyzed the recurrence-free survival (RFS) rates in EC patients or AEH patients by Kaplan-Meier method.

Results

Median follow-up period was 60 months. In initial therapy, pathological CR rate was 97% in AEH, 90% in G1/G2. The pregnancy rate after MPA therapy was 34% in AEH, 34% in G1/G2. After delivery or abortion, 2 year-RFS rate was 91% in AEH, 65% in G1/G2, and 5 year-RFS rate was 65% in AEH, 38% in G1/G2 (p=0.0038, Log-rank test). RFS rate was similar between patients after abortion or patients after successful delivery (53% vs. 50%, p=0.49).

Conclusion

Post-pregnancy RFS rate was low especially in patients with EC. Careful surveillance for intra-uterine recurrence is needed even after successful pregnancies.

RECURRENCE PREDICTION SCORE: DEVELOPMENT AND VALIDATION OF A SYSTEM TO PREDICT BASELINE RISK OF RECURRENCE IN STAGE I-II ENDOMETRIAL CARCINOMA

K. Takahashi¹, M. Yunokawa², I. Kuno¹, Y. Yoneoka¹, T. Tsukada¹, M. Kobayashi¹, K. Tate¹, H. Shimizu¹, T. Uehara¹, M. Ishikawa¹, S.I. Ikeda¹, T. Kato¹
¹National cancer center hospital, Department of gynecology, Tokyo, Japan
²Cancer institute hospital of JFCR, Medical Oncology Department, Tokyo, Japan

Aims

To develop and validate the 3-year recurrence prediction score (RPS) system for predicting the baseline risk of recurrence in stage I-II endometrial carcinoma.

Method

We reviewed 427 patients with FIGO stage I-II endometrial carcinoma who underwent surgery without any adjuvant therapy at our institution from 2005 to 2013. Multivariate analysis was performed using clinicopathological factors to identify the risk factors for 3-year recurrence-free survival (RFS) in 251 patients treated in odd-numbered years (test cohort). We assigned score points to each risk factor based on Cox regression analyses and the sum of the risk factor score points was defined as the RPS system. The scoring system was applied to 176 patients treated in even-numbered years (validation cohort).

Results

The significant risk factors were age ≥60 years, pathological type II, cervical stromal invasion, and positive peritoneal cytology and Cox regression analysis revealed that the regression coefficients of each factor were almost same, and we defined each score points as 1. Score distribution and the 3-year RFS rate for each RPS are shown in Table 1 and Table 2. The 3-year RFS was significantly higher in the low-RPS group (RPS 0-1) than in the high-RPS group (RPS 2-3) (97.7% vs. 71.1%, p < 0.01) (95.2% vs. 79.9%, p < 0.01) in both test and validation cohort (Figure 1).

A FEASIBILITY OF LAPAROSCOPIC SURGERY WITH PELVIC LYMPHADENECTOMY FOR EARLY-STAGE ENDOMETRIAL CANCER

N. Takahashi1, E. Yoshioka1, A. Mochizuki1, Y. Kasamatsu1, N. Kado1, M. Abe1, M. Takekuma1, Y. Hirashima1

1Shizuoka cancer center, gynecology, shizuoka, Japan

Aims

To investigate feasibility of laparoscopic surgery with pelvic lymphadenectomy for endometrial cancer.

Method

Laparoscopic surgery for endometrial cancer hadn't been covered by insurance until 2014 in Japan. Since 2015, we have performed laparoscopic surgery (LPS) for 93 endometrial cancer patients. Pelvic lymphadenectomy were performed for 35 of them. We judge the adaptation of lymphadenectomy for endometrial cancer from frozen-section results (Table 1). Insurance allows to perform total laparoscopic hysterectomy (TLH)+bilateral salpingo-oophorectomy (BSO)+pelvic lymphadenectomy, not to perform para-aortic lymphadenectomy. We compared them with 102 patients by laparotomy (LPT) with pelvic lymphadenectomy for endometrial cancer performed 2011-2016 about age, body mass index (BMI), operative time, blood loss, resected lymph nodes, intraoperative and postoperative complications.

Results

Patient characteristics were not significantly different between two groups (median age: 58(39-76) for LPT vs 58(24-78) for LPS, BMI: 23(16-36) vs 28(17-35), respectively). The median operative time was 341 min (225-596), blood loss 12 ml (0-191), resected lymph nodes 45 (18-78) in LPS, and 266 min (163-48), 325 ml (72-1018), 44 (24-82) in LPT. The operative time in LPS was longer (p < 0.01), although blood loss was less than LPT (p < 0.01). And resected lymph nodes were almost equal between the two groups.

The statistic difference on intra and perioperative complications between the two was not significant. (blood transfusion: 6.4% vs 0%, p = 0.08; injuries of other organs: 0% of both groups)

Also, the statistic difference on post-operative complications was not significant as well (surgical site infection: 4.9% vs 0%, p = 0.28; pelvic peritonitis: 6.9% vs 8.7%, p = 0.78; ileus: 0% of both groups).

Conclusion

Laparoscopic surgery with pelvic lymphadenectomy for endometrial cancer was feasible compared with conventional laparotomy.
A PREDICTION MODEL OF SURVIVAL FOR PATIENTS WITH BONE METASTASIS FROM UTERINE CORPUS CANCER
S. Takeshita¹, T. Yukiharu¹, K. Hidenori¹, S. Chisa¹
¹Hokkaido Cancer Center, Gynecology, Sapporo, Japan

Aims

The aim of the study was to establish a predictive model of survival period after bone metastasis from endometrial cancer.

Method

A total of 28 patients with bone metastasis from uterine corpus cancer were included in the study. Data at the time of bone metastasis diagnosis, which included presence of extraskeletal metastasis, performance status, history of any previous radiation/chemotherapy, and the number of bone metastases were collected. Survival data were analyzed using Kaplan–Meier methods and Cox proportional hazards models.

Results

The most common site of bone metastasis was the pelvis (50.0%), followed by lumbar spine (32.1%), thoracic spine (25.0%), and rib bone (17.9%). The median survival period after bone metastasis was 25 weeks. The overall rate of survival after bone metastasis of the entire cohort was 75.0% at 13 weeks, 46.4% at 26 weeks, and 42.9% at 52 weeks. Performance status of 3–4 was confirmed as an independent prognostic factor (HR, 3.5; 95% CI, 1.41–8.70) and multiple bone metastases tended to be associated with poor prognosis (HR, 2.4; 95% CI, 0.95–5.97). A prognostic score was calculated by adding up the number of these two factors. The 26-week survival rates after bone metastasis were 88.9% for those with a score of 0, 45.5% for those with a score of 1, and 0% for those with a score of 2 (p=0.0006).

Conclusion

This scoring system can be used to determine the optimal treatment for patients with bone metastasis from endometrial cancer.
EXPRESSION OF L1CAM IN CURETTAGE AND HIGH L1CAM LEVEL IN PREOPERATIVE BLOOD SAMPLES PREDICTS LYMPH NODE METASTASES AND POOR OUTCOME IN ENDOMETRIAL CANCER PATIENTS

I.L. Tangen¹, R. Kopperud², N. Visser³, A. Staff, S. Tingulstad⁴, J. Marcickiewicz⁵, F. Amant⁶, L. Bjørge⁷, J. Pijnenborg⁸, H. Salvesen¹, H. Werner¹, J. Trovik², C. Krakstad²

⁷Leuven Cancer Institute, Department of Oncology- Gynaecologic Oncology, Leuven, The Netherlands
⁸Radboud University Medical Center, Department of Obstetrics and Gynaecology, Nijmegen, The Netherlands

Aims

Several studies have identified L1CAM as a strong prognostic marker in endometrial cancer. To further underline the clinical usefulness of this biomarker, we here investigated L1CAM as a predictive marker for lymph node metastases and its prognostic impact in curettage specimens and preoperative plasma samples.

Method

Immunohistochemical staining of L1CAM was performed for 1134 curettage specimen from endometrial cancer patients. In addition L1CAM level in preoperative blood samples from 372 patients was determined using ELISA. Association between L1CAM level and clinicopathologic variables including lymph node status and survival was investigated.

Results

Expression of L1CAM in curettage specimen was significantly correlated to L1CAM level in corresponding hysterectomy specimen. Both in curettage specimen and preoperative plasma samples was L1CAM upregulation significantly associated with features of aggressive disease and poor outcome. L1CAM was an independent predictor of lymph node metastases, after correction for curettage histology, both in curettage specimen and plasma samples.

Conclusion

We demonstrate that preoperative evaluation of L1CAM levels, both in curettage or plasma samples, predicts lymph node metastases and adds valuable information on patient prognosis. Our results strongly support the usefulness of L1CAM as a biomarker in endometrial cancer.
MISMATCH REPAIR GENES DEFECT AMONG PATIENTS WITH ENDOMETRIAL CANCER
S. Tangjitgamol1, T. Kittisiam2, S. Tanvanich3
1Faculty Of Medicine Vajira Hospital, OB & Gyn, Bangkok, Thailand
2Faculty of Medicine Vajira Hospital, OB Gyn, Bangkok, Thailand
3Faculty of Medicine Vajira Hospital, Anatomical Pathology, Bangkok, Thailand

Aims
To evaluate the prevalence of mismatch repair genes defect (MMRd) among Thai patients with endometrial cancer (EMC), and its association with clinic-pathologic features.

Method
Formalin fixed paraffin-embedded blocks of EMC tissue from hysterectomy specimens of patients having surgery in our institution between Jan 1, 1995 and December 31, 2016 were assessed for the immunohistochemical expression of 4 MMRproteins (MLH, PMS, MSH2, MSH 6). MMR gene defect was determined by a negative expression of at least 1 protein.

Results
From 301 EMC tissues, the most frequent abnormal (negative) protein expression was MSH6 (40.9%), followed by PMS (36.2%), MLH (35.5%), and MSH2 (16.6%). Overall, 59.1% had negative expression of at least one protein. Except for age ≤ 60 years old which was nearly significant to have MMRd more frequently than age > 60 years, 63.7% vs 36.3% (p=0.052), no other clinic-pathologic features were significantly associated with MMRd. The 5-year cancer-specific survival (CSS) of the patients with MMRd was significantly higher than those without gene defect: 92.7% (95% confidence interval [CI] 88.6%-96.8%) vs 82.7% (95% CI 75.3%-90.1%) (p=0.032).

Conclusion
More than half of Thai EMC patients had MMRd. The patients who aged ≤ 60 years old tended to have higher prevalence of MMRd than older age. Except for the significantly longer CSS of the patients MMRd, no association of MMRd and other clinico-pathologic features were demonstrated.
IDENTIFICATION OF BIOMARKERS TO DIAGNOSE LYMPH NODE METASTASIS BASED ON GENE EXPRESSION PATTERNS IN PRIMARY LESION OF ENDOMETRIAL CARCINOMA

Y. Terao¹, E. Yoshida¹, Y. Ito¹, K. Fujino¹, S. Kusunoki¹, T. Oota¹, M. Itoh¹, H. Kawaji², S. Takeda¹
¹Juntendo University, OBGYN, Bunkyo Hongo, Japan
²Riken Center for Life Science Technologies, Division of Genomic Technologies, Yokohama, Japan

Aims

Discrimination between lymph node metastatic status in endometrial carcinoma before lymphadenectomy would be highly valuable, but no effective methods have been developed. Here, we attempted to identify biomarkers to diagnose lymphatic metastasis based on gene expression patterns in the primary lesion patients with endometrial carcinoma.

Method

We collected endometrial carcinoma tissue from 115 patients. Genome-wide gene expression was analyzed using cap analysis gene expression (CAGE) in 10 lymphatic metastasis-negative (LN-) and five lymphatic metastasis-positive (LN+) cases with G1 endometrial carcinomas with invasion less than or equal to 1/2 myometrial depth. Candidate genes used to distinguish between LN-/LN+ were identified and verified in all 115 samples by quantitative real-time reverse transcription polymerase chain reaction.

Results

Genome-wide screening based on CAGE and targeted examination based on qRT-PCR revealed a significant association of SEMA3D and TACC2 isoforms expressed through a novel promoter, with LN+/LN– status in a low-risk group. SEMA3D and TACC2 isoform were highly expressed in LN– (p <0.001) and LN+ (p <0.05) respectively. The difference in their expression levels was effective in discriminating between LN+/LN– status (AUC = 0.929).

Conclusion

SEMA3D and a novel TACC2 were identified as biomarkers to evaluate lymphatic metastasis in endometrial carcinoma. These biomarkers can diagnose lymphatic metastasis based on gene expression patterns in the primary lesion without so much as requiring Sentinel lymph node biopsy. Our findings pave the way for support clinical decisions that minimize irrelevant lymphadenectomy.

EXPRESSION OF THE PUTATIVE CANNABINOID RECEPTOR GPR55 IS INCREASED IN ENDOMETRIAL CARCINOMA
T. Ayakannu1,2, T. Anthony2, J. Chatterjee1, P. Ellis1, A. Tailor1, Q. Davies4, M. Esther4, S. Butler-Manuel1, J. Konje2,5
1University of Surrey - Royal Surrey County Hospital, Guildford Gynaecology Oncology Research Department, Guildford, United Kingdom
2University of Leicester, Endocannabinoid Research Group - Reproductive Sciences Section- Department of Cancer Studies and Molecular Medicine, Leicester, United Kingdom
3University of Leicester, Endocannabinoid Research Group - Reproductive Sciences Section- Department of Cancer Studies and Molecular Medicine, Leicester, United Kingdom
4University of Leicester, Department of Gynaecology Oncology, Leicester, United Kingdom
5Sidra Medical and Research Centre, Department of Obstetrics and Gynaecology, Doha - Qatar, Qatar

Aims

The GPR55 receptor is a potential key player in malignant transformation involving human tumours. Aim of this study was to evaluate GPR55 expression in endometrial carcinoma (EC).

Method

A total of 27 endometrial biopsies (21 ECs (15 type 1, six type 2)) and six normal age-matched controls atrophic endometrium were recruited. Samples were divided into two: one for this study and one for histological confirmation of diagnosis. GPR55 transcript levels were measured using Taqman multiplex qRT-PCR. Immunohistochemistry was performed using commercially available GPR55 antibodies. Statistical testing was performed using one-way ANOVA followed by Dunn’s ad hoc post-test or Mann-Whitney U-test.

Results

GPR55 transcript levels were significantly raised (p<0.0020) in the EC when compared with atrophic tissues. Sub-analyses revealed that GPR55 transcript level in patients with type 1 disease were significantly elevated compared to control patients (p<0.0007), but were not elevated in patients with type 2 disease (p< 0.1320). Furthermore, GPR55 transcript levels in patients with grade 1 and 2 EC type 1 were statistically significantly elevated (p<0.01) and (p<0.05), respectively, but not in grade 3 type 1 EC and type 2 (serous and carcinosarcoma) samples. IHC showed GPR55 immunoreactivity to be markedly increased in EC samples compared to atrophic endometrium, with differential staining intensities; atrophic< type 2 < type 1 EC, mirroring the transcript levels.

Conclusion

This study demonstrates that, GPR55 expression is elevated in EC and may play a role in the aetiopathogenesis of EC. GPR55 could be an invaluable as a diagnostic tool and a potential therapeutic target.

PRIMARY ENDOMETRIAL YOLK SAC TUMOURS

W.A.A. Tjalma¹, K. Watty², H. Marianne³, M. Huizing¹
¹Antwerp University Hospital, Multidisciplinary Breast Clinic - Unit Gynecological Oncology, Antwerp, Belgium
²AZ Delta, Multidisciplinary Breast Clinic Roeselare - Unit Gynecological Oncology, Roeselare, Belgium
³Sint Jozef Clinic, Multidisciplinary Breast Clinic Izegem - Unit Gynecological Oncology, Izegem, Belgium

Aims

Primary endometrial yolk sac tumours (EYSTs) are extremely rare. They can be divided in a pure and in mixed forms. Current presentation will discuss the outcome of the different EYSTs.

Method

A literature search was performed regarding EYSTs until May 1st, 2017. All published cases in the English literature were reviewed and an additional case recently seen at the University Hospital Antwerp was added.

Results

In total 26 EYSTs were identified (13 Pure forms and 13 mixed forms). The associated or mixed forms consisted of 4 adenocarcinomas, 2 serous adenocarcinomas, 2 carcinocarcomas, 1 endometrioid adenocarcinoma, 1 serous and endometrioid adenocarcinoma, 1 complex hyperplasia, 1 undifferentiated and endometrioid adenocarcinoma, and 1 undifferentiated, clear cell and serous adenocarcinoma. Of the pure type 64 % were premenopausal and of the mixed type 93 % are postmenopausal. The follow-up status for pure vs. mixed EYSTs for NED is 7 vs.1; for AWD 1 vs. 7 and for DOD 4 vs.3 and LTF 1 vs.1. The mean follow-up time for the pure EYSTs is 20 months and for the mixed EYSTs is 15 months.

Conclusion

The outcome between the pure and the mixed forms of EYSTs differs significantly. The poor outcome in mixed forms is likely to reflect therapy resistance.

IMPLICATIONS OF PARA-AORTIC LYMPH NODE METASTASIS IN PATIENTS WITH ENDOMETRIAL CANCER WITHOUT PELVIC LYMPH NODE METASTASIS

Y. Todo1, H. Yamazaki1, C. Shimada1, S. Takeshita1, H. Kato1

1Hokkaido Cancer Center, Gynecologic Oncology, Sapporo, Japan

Aims

The aim of this study was to confirm the incidence and implications of a lymphatic spread pattern involving para-aortic lymph node (PAN) metastasis in the absence of pelvic lymph node (PLN) metastasis in patients with endometrial cancer.

Method

We carried out a retrospective chart review of 754 patients with endometrial cancer treated by surgery at Hokkaido Cancer Center between 2003 and 2016. Of these patients, 380 (50.4%) who underwent PLN dissection and PAN dissection were reviewed retrospectively. We determined the probability of PAN metastasis in patients without PLN metastasis and investigated survival outcomes of PLN−PAN+ patients.

Results

The median numbers of PLN and PAN removed at surgery were 41 (range: 11–107) and 16 (range 1–65), respectively. Sixty-four patients (16.8%) had lymph node metastasis, including 39 (10.3%) with PAN metastasis. The most frequent lymphatic spread pattern was PLN+PAN+ (7.9%), followed by PLN+PAN− (6.6%), and PLN−PAN+ (2.4%). The probability of PAN metastasis in patients without PLN metastasis was 2.8% (9/325). The 5-year overall survival rates were 96.5% in PLN−PAN−, 77.6% in PLN+PAN−, 63.4% in PLN+PAN+, and 53.6% in PLN−PAN+ patients.

Conclusion

The likelihood of PAN metastasis in endometrial cancer patients without PLN metastasis is not negligible, and the prognosis of PLN−PAN+ is likely to be poor. The implications of a PLN−PAN+ lymphatic spread pattern should thus be taken into consideration when determining patient management strategies.

BREAST LOBULAR CARCINOMA INVOLVING TAMOXIFEN-ASSOCIATED ENDOMETRIAL METASTATIC CARCINOMA: CASE REPORT

I. Todorovska1, M. Todorovska2, A. Petrić3, R. Živadinović3, P. Vukomanović3, D. Krtsić4

1Clinic of oncology- Clinical center Nis, Gynecological oncology, Nis, Serbia
2Medical Faculty- University of Nis, Department of Pharmacy, Nis, Serbia
3Clinic of gynecology- Clinical center Nis, Clinic of gynecology, Nis, Serbia
4Clinic of oncology- Clinical center Nis, Clinical pharmacology, Nis, Serbia

Aims

Tamoxifen is a nonsteroidal triphenylethyl compound that is widely used as adjuvant therapy in the treatment of breast cancer. Tamoxifen prolongs overall and disease-free survival and reduces the likelihood of disease in the contralateral breast. The efficacy of tamoxifen is due to its anti-estrogenic properties. However, tamoxifen may also exert a weak estrogenic effect, resulting in a variety of endometrial proliferative lesions, including hyperplasia, polyps and adenocarcinomas. The aim of this work was to present an endometrial metastatic carcinoma case, having in mind that metastases to the endometrium from outside the female genital tract are rare.

Method

Diagnosis was made by positive immunohistochemical staining with the cytokeratin epithelial marker and estrogen-receptor and progesterone-receptor of the endometrial cells being positive.

Results

A 66-year-old multigravid woman with a history of lobular breast carcinoma who has already been on tamoxifen therapy for 4 years, presented with abnormal uterine bleeding. Histopathologic study of the endometrial curettage revealed malignant cells which did not correspond to a primary carcinoma of the endometrium. Comparative micromorphological and immunohistochemical analyses showed it was metastatic endometrial carcinoma originated from breast cancer. A complete clinical workup ruled out metastatic spread to the brain, lungs, skeleton, or abdomen. A total abdominal hysterectomy, bilateral salpingo-oophorectomy, and pelvic lymph node sampling were performed. Final pathology examination revealed primary breast carcinoma limited to the endometrium.

Conclusion

Abnormal uterine bleeding in patients with a history of malignancy should always alert the physician to consider the diagnosis of metastatic spread to the genital tract.
GLASSY CELL CARCINOMA OF THE ENDOMETRIUM: A CASE REPORT
I. Mamić¹, I. Alvir¹, L. Šušnjar¹, D. Danolić¹, M. Perić-Balja², D. Tomica³, M. Puljiz¹
¹University Hospital Centre Sestre Milosrdnice-University Hospital for Tumors, Department of Gynecologic Oncology, Zagreb, Croatia
²University Hospital for Tumors- Clinical Hospital Centre „Sestre Milosrdnice”-, Department of Oncological Pathology, Zagreb, Croatia
³General Hospital Scheibbs, Department of Gynecology and Obstetrics, Scheibbs, Austria

Aims

We present a case of 65-year old patient with glassy cell carcinoma of the endometrium, which is a rare neoplasm. To our knowledge, there are 14 previously cases reported in the literature. Microscopically, it is composed of malignant cells showing a "ground glass" cytoplasm, large nuclei with prominent nucleoli and distinct cell membranes. Nature of glassy cell carcinoma is still debatable, for now it is considered to be a poorly differentiated variant of adenosquamous carcinoma.

Method

A 65-year-old patient with ultrasonically found thickened endometrium underwent hysteroscopy. Histologically the tumor showed polyloid solid mass of epithelial cells with ground glass cytoplasm and large nuclei with prominent nucleoli. Immunohistochemical analysis confirmed diagnosis of glassy cell carcinoma of the endometrium. The patient underwent bilateral salpingo-oophorectomy, total abdominal hysterectomy and radiation therapy.

Results

She is alive, with no evidence of disease for 14 months after diagnosis.

Conclusion

There are no specific recommendations about treatment of this rare disease. Detailed analysis of more cases is required to evaluate the nature of glassy cell carcinoma and to determine accurate prognosis for this infrequent entity.
IMPACT OF COEXISTENT ADENOMYOSIS IN ENDOMETRIOD ENDOMETRIAL CANCER: A PROPENSITY SCORE–MATCHED ANALYSIS

⁴Akdeniz University School of Medicine, Department of Gynecopathology, Antalya, Turkey

Aims

We sought to compare outcomes of patients with endometrioid type endometrial cancer (EC) with or without adenomyosis.

Method

A total of 314 patients with endometrioid type EC were included in the analysis. Patients were divided into two groups according to the presence or absence of adenomyosis. Adenomyosis was identified in 79 patients (25.1%). A propensity score–matched comparison (1:1) was carried out to minimize selection biases. The propensity score was developed through multivariable logistic regression model including age, stage, and tumor grade as covariates. After performing propensity score matching, 70 patients from each group were successfully matched. Primary outcome of the study was disease–free survival (DFS), and the secondary outcomes were overall survival (OS) and disease–specific survival (DSS).
Results

Median follow-up time was 61 months for adenomyosis positive group, and 76 months for adenomyosis negative group. There were no statistically significant differences both in three– and five–year DFS, OS, and DSS rates between the two groups. Five–year DFS was 92% vs 88% (HR, 1.54; 95% CI, 0.56–4.27; P = 0.404), five–year OS was 94% vs 92% (HR, 1.60; 95% CI, 0.49–5.26; P = 0.441), and five–year DSS was 94% vs 96% (HR, 2.51; 95% CI, 0.46–13.71; P = 0.290) for patients with and without adenomyosis, respectively.

Conclusion

Coexistent adenomyosis in endometrioid type EC is associated with similar disease outcomes in comparison with adenomyosis negative tumors.
ENDOMETRIAL CANCER

ESGO7-1262

NEW ASPECTS IN PREVENTION AND EARLY DIAGNOSTIC OF ENDOMETRIAL CANCER IN A FIRST-DEGREE RELATIVES FROM FAMILIES WITH LYNCH SYNDROME.

I. Tripac

1Institute of Oncology, Gynaecology, Chisinau, Moldova

Aims

Accumulation of malignant neoplasms in families with Lynch syndrome, creates the need for screening for the early diagnosis and prevention of hereditary cancer.

Prevention and early diagnosis of endometrial cancer in families with high cancer risk will reduce the incidence and mortality of women with hereditary predisposition to endometrial cancer.

Method

Material and methods: We retrospectively followed 361 women who we were recruited to the National Register of Cancer Families between 2007-2013, including data on 145 families of probands with endometrial cancer (38 cases), ovarian cancer (36), colorectal cancer (CRC) (31 cases), Breast cancer (20 cases) and multiple primary malignant neoplasms (MPMN) (20 cases). As the control, the age-adjusted population frequencies of endometrial cancer were used. The work used clinical, instrumental and laboratory methods of investigation.

Results

Results: A total of 18 endometrial cancer cases with a frequency of 4.9 ± 1.14% were observed. Compared with women without family history, we found an increased risk of endometrial cancer for women from families with Lynch syndrome, which exceeds the population frequency by 490 times. The peak of the maximum incidence of women with endometrial cancer falls at the age of 45-52 years, while the peak incidence of EC in probands falls on the older age of 59-62 years.

Conclusion

Conclusions: A high percentage of accumulation of malignant pathology, including EC, among women from families with Lynch syndrome, underlines the necessary of screening for the early diagnosis and prevention of cancer in these families.
AN UNUSUAL CASE OF ISOLATED PULMONARY RECURRENT IN EARLY STAGE ENDOMETRIOID ENDOMETRIAL CARCINOMA EIGHT YEARS AFTER INITIAL DIAGNOSIS AND TREATMENT

B. Trivedi, S. Biswas
Kettering General Hospital, Obstetrics and Gynaecology, Kettering, United Kingdom

Aims

To present an interesting case of a 71 year old patient diagnosed with isolated pulmonary recurrence eight years after initial diagnosis and treatment of early stage endometrioid endometrial carcinoma.

Method

A 71 year old patient was initially referred with post-menopausal bleeding. Following an ultrasound scan showing suspicious features, she underwent a hysteroscopy and endometrial biopsy confirming endometrial cancer. Staging CT and MRI pelvis suggested more than 50% myometrial invasion but no other disease spread. After discussion within Gynaecology Multi-Disciplinary Team, she underwent a total abdominal hysterectomy and bilateral salpingo-oophorectomy. There was no other pelvic, abdominal or para-aortic disease at laparotomy. Histology from operative specimen confirmed this to be a Grade 1 Stage 1C (2008 FIGO Classification) endometrioid carcinoma which is equivalent to Stage 1B as per the revised 2009 FIGO staging. She was subsequently treated with brachytherapy and external beam radiotherapy.

Results

The patient continued to be followed up in secondary care beyond five years as she felt reassured by normal clinical examination. In the eighth year of follow up she reported generalised abdominal pain and a CT chest and abdomen revealed suspicious lung nodules which on subsequent biopsy were surprisingly confirmed to be recurrence of endometrial cancer.

Conclusion

Pulmonary recurrence is usually associated with advanced stage, high risk disease. There are no other reported cases in the literature describing solitary pulmonary recurrence of Grade 1 Stage 1B endometrial cancer. It is vital in this group of patients to investigate any unusual symptoms appropriately with a high index of suspicion during follow up.
Aims

To study the survival of uterus leiomyosarcomas

Method

We conducted retrospective analysis of 23 cases with uterine sarcoma for the period from 2009 to 2015. The most characteristic symptoms were abdominal pain 15 (65.2%), bleeding in postmenopausal women 12 (52.1%), menorrhagia 13 (56.2%) and the rapid growth of the uterus 17 (73.9%), every fourth patient with sarcoma uterus size corresponded to 20 weeks of gestation or more.

Results

We have studied the long-term results of treatment of 12 patients, whom were performed improperly supravaginal uterus amputation in non-specialized hospitals over alleged uterine fibroids. Later on 8 of 12 patients (group 1) - received chemo radiotherapy and were followed up, and in 4 of 12 them (group 2) an average of up to 3 months after non-radical surgery was performed second operation - extirpation of the cervical stump, followed by chemo radiotherapy. Of the 4 patients in the second group only in a patient there found lung metastases after the 7 years later, 3 others are alive and there are no recurrences. While those 8 patients in the first group had metastases in the period of from 2 to 6 years. When comparing the survival - after non-radical surgery patients operated radically found big difference in the survival of these patients, which amounted to 12.5% and 75%.

Conclusion

It should be noted that the most characteristic relapses within small pelvis in patients with uterus leiomyosarcoma, whereas for other morphological forms of malignant non-epithelial and mixed uterus tumors - development of distant metastases.
PROGNOSTIC BENEFIT OF POLE EXONUCLEASE DOMAIN MUTATIONS IN ENDOMETRIAL CANCER CANNOT BE EXPLAINED BY INCREASED SENSITIVITY TO ADJUVANT TREATMENT STRATEGIES

I.C. Van Gool¹, E. Rayner², E.M. Osse¹, I.P.M. Tomlinson², V.T.H.B.M. Smit¹, C.L. Creutzberg³, D.N. Church², N. de Wind⁴, T. Bosse¹, M. Drost⁴

¹Leiden University Medical Center, Pathology, Leiden, The Netherlands
²The Wellcome Trust Centre for Human Genetics, Molecular and Population Genetics Laboratory, Oxford, United Kingdom
³Leiden University Medical Center, Clinical and Radiation Oncology, Leiden, The Netherlands
⁴Leiden University Medical Center, Human Genetics, Leiden, The Netherlands

Aims

POLE exonuclease domain-mutant (EDM) endometrial cancers (ECs) have an excellent clinical outcome. To reduce overtreatment, minimization of adjuvant treatment has been proposed in early-stage POLE-mutant EC. However, studies showing prognostic significance of these mutations failed to conclude its independence of adjuvant therapy. Therefore, we tested treatment sensitivities of POLE EDMs in a model system.

Method

Three somatic POLE exonuclease domain hotspot mutations were generated in mouse embryonic stem cells using CRISPR/Cas9. Spontaneous mutation frequencies and spectra were determined through Hprt assays. Cells were treated with ionizing radiation or chemotherapeutic agents including nucleoside analogs. IC50s were calculated and compared between isogenic wild type and POLE EDM cell lines.

Results

Similarly to POLE-mutant ECs, POLE EDMs resulted in a mutator phenotype in mouse embryonic stem cells (~8–30x higher mutation frequency compared to wild type). POLE EDM cells did not show increased sensitivity to ionizing radiation ($P=0.8281$) or to chemotherapeutic agents (cisplatin, 5-FU, paclitaxel, doxorubicin, methotrexate and etoposide; $P=0.1091$–$0.9960$) compared to wild type cells. In contrast, POLE EDM cells displayed hypersensitivity to nucleoside analogs cytarabine and fludarabine (IC50 2.6 vs 6.5 μM, $P=0.0386$; IC50 18.0 vs 74.9 μM; $P=0.0002$, respectively).

Conclusion

Based on this study, hypersensitivity to currently used adjuvant treatments cannot explain the good prognosis of POLE-mutant (endometrial) cancers. These results support ongoing efforts to explore minimization of adjuvant therapy for early-stage POLE EDM ECs. Moreover, this study proposes nucleoside analogs as most effective chemotherapeutic agents for advanced-stage POLE-mutant cancers, which should be subject of further studies.
ENDOMETRIAL CANCER

THE IMPACT OF GRADE IN ENDOMETRIOID ENDOMETRIAL CANCER INVADING CERVICAL STROMA AFTER HYSSTERECTOMY AND BSO.

L. van Lonkhuijzen1, C. Mom1, R. Charles1, G. Fons1, M. Buist1, M. Tjong1, G. Kenter1, J. van der Velden1

1Center for Gynecologic Oncology Amsterdam CGOA- location AMC, Gynaeologic Oncology, Amsterdam, The Netherlands

Aims

To determine the impact of grade on recurrence pattern and survival in endometrial cancer patients with cervical stromal invasion and to analyze the literature to determine the spread pattern, risk on and pattern of recurrence in the same group with grade 1.

Method

A retrospective study was performed where 97 consecutive patients, treated by hysterectomy/BSO and adjuvant radiotherapy (RT) were analyzed with respect to age, grade, type of (adjuvant) treatment, presence of extra uterine disease and outcome. Literature studies, where it was possible to separately analyze grade 1 tumors, were analyzed regarding extra uterine disease, recurrence pattern and survival in relation to type of (adjuvant) treatment.

Results

34 patients (34.7%) had grade 1, 39 (40.3%) grade 2 and 24 (24.0%) grade 3. Extra uterine disease was found in 17%, 38% and 46% of grade 1, 2 and 3 patients respectively. Overall survival was significantly better in grade 1 versus grade 2, 3 patients (82.7% vs 63.2%, p=0.027). Only 1 patient with grade 1 died from disease. One study from literature was found, reporting specifically on 20 grade 1 tumors where only 1 recurrence was reported.

Conclusion

Grade 1 patients with endometrial cancer and cervical stromal invasion have an excellent prognosis. It is debatable if complete staging and/or adjuvant treatment, especially pelvic RT, results in a better outcome for this subgroup. Because all patients had adjuvant RT the role of staging and adjuvant RT remains unclear. The scarce literature confirms the excellent prognosis of the grade 1 subgroup but more detailed data are needed.
Aims

Endometrial cancer is the most common gynecologic cancer and the seven leading cause of cancer death in women of the developed countries. In Oaxaca, Mexico represents the third cause of gynec-oncology in 2003, 1731 new cases and 242 deaths were reported.

Method

Objective To present 14 consecutive cases of minimally invasive surgery for endometrial cancer, making a historical comparison with the procedures opened in the surgical oncology service of the Regional Hospital of High Specialty of Oaxaca.

Results

We report 14 consecutive cases, with a mean age of 49.09 years, Weight of 65.09 kg, Height of 1.48 m, BMI of 28.7 kg/m², Uterus size 9.8 cm, surgical time 210 minutes and 2.1 days of hospital stay, 7 cases low risk, 4 cases high risk and 3 intermediate risk, 100% of cases were endometrioid histology, 13 pelvic lymph nodes of rate, 210 ml of bleeding, 1 case of conversion secondary to uterus perforation. 1 case of bowel obstruction at 2 weeks resolved without surgery. A follow up of one year at least, 0% of major complications and mortality.

Conclusion

Laparoscopic surgery for endometrial cancer is safe and feasible with 0% of mortality, 0% of major complications and with comparable oncological results to open surgery.

VALUE OF SENTINEL NODE BIOPSY IN LOW-RISK ENDOMETRIOID CARCINOMA

O. Vazquez¹, O. Aristegui¹, A. Bombin¹, R. Ruiz¹, K.E. Goiri¹, J. Aguerre¹, M. Gorostidi¹, I. Jaunarena¹, A. Lekuona¹
¹H.U.Donostia, Ginecología y Obstetricia, San Sebastian, Spain

Aims

To analyze Sentinel Lymph Node (SLN) biopsy in low-risk endometrioid carcinoma (EC).

Method

42 patients with low-risk EC (< 50% miometrial infiltration, grade I-II and without risk factors) underwent laparoscopic surgery at our institution. Laparoscopic hysterectomy with bilateral adnexectomy and SLN biopsy were performed. We injected Indocyanine Green (ICG) into the cervix and uterine fundus. Then, we located and biopsied fluorescent nodes, first in the paraaortic area and later in the pelvis. All SLN were processed with an ultrastaging technique.

Results

The overall SLN detection rate was 95.2% (40/42) with a 57% (24/42) detection rate in the paraaortic area. In the pelvic area there were 5 cases of right side SLN detection, 3 cases with left side detection and 32 cases with bilateral detection (72%). In 3 cases presacral SLN were detected. Ultrastaging revealed 2 cases of micrometastasis (5%).

Conclusion

SLN biopsy can help detect lymph node metastasis in low-risk patients without increasing morbidity. 5% of the women in the low-risk group had affected lymph nodes, which would not have been detected without the SLN technique and ultrastaging. Low-risk EC has a good prognosis, but some relapses occur. We need more patient series to determine the prognostic value of lymphatic microdisease and the need for adjuvant therapies in these patients.

SENTINEL NODE BIOPSY IN ENDOMETRIAL CANCER WITH CERVICAL AND FUNDAL ICG INJECTION
1H.U.Donostia, Ginecología y Obstetricia, San Sebastián, Spain

Aims

To describe a novel sentinel lymph node (SN) tracer injection procedure featuring cervical and fundal green indocyanine (ICG) injection for endometrial cancer.

Method

Between June 26th 2014 and October 31st 2016, 111 patients underwent laparoscopic surgery for endometrial cancer at our Institution. In all cases SN biopsy with dual cervical and fundal ICG injection was performed. All SLN were processed with an ultrastaging technique. 69 patients also underwent total pelvic and paraaortic lymphadenectomy.

Results

The overall SN detection rate was 92.79% (103/111). The overall pelvic SN detection rate was 89.19% (99/111) and the bilateral pelvic SN detection rate was 61.26% (68/111). Paraaortic SN were detected in 59.46% (66/111). Isolated paraaortic SN detection was 4% (4/111). We found macroscopic Lymph Node metastases (LN) 11 patients (9.9%). In another 10 patients microdisease was present in LNs, raising global LN affectation to 18.92. There were 1 false negative case in wich SN was negative with a positive aortic lymphadenectomy, and another positive case in lymphadenectomy in wich was not detected the SN. The S was 94.44%, E 100%, VPN 97.83% and LHR(-) 0.06.
Conclusion

SLN biopsy with cervical and fundal ICG injection offers good overall detection rates and provides an improved mapping of the aortic area. SN ultrastaging increases the number of positive nodes.

IMPROVING USAGE AND ADHERENCE BY CONVERTING THE ENDOMETRIAL CANCER GUIDELINE INTO DECISION TREES

M. van der Aa1, S. Verboort2, M. Timmermans3, M. Sieswerda4, W. van Driel5, D. Bolf6, X. Verbeek6

1IKNL, Research, Enschede, The Netherlands
2IKNL, Oncology, Maastricht, The Netherlands
3IKNL, Research, Rotterdam, The Netherlands
4IKNL, ICT, Utrecht, The Netherlands
5NKI-AVL, Gynecologic Oncology, Amsterdam, The Netherlands
6Catharinaziekenhuis Eindhoven, Gynecologic Oncology, Eindhoven, The Netherlands

Aims

Oncological guidelines are often large documents with a huge amount of information on diagnostic procedures and treatment options. Due to this amount of information, inconsistencies are common and the recommendations in the guidelines are difficult to find. When new information based on relevant clinical trials becomes available it is difficult to implement this in these guidelines. Representing guidelines as decision trees is a way to overcome these hurdles. The aim of our study is to examine the feasibility of converting the Dutch multidisciplinary endometrial cancer guideline recommendations into easily accessible decision trees to facilitate guideline usage in daily practice.

Method

We converted the most recent Dutch endometrial cancer guideline into data driven decision trees using a structured method where nodes represent data-items and leaves represent recommendations and/or references to other decision trees.

Results

In total we developed 23 decision trees (www.oncoguide.nl). Currently, the decision trees are updated by professionals involved in treating patients with endometrial cancer. Furthermore, we identified information gaps which we can use in designing new trials and we were able to standardize terminology throughout the recommendations.

Conclusion

Converting guidelines into decision trees is feasible but also challenging. With the decision trees it is now possible to: 1) decide on treatment options easily in daily clinical practice, 2) use this information for shared decision making with the patient, 3) substantiate, document and/or evaluate a treatment advice, 4) use information for discussion at a multidisciplinary tumour board and 5) identify information gaps for which clinical trials could be developed.
TUMORAL SIZE AS A PROGNOSTIC FACTOR IN ENDOMETRIAL CANCER
C. Villalain Gonzalez1, C. Martinez Biosques1, G. Lopez Gozalez2, J.S. Jimenez Lopez2, A. Tejerizo Garcia2, M.D.L.R. Oliver Perez2
1Hospital Universitario 12 de octubre, Ginecología y Obstetricia, Madrid, Spain
2Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecologic Oncology and Endoscopy Unit, Madrid, Spain

Aims
On this study we aimed to evaluate the impact of tumoral size ≥20mm on overall survival (OS) and recurrence-free survival (RFS) in patients diagnosed of endometrial cancer

Method
We reviewed 327 consecutive cases of endometrial malignancies diagnosed and treated at our institution between 1/1/2001 and 31/12/2014 with follow-up until January 2016. Patients received as primary treatment hysterectomy and double adnexectomy and on cases of intermediate to advanced risk (ESGO criteria), pelvic and para-aortic lymphadenectomy and/or adjuvant therapy was performed. A univariate Cox regression analysis was established to study both OS and RFS.

Results
A univariate Cox regression analysis showed that tumors of ≥20mm were 1.63 to 7.98 more likely to relapse than those smaller (p<0.01). Relapse rate for those sized ≥20m was of 30.6% vs 11.1% on the smaller ones. OS were, respectively 69.4% and 88.9%, being these differences statistically significant (p<0.01).

Patients with tumors ≥20mm were 2.82 to 14.55 times more likely to die than those with smaller ones (p<0.01). Mortality rate was statistically significantly higher on patients with tumors ≥20mm, 29.9% vs. 3.2% (p<0.01) and OS was of 70.1% and 96.8% respectively.

Conclusion
Although tumoral size as a prognostic factor in endometrial cancer is still a controversial subject, there are many authors that still find associations with it and risk of lymph node invasion, RFS and OS. A tumoral size of ≥20 mm implies a negative prognostic factor diminishing RFS and OS on patients with a diagnosis of endometrial carcinoma and perhaps should be taken into account when considering adjuvant treatment.
ENDOMETRIAL CANCER

ESGO7-1152

LOWER UTERINE SEGMENT INVOLVEMENT AS A PROGNOSTIC FACTOR ON ENDOMETRIAL CANCER
C. Villalain González1, C. Biosques Martínez2, C. Bárcena García2, J.S. Jiménez López3, Á. Tejerizo García4, M.D.L.R. Oliver Pérez5
1Hospital Universitario 12 de Octubre, Obstetrics and Gynecology Department, Madrid, Spain
2Hospital Universitario 12 de octubre, Pathology Department, Madrid, Spain
3Hospital Regional Universitario Carlos Haya Málaga, Obstetrics and Gynecology: Chief Of Service, Malaga, Spain
4Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecologic Oncology and Endoscopy, Madrid, Spain
5Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecological Oncology and Endoscopy, Madrid, Spain

Aims

To evaluate the impact of the low uterine segment on both overall survival (OS) and recurrence-free survival (RFS) on patients diagnosed of endometrial cancer

Method

We reviewed 327 consecutive cases of endometrial malignancies diagnosed and treated at our institution between 1/1/2001 and 31/12/2014 with follow-up until January 2016. Patients received as primary treatment hysterectomy and double adnexectomy and on cases of intermediate to advanced risk (ESGO criteria), pelvic and para-aortic lymphadenectomy and/or adjuvant therapy was performed. A univariate Cox regression analysis was established to study both OS and RFS.

Results

87 patients presented with low uterine segment involvement (LUS). A univariate Cox regression model showed that tumors with LUS were 1.47 to 3.76 times more likely to relapse than those without it (p=0.01). Relapse rate for those with LUS was of 34.9% vs 18.6% on the rest of the study population.

RFS were, respectively 65.1% and 81.4%, being these differences statistically significant (p<0.01). Patients with LUS involvement were 1.52 to 4.10 times more likely to die than those without it (p<0.01). Mortality rate was statistically significantly higher on patients with LUS involvement 32.5% vs. 17.3% (p<0.01) and OS was of 67.5% and 82.7% respectively.

Conclusion

Although LUS has not been deeply studied on literature, it was been associated with lymphovascular invasion, RFS and OS. According to our study, LUS is a negative prognostic factor on both RFS and OS on endometrial cancer. Further studies are needed to evaluate its implications on treatment and prognosis on patients diagnosed of endometrial cancer.

2Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecologic Oncology and Endoscopy, Madrid, Spain
3Hospital Universitario 12 de octubre, Pathology Department, Madrid, Spain

Aims

To determine accuracy of preoperative endometrial sampling guided by histeroscopy.

Method

We reviewed 327 consecutive cases of endometrial malignancies treated at our institution between 1/1/2001 and 31/12/2014. Histology and tumoral grade were compared on preoperative and final reports. Cases where preoperative biopsy was not recorded or tumoral grade not informed were excluded.

Results

Histological and FIGO tumoral grade on preoperative and final reports are shown on Table 1 and 2 respectively.

Concordance on histology was found on 80.2%(256/319) of cases. On tumoral grade it was of 60.8%(144/237) and on 31.6%(75/237) an upgrade was observed on the final report. Global grade-histology concordance between preoperative and postoperative report was of 60.8%(144/237).
Conclusion

Hysteroscopy is still the gold standard technique for preoperative endometrial sampling although it isn’t exempt from inaccuracy on diagnosis.
A CHINESE MULTI-CENTRIC RESEARCH ON FERTILITY-SPARING THERAPY OF ENDOMETRIAL CANCER AND COMPLEX ATYPICAL HYPERPLASIA

Y. Wang¹, R. Zhou¹, J. Wang¹
¹Peking University People’s Hospital, Department of Obstetrics and Gynecology, Beijing, China

Aims
This multi-centric retrospective cohort study aims to provide experience for fertility-sparing therapy of endometrial cancer (EC) and complex atypical hyperplasia (CAH).

Method
Patients ≤40, diagnosed with IA (confined to endometrium) G1EC and CAH, plus ER and PgR positive were enrolled and treated according to procedure.

Results
Totally 15 national hospitals 68 patients were enrolled including 37 EC and 31 CA. (1) Oncologic and fertility outcome: Complete remission (CR) rate is 94%. With treatment time prolonged to 12, 15 and 18 months, CR rate increases to 85%, 91% and 94%. Pregnant rate is 46.9% and live birth rate is 40.6%. (2) Recurrence and retreatment: After median follow-up of 48 months, fifteen patients relapse (25.4%). Secondary CR rate is 79%, with the similar CR time as primary treatment (34 vs. 26 weeks, P=0.604). Secondary relapse rate is 30% after 48 months’ follow up. (3) Analysis of correlated factors: EC (compared to CAH, RR0.23, P=0.015), complicated with diabetes (RR0.06, P=0.017), BMI≥25kg/m² (RR0.31, P=0.049) are risk factors of CR failure at 6-months treatment. Multivariate analysis shows maintenance therapy significantly decrease recurrence rate (OR0.08, P=0.019). GnRHa combined with progesterone as second-line therapy when mono-agent reacts poorly seems decrease recurrence rate (OR0.013, P=0.143). Assisted reproductive benefits pregnancy rate (54.4% vs. 15.6%, P=0.018).

Conclusion
Fertility-preserving therapy for young IAG1 EC and CAH has high CR rate although is easy to relapse. Retreatment has the similar response as primary treatment. Simultaneous GnRHa could be considered as second-line therapy. We recommend maintenance therapy after CR and consider ART to promote conception.

PREOPERATIVE IMAGING MARKERS AND PDZ-BINDING KINASE TISSUE EXPRESSION PREDICT LOW-RISK DISEASE IN ENDOMETRIAL HYPERPLASIAS AND LOW GRADE CANCERS

A. Berg¹, I.L. Tangen¹, K. Woie², L. Bjorge¹, H.M.J. Werner¹, I.S. Haldorsen³, C. Krakstad¹
¹University of Bergen, Departement of Clinical Science, Bergen, Norway
²Haukeland University Hospital, Department of Gynecology and Obstetrics, Bergen, Norway
³University of Bergen, Departement of Clinical Medicine, Bergen, Norway

Aims

Distinguishing complex atypical hyperplasia (CAH) from grade 1 endometrioid endometrial cancer (EECG1) has clinical value, particularly in patients who wish to preserve their fertility or in patients with increased risk of perioperative complications due to obesity or co-morbidities. Surgical overtreatment of patients with CAH seems to exist, and this study search to identify imaging and tissue biomarkers to individualize treatment strategies.

Method

Clinicopathological data was available for 277 patients with CAH and EECG1. Preoperative histological diagnosis and radiological evaluation were compared with final histological diagnosis. Imaging characteristics by preoperative magnetic resonance imaging (MRI) and fluorodeoxyglucose positron emission tomography/computer tomography (FDG-PET/CT) were compared with tumor DNA oligonucleotide microarray data, immunohistochemistry findings and clinicopathological annotations.

Results

MRI assessed tumor volume was higher in EECG1 than in CAH (p=0.004) whereas apparent diffusion coefficient value was lower in EECG1 (p=0.005). EECG1 had increased metabolism with higher maximum and mean standard uptake values than CAH (p≤0.002). Unsupervised clustering of EECG1 and CAH revealed differentially expressed genes within the clusters, and identified PDZ-binding kinase (PBK) as a potential marker for selecting endometrial lesions with less aggressive biological behavior.

Conclusion

Both PBK expression and preoperative imaging markers at MRI and PET/CT are promising biomarkers that may aid in the differentiation between suspected EECG1 and CAH preoperatively. These biomarkers should be explored in larger patient series to define the potential role of these markers to accurately identify CAH patients having low risk of concomitant cancer or cancer progression, where conservative treatment might be the preferred treatment.
BUNDLED STRATEGY FOR SENTINEL LYMPH NODE DETECTION IN ENDOMETRIAL CANCER USING FLUORESCENT IMAGING: A PILOT STUDY

Y.B. Won1, J.W. Kim1, K.J. Eoh1, J.Y. Lee1, E.J. Nam1, S. Kim1, Y.T. Kim1, S.W. Kim1

1Yonsei University Severance Hospital, Dept of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

We developed a bundled strategy for sentinel node detection in endometrial cancer using fluorescent imaging. The aim of this study was to describe and evaluate the value of this strategy for sentinel node detection in endometrial cancer patients.

Method

We performed this sentinel node detection strategy in eighteen patients, who were treated at Yonsei Cancer Center for endometrial cancer. All the patients underwent laparoscopic staging surgery. After bicornual myometrium injection of fluorescent dye indocyanine green (ICG), the patients underwent paraaortic sentinel lymph node (SLN) biopsy. Pelvic SLN biopsy was done after cervical ICG injection. Intraoperative node detection and localization were guided by the PINPOINT® system for real-time imaging.

Results

Fourteen out of eighteen patients with endometrial cancer showed clear localization of paraaortic and pelvic sentinel nodes in relation to the abdominal and pelvic vessels. The paraaortic sentinel nodes and lymphatic flow were successfully localized and removed utilizing the ICG and PINPOINT® system. We observed a tendency of slower and weaker lymphatic drainage in
Conclusion

Our bundled strategy including cornual ICG injection followed by cervical ICG injection and the PINPOINT® system as intraoperative real-time imaging provides excellent detection and clear localization of paraaortic, pelvic sentinel nodes and lymphatic flow in relation to anatomic structures.

SENTINEL NODE BIOPSY (SNB) USING INDOCYANINE GREEN (ICG) AND FLUORESCENCE IMAGING IN ENDOMETRIAL CANCER WITH DA VINCI (SI) A SINGLE INSTITUTION ANALYSIS

F. Xu¹, K. Reisenberger¹
¹Klinikum Wels-Grieskirchen, Department of Obstetrics and Gynecology, Wels, Austria

Aims

Surgical staging of apparent uterine-confined endometrial cancers with pelvic and aortic lymphadenectomy has traditionally been performed in order to identify and triage patients that might benefit from adjuvant therapies. However, systematic retroperitoneal lymphadenectomy procedures have been associated with increased morbidities including lymphocysts, lymphedema and varying degrees of neuralgia.

Method

Fourteen patients with endometrial cancer G2 or G3 underwent prospectively robotic hysterectomy with lymphadectomy received SNB mapping with robotic fluorescence imaging. All patients received cervical injections of 4 ml ICG (1.6mg/ml) at 3 and 9 o’clock (2ml on each side, 1ml superficial submucosally, 1ml deep into cervical stroma with 22G spinal needle). the injection was done before port placement and docking of the robotic platform. The time taken from the cervical injection till beginning of the SN operation was medially 20 minutes.

Results

Twelve of fourteen patients had bilateral pelvic or aortic SN detected by fluorescence. The SNB detection rate was 86%. On average 7 (85/12) sentinel nodes were discovered. In only one Patient the pelvic SN was metastasized (1 right, 1 left), systematic lymphadectomy was negative (38). The histology of this Patient: G2 pT1a pN1(S) M0 R0 L1 V0 Pn0. Five patients with endometrial cancer G3 inclusive one serous type had no lymph node metastases.

Conclusion

Fluorescence imaging with ICG detected bilateral SN and metastases and seems to be reliable, safe and practical. Sentinel node mapping has the potential to decrease morbidity and avoid secondary operation and optimize the pathologic assessment of identified nodes in women with endometrial cancer.

ACCELERATED TUMOR PROGRESSION AFTER COMPLETE SURGERY IN PATIENTS WITH ADVANCED ENDOMETRIAL OR OVARIAN CANCER; CASE REPORTS

Y. Yano1, Y. Ikeda1, M. Hanaoka1, D. Ichikawa1, D. Shintani1, A. Ogasawara1, M. Miwa1, A. Yabuno1, T. Nishikawa1, A. Kurosaki1, H. Yoshida1, K. Hasegawa1, K. Fujiwara1, M. Yano2, M. Yasuda2

1Saitama Medical University International Medical Center, Gynecologic Oncology, Hidaka, Japan
2Saitama Medical University International Medical Center, Diagnostic Pathology, Hidaka, Japan

Aims

Surgery is considered as most reliable treatment option against various types of cancers; however, sometimes it causes unexpected results.

Method

We herein report our 2 case experiences with rapid disease progression after complete tumor resection.

Results

Case1: 49 years old woman with stage IIB ovarian undifferentiated carcinoma was treated by surgery including total hysterectomy, bilateral salpingo-oophorectomy, omentectomy and Hartmann’s operation. All tumors were completely resected visually. At post operative days (POD) 29, CT was performed because of uncontrollable fever and existence of multiple tumors at liver, skin, and pelvis were identified. Since then, her disease progressed rapidly and she passed away at POD 46.

Case2: 60 years old woman with stage IIIA endometrial endometrioid carcinoma grade 3 had been achieved complete surgery including total hysterectomy, bilateral salpingo-oophorectomy. At POD 33, CT was performed because of uncontrollable lower back pain, and identified existence of multiple metastases to lung, liver and bone. Her respiratory function was rapidly lost, and she passed away at POD 52.

Conclusion

We experienced 2 cases with accelerated disease progression after complete surgery. Surgical procedure might work as a trigger for rapid disease progression in these cases. Additional evaluation with larger sample size is required to identify the characteristics and etiology of such cases.
LYMPHATIC MAPPING AND SENTINEL-LYMPH-NODE BIOPSY IN ENDOMETRIAL CANCER: A PROSPECTIVE STUDY
B. Díaz de la Noval1, M.D. Diestro Tejeda1, I. Zapardiel1, J. Siegrist Ridruejo1, J. de Santiago García2, A. Hernández Gutiérrez1
1La Paz University Hospital, Gynaecology Oncology, Madrid, Spain
2MD Anderson Cancer Center, Gynaecology Oncology, Madrid, Spain

Aims

We aimed to assess if the detection rate and diagnostic accuracy by ultrastaging can improve the surgical staging.

Method

A prospective study of incident cases with clinical early-stage EC scheduled for laparoscopic staging surgery at La Paz University Hospital. Patients underwent preoperative SLN mapping with an intracervical injection of radiotracer-Tc-99m the day before surgery and intraoperative dye during surgery.

Results

From February 2012 to February 2017 143 patients were enrolled. Overall detection rate for the dual technique was 94.4% (n=135), bilaterally of 86.6%. 431 SLNs were obtained, mean of 3.2 SLNs per patient, usually in an iliac and obturator location (77%). Diagnostic rates were sensitivity 100%, specificity 95.16%, and NPV 100%.

Twenty-eight (6.5%) metastatic nodes: 8 (1.9%) macrometastases, 17 (4%) micrometastases, 3 (0.7%) ITC. Node metastases were identified in 25 (18.5%) patients, 20 (80%) were confined to SLNs, 65% of which had low tumor burden. In 13 cases (65%) the SLN was the only affected. Diagnostic rates (per patient) of SLN mapping to detect metastases after SLN-ultrastaging were sensitivity 50%, specificity 88.24%, NPV 90.91% and false-negative rate of 7.5%.

Mean follow-up of 55 months, 84.4% disease-free survival, and 93.3% overall survival. 28.6% of relapses had metastatic SLNs (p = 0.03); 65% of the patients with macrometastatic-SLN relapsed (p=0.001). Mean time to relapse of 14.8 months.

Conclusion

Though multicentre studies are underway, the high NPV of the SLN-technique accurately predicts nodal status, which could be considered as an alternative standard for staging early-stage endometrial cancer.
EPITHELIOID TROPHOBLASTIC TUMOR PRESENTING AS AN ISTHMOCELE: CASE REPORT OF A RARE DISEASE

M. Aban\textsuperscript{1}, F. Ozkan\textsuperscript{2}, R. Attar\textsuperscript{1}, G. Yıldırım\textsuperscript{1}, A.I. Doğan Ekici\textsuperscript{2}, A. Ayhan\textsuperscript{3}

\textsuperscript{1}Yeditepe University, Obstetrics and Gynecology, Istanbul, Turkey
\textsuperscript{2}Yeditepe University, Pathology, Istanbul, Turkey
\textsuperscript{3}Başkent University, Obstetrics and Gynecology, Ankara, Turkey

Aims

We reported a rare case of epithelioid trophoblastic tumor (ETT) which presented as an isthmocele but was diagnosed as ETT on hystopathologic examination after the operation.

Method

A 38-years-old woman presented to Department of Obstetrics and Gynecology Department at Yeditepe University with complaints of intermenstrual bleeding, pelvic pressure and discomfort for the last 7 months. She had 2 cesarean section deliveries and tubal ligation. Her last delivery was 1 year ago. Her ultrasound examination revealed a 4x3 cm mass with haematoma on the lower uterine segment. Her serum quantitative hCG on the day of surgery was negative. It was diagnosed as isthmocoele. Abdominal hysterectomy was performed due to patients choice.

Results

Histopathologic diagnosis of the hysterectomy specimen revealed epithelioid trophoblastic tumor of the lower uterine segment.

Conclusion

Although ETT is a rare GTD, it should be ruled out with patient presenting with a mass on the lower uterine segment.
ATTITUDE OF WOMEN WITH CANCER TOWARDS OOCYTE CRYOPRESERVATION

O. Al Kalbani¹, Y. AL Farsi², M. Al Khaduri³

¹Sultan Qaboos University, Obstetrics and Gynecology, Muscat, Oman
²Sultan Qaboos University, Family Medicine and Public Health, Muscat, Oman
³Sultan Qaboos University, Obstetrics and Gynecology, Muscat, Oman

Aims

This study aims to assess and compare the awareness, knowledge, attitude and opinion on oocyte cryopreservation in gynecology and oncology female patients in Sultan Qaboos University Hospital (SQUH).

Method

This is a cross sectional study in a form of a survey that included Omani oncology and gynecology female patients in SQUH in the age group 20-50 years. The data was collected by interviewing the patients. Inclusion and exclusion criteria were considered to select the patients for the study. SPSS and excel were used to analyze the data. The P value and odd ratio were measured to know the different between the two groups.

Results

The results showed that there is a high level of awareness among the oncology patients by 1.69 time than the gynecology patients and that is a significant difference. Also, both the groups have high acceptance of using oocyte cryopreservation for medical reasons with more acceptance in the oncology patients.

Conclusion

This study shows a significant different in the awareness and attitude about oocyte cryopreservation between oncology and gynecology patients. Moreover, the attitudes and opinion also differ between the two groups. The result show that the socio-demographic characteristic affect the awareness and attitude of the Omani females towards fertility and new methods that help infertile or cancer patients to preserve their ability to get pregnant.
ROLE OF PERIPHERAL BLOOD NATURAL KILLER CELLS IN UNEXPLAINED FEMALE INFERTILITY

P. Banga¹, M. Choudhury¹, K. Agarwal¹, R. Y²
¹Lady Hardinge Medical College, Pathology, New Delhi, India
²Lady Hardinge Medical College, Obstetrics and Gynaecology, New Delhi, India

Aims

Comparison of the levels of peripheral blood (PB) Natural Killer (NK) cells and its subsets in unexplained infertile women compared to fertile controls.

Method

This prospective study included 31 women with unexplained infertility and 33 healthy fertile women. Blood samples were analysed for the percentage and absolute counts of total blood NK cells and its various subsets.

Results

The percentage of total NK cells (CD56+CD3-) in infertile group was higher (8.12 ± 3.71%) but not significant (p>0.05) compared to fertile group (7.70 ± 4.34). The ratio of CD56dim/CD56bright NK cells was significantly increased in infertile group (31.36 ± 33.20) compared to fertile group (18.06 ± 11.58) (p<0.05). The mean percentage of CD56+ CD16+ NK cells and CD56dimCD16+ NK cells (out of total NK cells) was significantly raised in infertile group (7.04 ± 3.66 and 81.02 ± 18.17 respectively) compared to fertile group (4.96 ± 3.99 and 60.49 ± 0.76 respectively) (p<0.05). The mean percentage and absolute count of CD56+CD16- NK cells showed a significant increase (p<0.05) in fertile group (2.74 ± 3.62 % and 58.91 ± 89.67/ml) compared to infertile group (1.08 ± 1.01 % and 19.65 ± 25.78/ml). The mean percentage and absolute counts of CD56dimCD16- NK cells, showed a significant increase in fertile group (31.86 ± 32.67 % and 54.24 ± 86.80/ml) compared to infertile group (11.31 ± 12 % and 15.91 ± 21.01/ml) (p<0.05).

Conclusion

This study showed that unexplained infertility was associated with alteration of various NK cell subsets, thus providing an insight into the pathophysiology of unexplained infertility.

HORMONAL AND FERTILITY OUTCOME AFTER FERTILITY SPARING SURGERY AND CHEMOTHERAPY FOR OVARIAN NEOPLASMS: A RETROSPECTIVE STUDY

L. Ceppi1,2, M. Lamanna1,2, S. Magni1,2, F. Dell'Orto1,2, F. Galli4, A. Buda2, F. Sina1,2, D. Giuliani2, T. Grassi1,2, M. Delle Marchette1,2, R. Milani1,2, C.M. Bonazzi2, R. Fruscio1,2
1University of Milano-Bicocca, Department of Medicine and Surgery, Piazza dell'Ateneo Nuovo 1- 20126 Milan, Italy
2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33- 20900 Monza, Italy
3Istituto di Ricerche Farmacologiche “Mario Negri” - IRCCS, Laboratory of Methodology for Clinical Research - Department of Oncology, Via La Masa 19- 20156 Milan, Italy

Aims

Fertility sparing treatment (FST) for premenopausal women in ovarian neoplasms comprises surgical sparing of the gynecological apparatus and adjuvant chemotherapy (AC) according to risk factors. Little is known regarding the interaction between AC and the hormonal and fertility outcome in this population. We evaluated this cohort of patients in terms of during- and post-treatment ovarian function, conception and pregnancy outcome.

Method

A retrospective study was carried out in patients with epithelial (EOC) and non-epithelial (N-EOC) ovarian neoplasms undergoing FST with or without AC. Non parametric tests, univariate and multivariate (adjusted for age, histology, and relapse) logistic regression analyses were performed.

Results

573 patients (206 EOC, 367 N-EOC) treated in the period between 1980 and 2012 were included in this analysis, comprising of 40.3% patients treated with AC. Median follow-up was 12.3y with median age at diagnosis of 26.4y.

Overall, ovarian failure rates was 0.01%, childbearing desire was in 41.5%, with conception success rate of 84.5%.

At multivariate analysis, AC conferred higher risk of during-treatment amenorrhea [OR:18.45(95%CI5.19-65.62), p<0.0001], especially with platinum- etoposide-bleomicine schedule (p=0.0001), whereas post-treatment amenorrhea was rare and similar in both groups(p=0.69). Conception rate was lower in AC population (81.3%v.86.4%), yet not significant [OR:0.55(95%CI0.26-1.14),p=0.11]. Successful pregnancy rate was not affected by treatment (79.8%v.80.3%), [OR:0.94(0.51-1.75),p=0.85].

Conclusion

In this large cohort, AC affects during-treatment amenorrhea, with seemingly no significant impact on conception and successful pregnancy rates. Further follow up warrants more robust information regarding conception rates and non-surgical menopausal age. Pre-treatment counseling should discuss these risks in such young population.

FERTILITY AND SURVIVAL OUTCOME IN A LARGE COHORT OF BORDERLINE OVARIAN TUMORS: A SINGLE CENTER EXPERIENCE

M. Delle Marchette1,2, L. Ceppi1,2, M. Lamanna1,2, S. Magni1,2, F. Dell'Orto1,2, F. Galli3, A. Buda2, F. Sina1,2, D. Giuliani2, T. Grassi1,2, R. Milani1,2, C.M. Bonazzi2, R. Fruscio1,2

1University of Milano-Bicocca, Department of Medicine and Surgery, Piazza dell'Ateneo Nuovo 1- 20126 Milan, Italy
2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33- 20900 Monza, Italy
3IRCCS - Istituto di Ricerche Farmacologiche "Mario Negri", Laboratory of Methodology for Clinical Research - Department of Oncology, Via La Masa 19- 20156 Milan, Italy

Aims

Borderline ovarian tumors have excellent oncologic outcome and fertility sparing treatment in young women is indicated. However, pregnancy rate success is affected by multiple gonadal surgeries for relapse and it may be influenced by type of surgery (oophorectomy v. cystectomy). We investigated the effect of surgical fertility-sparing approach on fertility and survival.

Method

Borderline ovarian tumor patients treated at San Gerardo Hospital, Monza between 1978 and 2013 were considered. The effect of type of surgery on recurrence and death was analyzed. A Cox model was used to investigate the association between clinical variables and time to first post-surgical pregnancy, as well as the association between time to first recurrence.

Results

Among a larger cohort, 252 patients had desire of pregnancy and were included in the analysis: 121 patients underwent oophorectomy, 131 cystectomy, with comparable clinicopathological characteristics. Median follow-up time from date of diagnosis was 13.5 years. Results of the Cox model investigating factors potentially associated with recurrence showed: Advanced stage disease as significantly associated with the risk of recurrence (p<0.001), with bilateral cysts patients with higher risk of recurrence (HR= 2.20, IC95%= 1.41-3.44). The inverse weighted probability Cox model showed no effect of type of ovarian surgery on first recurrence (HR0.95; p=0.83), and on fertility (HR0.96; p=0.79). No detrimental effect on pregnancy rates was associated with histology, stage, laterality of the tumor or with a relapsing disease.

Conclusion

Type of surgery was observed not affecting recurrence risk and pregnancy success rate. These reassuring data can aid clinicians and patients tailoring the best treatment strategies.
SIGNIFICANCE OF CYTOGENETIC, ANTHROPOMETRICAL, AND MICROBIAL METHODS FOR THE EARLY DETECTION OF MALE INFERTILITY

G. Chander¹, S. Manohar², G. Naryanan¹
¹Jawaharlal Nehru Cancer Hospital & Research Centre, Department of Research, Bhopal, India
²Govt. MGM Post Graduate College ITARSI MP, Department of Zoology, Itarsi, India

Aims

The research work aims to look for any novel marker including various chromosomal, anthropometric and microbial markers to diagnose male infertility.

Method

Study conducted in two arms between the age group 18-45 years. Arm A composed of healthy control male having 150 volunteers and in B arm 50 infertile males. 30 volunteers from arm A having less than two inches AGD were included in arm B. Hence, the total infertile male in arm B was 80 males. A preliminary investigation was done by Physical examination, Anogenital Distance measurement followed by semen analysis, Lymphocyte culture to rule out chromosomal Anomalies and Microbial culture to investigate the type of microorganism present on genital tract.

Results

From arm B (infertile + <2 inch AGD) males having Anogenital distance < 2 inches 66.25% were found having abnormal sperm morphology, less sperm concentration, motility, viscosity, azospermic, and oligospermic. Microorganisms like staphylococcus aureus (23 %), candida albican (6.5%), streptococcus (13.5%) were the most common microorganisms found present in arm B. Among the infertile males 71.25% revealed abnormal chromosomal pattern as compared with the healthy individuals.

Conclusion

The study signatured with less Anogenital distance and marked chromosomal abnormalities in the infertile male. Moreover, the individuals having less AGD associated with chromosomal defects will certainly identify males at high risk of infertility. This will help the unmarried male individuals to get interventional therapy or may undergo another method of therapeutic modality so that the status of a healthy male partner after marriage may be achieved.
REPRODUCTIVE OUTCOMES AFTER GESTATIONAL TROPHOBlastic NEOPLASIA: A COMPARISON BETWEEN SINGLE-AGENT AND MULTIAGENT CHEMOTHERAPY. RETROSPECTIVE ANALYSIS FROM THE MITO-9 GROUP

R. Cioffi1, A. Bergamini2, A. Gadducci2, G. Cormio3, V. Giorgione4, M. Petrone4, E. Rabaiotti1, F. Pella1, M. Candiani1, G. Mangili1
1IRCCS San Raffaele Hospital, Gynaecology and Obstetrics, Milan, Italy
2University of Pisa, Gynaecology and Obstetrics, Pisa, Italy
3University of Bari, Gynaecology and Obstetrics, Bari, Italy

Aims

Gestational trophoblastic neoplasia (GTN) affects young women and is treated by chemotherapy. Possible concerns are the risk of infertility, early menopause, and teratogenic effects. Present study’s aim is to analyze menstrual and reproductive outcomes of women treated with single-agent versus multi-agent chemotherapy for GTN.

Method

One-hundred fifty-one patients were treated. Patients older than 45 years, with placental site/epithelioid trophoblastic tumor, undergoing hysterectomy by patient choice or hCG follow-up coinciding with analysis were excluded. Seventy-five patients were divided into sub-groups according to FIGO score: patients scoring <7, receiving single-agent chemotherapy (group A, n=42); patients scoring ≥7, receiving combination treatment (group B, n=33). Patients' outcomes were compared by univariate and multivariate analyses.

Results

Temporary amenorrhea occurred in 33% of A patients and 66.7% of B (p=0.01). Premature menopause occurred in 3 B patients (0% vs 9%, p=0.02).

Ten B patients underwent salvage hysterectomy.

Pregnancy desire did not differ between the two groups (p=0.555). In A, 57.1% became pregnant; in B, 36.4% did (p=0.060). Instead, pregnancy rate was 52.2% among high-risk patients not undergoing hysterectomy (57.1% vs 52.2%, p=0.449).

There was no difference in miscarriage (p=0.479) and premature birth (p=0.615) rates.

In a multivariate analysis including age, FIGO score, chemotherapy type, Assisted Reproductive Technologies, previous pregnancies and pregnancy desire, only age (p=0.006) and pregnancy desire (p=0.002) were independent factors.

Conclusion

Excluding the risk of premature menopause, a rare side-effect of combined treatments, single-agent and multi-agent chemotherapy can be safely administered to patients with childbearing desire. High-risk patients have worse reproductive outcomes because they undergo hysterectomy more frequently than low-risk patients.
Conization for the treatment of cervical intraepithelial lesion has been linked to an increased risk of preterm delivery. Valid data from Germany are lacking. Our study aimed to investigate the association between conization and the risk of preterm birth in subsequent pregnancies, using data from a German population database.

Method

We performed a retrospective cohort study on data from the German nationwide performance measurement program in healthcare quality. Women with history of conization prior to pregnancy were compared to a control group of women without. Only primiparas with singleton pregnancies were included for analysis. Outcome measures are gestational age at birth, birth weight, neonatal morbidity and perinatal mortality. Data were analyzed using univariate and multivariate statistical methods.

Results

The database included a total of 4,002,503 deliveries between 2009 and 2014. 1,573,200 could be included for analysis. 14,337 women had a history of conization. This group were more likely to be (self-) employed, single, older, had a lower body mass index and a lower mean birth weight of the babies than in the control group [mean (SD), 3.240g (± 603g) vs. 3.307g (±545g), p < 0.0001]. The preterm birth rate was significantly higher after conization compared to the non-exposed cohort (12.2% vs. 7.5%; Chi2 <0.0001). Conization was confirmed to be a significant risk factor for preterm delivery (odds ratio, OR 1.7; 95% CI: 1.65-1.83).

Conclusion

The data of this study are in accordance with the literature. Further analysis of the data should evaluate whether preterm delivery after conization affects the perinatal morbidity and mortality.
EVALUATION OF SERUM HE4 LEVELS IN UNCOMPPLICATED PREGNANCIES

R. Delić¹, M. Štefanovič², Š. Krivec³, V. Weber¹, J. Koren¹
¹General and Teaching Hospital Celje, Department of Gynecology & Obstetrics, Celje, Slovenia
²Sestre Milosrdnice University Hospital, Clinical Institute of Chemistry, Zagreb, Croatia
³General and Teaching Hospital Celje, Department of Laboratory Medicine, Celje, Slovenia

Aims

This study was undertaken to evaluate HE4 serum concentrations in first, second, and third trimester in uncomplicated pregnancies.

Method

In a retrospectively designed, monocentric study (Department of Gynecology & Obstetrics, General Hospital, Celje, Slovenia, EU), 146 women with uncomplicated pregnancies were included.

HE4 levels were obtained and analyzed with regard to each trimester of pregnancy.

HE4 levels were measured in consideration of reference interval less than 140 pmol/l (Elecsys HE4® assay, Roche Diagnostics Ltd., Rotkreuz, Switzerland).

Data were analyzed by ANOVA (MedCalc Software, Mariakerke, Belgium).

Results

While having practically all HE4 levels within reference range, differences in mean concentrations between study groups were found to be statistically significant (Group I, n=5, < 20 weeks of pregnancy, mean = 41.2 pmol/l; Group II, n = 25, pregnancies between 20-34 weeks of pregnancy, mean = 43.4 pmol/l; Group III, n =116, ≥ 34 weeks of pregnancy, mean = 57 pmol/l, p< 0.001).

Conclusion

Our findings confirmed that HE4 levels in uncomplicated pregnancies were within reference range provided by the manufacturer; however its serum concentration rises significantly in 3rd trimester.
ONCOLOGIC AND OBSTETRIC OUTCOME AFTER VAGINAL SIMPLE TRACHELECTOMY OR LEEP FOR CERVICAL CANCER

F. Demirkiran¹, I. Kahramanoglu¹, H. Turan¹, T. Bese¹, M. Arvas¹
¹Istanbul University Cerrahpasa School of Medicine, Obstetrics and Gynecology, ISTANBUL, Turkey

Aims

The purpose of our study is to evaluate oncologic and obstetric outcomes after vaginal simple trachelectomy or the loop electrosurgical excisional procedure (LEEP) for cervical cancer.

Method

The medical records of patients who underwent vaginal simple trachelectomy or LEEP with or without pelvic lymphadenectomy were retrospectively reviewed.

Results

The summary of the patients were presented in Table 1. The median age of patients was 31.1 years, and the median follow-up time was 22.2 months. There was no recurrence during follow-up and none died after treatment. A total of 7 patients attempted conceive after surgery, and 4 pregnancies were achieved in 4 women. Hence, the pregnancy rate among patients who attempted to conceive was 57.1%. Two babies were delivered by cesarean section at 24 and 37 weeks. Two cases of
miscarriage occurred in the second trimester.

**Conclusion**

Our data indicate that LEEP and vaginal simple trachelectomy in stage IA1-IB1 cervical cancer are effective procedures in patients who wish to preserve fertility. However, miscarriage was frequently observed. Thus, future studies should focus on prevention of complications during pregnancy.
PREGNANCY AFTER CHEMOTHERAPY FOR BRONCHOPULMONARY CARCINOMA

C. Goudeli\textsuperscript{1}, S. Patramani\textsuperscript{1}, I. Kokolakis\textsuperscript{1}, A. Karamani\textsuperscript{1}, D. Koutroulakis\textsuperscript{1}, S. Psiharaki\textsuperscript{1}, A. Makrigiannakis\textsuperscript{1}

\textsuperscript{1}University Hospital of Heraklion, Obstetrics-Gynecology, Iraklio- Creta, Greece

Aims

As the mean age of conception rises, the possibility of an upcoming cancer before parity is higher. Bronchopulmonary carcinoid tumors (BPC) arise from the neuroendocrine Kulchitsky cells and comprise 2-5\% of all primary lung cancers. Chemotherapy agents used as Etoposide (VP-16) and Cisplatin (CDDP) provoke impaired ovarian function, gonadal suppression and they are highly mutogenic and teratogenic. We herein report the case of a woman with two spontaneous conceptions and successful pregnancies after BPC treatment.

Method

A 40-year old unigravida-unipara presents in the Obstetrics Department for consultation of her second pregnancy. 10 years ago she had undergone excision of the middle lobe of her right lung due to atypical pulmonary carcinoma. Four circles of combined chemotherapy followed with VP-16 and CDDP. One year later she gave birth to a healthy child. Spirometry and laboratory exams are normal. Amniocentesis and anatomical ultrasound are normal.

Results

In 36+5 weeks she is admitted due to fetal heartbeat deterioration. A healthy male is born. Pregnancies within 6 months of the end of the chemotherapy compared with those occurring after this period have a higher spontaneous miscarriage rate, while there is no difference in the rate of congenital anomalies. The conception rate is higher in the single agent group, than in double agent chemotherapy.

Conclusion

The rate of treated for cancer patients is getting higher and on the other hand the mean age is lower. That is the reason we have to declare the effects of each type of cancer or each type of treatment on a pregnancy.
ROLES OF CONSERVATIVE SURGERY AND ADJUVANT CHEMOTHERAPY IN OVARIAN SERTOLI-LEYDIG CELL TUMORS: RESULTS FROM A MONOCENTRIC LONG-TERM ANALYSIS OF 23 PATIENTS
S. Gouy¹, A. Arfi¹, A. Maulard¹, P. Pautier², E. Bentivegna¹, A. Leary², C. Chargon², C. Genestie⁴, P. Morice¹
¹Gustave Roussy, Surgery, Villejuif, France
²Gustave Roussy, Oncology, Villejuif, France
³Gustave Roussy, Radiotherapy, Villejuif, France
⁴Gustave Roussy, Biology and pathology, Villejuif, France

Aims
To determine the management (i.e., conservative surgery and adjuvant chemotherapy) in ovarian Sertoli-Leydig cell tumors (SLCT).

Method
This retrospective analysis included 23 patients treated for ovarian SLCT. A centralized pathologic review of the tumors was conducted.

Results
Patients were referred to or treated in our institution for an ovarian SLCT between 1994 and 2015. The median age at diagnosis was 33 years (range, 4-82). According to the 2014 FIGO classification, tumors were classified as stage Ia (n=15; well-differentiated n=1; intermediate-differentiated n=8; undifferentiated n=4, and undefined n=2), stage Ib (n=1), stage Ic1 (n=5), stage IIc (n=1), and stage IIIc (n=1). Surgery was conservative in thirteen (Ia, n=7; Ib, n=1; Ic1, n=5) and radical in 10 (Ia, n=8; IIc, n=1; IIIc, n=1). Seven patients received adjuvant chemotherapy with a cisplatin-based regimen (Ia, n=2; Ic1, n=3; IIc, n=1) or docetaxel + gemcitabine (IIIc, n=1). Median follow-up was 61 months (range, 15-252). Eight patients experienced a relapse (Ia, n=2; Ib, n=1; Ic1, n=3; IIc, n=1; IIIc, n=1). Of these, 6 had at least one peritoneal carcinomatosis and 4 died (Ic1, n=2; IIc, n=1; and Ia [n=1]. Two patients had a local relapse (one uterus and one ovary) and survived without disease after relapse treatment. The median time between the initial treatment and relapse was 28 months (range 9-70).

Conclusion
Conservative surgery was safe for stage Ia ovarian SLCT. For stages Ic1 and more severe disease, radical surgery and adjuvant chemotherapy should be considered. The best chemotherapy regimen remains to be defined.
RESULTS OF FERTILITY-SPARING SURGERY FOR EXPANSILE AND INFILTRATIVE MUCINOUS OVARIAN CANCERS

S. Gouy¹, M. Saidani¹, A. Maulard¹, S. Bach-Hamba², E. Bentivegna¹, A. Leary², P. Pautier², M. Devouassoux-Shisheboran³, C. Genestie⁴, P. Morice¹

³Hospices Civils de Lyon, Department of Pathology, Lyon, France
⁴Gustave Roussy, Pathology, Villejuif, France

Aims

To determine the results of fertility-sparing surgery in stage I mucinous ovarian cancers analysed according to histotype (infiltrative versus expansile).

Method

Retrospective analysis of patients treated conservatively for ovarian mucinous carcinoma with preservation of the uterus and contralateral ovary from 1976 to 2016. The pathology of the tumours was reviewed by two expert pathologists according to the 2014 WHO classification criteria. Only stage I cancers were studied.

Results

The current study analysed the oncologic and fertility results of 21 cases, 12 with expansile and 9 with infiltrative cancer. All patients had a unilateral tumour and underwent unilateral salpingo-oophorectomy in one-step (n=6) or two-step (n=15) surgeries. All but one had complete peritoneal staging surgery based on cytology, omentectomy, and random peritoneal biopsies. Ten had nodal staging surgery. The FIGO stages were IA (n=9), IC1 (n=6), and IC2 (n=6); the nuclear grades were grade 1 (n=9), grade 2 (n=5), and grade 3 (n=1). Two patients recurred (1 expansile and 1 infiltrative type) 19 and 160 months after surgery. One stage IA, nuclear grade 2 expansile tumour recurred on the spared ovary; the patient remains alive. The other stage IA, infiltrative tumour recurred as peritoneal spread; the patient is alive with evolutive disease. Six patients became pregnant; 4 with expansile tumours and 2 with infiltrative tumours.

Conclusion

The type of mucinous cancer has no impact on the oncologic outcome. Fertility-sparing surgery should be considered for early-stage infiltrative type tumours.
Epidemiology of malignancies diagnosed in pregnancy in Czech Republic

M. Halaska¹, M. Hruda², T. Pichlik², H. Robova², L. Rob²

¹ 3rd Medical Faculty - Charles University and Faculty hospital Kralovske Vinohrady, Dept. of OB/GYN, Prague, Czech Republic
² 3rd Medical Faculty Charles University and Faculty hospital Kralovske Vinohrady, Dept. of OB/GYN, Prague, Czech Republic

Aims

Malignancy diagnosed during pregnancy represents a rare diagnosis, but the incidence of such a disease has sharply increased in recent decades. The reason for this tendency is the increased age of women becoming pregnant. Today, 21.9% of women in the EU are older than 35 years at delivery. Exact data on the incidence of malignant disease is sparse and in most cases inaccurate. However, there is a clear trend in coincidence of malignancy and pregnancy and there are some obvious differences between countries and races. Only a few reports are available that used a linkage of national oncological and birth registries to detect patients diagnosed with cancer during pregnancy. The aim of the work was to evaluate the incidence of malignancies diagnosed in pregnancy in Czech Republic.

Method

The desired data were obtained by linking the National oncological register with Birth and abortion register between 1996-2010.

Results

Malignant diseases in pregnancy occur approximately in 20-40 / 100,000 pregnant women. The most common diagnoses in Czech Republic include cervical cancer (5.5 / 100,000), breast cancer (2.58 / 100,000), melanoma (3.05 / 100,000) and haematological malignancies (2.78 / 100,000) and they account for 60-75% of all malignancies detected during pregnancy.

Conclusion

20-40 pregnancies per 100,000 pregnant women is complicated by malignant disease, most often cervical cancer, breast cancer, melanoma and hematologic malignancies.

This work was supported by the Charles University research program PROGRES Q 28 (Oncology).
THE REPRODUCTIVE OUTCOME AFTER FERTILITY PRESERVING TREATMENT FOR PREMALIGNANT AND MALIGNANT GYNECOLOGIC DISEASES: AN EXPERIENCE OF A TERTIARY CARE CENTER.

P. Hemida¹, E. Toson²

¹Obstetric and Gynecology department - Faculty of Medicine - Mansoura University, Gynecologic Oncology Unit, Mansoura, Egypt
²Clinical Oncology department - Faculty of Medicine - Mansoura University, Gynecologic Oncology Unit, Mansoura, Egypt

Aims

To evaluate the obstetric outcome of patients who had undergone fertility preserving treatment for gynecologic premalignant and malignant diseases.

Method

The study reviewed the pregnancy course and delivery data of 60 patients, who conceived after fertility sparing treatment for gynecologic premalignant and malignant diseases at Mansoura University Hospital from January 2012 to December 2015.

Results

The mean age of the studied patients was 24.9 years. The median follow up was 13 months (range:1-40). The preceding lesions included gestational trophoblastic neoplasia (GTN), 43 cases (71.7%) while early ovarian carcinoma (14 cases, 23.3 %) and least CIN III (2 cases, 3.3%) and micro-invasive cervical carcinoma (one case, 1.7%). All cases of GTN were treated with single or multiple agents’ chemotherapy. The 3 cases of cervical micro-invasive carcinoma and CIN III were treated with loop electrosurgical excision procedures (LEEP). Cases with stage 1a ovarian cancer were treated with unilateral salpingo-oophorectomy with peritoneal cytology and biopsy of the other ovary. Missed abortion was diagnosed in 4 cases (6.7%). The rate of caesarean delivery (CD) was high (70.9%). Intra-abdominal adhesions during CD were seen in (20.5%) of cases. The neonatal outcome was normal in 53 cases, and 2 cases (3.6%) of had congenital fetal malformations. The poor neonatal outcome was significantly correlated to number of chemotherapy cycles.

Conclusion

The reproductive outcome after fertility preserving treatment of GTN, micro-invasive carcinoma of cervix, CINIII, and stage 1 ovarian cancer is comparable to those of general population. However, there were increased rate of CD, Intra-abdominal adhesions, missed abortion and congenital fetal malformations.
Aims
Increasing numbers of young women are diagnosed with atypical hyperplasia (AH) and endometrial cancer (EC). Many studies have highlighted a treatment allowing fertility sparing management in case of lesion restricted to endometrium. The objectives of this review were: (i) to estimate the oncologic and reproductive outcomes over time (ii) to evaluate the prognostic factors associated with this fertility-sparing management.

Method
We performed a systematic review examining patients with AH or EC restricted to endometrium who underwent a fertility-sparing management. The primary outcomes were the remission, recurrence, progression and pregnancy probabilities. The secondary outcomes were the association of remission, recurrence, progression and pregnancy probabilities with the following factors: age, obesity, previous pregnancy, histology and medical treatment.

Results
A total of 652 patients from 39 studies were included. The remission probability reached a plateau at 12 months after medical therapy (78.4%), whereas the recurrence probability increased continually until five years after remission. Secondary treatment led to remission in 79.2%. The pregnancy probability reached a plateau of 44.1% at 36 months after medical therapy. On the hysterectomy specimen, 12% of patients had a tumour with at least myometrial invasion. In the multivariate analysis, age was associated with a lower probability of remission and EC with a higher probability of progression (compared to AH).

Conclusion
Fertility-sparing management should be re-evaluated if no remission occurs after 12 months. Secondary hormone treatment should be proposed when remission fails to occur after first line therapy. If no pregnancy has occurred after 36 months, hysterectomy should be considered.
IMPACT OF CANCER IN THE MANAGEMENT OF DELIVERY: 10 YEARS OF VARIATIONS
G. Parpinelli, B. Masturzo, C. Macchi, D. De Ruvo, M. Mitidieri, Z. Paolo
S.Anna Hospital, Obstetrics and Gynecology - Department of Surgical Sciences - University of Turin, Turin, Italy

Aims

To analyze the impact that the pregnancy-related neoplastic disease has on management of deliveries between 2006-2015 in S.Anna Hospital (Turin).

Method

We collected obstetric and oncological data about 205 patients bearing a history of cancer: 59 patients with active-during-pregnancy cancer (ADPC) and 146 patients with pregravidic not-active-during-pregnancy cancer (NADPC).

Results

In ADPC patients the distribution of cancers was: breast (45.8%), haematological malignancies (13.6%), cervical (13.6%), ovarian (5.1%), gastro-enteric (5.1%), melanoma (5.1%), thyroid (3.4%), other tumours (8.5%). We registered 3.4% miscarriage and 15.3% iatrogenic abortion. According to the type of delivery, 22% was vaginal delivery (VD) and 59.3% was cesarean-section (CS). Induction of labour was 14.6%, elective CS was 68.8%; the indication for these procedures was 78.6% oncological. The average gestational age was 35.5 weeks.

In NADPC patients the distribution of cancers was: breast (20.5%), haematological malignancies (22.6%), cervical (5.5%), ovarian (3.4%), gastro-enteric (3.4%), melanoma (6.2%), thyroid (15.8%), other tumours (22.6%). We registered 9.6% miscarriage and 8.2% iatrogenic abortion. The type of delivery was vaginal (43.2%) and cesarean section (39%). Induction of labour was 11.7%, elective CS was 36.7%; the indication for these procedures was 77.5% obstetrical. The average gestational age was 38.3 weeks.

Conclusion

10-years trends in ADPC patients and NADPC patients showed an increase of VD. We noticed a decrease in elective CS and an increase of induction of labour. In 10 years we observed not significative differences about timing of delivery and a contemporary decrease of oncological indications for CS in ADPC and NADPC patients.
ENDOMETRIOSIS-RELATED HEMOPERITONEUM: A DIAGNOSIS TO KEEP IN MIND

B. Malek\textsuperscript{1}, M. Slimene\textsuperscript{1}, Y. Ayari\textsuperscript{1}, S. Sakhri\textsuperscript{1}, M. Hechiche\textsuperscript{1}, J. Ben Hassouna\textsuperscript{1}, K. Rahal\textsuperscript{1}, J. Ben Hassouna\textsuperscript{1}

\footnotesize{\textsuperscript{1}Institut Salah Azeiz of Oncology, Oncologic Surgery, Tunis, Tunisia}

Aims

Endometriosis is an important gynecologic clinical entity, pathologically defined by the ectopic presence of endometrium and frequently associated with pelvic pain, that affects approximately 10% of females of reproductive age. A rare but severe complication of endometriosis is spontaneous hemoperitoneum, severe intraabdominal bleeding that can be life threatening. We report this case to remind to think to endometriosis in clinical presentation of hemoperitoneum.

Method

We retrospectively reported a case of a massive hemoperitoneum from endometriosis in a 35 years-old woman treated in 2017.

Results

A 35-year-old gravida 0 patient was admitted to the hospital for brutally abdominal pain and increased abdominal volume. She had no past medical history.

The patient’s main symptom was a severe stabbing pelvic pain. Examination revealed an ascite, without no needle aspiration performed, remarkable for a diffuse tenderness but no rebound and positive bowel sounds. The pain was steady and diffuse. The patient had a hemorrhagic shock.

the CT scan showed a massive hemoperitoneum. We decided to perform surgery because of the patient's worsening clinical features. The patient underwent a supraumbilical midline laparotomy under general anesthesia. Almost 1,500 mL of blood was aspirated from the peritoneal cavity. Pelvic exploration revealed an adhesive right fallopian tube and ovary with the right uterine wall. Active bleeding from the isthmus of the uterus was observed. After careful confirmation of hemostasis, the abdominal wall was closed.

Conclusion

Although the most common gynecologic cause of hemoperitoneum in a reproductive-age woman is ruptured ectopic pregnancy, endometriosis should also be considered, especially after exclusion of pregnancy.
FERTILITY / PREGNANCY

ESGO7-1270

PREGNANCY ASSOCIATED WITH VULVAR PRECANCEROUS LESIONS

D. Mocuta1, C. Aur1

1Faculty of Medicine and Pharmacy- County Clinical Hospital of Oradea, Obstetrics-Gynecology, Oradea, Romania

Aims

Vulvar intraepithelial neoplasia - VIN, should be considered a premalignant condition and is an increasingly problem among smoker women over 35 years old with immunodeficiency, but a very rare condition during pregnancy. The International Society for the Study of Vulvovaginal disease - ISSVD changed the terminology for VIN in 2015 to one similar to WHO's classification. Squamous VIN was classified anterior analog to the cervical CIN in 3 grades and now ISSVD recommends the terms low grade, respectively high grade - vulvar H-SIL.

Method

We present here the case of a non-smoker 25 years old pregnant woman G2P1, with a previous C-section, who was diagnosed when she was 14 weeks of gestation with VIN3, but carcinoma could not be ruled out by vulvar biopsy. Surgical excision was decided and performed. Evolution was complicated with varicella immediately after 20 weeks of pregnancy. No other events were reported until now, when she is still in her second trimester of pregnancy.

Results

In the diagnosis of VIN, colposcopy should be recommended, but biopsy should be performed anyway. When these lesions are diagnosed during pregnancy, treatment should be recommended for women with vulvar H-SIL because of the potential of occult invasion or if cancer is suspected, even if biopsies show vulvar H-SIL. Wide local excision should be performed when invasive cancer cannot be ruled out.

Conclusion

Gestational age and the type of vulvovaginal intraepithelial lesion are the most important factors in determining expectant management or surgical treatment in pregnant women diagnosed with VIN or vulvar carcinoma.
ULTRASOUND GUIDED EMBRYO TRANSFER: SUMMARY OF EVIDENCES TO CLOSE THE OPEN DEBATE.
LITERATURE REVIEW AND META-ANALYSIS

5University of Siena, Post Graduate School of Public Health, siena, Italy
6University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubljana, Slovenia

Aims

To collate all available evidence regarding the application of ultrasound techniques during embryo-transfer (ET). Through a meta-analytic assessment of randomized trials, comparing trans-abdominal ultrasound guided ET (TA-US ET) versus clinical touch (CT ET), we evaluated possible improvement in implantation, clinical pregnancy and ongoing pregnancy/live birth rates and associated reduction of ectopic pregnancy and miscarriage rates.

Method

A systematic literature search and meta-analysis (English written literature) was conducted. The literature search yielded 1522 publications. 32 manuscripts were available for the systematic review of which 12 for meta-analysis. Articles were included only if they reported evaluable data of TA-US guided ET compared to CT on: i) implantation-rate; ii) clinical pregnancy-rate; iii) ongoing pregnancy-rate/live birth-rate; iv) miscarriage-rate; v) ectopic pregnancy-rate.

Results

Meta-analysis demonstrated that implantation rate (OR 0.71, p<0.001; CI 95% 0.63-0.81, I² 0%), clinical pregnancy rate (OR 0.77, p<0.01; CI 95% 0.69-0.86, I² 52%), and ongoing/live birth rate (OR 0.84, p<0.05; CI 95% 0.72-0.97, I² 62%) were all reduced with CT ET compared to TA-US ET. This analysis found no statistically significant differences between CT ET versus TA-US ET for miscarriage and ectopic pregnancy rates.

Conclusion

The effect of TA-US ET on clinical pregnancy rate, implantation rate and ongoing pregnancy are mildly positive. Considering that ultrasound scan is a widely available and cost-effective tool in gynecology and human reproduction field its routine introduction during ET appears to have more benefits than disadvantages. Further studies are needed, indeed, to better understand potential value of this technique in other clinical outcomes such as ectopic pregnancy rate.
PREGNANCY AND ONCOLOGIC OUTCOMES OF BORDERLINE OVARIAN TUMORS: A CASE SERIES WITH LONG-TERM FOLLOW UP
M. Peiretti1, A. Proto1, G. Candotti1, F. Congiu1, E. Malune1, M. Onnis1, V. Mais1
1University of Cagliari, Division Of Obstetrics and Gynecology, Cagliari, Italy

Aims
The aim of this study was to evaluate the oncologic and reproductive outcomes of young women with borderline ovarian tumours (BOTs) treated by mini-laparotomy or laparoscopy with cystectomy or unilateral salpingooophorectomy (USO).

Method
The medical records of patients with BOTs treated in our Institute between 1997 and 2016 were reviewed retrospectively. All patients included into the study, before surgery declared to have strong pregnancy desire to have one at the present time or in the future. The reproductive outcomes were assessed by telephone interviews.

Results
We found a total of 26 patients with BOTs. The median age at the time of diagnosis was 35 years (range 19-45 years). Fourteen patients (54%) underwent USO and nine (34%) underwent cystectomy; 1 patient (4%) underwent bilateral cistectomy and 2 patients (8%) underwent USO plus contralateral cystectomy (laparoscopy: 21 patients; laparotomy: 5 patients). All patients had clinical FIGO Stage IA, except one (IC); final pathology included 13 (50%) serous types, 12 (46%) mucinous types and 1 (4%) endometrioid type. After a median follow up time of 75 months, only 1 patient relapsed in the other ovary after 24 months from the first surgery. None death was observed. Of all the 26 patients included, 14 (54%) attempted to conceive after surgery and 10 (38%) succeeded.

Conclusion
Conservative surgical treatment seems to be an approach for women with BOTs who wish to preserve fertility. Our results in terms of fertility and pregnancy outcomes were consistent with international English data.
GESTATIONAL TROPHOBlastic DISEASE

D. Pejić1, B. Stanimirović2, J. Mrđa3, D. Gvozden4

1General Hospital Gradiška- Gradiška- Bosnia and Herzegovina, Department of Obstetrics and Gynecology, Gradiška, Bosnia - Herzegovina
2University hospital- Clinical center- Banjaluka- Bosnia and Herzegovina, Clinic of Pediatrics, Banja Luka, Bosnia - Herzegovina
3University hospital- Clinical center- Banjaluka- Bosnia and Herzegovina, Clinic of Internal medicine, Banja Luka, Bosnia - Herzegovina
4General Hospital Gradiška- Gradiška- Bosnia and Herzegovina, Department of Obstetrics and Gynecology, Gradiška, Bosnia - Herzegovina

Aims

Gestational trophoblastic disease (GTD) is a condition of uncertain etiology, comprised of hydatiform mole (complete and partial), invasive mole, choriocarcinoma, epithelioid trophoblastic tumor and placental site trophoblastic tumor.

A partial hydatidiform mole develops when dispermy occurs, and the resulting conceptus is triploidy.

The incidence of complete hydatidiform mole is approximately 1 in 1500 pregnancies in the United States. The incidence of partial hydatidiform mole is approximately 1 in 750 pregnancies.

Complete hydatidiform mole is usually due to an androgenetic diploid conception, in which a haploid sperm fertilizes an egg that lacks female chromosomes.

Method

On admission she had irregular vaginal bleeding, lower abdominal pain, syncope, a headache, excessive vomiting, transvaginal expulsion of grape-like vesicles, abnormally enlarged uterus and features of eclampsia.

Results

A 38-year-old woman, Gravida 3, Para 1, with two previous vaginal delivery of a normal female and male infants, who was 17 weeks pregnant was scheduled for emergency surgical treatment. She was diagnosed with a hydatidiform mole and eclampsia in our hospital for further treatment.

Pre-treatment beta human chorionic gonadotropin (β-HCG) level was extremely high 1 183 900 mIU/ml. The obstetricians considered septic complications from the partial hydatidiform mole and we decided to perform an emergency Sectio parva.

Two weeks after delivery, the serum β-hCG level was 11 341 mIU/mL and normalized gradually within two months without any citotoxic therapy.

Conclusion

Partial mole hydatidosa (PMH), as a milder form of GTD can go along with malignant complications with fatal consequences.
FERTILITY / PREGNANCY

ESGO7-0168

ONCOLOGY RESULTS AFTER LESS RADICAL FERTILITY SPARING SURGERY (SENTINEL LYMPH NODE MAPPING FOLLOWED BY LAPAROSCOPIC PELVIC LYMPHADENECTOMY AND SIMPLE TRACHELECTOMY

L. Rob1, H. Robova1, M. Halaska1, T. Pichlik1, K. Tikovsky1, P. Skapa2, M. Hruda1

1Faculty Hospital Kralovske Vinohrady and Charles University - 3rd Medical Facult, Obstetrics and Gynecology, Prague 10, Czech Republic
2Faculty Hospital Motol- 2nd Medical Faculty- Charles University, Pathology and Molecular Biology, Prague 5, Czech Republic

Aims

There are a lot of surgical techniques how to preserve fertility. We present oncological results after laparoscopic lymphadenectomy and simple tracheectomy.

Method

85 women with cervical adenocarcinoma(18-21.2%), adenosquamous(4-4.7%) or squamous(63-74%) carcinoma smaller than 2 cm that doesn’t exceeded half of stromal invasion, were included into study. Sentinel lymph node mapping(SLNM) was performed in all patients. If frozen section of SLN was negative, pelvic lymphadenectomy and simple tracheectomy were performed.

Results

We included seven women with IA1 LVSI positive tumor, 14 with IA2 tumor and 64 with IB1 tumor. LVSI were diagnosed overall in 36(42.4%) women. Cone biopsy preceded fertility sparing surgery in 67(78.8%) women. 39(58.2%) women had residual disease after conisation. Fertility was spared in 71(83.5%) women. Three women underwent radical hysterectomy for positive margins. Three women decide underwent vaginal hysterectomy less than 6 month after surgery for different reasons. Eight women underwent radical hysterectomy because of positive SLN(frozen section 7 cases, imunohistochemistry 1 case). Blue dye was used for SLNM in first 9 cases and combination of blue dye and radiocoloid Tc99 in subsequent 76 cases. Detection rate in cases when combination was used, were 100%. Three(4.2%) women had local recurrence and they are after treatment without evidence of disease. Adenocarcinoma was diagnosed 3 year after primary treatment in one woman that had originally squamous carcinoma. She died of disease.

Conclusion

SLN mapping followed by pelvic lymphadenectomy and simple tracheectomy is safe procedure in small cervical cancers. Recurrence rate is 4.2% and we don’t mentioned any death after this procedure.
PREGNANCY RESULTS AFTER FERTILITY SPARING SURGERY – SIMPLE TRACHELECTOMY AND PELVIC LYMPHADENECTOMY IN 85 WOMEN.
H. Robova¹, L. Rob¹, T. Pichlik¹, K. Tikovsky¹, M. Halaska¹, P. Skapa², M. Hruda¹
¹Faculty Hospital Kraľovské Vinohrady and Charles University-3rd Medical Facult, Obstetrics and Gynecology, Prague 10, Czech Republic
²Faculty Hospital Motol- 2nd Medical Faculty- Charles University, Pathology and Molecular Biology, Praha 5, Czech Republic

Aims

Currently increase age of first delivery in developed countries and increase number of women with cervical cancer that wish pregnancy. There are a lot of different surgical techniques how to save fertility. We present pregnancy results after laparoscopic lymphadenectomy and simple vaginal trachelectomy.

Method

85 women with squamous cell, adenocarcinoma or adenosquamous carcinoma with tumor smaller than 2 cm and infiltrating less than half of cervical stroma were included into study from 1999–2016. Mean age was 28.0 years. They were subdivided into three groups by period when surgery was performed (1999-2005, 2006-2010, 2010-2016).

Results

85 women were included into study, fertility was spared in 71(83.5%). Three(4.2%) women aren’t planning pregnancy, 58(81.7%) wished pregnancy and 44(75.9%) of them became pregnant. Ten women are planning pregnancy. 39 women delivered 45 babies (33 term deliveries, 4 deliveries 24-32w of pregnancy, 8 deliveries 33-36w of pregnancy). Four women underwent interruption, one had extrauterine pregnancy, seven women miscarried in first trimester (four of them 2times) and three in second trimester (two of them 2times). In first period 14 women from 20 delivered 14 babies, none of these women currently plan pregnancy. In second period 16 women from 28 delivered 21 babies, two women are planning pregnancy. In third period 10 women from 23 delivered 10 babies and 8 women are planning pregnancy and 3 are pregnant.

Conclusion

Pregnancy results after simple trachelectomy and laparoscopic lymphadenectomy are good. Pregnancy rate is 75.9% and 62% of women delivered babies. Only 8.8% women delivered before 32w of pregnancy.
FERTILITY / PREGNANCY

ESGO7-1139

APPROACH TO ADNEXAL MASSES DURING CAESAREAN SECTION
B. Dincgez Cakmak¹, A.E. Yumru², B. Dundar¹, V. Sal²
¹Saglik Bilimleri University- Bursa Yuksek Ihtisas Research and Training Hospital, Obstetrics and Gynecology, Bursa, Turkey
²Saglik Bilimleri University- Sisli Hamidiye Etfal Research and Training Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

Removal of incidentally detected adnexal masses during caesarean section is a challenging issue for obstetricians. There is only a few study in the literature comparing the removal of these adnexal masses during caesarean section or later removal. In this study, we aimed to evaluate our cases with incidentally detected adnexal masses during caesarean section retrospectively.

Method

A total of 45 incidentally detected adnexal masses and removed during caesarean section over a five year period were included in this study. Age, gravida, histopathological results of all patients were recorded from the medical records.

Results

Mean age of the patients were 30.23±9.1 years and median gravida were 2(1:5). According to the histopathological findings; corpus luteum cyst was detected in 10 (22.3%) patients, serous cysts or cystadenomas in 8 (17.8%) patients, mucinous cystadenomas in 7 (15.6%) patients, endometriomas in 5 (11.2%) patients, borderline serous cystadenoma in 4 (8.9%) patients, mature cystic teratomas in 3 (6.6%) patients, inclusion cyst 3 (6.6%) in patients, paraovarian-paratubal cysts 2 (4.4%), fibroma in 1 (2.2%) patients, serous adenocarcinoma in 1 (2.2%) patient, mucinous adenocarcinoma in 1 (2.2%) patient. Bilateral salpingo-oophorectomy were performed for malign cases.

Conclusion

Adnexal mass detected during caesarean section is a rare condition. Although they are mostly benign, it can be borderline or malignant. We suggest that excision of these masses should be considered during caesarean section to avoid the risk of malignancy and also subsequent surgery could be performed for staging for selected malignant cases.
UNUSUAL GESTATIONAL CHORIOCARCINOMA ARISING IN AN INTERSTITIAL PREGNANCY

M.S. Rhim¹, H. Salhi², M. Rezgani², O. Jaidane¹, I. Zemni², J. Ben Hassouna², T. Dhiab², M. Hechiche², A. Haddad¹, K. Rahal², R. Faleh¹

¹Maternity Center, Department of Gynaecology and Obstetrics, Monastir, Tunisia
²Salah Azaiez Institute, Surgical Oncology Department, Tunis, Tunisia

Aims

Choriocarcinoma is a highly malignant trophoblastic neoplasm. Its association with ectopic pregnancy is very rare and usually with aggressive behavior. We will try to specify its characteristics.

Method

We report a new case arising in an interstitial pregnancy occurring in a 46-year-old woman.

Results

The patient was admitted for severe pelvic pain and abundant metrorrhagia. One month ago, she had had a laparoscopic resection of an interstitial pregnancy subsequent to failure of chemotherapy by methotrexate. The raise of serum βhCG level and the hyperechoic intrauterine mass were in favor of gestational trophoblastic disease. Urgent laparotomy was performed for circulatory collapse. Hysterectomy was done. Histological examination revealed a choriocarcinoma. The patient underwent chemotherapy. Two years later, neither metastasis nor recurrence was detected.

Conclusion

The current trend of the treatment of ectopic pregnancy by conservative surgery requires adequate monitoring of βhCG and careful examination of pathologic specimens to avoid misdiagnosis of ectopic gestational trophoblastic disease.
TAILORED THERAPY FOR FERTILE WOMEN WITH ENDOMETRIAL CANCER: THE DUTCH EXPERIENCE

M. van Gent¹, M. Kagie², T. Bosse³, B. Trimbos⁴, C. de Kroon⁴

¹Center of Gynaecological Cancer Amsterdam, Antoni van Leeuwenhoek, Amsterdam, The Netherlands
²Haaglanden Medical Center, Gynaecology, The Hague, The Netherlands
³Leiden University Medical Center, Pathology, Leiden, The Netherlands
⁴Leiden University Medical Center, Gynaecology-K6-P, Leiden, The Netherlands

Aims

To evaluate the oncological and obstetrical outcomes after the introduction of a nationwide protocol for tailoring therapy in young women with endometrial cancer (EC) with the wish to preserve fertility.

Method

Patients with low-grade, stage I endometrioid EC were treated with progesterones. Staging was done by physical examination, ultrasound and contrast enhanced MRI. Strict follow-up rules were defined. Complete response (CR) was defined as two subsequent endometrial biopsies with normal histo-pathological findings.

Results

33 patients were treated since the introduction of the protocol. Mean age: 33 yr. Mean BMI: 28 kg/m². The majority (n = 23, 70%) was treated with medroxyprogesterone 200 mg/day. Mean follow-up: 44 months (median 33 months). CR was obtained in 61% (20 /33). Mean time to CR was 8 months (median 7.5 months). Recurrence rate was 65% (13/20). Mean time to recurrence after end of therapy was 13.4 months (median 11 months). CR after re-treatment for recurrence was 67 % (6/9). Recurrence after second course: 50 % (3/6). Mean time to recurrence: 23.3 months (median 15 months). 17 pregnancies resulted in 7 deliveries and 2 current third trimester pregnancies in 7 patients. Five out of 15 patients undergoing hysterectomy had no residual disease, 10 had grade 1 disease (9 stage 1A, 1 stage III). One patient suffered from ovarian recurrence after hysterectomy with USO (18 months after hysterectomy).

Conclusion

The results confirm previous findings in literature on efficacy and safety of fertility preserving therapy in endometrial cancer. Women should be informed about recurrence rates after complete response.
Aims

The aim of the study was to evaluate the fertility of women after laparoscopic procedure for endometriosis-associated infertility.

Method

Laparoscopic correction of endometriosis defect. 50 patients were operated because of ovarian endometriosis. Data were obtained from medical records (diagnostic tests, medical reproductive and surgical history, clinical status during surgery). The survey included issues related to the birth rate of women during the 24-month period after surgical treatment (conception, subsequent pregnancy, relapse of endometriosis).

Results

The endometriosis group (EG) was divided into two subgroups: women with a single endometrioma and women with endometrioma and coexisting peritoneal endometriosis. The study showed a slightly lower risk of pregnancy in the group of advanced endometriosis compared with the group of a single endometrioma. A 24-month follow-up period revealed 35 women with a single endometrioma, became pregnant and gave birth to healthy children by caesarean section at 39-40 weeks gestation (70%). 15 (30%) patients did not have a pregnancy.

Histological analysis performed in all 50 cases revealed the presence of endometriosis in 45 women (90%).

Conclusion

The degree of pregnancy in endometriosis-associated infertility after cystectomy of the endometrioma is much lower. That is why the decision on surgical treatment among women of childbearing should be well thought out because of the risk of subsequent surgery in the future.
INSULIN RESISTANCE AFFECTS THE THERAPEUTIC EFFECT OF FERTILITY-SPARING TREATMENT IN PATIENTS WITH ENDOMETRIAL ATYPICAL HYPERPLASIA

B. Yang¹, X. Chen², X. Luo¹, Y. Cheng³, W. Shan¹
¹, gynecological department, shanghai, China
², gynecologic department, shanghai, China
³, shanghai, China

Aims

To evaluate the effect of progestin combined with hysteroscopy on fertility-sparing treatment of endometrial atypical hyperplasia (EAH) and cancer (EC). And to investigate the impact of insulin resistance on the therapeutic effect.

Method

One hundred and forty-eight EAH patients and 36 stage IA, grade 1 EC in Ob&Gyn Hospital of Fudan University from September 2011 to June 2016 were retrospectively investigated. All patient received high dose progestin combined hysteroscopy therapy. Therapeutic effect was evaluated by hysteroscopy every 3 month during treatment.

Results

The median age of the EAH was 33 (8) years, and that of EC was 31 (9) years. 40.54% EAH and 52.78% EC showed insulin resistance. 43.24% EAH and 44.44% EC were considered overweight (BMI ≥ 25kg/m²). 104 of the 148 EAH patients (70.27%) showed CR after 6 months’ treatment and 95.85% (129/136) achieved CR after 12 months’ treatment. 69.44%(25/36) and 94.12%(32/34) of EC patients achieved CR after 6 and 12 months of treatment. The mean length of treatment for achieving CR was 5.36 months and 5.44 months in EAH and EC patients respectively. The CR rate was significantly higher in EAH patient without IR (67.31% vs. 59.09%, p=0.003) at 6 month of treatment. EAH patients with both IR and BMI ≥ 25kg/m² had the lowest therapeutic effect at 6 month of treatment (51.22% vs. 68.42% for IR+BMI-, 76.92% for IR-BMI-, and 86.96% for IR-BMI+, p=0.009).

Conclusion

Insulin resistance and higher BMI negatively affect the therapeutic effect of fertility sparing treatment of EAH.
CAN TUMOR MARKERS HE4 AND CA125 BE USEFUL IN DIFFERENTIATION INTRA-PELVIC FROM EXTRA-PELVIC ENDOMETRIOSIS?

N. Abdalla¹, R. Piorkowski¹, A. Timorek¹, P. Stanirowski¹, K. Cendrowski¹, W. Sawicki¹
¹Medical University of Warsaw, Chair and Department of Obstetrics- Gynecology and Oncology, Warsaw, Poland

Aims

The aim of the study was to compare the serum level of tumor markers HE4 and CA125 between group of patients with intra-pelvic endometriosis (IPE) and group of patients with features of extra-pelvic endometriosis (EPE).

Method

A total of 67 patients were included in the retrospective study. The serum level of HE4 and CA125 was measured for each patient before surgical intervention. The final diagnosis of endometriosis was established according to histological examination of endometriosis foci. Patients were divided into two groups according to anatomic localization of endometriosis. The first group included patients with only features of intra-pelvic endometriosis. The second group include patients with features of extra-pelvic endometriosis with or without intra-pelvic endometriosis. U Mann-Whitney test was used in statistical analysis.

Results

The age range was 20-59, with a mean of 36.1 years, standard deviation (SD) = 8.7 years. A total of 52 (77.61%) patients had only intrapelvic endometriosis while 15 (23.39%) had extra-pelvic endometriosis. The mean of serum level of HE4 in IPE and EPE group was 48.21 (SD 14.29) pmol/L and 47.41 (SD 10.81) pmol/L, respectively. The mean of serum level of CA125 in IPE and EPE groups was 64.14 (SD 63.51) U/ml and 62.75 (SD 41.64) U/ml, respectively. The serum level of HE4 and CA125 didn’t differ significantly between IPE and EPE groups (p level 0.875 and 0.718, respectively).

Conclusion

Both tumor markers HE4 and CA125 were not useful for differentiation the main localization of endometriosis whether intra-pelvic or extra-pelvic.

MULTIPLE GIANT MANIFESTATIONS OF CONGENITAL LYMPHANGIOMA CIRCUMSCRIPTUM, A CASE REPORT
S. Akhavan¹, J. Agah², F. Nili³
¹Tehran university of medical sciences- Tehran- Iran, Department of Gynecology Oncology, tehran, Iran
²Sabzevar university of medical sciences, department of obstetrics and gynecology, Sabzevar, Iran
³Cancer institute- Imam Khomeini hospital complex- Tehran- Iran, Department of pathology, Tehran, Iran

Aims

Objectives: Vulvar lymphangioma circumscriptum is a rare benign disorder of lymphatic channels which is mostly acquired following pelvic lymphadenectomy or radiotherapy. Herein, we present a rare case of congenital lymphangioma with multiple extremely enlargement

Method

Case report: A G2L2 33-year-old woman attended our clinic with large verrucous warty masses in labia major, perinea and end-portion of spine measuring about 15x7cm, 9x7cm and 8x8cm respectively. Notably, her right upper and left lower limbs had gross congenital lymphedema. Since puberty she noticed vesicular lesions which gradually progressed in subsequent years till the past three years, after the second delivery, significant enlargement of lesions occurred. The masses were removed by superficial partial vulvectomy with a qualified margin and repaired without skin graft.

Results

Several months follow-up revealed normal healing and no recurrence.

Conclusion

Conclusion: congenital lymphangioma can be triggered by hormonal stimulating situations like puberty and pregnancy. So it is rather to visit the affected cases timely in order to excise these lesions before massive enlargement. In our experience, a superficial partial vulvectomy without skin graft can be a sufficient procedure of course, with meticulous approach during and after surgery.

A PROSPECTIVE STUDY EVALUATING THE EFFICACY OF SURGICAL CARE BUNDLE IN REDUCING SURGICAL SITE INFECTIONS IN LAPAROTOMIES PERFORMED FOR GYNAECOLOGICAL MALIGNANCIES

R. Agarwal¹, A. Rajanbabu¹
¹Amrita Institute of Medical Sciences, Gynecology Oncology, Kochi, India

Aims

To investigate whether implementing a care bundle, defined as a set of evidence-based practices performed collectively, can reduce 30-day surgical site infections (SSI) in women undergoing laparotomy for gynaecologic malignancies

Method

The surgical site infection reduction care bundle consisting of 14 processes throughout the surgical encounter, including preoperative, intraoperative, post-operative and post discharge elements were implemented at Amrita Institute of Medical Sciences from January 2016. Some practices were established earlier and some new interventions like patient education, sterile closing tray and staff glove change for fascia and skin closure, dressing removal at 24–48 hours etc, were incorporated.

End points measured were the rate of Superficial SSI, Deep SSI, organ space SSI, length of hospital stay due to SSI and 30 day re admission rate.

The infection rate in intervention period was compared with the infection rate of the patients undergoing laparotomy in the pre intervention period.

Results

Overall 30-day surgical site infection rate significantly reduced from 19.5% (43/220) in the pre-intervention period to 5.8% (6/104) in the intervention period (P <0.001). Superficial SSI rate significantly reduced from 15.9% to 5.8% (P =0.11). There was no organ/space infection seen during the intervention period. Prolonged hospital stay rate due to SSI reduced from 2.3% to 0.9%. None of the patients during the intervention period were readmitted with SSI.

Conclusion

Implementation of an evidence-based surgical care bundle was associated with substantial reduction in surgical site infection in patients undergoing laparotomy for gynaecological malignancies.

SYNTHESIS OF A THERANOSTIC AGENT: RADIOIODINATED PEGYLATED PLGA-INDOCYANINE CAPSULES AND IN VITRO DETERMINATION OF THEIR BIOAFFINITY ON OVARIAN, CERVICAL AND BREAST CANCER CELLS

L. Akman1, F.Z. Biber Muftuler2, A. Bilgi1, A. Yurt Kilcar1, S.G. Gokulu1, E.I. Medine2, M.C. Terek1

1EGE UNIVERSITY FACULTY OF MEDICINE, OBSTETRICS AND GYNECOLOGY, IZMIR, Turkey
2Institute of Nuclear Sciences- Ege University, Department of Nuclear Applications, IZMIR, Turkey

Aims

The aim of current study is to synthesize atheranostic (multi-functional) agent, which is targeted on ovary, cervical and breast cancer types with diagnosis and treatment potential and to determine its bioaffinity by using in vitro methods.

Method

Indocyanine (ICG) was preferred as the first modality of our agent due to its fluorescence properties. Then, ICG was encapsulated with PEGylated PLGA (IPP). Additionally, Paclitaxel (PAC) was conjugated with IPP (IPPP) to target the agent to reproductive organs like ovary, cervix and breast. Lastly, IPPP was radiolabeled with 131I as the second modality of developed theranostic agent. In vitro incorporation and cytotoxicity assays, and fluorescent imaging assays were performed.

Results

Incorporation values of 131I-ICG and 131I-IPP were similar on all cell lines during study period. 131I-IPPP has higher incorporation values than 131I-PAC on MCF-7, MDAH-2774 and HeLa cells at all time points. The highest uptake values are observed for 131I-PAC and 131I-IPPP at 240 min on MDAH-2774 cells as 18.88 ± 2.24 and 22.05 ± 2.85, respectively. The incorporation values of 131I-IPPP at 30 min on MCF-7 and MDAH-2774 cells were higher 1.70 and 1.62 times than 131I-PAC.

The cellular uptake study confirmed the high binding efficiency of 131IIPPP with MDAH-227 cells. Fluorescence microscopy demonstrated that both ICG and IPPP successfully bound target cancer cells.

Conclusion

The designed compound(IPPP), which has fluorescence capability (from Indocyanine), encapsulated structure (with PEGylated PLGA), included an anticancer drug (Paclitaxel) for targeting and radionuclidic tracer (131I) content for tracing, has bioaffinity and promise for diagnosis and therapy on ovarian, cervical and breast cancer cell lines.
Aims

OBGETIVES: Granulosa cell tumors of the ovary are derived from the sex cords and the ovarian stroma. The objective of this study is review the incidence, natural history and prognosis of this type of tumor.

Method

The study group included 3 patients with granulosa cell tumor treated by the Gynecologic Oncology division at Principe de Asturias Hospital over a period of 1997 - 2017. A retrospective review was performed. Data was collected on clinical and pathological features, treatment, recurrence and survival rate.

Results

This study includes 3 patients with the diagnosis of granulosa cell tumor of the ovary treated between 1997 and 2017. Median age at diagnosis was 50 years (25-79). The stage according to FIGO was Ia in the 3 cases. Median tumor size was 60 mm (40-80). Post-menopausal bleeding was diagnosed in one case, and hypermenorrheas in the other two cases, with endometrial hyperplasia in all cases (100%). Two patients were treated with primary radical surgery, and the youngest patient with conservative surgery. The 3 patients are alive with no evidence of disease, except the youngest patient who presented a pelvic recurrent disease 14 years after the primary surgery. The treatment realized was radical surgery and adjuvant chemotherapy. Ten years survival rate was 100%.

Conclusion

Granulosa cell tumors are uncommon neoplasms that are characterized by late recurrence and high survival rates. Their extreme rarity represents a limitation in our understanding of their natural history management, and prognosis.
ADVANCED STAGE ENDOMETRIAL STROMAL SARCOMA DIAGNOSED DURING PREGNANCY: A CASE REPORT

D. Altin¹, A. Usubütün², Ş. Şalvarlı³, S. Taşkin¹, F. Ortaç¹

¹Ankara University Faculty of Medicine, Gynecology and Obstetrics, Ankara, Turkey
²Hacettepe University Faculty of Medicine, Pathology, Ankara, Turkey
³Guven Hospital, Radiodiagnoics, Ankara, Turkey

Aims

Endometrial stromal neoplasia is a rare malignancy of uterus. It is usually seen in perimenopausal ages. It is usually not seen during antenatal or postnatal period. There are few cases of endometrial stromal sarcoma found incidentally on placenta specimens and presented with postpartum hemorrhage. There is only one case presented during pregnancy but it was undifferentiated endometrial sarcoma.

Method

We present a case of 27-year old woman who had myomectomy 4 years before pregnancy and misdiagnosed as myoma uteri, but actually had endometrial stromal sarcoma. She presented with multiple abdominal masses during 20th week of pregnancy. A biopsy was obtained by interventional radiology during pregnancy from one of the masses and the result was low grade endometrial stromal sarcoma. At 34th week of pregnancy cesarean was done. On abdominal exploration, there were tumoral implants on the uterus, in the abdominal wall, on transvers colon and on cecum. A total hysterectomy with bilateral salpingo-oophorectomy, cecal and partial colonic resection and anastomosis, debulking of intraabdominal and abdominal wall masses with bilateral pelvic lymph node dissection was done. No macroscopic residual tumor was left. Pathologic studies revealed endometrial stromal sarcoma. She received progesterone treatment with megestrol acetate 160 mg/day.

Results

not available

Conclusion

Uterine fibroids, endometrial carcinoma and other uterine sarcomas should be differentiated from ESS. If the right diagnosis could had been done and hormonal therapy was administered after the initial surgery, recurrence might had been not occurred.

A CASE OF UTERINE TUMOR RESEMBLING OVARIAN SEX CORD TUMOR TREATED WITH UTERINE WEDGE RESECTION

D. Altin\textsuperscript{1}, S. Taşkin\textsuperscript{1}, F. Ortaç\textsuperscript{1}

\textsuperscript{1}Ankara University Faculty of Medicine, Gynecology and Obstetrics, Ankara, Turkey

Aims

Uterine tumor resembling ovarian sex cord tumors (UTROSCT) are infrequent forms of uterine tumors. It should be distinguished from endometrial stromal tumors with sex cord like elements (ESTSCLE) since the latter one is more aggressive and the outcome is poorer. Hysterectomy with or without adnexectomy is the preferred choice of treatment. Fertility preserving treatment options are getting common in the last decade for young patients. Hysteroscopic resection of the tumor is the most frequent approach. To our knowledge this is the first case of UTROSCT who was treated with uterine wedge resection.

Method

We describe here a case of 26-year-old nulligravid woman with menometrorrhagia whose ultrasonographic examination revealed 4 cm submucous myoma. Abdominal myomectomy was done but the pathological result was UTROSCT. An abnormal lesion was detected in her control ultrasonography and PET/CT. She then underwent uterine wedge resection with clear surgical margins. She is being followed up for 6 years with no evidence of disease.

Results

not available

Conclusion

UTROSCT is usually seen in elderly women. Conservative management can be an option for younger women who have fertility desire. It seems like it is an acceptable choice since the tumor has low malignant potential. More cases are needed to support the safety of fertility preserving treatment and the outcome.
A LONGITUDINAL STUDY OF CHANGES IN PATIENT PERCEPTION OF CHEMOTHERAPY SIDE EFFECTS IN BREAST AND OVARIAN CANCER PATIENTS - A PROSPECTIVE TRIAL.

B. Ataseven¹, J. Frindte¹, P. Harter¹, G. Goekte¹, J. Holtschmidt², J. Podkowinski¹, V. Caroline¹, V. Blunf², M. Vincent², F. Heitz¹, S. Kuemmel¹, S. Prader¹, M. Sporkmann¹, S. Schneider¹, A. du Bois¹

¹Kliniken Essen-Mitte, Gynecology & Gynecologic Oncology, Essen, Germany
²Kliniken Essen Mitte, Senology, Essen, Germany

Aims

Knowledge regarding changes of patient perception of chemotherapy side effects (CSE) over the complete treatment period is limited. In this longitudinal prospective study, we aimed to evaluate potential changes. Interim analysis results will be presented.

Method

Breast (BC) and ovarian cancer (OC) patients were recruited before start of chemotherapy. At three different visits (before (T1), week 12+/-3 (T2), and at the end of chemotherapy (T3)) patients were asked to identify out 72 cards displaying potential physical and non-physical CSE the ten most burdensome and rank them finally to top five by severity. The top five most troublesome effects at each visit are reported.

Results

In total, 141 patients (95 BC and 45 OC) were recruited. Median age was 54 years (range 24-80). All three interviews were completed by 113 patients, so far. Over the complete observation period “affects my family/partner” and “difficulty sleeping” were among the top five severe side effects. “Feeling of not coping” and “nausea” were ranked only at T1 but not at T2/T3. “Loss of hair” was ranked at T1/T2, but no longer at T3. In contrast, “numbness in limbs” became relevant in T2/T3 (table 1).

Conclusion

Data from this study demonstrate that patient perception of CSE changes over the treatment period. However, social concerns like “affecting family/partner” and “sleeping disorders” remain long-lasting problems.

CHANGE OF PATIENT PERCEPTIONS OF CHEMOTHERAPY SIDE EFFECTS IN BREAST AND OVARIAN CANCER PATIENTS

J. Frindte1, B. Ataseven1, H. Philipp1, G. Goeke1, J. Holtschmidt2, J. Podkowinski1, C. Vogt1, V. Blun2, M. Vincent2, A. Traut1, F. Heitz1, S. Kuemmel2, S. Prader1, M. Sporkmann1, S. Schneider1, A. du Bois1

1Kliniken Essen-Mitte, Gynecology & Gynecologic Oncology, Essen, Germany
2Kliniken Essen Mitte, Senology, Essen, Germany

Aims

In 1983, 1993, and 2002 results of studies identifying patient perceptions and individual ranking of chemotherapy side effects (CSE) were reported. We aimed to update this survey and evaluate changes in patient perceptions a further decade later.

Method

Patients with breast (BC) and ovarian cancer (OC) planned for chemotherapy were recruited in this prospective study. At week 12 +/- 3 weeks after chemotherapy initiation patients were asked to identify from 72 cards displaying potential physical and non-physical CSE the ten most burdensome and ranking them finally to top five by severity. Results are reported for the entire group and in comparison to published data. Additionally, socio-demographic and clinical characteristics were evaluated.

Results

In total, 126 patients (85 BC and 41 OC) were interviewed. The most severe CSE reported was “difficulty sleeping” compared to “vomiting” in 1983, “nausea” in 1993, and “affects my family/partner” in 2002 (table 1). “Loss of hair” remained a top concern over all studies. The most severe CSE in BC patients was “loss of hair” in contrast to “difficulty sleeping” in OC patients.

Conclusion

Patient perceptions of CSE have changed markedly compared with previous studies. Especially taxane related CSE are reported more frequently. However, “loss of hair” has remained an unsolved problem over decades. Ranking the most severe CSE by cancer type demonstrated clinically relevant differences.
ANGIOMYOFIBROBLASTOMA OF THE RETRORECTAL REGION: A CASE REPORT

H. Aydin¹, A. Aydin², M. Yaprak³, I.E. Gurer³, H.E. Pestereli³, T. Simsek⁴
¹Akdeniz University, Gynecologic Oncological Surgery, Antalya, Turkey
²Akdeniz University, General Surgery, Antalya, Turkey
³Akdeniz University, Medical Pathology, Antalya, Turkey
⁴Akdeniz University, Gynecologic Oncological Surgery, Antalya, Turkey

Aims

Angiomyofibroblastoma (AMF) is an uncommon, benign neoplasm that most commonly involves the vulvovaginal region. We herein report a case of a 44-year-old woman with a pelvic AMF which showed a benign clinical course.

Method

Case

A 44-year-old woman was initially admitted to the Department of Gynecologic Oncology, School of Medicine Akdeniz University in December 2016. The patient presented with pelvic pain for the last 8 months. A palpable, solid mass was identified on the left lateral wall of the vagina. Bimanual examination showed a 8x7 cm mobile mass in relation to the adjacent tissues, associated with vagina in the retrorectal region. The mass was a well-circumscribed soft tissue mass with heterogeneous internal echoes. The patient underwent operative removal of the tumor. On microscopy a well-circumscribed lesion was seen and composed of spindled to epithelioid cells. There were alternating hypo and hypercellular areas. Randomly distributed blood vessels were present and a perivascular concentration of the stromal cells was appreciated. On immunohistochemistry, the stromal cells were positive for desmin and vimentin. Actin and S 100 staining of stromal cells was negative. The stromal cells were also positive for estrogen receptor (ER) and progesterone receptor (PR). The blood vessels were well-highlighted by smooth muscle actin (SMA).

Results

Angiomyofibroblastomas are benign with little or no tendency for local recurrence. A careful histopathological examination of the vaginal lesions helps in differentiating angiomyofibroblastomas from other mesenchymal tumors.

Conclusion

It is important to identify this entity so that the patient can be saved from unnecessary follow-up and intervention post excision.
Aims

To analyse patients’ opinion about communication with a surgeon before and after the surgical treatment of endometrial cancer using the CAHPS®.

Method

Perspective cohort study of 57 (response rate 79.2%) patients treated for endometrial cancer in Lithuanian University of Health Sciences Hospital. The translated CAHPS® and Rosenberg Self-Esteem Scale (group A – low self-esteem, <15 points (n=10), group B – moderate and high self-esteem, >15 points (n=47)) was used with 2 additional questions about pain. χ² tests were made, data was considered statistically significant if p<0.05.

Results

Results were analyzed according to composites of CAHPS®. 79.8% of patients were informed fully about preparation for the surgery. 38.6 % were informed fully about the treatment and visual aids were disclosed. Surgeon communicated very well before the surgery in 86.9% of cases. 96.5% of surgeons were attentive on the day of surgery and 53.1% disclosed information fully on how to recover. 91.2% of surgeons communicated very well after the surgery. Answers to the survey were not different between groups except that surgeon’s visit before the surgery made more patients calm in group B (97.8% versus 77.8%, p=0.048). Patients in group A felt pain 4 weeks after the surgery more often (100% versus 46.8%, p<0.001).

Conclusion

Overall surgeons communicated very well with the patients, but information was not always disclosed. CAHPS® results were similar among patients with different self-esteem. Surgeon’s visit before the surgery made less patients with low self-esteem calm and pain 4 weeks after the surgery was related with low self-esteem.
Aims
The differential diagnosis of axillary tumors will be discussed on the basis of a case of axillary schwannoma.

Method
Symptoms, diagnosis, anatomical findings and histological findings as well as potential therapeutical approach will be presented. We searched the Medline for english articles using axillary schwannoma, axillary peripheral neural sheath tumor, brachial plexus tumors, axillary swelling, sonographic appearance schwannoma, and radiologic appearance schwannoma as key words.

Results
Schwannomas are tumors of the nerve sheath, they evolve from swann-cells of myelinised nerves. Ususally, axillary schwannomas present as a slow growing mass without pain or neurological deficiencies. Usually, they have a capsule. In sonography they appear like clearly defined cysts without blood flow. Pathognomonic is a hyperintensity in periphery of a clearly defined cystic mass in T2 weighting in MRI. We identified three further case reports describing cystic axillary schwannoma.

Conclusion
An axillary schwannoma represents a very rare condition, especially presenting as a cystic mass. Tumors of the nerve sheath should be considered in the diagnostic work-up.

PROGNOSTIC ROLE OF PLASMA FIBRINOGEN IN PATIENTS WITH UTERINE LEIOMYOSARCOMA – A MULTICENTER STUDY

C. Bekos¹, E. Petru², L. Heller³, D. Reimer⁴, H. Koch⁵, S. Polterauer⁶

¹AKH Wien, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria
²Medical University Graz, Department of Obstetrics and Gynaecology, Graz, Austria
³Krankenhaus der Barmherzige Schwestern- Linz, Department for Gynaecology, Linz, Austria
⁴Medical University Innsbruck, Department of Obstetrics and Gynaecology, Innsbruck, Austria
⁵Medical University Salzburg, Department of Obstetrics and Gynaecology, Salzburg, Austria
⁶Medical University Vienna, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria

Aims

Fibrinogen plays an important pathophysiological role in tumor cell progression and development of metastases in different types of cancer. The aim of the present study was to evaluate the value of pre-treatment fibrinogen plasma levels as a prognostic biomarker in patients with uterine leiomyosarcoma (ULMS).

Method

Data of women with ULMS were extracted from a multi-center database. Pre-treatment fibrinogen plasma levels were measured. The association between fibrinogen plasma levels and clinico-pathological parameters was investigated and univariate and multivariable survival analyses were performed.

Results

A total of 70 patients with ULMS was included into this analysis. Mean (SD) pre-therapeutic fibrinogen plasma level was 480.2 (172.3) mg/dL. Patients with advanced tumor stage had higher fibrinogen levels (p=0.02). Five-year overall survival (OS) rates in ULMS patients with increased fibrinogen levels were 25.0% compared to 52.9% in ULMS patients with normal fibrinogen. Univariate survival analyses revealed that elevated fibrinogen plasma levels (p=0.003), advanced tumor stage (p<0.001) and high histological grade (p=0.004) were associated with unfavorable OS. In multivariable analysis, only histological grade (p=0.07) was independently associated with survival.

Conclusion

Elevated fibrinogen plasma levels were associated with advanced disease and unfavorable prognosis in women with ULMS in univariate survival analysis. After validation in future studies fibrinogen might be a useful biomarker for tumor stage and prognosis in ULMS patients.

AN ONCO-GERIATRIC SCREENING TO TAILOR TREATMENT IN ELDERLY PATIENTS WITH GYNAECOLOGIC MALIGNANCIES IN A MULTIDISCIPLINARY UNIT

C. Bellobi1, L. Ferrer-Mileo2, M. Gil-Martin2, S. Recalde2, S. Marin i Borras3, V. Navarro4, J.M. Piulats2, B. Pardo2

1Institut Catala d’Oncologia- Hospital Duran i Reynals. IDIBELL, Nursing Oncology, L’Hospitalet-Barcelona, Spain
2Institut Catala d’Oncologia- Hospital Duran i Reynals. IDIBELL, Medical Oncology, L’Hospitalet-Barcelona, Spain
3Institut Catala d’Oncologia- Hospital Duran i Reynals. IDIBELL, Radiation Oncology, L’Hospitalet-Barcelona, Spain
4Institut Catala d’Oncologia- Hospital Duran i Reynals. IDIBELL, Clinical Investigation Unit, L’Hospitalet-Barcelona, Spain

Aims

To evaluate the feasibility of an Onco-geriatric screening tool and subsequent therapeutic decisions in a Gynaecologic Oncology Multidisciplinary Unit.

Method

The screening tests consisted of Barthel, Pfeiffer and G8 scales, conducted by the specialized Nurse. The screening was positive if the woman was older than 85yo, or if 75-85yo with 2 risk factors: Barthel test <90, >2 mistakes in Pfeiffer scale and G8 test with ≤14 points, and lack of social resources. After a positive screening, a comprehensive geriatric assessment was recommended, and the oncologist decided the most appropriated treatment.

Results

Seventeen patients were included in the analysis since November/2015 to April/2017, with a median age of 82 yo. They were distributed in 2 cervical, 5 endometrial, 5 ovarian and 5 vulvar tumors; 59% of cases in advanced disease. Tests results were: 94% patients had Barthel <90, 11.8% >2 mistakes in Pfeiffer scale and G8 test with ≤14 points, and lack of social resources. After a positive screening, a comprehensive geriatric assessment was recommended, and the oncologist decided the most appropriated treatment.

Conclusion

Gynaecologic oncology frail patients can be appropriately selected with an Onco-geriatric screening test that permits patients to benefit from a tailored treatment.
THE CURIOUS CASE OF A DEVIANT MOLE: A CASE OF AN INVASIVE MOLE METASTATIC TO THE OVARY

M. Cabatu¹, A.M. Trinidad¹, M.C.Z. Gamilla¹, J.K. Beltran¹
¹University of Santo Tomas Hospital, Obstetrics and Gynecology, Manila, Philippines

Aims

To emphasize the rarity of the case and how it can present differently, posing diagnostic dilemma.

Method

A case report of a metastatic invasive mole.

Results

This is a 33 year old, G3P1 (1021), presenting with left lower quadrant pain. The positive pregnancy test and previous complete mole, lead to Gestational Trophoblastic Neoplasia, probably ruptured vs. Ectopic Pregnancy. Transvaginal ultrasound showed an anteverted, homogenous uterus; hyperechoic, intact endometrium; normal size ovaries; complex mass posterior to the uterus measuring 6.0 x 2.64 x 4.87 cm with multiple cystic spaces; fluid in the cul-de-sac, 22cc volume. Emergency exploratory laparotomy was done. On laparotomy, a right ovarian mass exuding vesicular tissues and a bluish-black discoloration at the right postero-lateral aspect of the uterus were noted. With these findings, total abdominal hysterectomy with right salpingo-oophorectomy was performed. Histopathologic examination revealed an invasive mole metastatic to the ovary.

Conclusion

Invasive mole metastasizing to the ovary is not an impossibility, simply because of the adjacency of both organs. This is a manifestation that truly, invasive mole, can invade or overrun any organ for that matter, far or near, as the latter in our case, the neighboring ovary. The impression of GTN at any given time and place, should tweak the curiosity in us, “What and where it is this time?” And this time, it is the ovary!
IS SURGICAL TUMOR FRAGMENTATION AN INDEPENDENT PROGNOSIS FACTOR IN THE OVERALL SURVIVAL OF UTERINE SARCOMAS?

V. Benito¹, A. Lubrano¹, S. Carballo¹, O. Arencibia¹, N. Medina¹, M. Andújar², M. Morí³, M. Federico⁴, F. Molano⁵
¹Complejo hospitalario universitario insular-materno infantil, gynecology oncology, las palmas de gran canaria, Spain
²Complejo hospitalario universitario insular-materno infantil, pathology, las palmas de gran canaria, Spain
³Hospital universitario Dr. Negrín, Medical Oncology, Las Palmas de Gran Canaria, Spain
⁴Hospital universitario Dr. Negrín, Radiation Oncology, Las Palmas de Gran Canaria, Spain
⁵Complejo hospitalario universitario insular-materno infantil, Medical Oncology, las palmas de gran canaria, Spain

Aims

To evaluate clinicopathologic data and prognostic factors for patients with uterine sarcomas (US), with special emphasis on uterine fragmentation during surgery.

Method

Retrospective analysis of all consecutive patients with US treated between 1990-2016. During this period 1,863 patients with uterine malignancies were diagnosed, of which 1,681 were excluded for endometrial carcinoma and 85 for carcinosarcomas, so finally the study sample included 97 patients (5.2% incidence). Survival rates were analysed using the Kaplan-Meier method.

Results

The distribution by histological-type was: 46.4% leiomyosarcoma; 23.7% high-grade ESS; 17.5% low-grade ESS; 11.3% adenosarcomas and 1% liposarcoma. Median age was 52 years (25-90) and 49.5% were premenopausal. The most frequent preoperative diagnosis was uterine fibroids in 49.5%. Tumor surgical rupture occurred in 25.9% of cases. FIGO stages I-II and III-IV were identified in 74% and 26% of patients, respectively. Median tumor size was 8 cm (2-40). EFS rates after 2, 5, and 10-years were 71%, 57%, and 53% respectively, with a median time of 63 months (95%CI, 35.5-90.4). OS rates after 2, 5, and 10-years were 66%, 53%, and 38% respectively, with a median time of 19 months (95%CI, 1-43.7). Multivariate analysis showed that stage; histological type and surgical tumor rupture were independent prognostic factors [(OR7.9; CI95% 1.6-38.2; p=0.01); (OR5.3; CI95% 2.1-13; p<0.0001) and (OR2.6; CI95% 1.1-6.5; p=0.03)].

Conclusion

US are rare but aggressive tumors whose prognosis is strongly influenced by FIGO-stage, histological-type and tumor surgical rupture. Efforts should be made to avoid any type of uterine fragmentation during surgery since it seriously compromises the prognosis of this pathology.

INCIDENCE AND SURVIVAL OF GYNECOLOGIC CARCINOSARCOMAS IN ISRAEL
A. Blecher1, Y. Brudner1, G. Haran1, B.G. Silverman2, M. Hallak1, I. Bruchim1
1Hillel Yaffe Medical Center, Gynecologic Oncology Division - Department of Obstetrics and Gynecology, Hadera, Israel
2Israel Ministry of Health, Israel National Cancer Registry, Ramat Gan, Israel

Aims

Gynecologic carcinosarcoma is a rare and aggressive tumor. Following latest immunohistochemically studies the carcinosarcomas are considered subtypes of carcinomas but seem to have a distinct natural history and presumably worse prognosis. The aim of this study is to report the incidence and outcome of gynecologic carcinosarcomas in Israel.

Method

Records of gynecologic carcinosarcomas diagnosed between 1980-2014 were extracted from the Israeli National Cancer Registry and classified according to ICD-03. Age-standardized incidence rates (ASRs), 1&5 year and overall survival rates were calculated according to anatomical site, population group, stage and grade at diagnosis.

Results

935 new gynecologic carcinosarcomas were diagnosed in Israel between 1980-2014. During the last 15 years there was a substantial increase in ASR from 8 to 11 per million females with a significantly higher incidence in Jewish compared to Arab population (13 vs 4 per million females respectively). Incidence was highest in women 55-75 years old and extremely low in women younger than 30 years old. The most common anatomical site was uterus (83%) followed by ovary (11%). The survival rates increased significantly between 1985-1990 and 2010-2014 but were lower than the survival rates for sarcomas. There was no significant difference in survival rates between the populations.

Conclusion

Gynecologic carcinosarcomas seem to have a distinct behaviour in regard to incidence, age at presentation and survival rates compared to gynecological sarcomas. This is to our best knowledge the first study evaluating this rare histologic subtype in Israeli population and provides important information for clinical practice and further research.
RARE CASE OF PRIMARY SEROUS CARCINOMA OF PERITONEUM IN PATIENT PREVIOUSLY TREATED WITH TOTAL HYSTERECTOMY AND BILATERAL SALPINGOOPHORECTOMY DUE TO CINIII

N. Blountzos¹, C. Iavazzo¹, V. Vafias¹, G. Vorrias¹, N. Kalinoglou¹
¹Metaxa Memorial Cancer Hospital, Gynecology, Piraeus, Greece

Aims

The aim of our study is to present a rare case of primary serous peritoneal carcinoma in a patient who had previously undergone a total hysterectomy with bilateral salpingoophorectomy due to high grade cervical intraepithelial neoplasia (CINIII).

Method

A 53-years-old woman attended our clinic for further investigation of high CA-125 levels found during the typical follow-up. The pathological report of hysterectomy specimen revealed free surgical margins and no malignancy. Three years postoperatively, elevated levels of CA-125 and HE4 (418.1 and 185 respectively) were present, while the endoscopic evaluation of gastrointestinal track and pap-smear test were normal. Abdominal MRI indicated small quantity of ascites in the pouch of Douglas and the space of Morison, as well as multinodularity on the greater omentum.

Results

The patient underwent diagnostic laparoscopy. The perioperative assessment confirmed the existence of free peritoneal fluid in the pouch of Douglas and multiple nodules measuring few millimeters in diameter in the parietal peritoneum and the diaphragmatic surfaces. The greater omentum was widely invaded. No ovarian tissue was recognized. The histological analysis of the relevant biopsies revealed a low differentiated malignant neoplasm. Given the immunohistochemical examination, the history of the patient and the laboratory findings, the diagnosis of a primary serous peritoneal carcinoma was set. MDT decided for the patient to be treated with chemotherapy (carbo taxol).

Conclusion

Despite its rarity, PPC should always be included in the differential diagnosis of every patient with laboratory and/or imaging indications, independently of previous salpingoophorectomy, due to its aggressive course.
CLINICAL AND LABORATORY CHARACTERISTICS OF PRIMARY PERITONEAL SEROUS CARCINOMA
N. Blontzos1, C. Iavazzo1, E. Vafias1, E. Karavioti1, G. Vorgias1, N. Kalinoglou1
1Metaxa Memorial Cancer Hospital, Gynecologic Oncology, Piraeus, Greece

Aims
To present the clinical and laboratory characteristics of patients with primary peritoneal serous carcinoma (PPSC).

Method
This is a retrospective study of 19 patients with PPSC who were treated between 2002 and 2017 in Metaxa Memorial Cancer Hospital, Piraeus, Greece. Our electronic database and medical notes were retrospectively studied for each individual.

Results
The median age of the patients was 64.8 years ranging from 44 to 76 years. Clinically PPSC presented with abdominal distention and pain (17/19 cases), constipation (6/19), while 14 patients complained of loss of appetite. Two of the patients did not report any symptoms and the only findings suggesting the disease were an abnormal cervical smear and elevated Ca-125 levels respectively. All patients except for one had abnormal values of CA-125 at the time of initial diagnosis, ranging from 119 to 12767.3 U/ml with a median value of 1719.2 U/ml. HE4 was measured in the most recent 4 patients and the average was 372.85 pmol/l. Median values of NLR (neutrophil-to-lymphocyte ratio) and PLR (platelet-to-lymphocyte ratio) were calculated and the median values were found to be 5.94 and 140 respectively. Postoperative PCI (peritoneal cancer index) ranged from 6 to 20 (average: 13). Optimal debulking was achieved in 5 cases. All patients were staged as IIIC PPSC and received standard carbo-taxol chemotherapy, whereas Avastin was added in 5 recent cases. Median overall survival was 24.5 months.

Conclusion
PPSC is a rare neoplasm that mimicks ovarian cancer, has poor prognosis and requires multidisciplinary management.
PRIMARIE PERITONEAL CARCINOMA DIAGNOSED IN ABNORMAL PAPANICOLAOU TEST

N. Blontzos¹, C. Iavazzo¹, E. Vafias¹, E. Galati¹, M. Diakosavvas¹, G. Vorgias¹, N. Kalinoglou¹

¹Metaxa Memorial Cancer Hospital, Gynecologic Oncology, Pireaus, Greece

Aims

To report a rare case of primary peritoneal carcinoma detected by an abnormal cervical smear.

Method

A 59-year-old woman presented with granular atypia on routine Papanicolaou smear. Transvaginal ultrasound depicted an endometrial thickness of 8mm and free peritoneal fluid. Bilateral salpingoophorectomy had been performed 15 years ago due to endometriosis. Ca-125 was found 119 U/ml. Endocervical and endometrial curetage was scheduled and the pathology report showed an adenocarcinoma with focal squamous differentiation and uncertain further classification. Abdominal MRI detected multinodularity of the great omentum, great amount of ascites and possible endometrial tumor.

Results

The patient underwent exploratory laparotomy, which confirmed the existence of ascites, wide omental involvement and small implants of the tumor on the pouch of Douglass and the bladder serosa. Extensive debulking was performed to R1 disease. Histological and immunohistochemical analysis revealed extended infiltration of the great omentum and the external cervical surface consistent with primary peritoneal serous carcinoma. Atrophic endometrium was found. Pelvic washings showed metastatic adenocarcinoma. The patient postoperatively received adjuvant chemotherapy.

Conclusion

Abnormal pap smear could rarely be suggestive of extrauterine malignancies, such as peritoneal cancer.

MISCELLANEOUS INCIDENCE AND SURVIVAL OF GYNECOLOGIC SARCOMAS IN ISRAEL

Y. Brudner1, G. Haran1, A. Blecher1, B.G. Silverman2,3, M. Hallak1, I. Bruchim1

1Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
2Israel Ministry of Health, Israel National Cancer Registry, Ramat Gan, Israel
3Tel Aviv University, Seckler School of Medicine, Tel Aviv, Israel

Aims

Survival after gynecologic sarcomas is known to be poor, although limited data are available on the subject. A recent British report showed a substantial survival increase, explained perhaps by improved therapies. The aim of this study is to report the incidence and outcome of gynecologic sarcomas in Israel.

Method

Records of gynecologic sarcomas diagnosed between 1980-2014 were extracted from the National Israeli Cancer Registry and classified according to ICD-03. Age-standardized incidence rates (ASRs), 1&5 year and overall survival rates were calculated according to anatomical site, morphology subtype, population group, stage and grade at diagnosis.

Results

1271 new gynecologic sarcomas were diagnosed in Israel during 1980-2014, with incidence increasing between 1980-2010 years up to ASR of 15.7 per million females in 2010. ASR was significantly lower in the Arab compared to Jewish population (7.7 vs. 16.4 per million females in 2010 respectively), with a more substantial increase during the years. Incidence was highest in women 40-65 years old. The most common histologic diagnosis was leiomyosarcoma (47%) and most common anatomical site was uterus (89%). The observed survival rates were comparable to previous reports in literature, with no difference between the Jewish and Arabic populations.

Conclusion

Although the incidence of gynecologic sarcomas in the Israeli population is higher than in European populations, the distribution of histologic types and anatomic sites is similar. We found no significant difference in survival rates between Arabic and Jewish population through the years. These results provide important information regarding gynecologic sarcoma incidence and survival in Israel.

Aims

To review the outcomes of different urinary diversion techniques following post radiotherapy pelvic exenteration for recurrent/persistent gynaecological cancers.

Method

The current study pertains to those patients undergoing urinary diversion following pelvic exenteration between August 1993 to December 2013. These diversions were performed by a urological consultant. Data regarding age, type of cancer, previous treatment, time and site of recurrence, surgical details and complications as well as follow-up and long term sequelae were collected.

Results

There were a total of 86 patients who underwent pelvic exenteration between the study dates. Of these 60 underwent a urinary diversion procedure (69.7%). 31 had cervical cancer (51.7%), 12 vaginal cancer (20%), 9 endometrial cancer (15%) and 8 were vulval cancer (13.3%). Of these 60 cases 13 (21.6%) had a Mitrofanoff continent urinary diversions, 45 (75%) had an ileal conduit, 1 (1.7%) had a transverse colonic conduit and 1 (1.7%) had a Mainz-Sigma II procedure. Common early complications included UTI and stenosis of the Mitrofanoff. Later complications included revision of Mitrofanoff (5), and stones requiring percutaneous removal (1). There was one anastomotic leak [from an ileal conduit], treated conservatively. 41 (68%) patients have since died of disease [median time to death after exenteration being 18 months (3 months to 13 years)], and 18 (30%) are alive with 1 lost to follow up. Median follow up was 10 years (7 months to 20 years).

Conclusion

In our cohort of 60 patients undergoing pelvic exenteration over a 20-year period, there was a very acceptable rate of complications related to urinary diversion.
VULVAL/VAGINAL RECONSTRUCTION FOLLOWING PELVIC EXENTERATION: A 20-YEAR EXPERIENCE AT THE ROYAL MARSDEN HOSPITAL

S. Bryan1, D. Kolomainen2, S. Natsis1, A. Laios1, K. Power3, D. Barton1

1The Royal Marsden Hospital, Gynaecology Oncology, London, United Kingdom
2Southend University Hospital, Gynaecology Oncology, Westcliff-on-Sea, United Kingdom
3The Royal Marsden Hospital, Plastic Surgery, London, United Kingdom

Aims

To review the outcomes of vulval/vaginal reconstruction following post radiotherapy pelvic exenteration

Method

The current study was based on those patients having vulval/vaginal reconstruction following pelvic exenteration between August 1993 to December 2013. These reconstructions were performed by a consultant plastic surgeon. Data regarding age, type of cancer, previous treatment, time and site of recurrence, surgical details and complications as well as follow-up and long term sequelae were collected.

Results

A total of 86 patients underwent pelvic exenteration between the study period. 25 underwent vulval/vaginal reconstruction (29%). Thirteen had vulval cancer (52%), 6 vaginal cancer (24%) 5 had cervix cancer (20%), and 1 (4%) had endometrial cancer. The vaginal and vulval reconstructions were 12 (48%) VRAM or ORAM flaps, in 7 (28%) patients the bladder dome was used to create a neovagina, 2 lotus petal flaps, 1 latissimus dorsi, 1 gluteal flap and 2 vaginal reconstructions utilising the large bowel. Early complications included wound infections and flap necrosis – one returned to theatre for debridement, 2 partial treated conservatively. Later complications included phantom symptoms (1) and 1 later incisional hernia repair following VRAM flap. Fifteen (60%) patients have since died of disease and 9 (36%) are alive with 1 lost to follow up. Median follow up was 48.9 months (7 months to 20 years). Median time to death post-surgery was 14 months (7.8 months to 8 years).

Conclusion

In our series, vaginal reconstruction was not commonly requested or performed. This may reflect the recognised poor functional results from neovaginal reconstruction following pelvic radiotherapy.

ROBOT-ASSISTED SURGERY IN ELDERLY AND VERY ELDERLY WOMEN AFFECTED BY GYNECOLOGICAL MALIGNANCIES: OUR SINGLE INSTITUTION EXPERIENCE ABOUT INTRAOPERATIVE AND POSTOPERATIVE OUTCOMES

V. Gallotta1, M. D'Indinosante1, A. Federico2, A. Biscione1, C. Conte1, S. Pelligrin1, G. Vizzielli1, B. Costantini1, M.T. Giudice1, V. Chiantera1, A. Fagotti1, G. Scambia1, M.G. Ferrandina1

1Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome, Italy
2Università Cattolica del Sacro Cuore, Gynecologic Oncology, Roma, Italy
3Università Cattolica del Sacro Cuore, Gynecologic Oncology, Palermo, Italy

Aims

To assess the role of robotic surgery for the management of elderly patients with gynecological malignancies.

Method

Between December 2015 and March 2017, 112 patients underwent robotic-assisted laparoscopic surgery procedure for gynecological malignancies were retrospectively evaluated. 41 patients age> 75 years (very elderly group) were compared with 71 patients age from 65 to 74 years (elderly group). Demographic, operative and perioperative outcomes were analyzed retrospectively.

Results

The mean age was 68 years (range, 65-74 years) in the elderly group and 77.0 years (range, 75-87 years) in the very elderly group. There were no differences between two groups in body mass index, preoperative comorbidities and ASA (p 0.247).

Patients underwent surgery for different gynecologic oncological disease: 12 (11%) cervical cancer, 2 (1%) ovarian cancer, 98 (88 %) endometrial cancer.

The types of surgical procedures performed were: 112(100%) radical hysterectomies with bilateral salpingo-oophorectomy, 44 (39%) pelvic lymphadenectomy, 11 (10%) aortic lymphadenectomy, 5 (4.5%) total omentectomy, and 2 (1.8%) pelvectomy. No difference were revealed between the two groups in terms of estimated blood loss, median operative time, median hospital stay and conversion rate. Rate of pulmonary failure was higher in elderly group (4% vs 0%). There were no between-group differences in postoperative infectious morbidity, cardiovascular complications, reoperation and intensive care unit admission.

Conclusion

The perioperative complication rate of robotic-assisted surgery are comparable in very elderly women and elderly women. This study support the feasibility and the role of robotic surgery in elderly and very elderly patients affected by gynecological cancers.
A COMPARATIVE ANALYSIS ON THE INFUSION REACTION OF PACLITAXEL BETWEEN ORIGINAL AND GENERICS DRUG IN GYNECOLOGIC CANCER

P. Chaitosa

1Nurse, Gynecology Oncology, Bangkok, Thailand

Aims

The purpose of this study was to compare to the present of Infusion Reaction between Original and Generics drug in Gynecologic Cancer of Ramathibodi Hospital

Method

Four hundred and forty six patients were recruited from Gynecology Oncology Department in Ramathibodi hospital. The patients who had received Paclitaxel chemotherapy cycle 1. This study were retrospective study from 1 January 2013 to 31 December 2015. The patients received Generic drug 219 cases (cervix cancer 62 case, ovary cancer 89 case and endometrium cancer 68 case) and Original drug 227 cases (cervix cancer 35 case, ovary cancer 125 case, endometrial cancer 64 cases and other 3 cases)

Results

Eighty three patients who met inclusion criteria of Infusion Reaction after paclitaxel injection (Generic drug forty one patients and Original drug forty two patients). 78 cases were noted as mild reaction and 5 cases presented severe reaction of anaphylactoid. The average age of patients received Generic drug was 55-64 years number 78 cases and received Original drug was 55-64 years number 96 cases.

Conclusion

The results of this study demonstrated the Infusion Reaction of Paclitaxel between Original and Generic drug are equivalent when they are used in the first line of treatment for Gynecology Cancer.
SERVICE UTILISATION IN A NEWLY ESTABLISHED INDIAN HEREDITARY CANCER CLINIC

B. Chakraborti1, R. Ahmed2, N. Arora3, S.S. Dutta4, A. Mukhopadhyay1, J. Bhaumik1

1Tata Medical Centre, Gynaecological Oncology, Kolkata, India
2Tata Medical Centre, Breast Oncosurgery, Kolkata, India
3Tata Medical Centre, Genomics, Kolkata, India
4Tata Medical Centre, Palliative care and Psycho oncology, Kolkata, India

Aims

Testing for hereditary gynaecological and breast cancers is a relatively recent inclusion in treatment protocols, but little data is available from developing countries.

Method

A Women’s Clinic for Family Cancers was established in 2016. Women diagnosed with breast, ovarian or endometrial cancer who met international guidelines for genetic testing were offered counselling. Those who consented underwent Next-Generation Sequencing. Individuals had an option to consult a psychologist before and after testing. We present an analysis of service utilisation and summary of test results.

Results

In total 129 individuals were counselled. 80 affected with breast, ovarian, endometrial or colon cancer and 7 unaffected family members underwent testing. Twenty four (27.6%) tested positive for known germline mutations, and another 8 (9.2%) had variations of unknown significance (VUS). 45 reports were normal. Of 80 individuals affected with malignancy, 20 had only ovarian cancer, 39 only breast cancer, 6 both breast and ovarian cancers, and 6 had other malignancies. Among 25 patients with ovarian cancer, 15 had abnormal results, 8 (32%) with known mutations (5 BRCA1, 3 BRCA2). Among 52 patients with breast cancer, 7 (13.5%) had BRCA1 or BRCA2 mutations. Overall, 15 (18.6%) tested patients were diagnosed with HBOC Syndrome and 9 (11.3%) had other inheritable genetic abnormalities (MLH1, PMS2, MSH2, ATM, TP53, PALB2).

Conclusion

Frequent germline mutations were identified in patients who consented to be tested, although many were classified as VUS. Cascade testing was not widely taken up.
ENHANCED RECOVERY AFTER SURGERY (ERAS) FOR GYNAECOLOGY CANCER PATIENTS: OUR SGH EXPERIENCE

G.K. Chew¹, G.W. Su², A. Kong²
¹Penang Adventist Hospital, Obs and Gynae, Georgetown, Malaysia
²Singapore General Hospital, Obstetrics and Gynaecology, Singapore

Aims

We adapted the existing Enhanced Recovery After Surgery (ERAS) Programme in SGH to accommodate our patients undergoing major complicated gynaecology cancer surgery.

Our programme required all our patients to attend pre-op anaesthetic assessment. Laparoscopic surgery was done, where appropriate. We optimised patient’s nutrition pre-operatively and reduced the fasting period with high glucose/electrolyte drinks and intravenous hydration. Multimodal analgesics was employed to reduce opiates requirement. Early reintroduction of diet and mobilisation were encouraged.

We present the ERAS results of patients undergoing major cancer surgery under 1 consultant in 2016.

We wanted to evaluate ERAS programme for gynaecology cancer patients on

- efficacy of the programme
- safety and readmission rate
- Rate limiting factors

Method

All women undergoing major surgery for gynaecological cancer in 2016 were included. Our cohort consisted of 101 women.

Our endpoints measures include:

- Length of hospital post-oper stay (LOS)
- Readmission rates
- Safety issues

Results

The average length of stay is 7 days, with 61% women going home on 5th post-op day. Twenty four women underwent concomitant bowel surgery, accounting for 62% of LOS >5 days. While complications and social issues contributed to longer stay, most were related to stoma care.

There was no reported aspiration pneumonia from the pre-operative drinks.
Readmission rate was less than 5%.

**Conclusion**

We have demonstrated benefits and safety of ERAS in gynaecology cancer patients. We plan to improve our practice by holding classes on stoma care before the operation.
PATIENTS’ ACCEPTABILITY OF DIFFERENT SCREENING TESTS FOR GYNAECOLOGICAL MALIGNANCY IN LYNCH SYNDROME CARRIERS

M.M.Y. Chu\textsuperscript{1}, S.F. Ngu\textsuperscript{1}, K.Y. Tse\textsuperscript{1}, K.K.L. Chan\textsuperscript{1}, H.Y.S. Ngan\textsuperscript{1}

\textsuperscript{1}Queen Mary Hospital - The University of Hong Kong, Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong S.A.R.

Aims

To evaluate patients’ acceptability of different screening tests for gynaecological malignancy in Lynch syndrome carrier

Method

All the Lynch Syndrome carriers who were referred to our center for gynaecological malignancy screening were invited to participate in this study. The subjects’ perception and experience of different screening methods – endometrial aspiration, transvaginal ultrasound and blood tests for Ca125 were assessed by a self-administered questionnaire immediately after the clinic visit. Beck Anxiety Inventory (BAI) was also administered to subjects immediately before the consultation and also when the subjects returned for the test results.

Results

Sixty-four patients were included in this study. The patients’ perception of the effectiveness of different screening methods was shown in Table 1. Most patients reported mild discomfort only with the three screening tests (Table 2). Moderate or severe anxiety was present in 6 (9.5%) and 2 (3.2%) patients respectively before the first consultation. There was no statistically significant difference in the BAI score when they returned for the results.

\begin{table}
\centering
\begin{tabular}{|l|c|c|}
\hline
 & Endometrial Cancer & Ovarian Cancer \\
\hline
Pelvic Examination & 79.7\% & 78.1\% \\
Ca125 & 75\% & 76.6\% \\
Cervical smear screening & 79.7\% & 71.9\% \\
Endometrial aspiration & 81.3\% & 76.6\% \\
Transabdominal ultrasound & 67.2\% & 71.9\% \\
Transvaginal ultrasound & 71.9\% & 68.8\% \\
\hline
\end{tabular}
\caption{The percentage of patients who perceived that the screening method is effective in screening for Endometrial or Ovarian cancer}
\end{table}
Conclusion

The screening tests for gynaecological malignancy were acceptable to most of the Lynch syndrome carriers, but moderate or severe anxiety was present in over 10% of the subjects.
INCISIONAL NEGATIVE PRESSURE WOUND THERAPY IN ONCOLOGICAL PATIENTS.
M.T. Climent1, C. Molinet Coll2, M.D. Martí Cardona2, M. Barahona Orpinell1, J. Rovira Montané1, M.J. Pla Farnós1, J. Ponce Sebastià1
1Bellvitge University Hospital, Gynecology, Barcelona, Spain
2Hospital Sant Joan de Déu, Gynecology, Barcelona, Spain

Aims
This study evaluates the efficacy of negative – pressure therapy in prevention of complications in the surgical site in surgical oncologic patients.

Method
All major oncologic procedure performed with a laparotomy incision performed in two years. We performed a retrospective descriptive cohort study. We evaluated two cohorts, patients undergoing surgery in 2014 and cohort in 2016. The goals of the statistical analyses were to assess the wound complications and days of hospitalization were distributed differently between the incisional negative pressure wound therapy group (INPWT) and the NON-INPWT group.

Results
We included 147 patients. Of the total of patients, 39.6% of the patients used this dispositive. (mean of days to use it was 3 days). The total complication rate in our sample was 21.1%.

Rates of surgical complications in patients treated with INPWT was 2.7% compared with patients which no use INPWT was 18.4% (p=0.000) Performing a stratified analysis of complications; Infection (p=0.001), seroma (p=0.005), dehiscence (p=0.001) and were observed significant differences with a lower incidence of complications in INPWT group, an exception hematoma which no significant difference was found.(p=0.063).

Evaluating the hospital stay, we obtain a decrease in two days of admission, with statistically significant differences. (p=0.048)Conclusion

Prophylactic use of closed-wound negative pressure therapy may decrease wound complications in oncological patients.
LEIOMYOSARCOMA, A DISTRICT GENERAL HOSPITAL EXPERIENCE OF ITS IMAGING AND DIAGNOSIS

S. Cook¹, A. Veitch¹, M. Khan², A. Kingston³
¹Salisbury District General Hospital, Clinical Radiology, Salisbury, United Kingdom
²Salisbury District General Hospital, Histopathology, Salisbury, United Kingdom
³Salisbury District General Hospital, Gynaecology, Salisbury, United Kingdom

Aims

We present several cases of uterine leiomyosarcoma imaged at our institution and highlight the challenges in diagnosing these rare tumours.

Method

Leiomyosarcoma represents approximately 5% of all uterine malignancies. Its non specific appearance on imaging make it notoriously difficult to diagnose radiologically. A high level of clinical suspicion and correlation with symptoms is necessary for prompt diagnosis. We present several cases of uterine leiomyosarcoma and discuss the imaging findings common to these tumours and pitfalls in their diagnosis. We compare these to some benign leiomyomas which have a varied appearance and can complicate the diagnosis of cancer.

Results

Several cases of predominantly post menopausal women ultimately diagnosed with leiomyosarcoma are presented with ultrasound, CT and MR imaging. These are compared to non malignant leiomyomas and other non gynaecological sarcomas for reference. Although imaging cannot be conclusive in its diagnosis, some common features are highlighted when investigating this malignancy.

Clinical ‘red flags’ include rapid increase in size of a pre-existing fibroid, new pressure symptoms in post menopausal women and postmenopausal bleeding.

Imaging appearances are varied but some consistent features are seen including heterogeneous signal change on MR, heterogeneous enhancement post IV contrast, ill defined borders, ascites and enlarged nodes. Metastases may be seen in a later diagnosis.

Conclusion

Although difficult to diagnose on imaging alone we found that some features were consistently seen with a proven histological diagnosis of leiomyosarcoma. Clinical symptoms should raise the possibility of this cancer, however radiology can be supportive and aid prompt diagnosis.
LAPAROSCOPY: A TOOL IN DIAGNOSIS OF MALIGNANT PERITONEAL MESOTHELIOMA AS A RARE CAUSE OF ASCITES – CASE REPORT

V. Janša¹, B. Cvjetičanin¹, N. Lebić Belcijan², B. Kobal¹
¹University Medical Center Ljubljana, Department of Gynecology, Ljubljana, Slovenia
²University Medical Center Ljubljana, Department of Pathology, Ljubljana, Slovenia

Aims

Malignant mesothelioma is an uncommon tumor that usually arises in the pleural cavity. Malignant peritoneal mesothelioma is a rare entity. It can masquerade as an ovarian epithelial neoplasm, with similar presenting clinical symptoms and imaging findings. The golden standard is histologic examination.

Method

Case report: 77 years old female found to have ascites and pleural effusion. The patient denied any previous exposure to asbestos. CT scan revealed carcinosis of peritoneum of unknown origin. Citology exam of pleural effusion revealed mesothelial proliferations with cytologic atypia. We perform a diagnostic laparoscopy and found diffuse carcinomatosis of upper and lower peritoneal cavity. Although the malignant proces was concluded to be inoperable, we perform bilateral adnexectomy, peritoneal biopsy and partial omentectomy aiming to get histological diagnosis and as part of staging disease.

Results

Histopatological examination revealed malignant mesothelioma. The patient was referred to medical oncology where she underwent four cycles of cisplatin and gemcitabin.

Conclusion

Malignant peritoneal mesothelioma is extremely rare entity and usually have similar clinical presentation as ovarian cancer, therefore these patients will likely present to gynecologist. In our case the patient went to surgery for suspected ovarian cancer, but histological examination revealed malignant mesothelioma. Our case report highlights that malignant mesothelioma should be considered as differential diagnosis in case of ascites, pleural effusion and suspected ovarian cancer. Laparoscopy in case of suspected ovarian cancer and differential diagnosis such as malignant peritoneal mesothelioma is a safe and cost effective diagnostic modality and in combination with histologic examination is key to definitive diagnosis.
GASTROINTESTINAL STROMAL TUMOURS (GIST) MIMICKING A HUGE OVARIAN NEOPLASM IN NORTH-EAST INDIA.

A. Baruah

Gastrointestinal Surgery, Gauhati Medical College and Hospital, Obstetrics and Gynaecology, Guwahati, India

Aims

1. GIST do not have any unique clinical signs and symptoms or unique appearance in USG. If a pelvic mass is detected, the possibility of a non-gynaecological tumour like GIST has to be considered.
2. A timely referral to get better surgical treatment and post-operative chemotherapy or radiotherapy in a tertiary care centre.

Method

A 50 years old female, P5+0, post-menopausal, came with pain abdomen and lump lower abdomen for 4 months. Swelling over the left side initially which later attained huge size up to the umbilicus within a short duration. Patient lost about 5kgs in 4 months. Mass was about 15x15 cm² size, firm and mobile.

Results

Apart from routine investigations of blood and urine, she underwent USG whole abdomen which showed a predominantly solid ovarian tumour 12.5x8x11.3cm³ in size, without ascitis. MRI Pelvis revealed a well defined encapsulated heterogeneously enhancing mass lesion abutting the anterolateral wall of uterus and distal ileal loop with internal haemorrhage and necrotic areas. Laparotomy revealed 15x12x10cm³ mass arising from ileum about 40cm proximal to ileocaecal junction. Resection of the mass and end-end anastomosis was done. Histopathological report- high grade GIST. Immunohistochemistry was CD117/C-KIT positive.

Conclusion

GIST may mimic gynaecological pelvic masses like ovarian malignancy especially in postmenopausal women. Although, GIST do not have a unique USG characteristic, if a pelvic mass is detected in clinical practice, with unusual clinical signs the possibility of non-gynaecological tumours like GIST related to small bowel has to be considered.
A NEW DIAGNOSTIC ALGORITHM FOR THE MANAGEMENT OF UTERINE MASSES: THE UMG (UTERINE MASS MAGNA GRAECIA) RISK SCORE

A. Di Cello¹, M. Borelli², M.L. Marra³, F. Marco⁴, R. Venturella⁵, F. Zullo³

¹University Magna Graecia, Unit of Obstetrics and Gynecology - Department of Experimental and Clinical Medicine - University "Magna Graecia" of Catanzaro - Italy, Catanzaro, Italy
²University Magna Graecia ok Catanzaro, PhD School of PhD Programmes Life Sciences and technologies-, Catanzaro, Italy
³University Magna Graecia oggi Catanzaro, Unit of Obstetrics and Gynecology- Department of Experimental and Clinical Medicine-, Catanzaro, Italy
⁴University of Trieste, Department of Life Sciences, Trieste, Italy
⁵University "Magna Graecia" of Catanzaro- Italy, Unit of Obstetrics and Gynecology- Department of Experimental and Clinical Medicine, Catanzaro, Italy

Aims

To identify a reliable non-invasive predictive tool to classify uterine masses according to the risk of malignancy.

Method

The charts of 3107 patients who underwent surgical treatment for uterine masses at our institution between 2004 and 2016 were retrospectively reviewed. Clinical, biochemical, imaging, surgical and pathological data of 2750 women with uterine fibroids and 43 patients with uterine sarcomas were analysed. The statistical relationships between relevant characteristics and the final pathology were analysed.

Results

In univariate analyses, a small set of possible predictors (age; CA125, LDH-1% and LDH-3% isoenzyme serum levels; central and peripheral vascularization of the uterine mass) was identified (p<0.005). Regression tree analysis and model selection revealed that the best predictive score [herein called the "uterine mass Magna Graecia (UMG) score"] was associated with LDH-1% and LDH-3% isoenzyme serum levels. Moreover, considering the presence or absence of central vascularization in women with a "UMG score">29, it was possible to classify patients into three different risk categories, coded for mnemonic reasons as green (≤29), yellow (>29 without the presence of central vascularization) and red (>29 with the presence of central vascularization). With an area under the ROC curve of 99.9%, 99.6% specificity, 100% sensitivity and a negative predictive value of 100%, the UMG score represents an accurate tool for excluding oncologic risk in uterine masses.

Conclusion

We have identified an easy and inexpensive score we used to reliably classify more than 2750 patients with uterine masses with a negative predictive value in excluding the risk of sarcoma of 100%
"REAL WORLD" FACTORS IMPACTING ON TIMING OF ADJUVANT TREATMENT IN PATIENTS WITH GYNAECOLOGICAL CANCER

F. Drews¹, L. Hannah², R. Jones², E. Hudson², K. Lim¹, R. Howells¹, A. Sharma¹
¹Cardiff University, Gynaecological Oncology, Cardiff, United Kingdom
²Velindre Hospital, Oncology, Cardiff, United Kingdom

Aims
To evaluate timing of adjuvant treatment in gynaecological cancer.

Method
A retrospective study of consecutive patients with gynaecological cancer undergoing adjuvant treatment, presenting to a tertiary cancer centre during two 4-monthly time-intervals in 2013 and 2016. Patients were identified from Welsh Cancer Services records. Main outcome measures included timing of adjuvant treatment and reasons for treatment delay.

Results
Of 321 patients operated for presumed gynaecological cancer, 100 women undergoing adjuvant therapy were identified. Most women were treated for endometrial or ovarian cancer (51%; 40%), while a minority had cervical or vulval cancer (6%; 3%). Commencing adjuvant treatment >8 weeks following surgery occurred amongst endometrial, ovarian, cervical and vulval cancers in 51%, 15%, 33.3% and 100% respectively. For ovarian cancer, this occurred in primary surgery in 23.8% and for interval debulking in 5.3% (p<0.001).

In endometrial cancer, reasons for commencing adjuvant treatment >8 weeks included referral to oncology unit closer to home (28%), availability of radiotherapy treatment slots (24%), postoperative complications (20%), histopathology required 2º opinion (8%), and in one case respectively ambivalence towards treatment requiring further counselling, referral for 2º MDM opinion, patient unwell, delay in postoperative staging. In ovarian cancer: 2º histopathological opinion (60%) or postoperative complications (20%). In cervical cancer: referral to oncology unit closer to home (16.7%) and awaiting postoperative staging investigations (16.7%). All vulval cancers started adjuvant treatment >12 weeks following surgery due to postoperative complications.

Conclusion
Adjuvant treatment commencement >8 weeks was a common occurrence, necessitating improvements in cancer pathways. A trial to investigate impact on survival is desirable.
FIRST RESULTS OF THE GERMAN PROSPECTIVE REGISTRY FOR GYNECOLOGICAL SARCOMAS (REGSA): A COLLABORATION OF NOGGO, AGO STUDY GROUP, AGO KOMMISSION UTERUS, AGO KOMMISSION OVAR, ARO

**Aims**

The aim of this register is to prospectively collect data of patients with gynecological sarcomas to describe their course of disease, diagnostics and therapies.

**Method**

An electronic case report was designed to register clinical data from patients in Germany such as disease, surgery, therapy and success of therapy after informed consent.

**Results**

Within 20 months 170 patients from 87 sites have been included into the study. 152 of the patients are evaluable. Patients were between 24 and 87 years old (mean 56 years), 106 of them with primary diagnosis and 46 with recurrent disease. There were 74 leiomyosarcomas, 33 endometrial stromal sarcomas (high grade 11, low grade 22), 6 undifferentiated uterine sarcomas, 9 adenosarcomas and 23 others (e.g. rhabdomyosarcoma among others). 15 patients presented with distant metastases at primary diagnosis. Vaginal bleeding was the most common symptom for diagnosis followed by stomach pain. 18 patients showed no symptoms at the time of initial diagnosis. 49 women had myoma diagnosed in advance to the initial diagnosis of sarcoma. In 88 patients with primary diagnosis (43 leiomyosarcomas, 22 endometrial stromal sarcomas, 3 undifferentiated uterine sarcomas, 6 adenosarcomas and 14 others) surgery has been performed - in 13 cases (14.8%) with morcellation. Morcellation was conducted in 8 leiomyosarcomas, 4 endometrial stromal sarcomas and 1 STUMP.

**Conclusion**

Due to a first analysis of the patients’ data there has been insight into characteristics of gynecological sarcoma patients and their treatment. Morcellation was performed in a non-neglectable number of patients with sarcoma. Further follow up is ongoing.
WEEKLY PACLITAXEL IN REFRACTORY CHORIOCARCINOMA

T. Elger¹, M. Battista¹, S. Krajnak¹, A.S. Heimes¹, A. Hasenburg¹, M. Schmidt¹
¹Unimedizin Mainz, Department of Gynecology and Obstetrics, Mainz, Germany

Aims

Gestational trophoblastic disease (GTD) ranges from pre-malignant hydatidiform moles to aggressive choriocarcinoma. We report a case of refractory gestational choriocarcinoma successfully treated with weekly paclitaxel.

Method

We describe a Nigerian patient with the diagnosis of gestational choriocarcinoma. We report symptoms, histological findings, FIGO score when first diagnosed, the progression of human chorionic gonadotropine while treated as well as the outcome and follow-up.

Results

The patient presented (VIG/VIP, B-HCG of 516.821 U/l, FIGO score 12, liver, pulmonary and splenic metastases) showed an increase of human chorionic gonadotropin during thirteen cycles of EMA/CO (actinomycin, etoposide, methotrexate, cyclophosphamide, vincristine) despite early decline. Therefore the patient received three cycles of BEP (bleomycin, etoposide, cisplatin) while human chorionic gonadotropin was still high, followed by five cycles of cisplatin and ifosfamide which showed a further decrease of human chorionic gonadotropin. However to achieve human chorionic gonadotropin values in the normal range, eighteen cycles of weekly paclitaxel were necessary. The follow-up showed no signs of recurrence until April 2017.

Conclusion

Choriocarcinoma is a rare and highly malignant disease. Weekly paclitaxel is an option in refractory disease.

YOLK SAC TUMOR OF THE CLITORIS IN A FIFTEEN-MONTHS-OLD CHILD
T. Elger, M. Battista, D. Macchiella, S. Krajnak, S. Maurer, A. Hasenburg, K. Rommens
1Unimedizin Mainz, Departement of Gynecology and Obstetrics, Mainz, Germany

Aims

Extragonadal yolk sac tumor as a possible and rare diagnosis in pediatric patients with clitoromegaly will be discussed on the basis of a case of a fifteen-month-old child that was treated at the university hospital of Mainz, Germany.

Method

We describe a young girl aged fifteen months with the diagnosis of a yolk sac tumor of the clitoris. We report symptoms, histological findings, staging and therapeutic approach. Due to MedLine and PubMed research we found our case to be the 17th described case of vulvar yolk sac tumor and only the third described case of clitoral yolk sac tumor.

Results

The patient presented (prepuberal child, no pre-existing conditions, normal development) showed a growing tumor of the clitoris which was first noticed in September 2016. The tumor was successfully resected by local excision, histologically showing to be a yolk sac tumor. The staging scans showed no signs of further metastases. The patient began a chemotherapy with cisplatin, etoposide and ifosfamide in November 2016.

Conclusion

Vulvar yolk sac tumors are uncommon malignancies. Especially the prepuberal age and the rare localisation at the clitoris make this case worth presenting. Yolk sac tumors must be considered as a possible cause of clitoral enlargement in the prepuberal population.
THE FEASIBILITY OF LAPAROSCOPIC SURGERY AND SAME-DAY DISCHARGE IN GYNECOLOGIC ONCOLOGY FOR OBESE AND VERY OBESE PATIENTS

J. Peng\textsuperscript{1}, S. Sinasac\textsuperscript{2}, K. Pulman\textsuperscript{2}, L. Zhang\textsuperscript{2}, J. Murphy\textsuperscript{2}, T. Feigenberg\textsuperscript{2}

\textsuperscript{1}University of Toronto, Faculty of Medicine, Toronto, Canada
\textsuperscript{2}Trillium Health Partners, Gynecologic Oncology, Mississauga, Canada

Aims

Surgical interventions are the mainstay of treatment for many gynecological cancers. Minimally invasive surgery offers many potential advantages, including same day discharge. However, performing laparoscopic pelvic surgery in obese patients remains challenging.

Objective: To examine the feasibility and safety of performing laparoscopic gynecologic-oncology procedures with same day discharge in obese and morbidly obese patients.

Method

A retrospective study of patients who underwent laparoscopic surgeries by a gynecologic oncologist from January 2012-June 2016, at a designated cancer centre. Using BMI, patients were categorized as non-obese (BMI<30 kg/m\textsuperscript{2}), obese (BMI30-40kg/m\textsuperscript{2}) and morbidly obese (BMI≥40 kg/m\textsuperscript{2}). Intra and post-operative complications and length of hospital stay were recorded. Group differences were compared with Kruskal-Wallis nonparametric test or Fisher exact test. Univariate and multivariate regressions were done for same day discharge.

Results

Of 497 patients, 288 were non-obese (58%), 162 obese (33%) and 47 morbidly obese (9%). Complex surgical procedures were performed in 58.0% of obese patients and 55.3% of morbidly obese patients. Conversion to laparotomy occurred in less than 9% of all patients with no group differences. Low intra-operative (9-11%) and severe post-operative (2%) complication rates were observed with no group differences. Of 182 (36.7%) patients who had same day discharge, younger age and shorter procedure length increased the likelihood of same day discharge success (p<0.01). Obese patients had a much lower rates of same day discharge compared to non-obese patients (30.2% vs. 69.8%, OR 3.2).

Conclusion

While laparoscopic gynecologic-oncology procedures for obese patients are safe and feasible, much lower success of same day discharge was observed.

ESGO7-1024

EXPRESSION AND THE PROGNOSTIC RELEVANCE OF P53, BCL-2, BAX AND KI-67 IN UTERINE LEIOMYSARCOMA

I. Gagua

Research Institute of Clinical Medicine, Gynecology, Tbilisi, Georgia

Aims

Uterine leiomyosarcomas (LMS) are rare, aggressive gynecological malignancies. The aim of our study was to evaluate the expression of p53, Bcl-2, Bax and Ki-67 and their prognostic relevance.

Method

A retrospective chart review was done to 198 patients with LMS from 1971 to 2016. Immunohistochemical (IHC) staining for 20 patients was performed for p53, Bcl-2, Bax and Ki-67. Negative and positive IHC staining was scored for each marker. Survival was determined from the time of initial diagnosis to last follow-up.

Results

Ten (50%) patients with LMS expressed p53. P53+ patients mostly had multiple metastases, compared to p53− patients with solitary metastases (60% against 20%) (p<0.05). Eleven (55%) patients expressed Bcl-2 and 4 (20%) expressed Bax. In Bcl-2+ patients distant metastases were observed in 45.5%, compared to Bcl-2− patients, we observed metastatic disease in 77.8% (p=0.068). Expression of ki-67 was observed in 15 patients (75%).

Conclusion

LMS patients with p53 expression had a poorer survival compared to LMS patients with negative expression (p53− 26.7±18.4% and p53+ 80.0±12.6%) (p<0.05). On opposite, the disease-free survival is better in bcl-2+ patients, compared to patients, who don’t express bcl-2 (47.2±19.6% and 28.1±18.0%, respectively (p>0.05). We didn’t observe statistical significant difference in survival depending on Bax expression. LMS patients with Ki-67 expression had a poorer survival compared to LMS patients with negative expression (34.9±13.1% and 60.0±20.7%), respectively (p>0.05). Our study indicates that p53 expression may serve as a prognostic marker for LMS patients.
COST UTILITY ANALYSIS OF METHOTREXATE VERSUS ACTINOMYCIN-D IN LOW RISK GESTATIONAL TROPHOBLASTIC NEOPLASIA

J. Geisler¹, K. Manahan²
¹CTCA, Gyn Oncology, Newnan, USA
²CTCA, Gyn Oncology, USA

Aims

To determine the most cost effective first line regimen for women with low risk gestational trophoblastic neoplasia (GTN) (WHO risk score 0-4 and no choriocarcinoma).

Method

Markov decision model (1000 patients) was used to analyze published data GOG 174. Arm 1 was weekly methotrexate at 30 mg/m² weekly while arm 2 was actinomycin-D 1.25mg/m² biweekly. Costs were based on average sale price (ASP) +6%. Utility values were determined by rating scale.

Results

The mean cost of therapy for methotrexate arm was $11,970/quality adjusted cure (95%CI $11,149-$12,791). The mean cost of the actinomycin-D arm was $26,865/quality adjusted cure ($26,780-$26,950). Weekly methotrexate dominated actinomycin-D as first line therapy.

Conclusion

First line therapy of low risk GTN should be weekly methotrexate.

11La Paz University Hospital, Gynecologic Oncology Unit, Madrid, Spain

Aims

To assess survival impact of salvage surgery in recurrent cervical or endometrial cancer and to determine prognostic variables for improved oncological outcome

Method

Retrospective multicenter analysis of medical records of 518 patients with cervical (N=288) or endometrial cancer (N=230) who underwent surgical treatment for disease recurrence and who had available at least one year follow-up

Results

Median survival reached 57 and 112 months after surgical treatment of recurrence in patients with cervical and endometrial cancer (p=0.036). Histological subtype had significant impact on overall survival, with the best outcome in endometrial- endometroid cancer (120 months) followed by cervical squamous-cell carcinoma, cervical adenocarcinoma or other types of endometrial cancer (81 vs. 35 vs. 35 months; p<0.001). Site of recurrence did not significantly influence survival in cervical cancer (81, 45, 35, and 45 months for vagina, pelvis, lymph nodes, abdomen) nor in endometrial cancer (56, 48, 120, 112 months for vagina, pelvis, lymph nodes, abdomen). Stage at the first diagnosis, tumor grade, lymph node status at recurrence, PFI after first diagnosis, free resection margins were associated with improved OS on univariate analysis. On multivariate analysis, stage at first diagnosis and resection margins were significant independent predictive parameters of improved oncological outcome

Conclusion

Long-term survival can be achieved after surgical treatment in selected patients with recurrent cervical and endometrial cancer. Excellent results can be obtained, especially in patients with endometrial cancer, even if site of recurrence is in lymph nodes or in abdomen. Achieving free resection margins is the most significant prognostic factor in both types of cancer
VASCULAR INJURIES DURING PELVIC AND PARAORTAL LYMPH NODE DISSECTION – LAPAROSCOPIC MANAGEMENT

S. Baydo¹, A. Vinnytska², D. Golub²

¹LISOD – Israeli Oncological Hospital, surgery, Kyiv, Ukraine
²LISOD – Israeli Oncological Hospital, gynecology, Kyiv, Ukraine

Aims

Major vessels injury during laparoscopic surgery is rare but very dramatic complication. Almost always it required conversion to laparotomy for completion of hemostasis. We represent our experience in performing laparoscopic hemostasis after vascular injuries during pelvic (PLND) and paraaortal (PALND) lymph node dissection.

Method

In 2010-2017 we performed 267 PLND and 396 PALND. Among them 581 single-region dissection: 226 PLND and 355 PALND, while 41 - both regions. Indications: cervical – 130(20,9%), endometrial – 122(19,6%), ovarian – 15(2,4%), colorectal – 343(55,1%), other malignancies – 12(1,9%). We obtained 7 major vascular injuries (1,1%): 2 – aorta, 2 - vena cava inferior, 2 – v.ilia, 1 – a.ilia. All vascular injuries occurred in patients with history of chemoradiotherapy, and there weren’t any in primary treated patients. In all cases we performed laparoscopic hemostasis. To achieve hemostasis we used next steps: 1) pressure of vascular wound; 2) round dissection of vessel and applying of vascular clamps for injuries longer than 2mm; 3) suturing the vascular damage (prolene 5/0).

Results

Size of vascular damage: up to 2mm in 5, 5 and 8mm in 2 cases of vena cava injury. Average time from injury to completion of hemostasis - 17min (11-34). The estimated blood loss – 150ml (45-700). There was no need for transfusion. Median hospital stay in case of vascular injury was 4,9 days versus main group (4,5). No thrombotic complications and death occurred.

Conclusion

Vascular injury of major vessels during lymphadenectomy is rare but very serious complication that can be successfully treated laparoscopically by experienced surgeon.
EXTRAPERITONEAL PARA-AORTIC LYMPHADENECTOMY BY ROBOT-ASSISTED LAPAROSCOPY WITH DAVINCI XI SYSTEM VS. CONVENTIONAL LAPAROSCOPY

Aims

This study aimed to compare the outcomes of extraperitoneal para-aortic lymphadenectomy (EPL) performed by robot-assisted laparoscopy (EPLRL) with the DaVinci Xi system, to conventional laparoscopy.

Method

A retrospective case-control study was conducted to evaluate the outcomes of 18 patients submitted to EPLRL matched to patients submitted to laparoscopic-EPL (1:2). Data regarding patient's characteristics, type of surgery (infra-renal/infra-mesenteric lymphadenectomy), operating time, surgical complications, lymph nodes and post-operative stay were collected.

Results

Fifteen patients who underwent EPLRL and 30 patients who underwent laparoscopic-EPL were included. Three cases in the robot group were excluded due to pneumoperitoneum and one conversion to transperitoneal lymphadenectomy. There were no differences regarding age, BMI and OMS between both groups. There was no significant difference in the operating time (180 vs. 150min, p=0.28), lymph nodes (16 vs. 17, p=0.54) or post-operative stay (1 vs. 2days, p=0.49) between the robotic and laparoscopic approach. The estimated blood losses were similar: 50cc (30-300) in the robot group and 30cc (10-200) in the laparoscopic group. In the robot group there were one lesion of the left mesoureter (a ureteral stent was placed without sequel) and a 22.2% rate of pneumoperitoneum. In the laparoscopic group there were 2 cases of lymphocele (surgical drainage or under Ct scanner).

Conclusion

There were no major difference between the surgical outcomes and both approaches. The 22.2% rate of pneumoperitoneum with EPLRL may be due to the placement of the 4th trocar.
GESTATIONAL TROPHOBLASTIC DISEASE: ALTERNATIVE TREATMENT OPTIONS?

M. Huang¹, A. Pinto², R.P. Castillo³, B. Slomovitz⁴
¹University of Miami, Gynecologic Oncology, Miami, USA
²University of Miami, Pathology, Miami, USA
³University of Miami, Radiology, Miami, USA

Aims

Gestational trophoblastic neoplasia (GTN) usually has high cure rates. However, in patients presenting with advanced disease, only 60-70% achieve complete remission with current chemotherapies. We present a case of choriocarcinoma and introduce a novel treatment option.

Method

Case X medical records were reviewed and treatment history summarized. Molecular genomic testing was performed to identify potential targetable pathways.

Results

Ms X is a 26 y.o presenting with stage IV choriocarcinoma with a WHO score of 18 initiating treatment with multi-agent EMA-CO every 2 weeks. Patient developed brain metastasis on treatment, received gamma knife therapy and changed to EMA-EP regimen. Treatment was complicated by grade 3 thrombocytopenia requiring treatment delays resulting in rising beta HCG levels (Table 1). Molecular testing demonstrated PD-L1 IHC positive, 2+ (90%), TP53 exon 7, G245S mutation, Her2/Neu IHC positive 3+ (30%), TOP2A IHC positive 1+ (90%) and RRM1 IHC negative 2+ (10%). Based on results, treatment with PD1 inhibitor was given with normalization of BHCG following two cycles and near complete response.

Conclusion

Targeted therapy with PD-1 receptor blockade may be a more efficacious and tolerable treatment option than current standard multi-agent chemotherapies. Prospective clinical trials should explore this therapy.
WHERE IS THE BLUE LYMPH NODE? A TEACHING VIDEO PRESENTING STEP BY STEP THE TECHNIQUE FOR LAPAROSCOPIC SENTINEL LYMPH NODE DETECTION WITH INDOCYANINE GREEN (ICG)

S. Imboden1, A. Papadia1, F. Siegenthaler1, S. Mohr1, M. Mueller1
1University Hospital Bern, Obstetrics and Gynecology, Bern, Switzerland

Aims

Minimal invasive sentinel lymphadenectomy (SLN) is a modern technique to evaluate tumor spread and tailor adjuvant treatment in gynecological cancers. Indocyanine green (ICG) with near infrared optic systems seem to lead to higher bilateral detection rates compared to technetium +/− patent blue and shows an excellent safety profile.

Method

The laparoscopic SLN biopsy technique with ICG has been applied in the University Hospital of Berne in endometrial and cervical cancer since 2012. Until March 2017 over 180 such operations were performed with bilateral detection rates of over 90%. Over time the technique has been optimized. Selected cuts from videos of these operations were summarized to a video. This video is made to present a step by step demonstration on how to successfully find the SLN. Also, more difficult cases are presented and discussed.

Results

A learning video for a successful laparoscopic bilateral detection of the SLN with near infrared optic system is presented.

Conclusion

Laparoscopic SLN biopsy with ICG is an easy learnable technique and shows high bilateral detection rates and is also effective in more difficult cases.

METASTATIC TUMORS OF CLITORIS-A LITERATURE REVIEW
S. Jiang¹, Q. Li², X. Sheng¹
¹Shandong Cancer Hospital and Institute, Department of Gynecologic Oncology, Jinan, China

Aims

The metastatic tumors of the clitoris are an extremely rare phenomenon. Here, we present a literature review in an attempt to ensure sufficient awareness of the occurrence of pain in the vulvas and masses in the clitorises of patients with malignant tumours.

Method

We performed a thorough search of PubMed that focused on the metastases of various primary tumours to the clitoris. Vulval malignancy with clitoral extension was excluded.

Results

The identified primary tumours that spread to clitoris were, in decreasing order of prevalence, from the urinary system (31.58%, 6/19), cervical carcinoma (21.05%, 4/19), endometrial carcinoma (15.79%, 3/19) and from the digestive system (15.0–79%, 3/19). Metastases from other sites were relatively rare.

Conclusion

A swollen painful vulva should draw sufficient attention and should not be roughly attributed to the primary tumour or inflammation in patients with malignant tumours.
SCHWANNOMAS OF FEMALE GENITALIA - A REVIEW OF THE LITERATURE

S. Jiang
1Shandong Cancer Hospital and Institute, Department of Gynecologic Oncology, Jinan, China

Aims

We present an illustration of the distribution sites of schwannomas in the female genital tract and summarize the association of pregnancy conditions with pelvic schwannomas.

Method

Review the literature.

Results

In total, 63 schwannomas arising from the female genital tract have been reported. 73.02% (46 cases) were located in the lower genital tract, and 26.98% (17 cases) were located in upper genital tract. The site distribution was, in decreasing order of prevalence, vulva (26.98%, 17/63), cervix (23.81%, 15/63), clitoris (12.70%, 8/63), vagina (9.52%, 6/63), broad ligament (7.93%, 5/63) and other sites. Eight cases of pelvic schwannomas occurred during pregnancy. Seven of the women delivered by Cesarean section, and three cases resected the schwannoma concomitantly. Four cases underwent exploratory laparotomy, but the mass was not identified in two of the cases (Table 1).

Conclusion

Schwannomas in the female pelvis are very rare. Cesarean section was the main delivery method in cases of pregnancy with pelvic schwannoma. Exploratory laparotomy and Cesarean section are not effective for finding and resecting the pelvic schwannoma during pregnancy given the poor exposure due to the gravid uterus. Given the rarity of such cases, the association of fertility and pelvic schwannoma is unknown.

FACTORS PREDICTING SEXUAL DYSFUNCTION IN THAI PATIENTS WITH CANCER AFTER TREATMENT

T. Junda¹, B. Sumdaengrit¹
¹Ramathibodi Hospital, Ramathibodi School of Nursing, Bangkok, Thailand

Aims

Purpose of this research was to study factors predicting sexual dysfunction in Thai patients with cancer after treatment.

Method

This study was a cross-sectional research. Samples included 55 females with breast cancer and 55 males with cancer at prostate, bladder, colon and rectum. They were all completed treatment for 6 months - 2 years from a university hospital, and 2 cancer hospitals during March – June 2013. The instruments were (1) the personal information and disease related treatment (2) Dyadic Adjustment Scale developed by Kasemkitawatana (1993) (3) World Health Organization quality of life – Thai version (WHOQOL-BREF-THAI) (2002). (4) the Sexual Health Dysfunction developed by Kumdaeng (2007). Alpha Cronbach’s coefficient were .89, .90, and .89 for Dyadic Adjustment, WHOQOL-BREF-THAI, and Sexual Health Dysfunction respectively. Data were analyzed by descriptive and multiple regression.

Results

Results found that gender, affection expression and love, and social dimension of quality of life could predict the sexual dysfunction at .01 level, whereas age, treatment, disease, marital status, and other dimensions of QOL could not predict the sexual dysfunction in patients with cancer after treatment.

Conclusion

Results showed that female patients with breast cancer seemed to suffer from sexual dysfunction more than male who had cancer. Affection and love and support from spouses had negative influence on sexual dysfunction. These results can be used as evidence-based to provide and improve sexual health in patients with cancer after treatment especially in women with breast cancer.
DISTRIBUTION OF HIGH-RISK HPV TYPES IN WOMEN WITH VULVAR CANCER IN KAZAKHSTAN

R. Bolatbekova1, R. Shalbayeva1, A. Östrbenk2, M. Kairbayev1, A. Šterbenc2, L. Hošnjak2, D. Kaidarova1, M. Poljak2
1Kazakh Research Institute of Oncology & Radiology, Gynaecological Cancer Centre, Almaty, Kazakhstan
2University of Ljubljana, Institute of Microbiology and Immunology- Faculty of Medicine, Ljubljana, Slovenia
3SEMA hospital, Division of Gynaecological Oncology, Almaty, Kazakhstan

Aims

HPV is a known factor for some vulvar cancers. The objective was to evaluate the distribution of hrHPV types in vulvar cancer samples obtained from Kazakhstani women.

Method

A total of 64 archival formalin-fixed paraffin-embedded (FFPE) tissue samples obtained from the same number of Kazakhstani women with histologically confirmed invasive squamous cell carcinoma of the vulva were included in the study. DNA was extracted using a DNA Mini Kit (Qiagen, Hilden, Germany), following our in-house protocol. Detection of hrHPV types was performed using a RealTime High Risk HPV Test (Abbott, Wiesbaden, Germany), which enables concurrent separate genotyping of HPV16 and HPV18 and pooled detection of 12 other hrHPV types: HPV31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, and 68.

Results

Out of 64 samples tested, 2 (3.1%) were excluded from the analysis due to invalid results for amplification of beta-globin. In total, 20/62 (32.3%) samples tested positive for the presence of hrHPV types. HPV16, HPV18, and other hrHPV types were present in 17/20 (85.0%), 1/20 (5.0%), and 2/20 (10.0%) samples, respectively. Only single infections were detected.

Conclusion

To the best of our knowledge, this is the first study to evaluate the distribution of hrHPV types among Kazakhstani women with vulvar cancer. Approximately 32% of samples tested positive for the presence of hrHPV types, of which HPV16 (85.0%) was the most common hrHPV type detected, suggesting HPV vaccine could have a substantial impact on the incidence rate of vulvar cancer in Kazakhstan. However, further studies are needed to confirm our observations.

PRIMARY PARAMETRIAL DIFFUSE LARGE B-CELL LYMPHOMA SIMULATING A LOCAL ADVANCED CERVICAL CARCINOMA: A CASE REPORT

S. Kilzie, F. Sartori, A. Martin Jimenez

1 Fundació Hospital Son Llàtzer, Obstetrics and Gynaecology, Palma de Mallorca, Spain
2 Son Espases University Hospital, Hematology and Hemotherapy, Palma de Mallorca, Spain

Aims

We present a case of a 30 year-old woman with an unusual clinical presentation of a lymphoma involving uro-gynaecological structures.

Method

Case report.

Results

30 year-old woman with a history of high blood pressure in the last two years; a blood text reveals an altered creatinine level; to study the kidney functional alteration, a TC is performed and ureterohydrenephrosis is observed and the renal gammagraphy evidences a residual right kidney function of 14%. The MRI suggests the diagnosis of a cervical neoplasia because of the presence of a 4-cm parametrial mass with fibrotic characteristics and irregular borders causing terminal ureter stenosis and pathological signal in the anterior portion of cervix and first proximal part of anterior vagina. Endocervical biopsy and exocervical cytology were normals. In the physical exploration we detect a stony, fixed, asymptomatic mass between right pelvic wall and uterus; we performed a diagnostic laparoscopy opening the right posterior broad ligament, identifying a pearly parametrial mass involving right ureter which we biopsied. The anatomopathological examination reveals a diffuse large B-cell lymphoma non germinal center type and the patient is remitted to the Hematologist and she is in treatment with R-CHOP-Lenalidomide.

Conclusion

We report a case of a rare uro-gynecological presentation of a NHL that should always be considered in the differential diagnosis in such cases.
LATERALLY EXTENDED ENDOPELVIC RESECTION FOR THE PELVIC SIDE WALL TUMORS: EXPERIENCE FROM A PROSPECTIVE COHORT STUDY

L. Maria¹, K. Se Ik¹, H.S. Kim¹, K. Jae Weon¹

¹Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To evaluate the efficacy and safety of laterally extended endopelvic resection (LEER) for removing the pelvic side wall tumors in a prospective cohort study.

Method

We enrolled patient with primary (n=12) and recurrent (n=10) diseases between March 2014 and April 2017. All patients showed tumor invasion to the pelvic side wall by gynecologic examination and preoperative imaging studies. We evaluated the feasibility of LEER by using the learning curve related with surgical outcomes. Furthermore, we investigated survival after LEER, and relevant complications.

Results

Among a total of 22 patients, 16 (72.9%), 3 (13.6%), 1 (4.5%), 1 (4.5%) and 1 (4.5%) showed cervical cancer, ovarian cancer, endometrial stromal sarcoma, Müllerian adenosarcoma and malignant melanoma. Among all patients, 16 patients (72.7%) showed negative resection margin and 18 (81.8%) preserved at least one pelvic organ after LEER. Perioperative outcomes improved as our experience of LEER increased in recurrent diseases despite no change in primary diseases. After LEER, grade 2 or 3 neuropathy, hydronephrosis, infected lymphocele, grade 3 lymphedema developed in 7 (35%), 1 (5%), 4 (20%), 2 (10%) and 2 (10%) patients without no treatment-related death. In locally advanced cervical cancer, LEER showed similar survival outcomes to primary chemo-radiation, and response to neoadjuvant chemotherapy was related with better survival.

Conclusion

LEER may require a training period for improving surgical outcomes. It can be considered to be feasible and safe for patients with the pelvic side wall tumors if no effective alternative to control local tumors (No. NCT02986568).

⁴Kyung Hee University Hospital at Gangdong-Kyung Hee University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea
⁵Korea Cancer Center Hospital- Korea Institute of Radiological & Medical Sciences, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

To investigate current clinical management of leiomyosarcoma (LMS) in Korea

Method

We conducted a web-based survey of members of the Korean Gynecologic Oncology Group (KGOG) on their treatment of LMS.

Results

In total, 75 of 277 (27.1%) members responded to the survey. For surgical treatment of stage I LMS, 26.8% indicated total hysterectomy (TH) only, 16.9% TH with bilateral salpingo-oophorectomy (BSO). Also, lymph node dissection (LND) was indicated by 54.9% of respondents, while 46.5% stated that BSO could be omitted in young patients. More than half of the respondents (57.7%) recommended against adjuvant treatment. For stage I LMS diagnosed after morcellation, 79.2% of respondents recommended LND, 56.4% recommended adjuvant therapy. As for advanced-stage LMS, in cases of complete resection, adjuvant chemotherapy was preferred by 63.1%. For incomplete resection, combined radiotherapy/chemotherapy was the most preferred adjuvant therapy (63.1%).

Conclusion

Among KGOG members, there are many discrepancies in current clinical management of LMS. A large-scale prospective study to establish treatment guidelines is needed.
THE CLINICOPATHOLOGICAL STUDY OF 21 CASES WITH UTERINE SMOOTH MUSCLE TUMORS OF UNCERTAIN MALIGNANT POTENTIAL: CENTRALIZED REVIEW CAN PURIFY THE DIAGNOSIS.

D. Basaran¹, A. Usubutur², M.C. Salman³, M.A. Narin¹, G. Boyraz³, O. Turkmen¹, G. Kimyon Comert¹, A. Karalok¹, D. Bulbul⁴, T. Turan¹, N. Ozgul⁶, K. Yuce⁶

³Hacettepe University Faculty of Medicine, Department Obstetrics and Gynecology, Ankara, Turkey
⁴Etlik Zubeyde Hanım Research and Training Hospital, Department of Clinical Pathology, Ankara, Turkey

Aims

To investigate the clinicopathological features and factors associated with recurrence in patients with uterine smooth muscle tumor of uncertain malignant potential (STUMP).

Method

Forty-six cases diagnosed between 2000 and 2014 from two tertiary centers underwent blind slide review. Initial diagnosis included smooth muscle tumors with equivocal diagnosis, STUMPs and cases that were named as leiomyosarcomas (LMS) or low grade LMS despite not fulfilling the Stanford criteria. (Figure-1)

Results

In total, 21 patients with a final diagnosis of STUMP were available. 15/22 of (68.1%) patients with an initial diagnosis of STUMP, 4/18 (22.2%) of cases with an equivocal smooth muscle tumor diagnosis and 2/6 of (33.3%) cases with an initial diagnosis of LMS were interpreted as STUMP after slide review (Table 1). The mean age at diagnosis was 43 years (range 20-64 years). The mean follow-up time was 65.9 months (range 10-154 months). Four (19.0%) patients developed recurrent disease. Recurrent tumors were LMS in 3 (75%) patients. One (4.8%) patient with recurrence succumbed to disease (Table 2). There was no difference in patients’ age (p=1.0) or type of initial surgery (uterus conserving versus hysterectomy) (p=0.57) between patients who recurred and did not recur.

---

**Conclusion**

Most cases with uterine STUMPs have favorable oncological outcomes, however; some may have a more aggressive clinical course associated with recurrence and death. Uterine mesenchymal tumors other than ordinary myomas and overt sarcomas deserve a second opinion in centers with experience because the real diagnosis may vary significantly.
CESAREAN SCAR CHORIOCARCINOMA, A CASE REPORT AND REVIEW OF LITERATURE

T. Kittisiam¹, T. Thavaramara¹, C. Chavanisakun², S. Srijappracharoen¹, S. Tanjitgamol¹
¹Vajira Hospital Navamindradhiraj University, Obstetrics and Gynecology, Bangkok, Thailand
²Vajira Hospital Navamindradhiraj University, Pathology, Bangkok, Thailand

Aims

Reported clinico-pathological findings of a patient with gestational choriocarcinoma occurring at unusual site of cesarean scar.

Method

A case of cesarean section scar gestational choriocarcinoma who treated at our institute was review.

Results

A 52-year old woman with previous cesarean section had abnormal uterine bleeding after abortion 2 weeks ago. Her serum beta-hCG elevated from 1,448 to 4,315 mIU/ml. An ill-defined heterogenous echoic hypervascularized lesion sized 2.27x1.85 cm with high doppler signal at lower uterine segment extending into myometrium was observed from Transvaginal ultrasonography (Fig 1). Provisional diagnoses were cesarean scar pregnancy or gestational trophoblastic tumor. She decided to have abdominal hysterectomy.

Intraoperative finding reported a 3 cm hemorrhagic lesion at right lateral aspect of lower uterine segment extending from endometrial surface through the serosal surface (Fig 2). Other areas were unremarkable. Histopathologic examination reported choriocarcinoma (Fig 3) and she was diagnosed a GTN(I:3). She declined postoperative adjuvant chemotherapy and attached to a surveillance program. She was doing well with normal beta-HCG levels for 25 months after surgery.
Cesarean section scar choriocarcinoma is extremely rare disease with only 5 cases found from English MEDLINE database search between 1996 and 2016. Our case had shortest time to develop choriocarcinoma after abortion. The patient was closely monitored until 25 months after diagnosis when she was doing well without any evidence of disease despite no adjuvant chemotherapy treatment.

**Conclusion**

Cesarean section scar choriocarcinoma is extremely rare disease with only 5 cases found from English MEDLINE database search between 1996 and 2016. Our case had shortest time to develop choriocarcinoma after abortion. The patient was closely monitored until 25 months after diagnosis when she was doing well without any evidence of disease despite no adjuvant chemotherapy treatment.
ENDOARTERIAL CHEMOTHERAPY AND TRANS–ARTERIAL CHEMOEMBOLIZATION IN GYN CANCER PATIENTS WITH PELVIC RELAPSES IN PREVIOUSLY IRRADIATED ZONES.

J. Kreynina¹, L. Shevchenko¹, N. Khoronenko², M. Kaskulova¹
¹Russian scientific center of roentgenradiology, Brachytherapy, Moscow, Russia
²Russian scientific center of roentgenradiology, Endovascular Technologies, Moscow, Russia

Aims

Pelvic relapse is a fatal outcome for majority of GYN cancer patients, with severe complications of tumor progression, low life quality, ≤10-20% significant response to conventional therapy. Endovascular chemotheraphy can overcome tissue and vessel changes for tumors in previously irradiated zones.

Method

8 pelvic relapsed patients after 40-84Gy irradiation were included, 4 (50%) - with cervical, 1 (12,5%) – uterine, 2 (25%) – vulvar, 1 (12,5%) – ovarian cancer recurrences, localised centrally in 2 (25%) pts, lateral or centro-lateral with pelvic wall involvement – in 6 (75%). All relapses were symptomatic, with severe pain in 6 (75%), bleeding – in 4 (50%), severe lymphedema in low extremities – 3 (37,5%). Endoarterial prolonged infusions of Cisplatin 75-100mg/m² were performed in all 8 (100%) pts., twice – in 6 (75%) pts with 18–21 day intermission, chemoembolization (Hepasphere®) with Carboplatinum AUC3-4 – in 2 (25%).

Results

Clinical response RECIST 2.0 was achieved in 7 (87.5%) pts., no complete response, PR >50% – in 3 (37,5%) pts, 25–45% of tumor volume reduction – in 4 (50%) pts. Local progression with bladder and rectal fistulas was diagnosed in 1 (12.5%). Salvage surgery was performed successfully in 2 (25%) pts in 6-10 weeks, interstitial brachytherapy or hypofractioned IMRT – in 5 (62,5%) pts in 2-6 weeks after endovascular procedures.

Conclusion

Endoarterial chemotherapy and trans–arterial chemoembolization are the perspective ways to improve overall results and life quality for GYN cancer patients with loco-regional relapses in previously irradiated zones, opening new treatment options for salvage therapy.
CARCINOMA FALLOPIAN TUBA AS INCIDENTAL FINDINGS; A CASE REPORT

V. Krsic¹, B. Jocic pivac¹, J. Milojevic², J. Krsic³, D. Jovanovic¹
¹Clinic Ob Gyn Narodni Front, OB GYN, Belgrade, Serbia
²Hospital Lazarevac, obgyn, Belgrade, Serbia
³Military Academy, chirurgico, Belgrade, Serbia

Aims

Primary Fallopian tube cancer (PFTC) is a very rare gynecological malignancy. It accounts for 0.14% to 1.8% of all female genital malignancies. The most common age is between 40 to 65 years. The etiology of PFTC is unknown and often mistaken for pelvic inflammatory disease or ovarian cancer. On the other side we discover this carcinoma when the disease has spread or by accident.

Method

64 years old postmenopausal woman admitted in our hospital because of total vaginal prolapse of uterus. Ultrasound examination showed normal genital organs for ages, without any free fluid in abdominal cavity. We performed vaginal hysterectomy with bilateral adnexectomy. Operative and post operative course was duly passed.

Results

Histopathological examination of removed genital organs revealed small (0.5mm) poorly differentiated adenocarcinoma of the left Fallopian tube without lymphovascular invasion and without lamina propriae involvement. The other organs were healthy. The tumor marker Ca 125 and CEA were normal. We did laparoscopy to do staging and performed partial omentectomy and there was no malignant changes.

Conclusion

In our case we would like to show and recommend if we do vaginal hysterectomy in postmenopausal women it should be benefit for patients to perform and bilateral adnexectomy because of possibility like this case showed.
IMPLEMENTATION OF AN ENHANCED RECOVERY PROGRAM IN GYNAECOLOGIC SURGERY: PRELIMINARY RESULTS FOR ONCOLOGICAL INDICATIONS.

E. LAMBAUDIE\textsuperscript{1}, C. LAPLANE\textsuperscript{1}, C. BRUN\textsuperscript{2}, L. N’GUYEN DUONG\textsuperscript{2}, J.M. BOHER\textsuperscript{3}, C. JAUFFRET\textsuperscript{1}, G. BLACHE\textsuperscript{1}, S. KNIGHT\textsuperscript{1}, E. CINI\textsuperscript{1}, G. HOUVENAEGHEL\textsuperscript{1}, J.L. BLACHE\textsuperscript{2}

\textsuperscript{1}Institut Paoli Calmettes, Département de Chirurgie Oncologique 2, Marseille, France
\textsuperscript{2}Institut Paoli Calmettes, Département d’Anesthésie Réanimation, Marseille, France
\textsuperscript{3}Institut Paoli Calmettes, Département Biostatistique, Marseille, France

Aims

Enhanced Recovery Program (ERP) is a multimodal approach of perioperative patient’s clinical pathways that results in a faster recovery after surgery and decreased length of stay (LOS).

The objective of this study is to evaluate the results of the implementation of ERP in gyn oncological indications on LOS, morbidity and readmissions.

Method

A prospective observational study was performed at Paoli-Calmettes Institute Cancer Center (Marseille, FRANCE) between December 2015 and June 2016. All the patients referred for hysterectomy and/or pelvic or para-aortic lymphadenectomy for gynaecological cancer were managed with a standardized ERP. Our results were compared to a control group including 100 patients, previously managed in our center between April 2015 and November 2015, without ERP.

Results

A total of 100 patients were included. 87% of the procedures were performed by conventional or robotic assisted laparoscopy. The readmission rate was 6% and the total complication rate was 25% (2% intraoperative, 3% major (grade III, IV) and 20% minor (grade I, II) according to Clavien Dindo classification). After ERP implementation, median length of stay of our cohort was significantly reduced (3.15 days vs. 3.89 days; \( p=0.002 \)), particularly for laparoscopic approaches (2.67 days vs 3.33 days; \( p=0.0005 \)). The percentage of patients discharged before 2 days increased (45% vs. 24%; \( p=0.002 \)) without increasing major complications rates.

Conclusion

ERP in gynaecological surgery is safe and feasible. We demonstrate the interest of patient centered clinical pathway to standardize outcomes and reduce length of stay in respect with patients’ safety, particularly in gyn oncological indications.

HYSTERECTOMY IN POLAND - CHANGES IN THE SURGICAL APPROACH.

P. Lepka¹, K. Zalewski²,³, M. Misiek⁴, M. Jędryka⁴
¹Wroclaw Medical University, Department of Oncology-Gynaecological Oncology Clinic, Wroclaw, Poland
²Holycross Cancer Center, Department of Gynaecologic Oncology, Kielce, Poland
³Warsaw Medical University, Department of Obstetrics-Gynaecology and Oncology, Warsaw, Poland
⁴Wroclaw Medical University, Department of Oncology-Gynaecological Oncology Clinic, Wroclaw, Poland

Aims

The aim of the study was to evaluate the changes in the incidence of different surgical approach to hysterectomy in Poland after the U.S. Food and Drug Administration (FDA) warning statement discouraging the use of power morcellation.

Method

Using data from the Polish National Health Institution (NFZ) we calculated and compared the incidence of different types of hysterectomies performed in 2011-2015.

Results

We identified a total 182,384 women who underwent inpatient hysterectomy between 2011 and 2015. In this period of time we observed a decrease of 18% in the incidence of total number of abdominal hysterectomies (TAH) (from 24626 in 2011 to 20121 in 2015) and increase of the surgeries performed laparoscopically (TLH) by 155% (from 62 in 2011 to 166 in 2015). The number of supracervical hysterectomies (SLH) increased in years by 151% (from 788 in 2011 to 1983 to 2014) then declined by 69% (632 in 2015). The number of procedures performed vaginally (VH) was stable over the whole analyzed period.

Conclusion

The number of inpatient hysterectomies performed in Poland has declined substantially over the past 5 years. There was a rising trend in the incidence of TLH comparing to abdominal approach. There was observed a significant decrease in the number of SLH in 2015 that could be related to the Food and Drug Administration Morcellation Warning issued in November 2014.

EFFICACY OF RAD-P53 COMBINED WITH CHEMOTHERAPY IN THE TREATMENT OF RECURRENT UTERINE SARCOMA

X. Li¹, Y. Xia¹
¹Shengjing Hospital Of China Medical University, The department of obstetrics and gynecology, Shenyang, China

Aims

The aim of this study was to investigate the clinical effect of rAd-p53 combined with chemotherapy in advanced or recurrent uterine sarcoma.

Method

The clinical data of 12 patients with advanced or recurrent uterine sarcoma, who received treatment with rAd-p53 combined with chemotherapy in our hospital between 2009 and 2015 were retrospectively analyzed. We estimated the overall remission rate [complete response (CR) + partial response (PR)], clinical effective rate [CR + PR+ stable disease (SD)], progression-free survival (PFS), and evaluated treatment safety and toxicity reactions.

Results

Of the 12 patients, no one achieved CR, 8 achieved PR, 3 achieved SD, and 1 achieved progressive disease. The overall response rate was 66.7%, effective rate was 91.7%. During follow-up, the overall median PFS was 13.0 months. Four patients received surgery opportunity again and 2 cases with liver metastatic lesions received CR. Treatment-related adverse reaction is self-limiting fever.

Conclusion

Therefore, rAd-p53 combined with chemotherapy was able to effectively control advanced or recurrent uterine sarcoma, and is considered to be a safe and effective candidate treatment for this type of tumor.

ANALYSIS AND TREATMENT OF 45 PLATINUM-ALLERGIC GYNECOLOGIC MALIGNANT TUMORS

X. Ma¹, X. Li¹
¹Shengjing Hospital Of China Medical University, The department of obstetrics and gynecology, Shenyang, China

Aims

This study aimed to explore the potential risk factors of platinum allergy and follow-up treatment to provide a reference for the clinical prevention and treatment of platinum-allergic reactions in patients with gynecological tumors.

Method

The study retrospectively analyzed 45 cases of platinum-allergic reactions that occurred in Shengjing Hospital affiliated to China Medical University from August 2010 to July 2016. Analysis of risk factors included the cumulative dose, treatment course and time intervals.

Results

The cumulative carboplatin dose in allergic patients ranged from 900 mg to 10250 mg (average: 4845 mg). The 45 allergic reactions occurred between the 3rd and 25th course of treatment (average: 11.4 courses). The average re-treatment interval of carboplatin allergic patients was 28.1 months, including 93.3% of patients with platinum re-treatment interval of more than 1 year. The allergic reaction occurred in the 2nd or 3rd course of re-treatment in 26 patients, accounting for 70.3% of all patients with recurrence. Seventeen patients were subjected to desensitization therapy, among which 13 cases were well tolerated.

Conclusion

Patients who received more than 8 courses of carboplatin or a cumulative dose of more than 3500 mg were the high-risk population for platinum allergy. The 2nd and 3rd treatment course after restarting carboplatin treatment after an interval time of more than 1 year was the high incident period of carboplatin allergy. Skin tests should be conducted in patients with high risk of carboplatin allergy. In cases of carboplatin allergy, patients could receive carboplatin or oxaliplatin desensitization therapy.
THE RESULTS OF TREATMENT WITH HIGH-DOSE CHEMOTHERAPY AND PERIPHERAL BLOOD STEM CELL SUPPORT FOR GESTATIONAL TROPHOBLASTIC NEOPLASIA

M. Frijstein¹, C. Lok¹, D. Short², K. Singh³, R. Fisher², B. Hancock², J. Tidy², N. Sarwar³, M. Winter³, P. Savage², M. Seckl²

¹Center of Gynaecologic Oncology Amsterdam, Department of Gynaecology, Amsterdam, The Netherlands
²Charing Cross Hospital, Department of Medical Oncology, London, United Kingdom
³Weston Park Hospital, Trophoblastic Disease Centre, Sheffield, United Kingdom

**Aims**

Most women with gestational trophoblastic neoplasia (GTN) are cured, but a small number become refractory to all standard chemotherapy regimens. The value of high-dose chemotherapy (HDC) with peripheral blood stem cell support (PBSCS) and the optimal number of courses (1 or 2) for refractory choriocarcinomas and poor prognosis PSTT/ETTs is unclear.

**Method**

Databases of two referral centers for GTN were searched. All patients treated with HDC between 1994 and 2015 were eligible for the study. Patient files were analyzed and tissue samples were retrieved for genetic evaluation. In total 32 patients were identified.

**Results**

The majority of the patients were initially high-risk according to their FIGO score and had multiple lines of chemotherapy and surgery. Twenty-two patients were treated with 1 course HDC and 10 patients with 2 courses. An hCG response occurred in 44% (14/32), and overall, 41% (13/32) of the patients remained disease free after HDC. Thirty-two percent of the patients treated with 1 course HDC survived compared to 60% of the patients treated with 2 courses, (p=0.244).

**Conclusion**

HDC with PBSCS appears to be active in salvaging selected patients with poor prognosis PSTT/ETTs and drug resistant choriocarcinomas. Whilst two courses of HDC seem more beneficial for survival, this may be explained by tumour stage, clinical performance status and toleration of the first course of treatment. HDC should only be given in centers with adequate experience, both in treatment of patients with GTN and in administration of HDC.

QUALITY OF LIFE AND DEPRESSION IN GYNECOLOGIC ONCOLOGY PATIENTS RECEIVING CARBOPLATIN AND PACLITAXEL

W. Maskasame

Faculty of Ramathibodi Hospital - Mahidol University, Home Health Care, Bangkok, Thailand

Aims

To study the effects of treatment with Carboplatin and Paclitaxel on quality of life and depression of gynecologic oncology patients at Ramathibodi hospital.

Method

Subject of this descriptive research are to examine the quality of life and depression in gynecologic oncology patients after treatment with the third cycle of Carboplatin and Paclitaxel. Sixty nine patients were recruited from the gynecologic oncology department of Ramathibodi hospital. The instruments used in study were 1. Demographic data form, disease and treatment questionnaires, 2. Function Assessment Cancer Therapy - Ovarian questionnaires (FACT-O) v4.0 and 3. Thai Depression Inventory (TDI), were used for assessing the quality of life and depression of the patients within 7 days after receiving the third cycle of Carboplatin and Paclitaxel protocol.

Results

The results revealed the top five factors affecting the patient’s quality of life which were exhaustion, a decrease of friendship, a problem of coping with illness, a decrease of enjoyment and a decrease of libido. Also, a decrease of libido, insomnia, physical symptoms such as tachycardia, anorexia and feelings of worthlessness were identified as the top five symptoms found in the depressive aspect.

Conclusion

With these results, the psychosocial effects of this regimen on gynecologic oncology patients are highlighted and can be the considering factors for approaching the holistic treatment.

ENTEROSORPTION AS A SUPPORTIVE TREATMENT DURING EXTERNAL RADIOTHERAPY IN PATIENTS WITH UTERINE AND CERVICAL CANCER

V. Matkovic¹, K. Katic¹, A. Corusic¹, R. Likic²

¹Clinic for Obstetrics and Gynecology- University Hospital Centre Zagreb, Department of gynaecologic oncology, Zagreb, Croatia

²University Hospital Centre Zagreb, Department of Clinical Pharmacology-, Zagreb, Croatia

Aims

The most common adverse reactions of external pelvic radiotherapy include: frequent stools, frequent urination, dysuria, tenesmus, abdominal pain and blood count changes. To reduce them, patients should mind their diet, take enough fluids and use medications. One of the possibilities is Enterosgel, a selective enterosorbent.

Method

We administered Enterosgel as a part of a clinical study “The role of Enterosgel in prevention of gastrointestinal adverse reactions of percutaneous radiation”. 90 patients with uterine or cervical cancer, treated by external pelvic radiotherapy, were divided into 2 groups: the first group included 46 patients who were given 45 g of Enterosgel per day, and the second group included 44 patients who didn’t take Enterosgel. We monitored the following parameters: ECOG, body weight, diarrhoea, nausea, leukocytes, thrombocytes and erythrocytes count and potassium and sodium levels.

Results

There was no statistically significant difference between the two groups for blood count, electrolytes levels and ECOG. We found a statistically significant difference for body weight, number of diarrheal stools and number of days without nausea. Compared to patients who weren’t taking Enterosgel, patients in Enterosgel group lost 0.49 to 2.17 kg less (p-value = 0.00234), had 0.47 to 6.29 less diarrheal stools (p-value = 0.02325), and had 1.03 to 5.71 less days with nausea (p-value = 0.00558).

Conclusion

Preliminary results indicate that Enterosgel can be recommended as a supportive treatment during pelvic radiation, because it is well tolerated and effectively reduces gastrointestinal problems and weight loss. However, additional studies that will include more patients are needed.

RIVER FLOW INCISION: A MODIFIED INCISION TECHNIQUE FOR DECREASING MORBIDITY OF ILIO-INGUINAL DISSECTION

M.D. Ray, A. Mishra

1 DR BRA IRCH- All India Institute of Medical Sciences, Surgical Oncology, New Delhi, India

Aims

Ilio-Inguinal LND is an important component of surgical treatment for Ca Penis, Vulva, Primary cutaneous cancer, STS, melanoma etc. Skin flap necrosis is one of the most common complications after IILND with reported frequency up to 65% in published literature. Our experience with a modified surgical approach of River flow incision has been most successful in eliminating flap necrosis.

Method

A modified skin incision was used to perform IILND in 74 prospective patients. Irrespective of primary histology or timing, same technique was used in all cases. Two curvilinear parallel skin incisions were made; each sited about 4 cm above and below inguinal ligament. Flaps were raised below Scarpa’s fascia. LND was performed in both inguinal and iliac basin with a standard technique. All Patients were followed up prospectively for 30 days after surgery and complications if any, were recorded according to Clavein-Dindo System of reporting surgical complications.

Results

74 patients underwent 104 IILND from July 2012 till Dec 2016. Unilateral dissection was performed in 44 patients and 30 underwent bilateral ILND. There was only one instance of flap necrosis/loss. Complications recorded were Seroma (14.4%), Lymphedema (4.8%), Surgical site infection (4.8%), Deep vein thrombosis (2.7%), partial wound dehiscence (7.9%), partial skin flap loss (2%) all corresponding to Clavein–Dindo Grade 1 & 2.

Conclusion

‘River Flow’ Incision is a simple but effective surgical modification which has enabled us to perform therapeutic ILND safely. Avoidance of flap necrosis, significantly decreased morbidity and almost no learning curve are highlights of this modification of surgical technique.
COST IMPLICATIONS OF DELAYS IN DISCHARGE DUE TO SOCIAL REASONS FOLLOWING GYNAECOLOGICAL ONCOLOGY SURGERY

L. Bradley¹, B. Ghosh¹, C. Robotin¹, M. Datta¹, B. Worsnop¹, M. Smith¹, R. Slade¹, B. Winter-Roach¹, E. Myriokefalitaki¹
¹The Christie NHS FT UK, Gynaecological Oncology, Manchester, United Kingdom

Aims

To identify reasons for delayed discharge for patients who are medically fit for discharge and cost implications of such delays.

Method

Retrospective study of all 295 cases that underwent surgery by the gynaecological oncology team at The Christie, between 1/1/2016 and 31/7/2016. We excluded minor, day cases and joint procedures for non gynaecological primary cancers. Data collection included patient demographics, level and complexity of surgery, surgical outcomes (peri and post-operative morbidity, mortality, length of hospital stay, readmissions), reasons for delays in discharge. Analytical reports of costs from finances were retrieved in order to calculate cost implications.

Results

We reviewed all cases with length of hospital stay above the 3rd interquartile per type of surgery and identified 9 cases (4.1%) who although deemed fit for discharge stayed as inpatient for a cumulative total of 62 days (mean 6.9 days/case). Reasons for delayed discharge were attributed 20% to Occupational Therapy and 80% to social services. The additional cost was calculated to £49133, an average cost of £792.5 / day.

Conclusion

Early identification of needs and timely referrals can potentially reduce delayed discharges and reap associated financial benefits as well as benefit patients. Enhanced Recovery Nurse can facilitate communication with the appropriate teams to ensure timely discharges. Since then we implemented pre-op assessment and initiation of referral processes.

IDENTIFICATION OF INGUINO-FEMORAL SENTINEL LYMPHNODE IN VULVAL CANCER: SINGLE INSTITUTE EXPERIENCE

B. Ghosh\textsuperscript{1}, E. Myriokefalitaki\textsuperscript{1}, C. Robotin\textsuperscript{1}, M. Datta\textsuperscript{1}, B. Worsnop\textsuperscript{1}, M. Smith\textsuperscript{1}, R. Slade\textsuperscript{1}, B. Winter-Roach\textsuperscript{1}

\textsuperscript{1}The Christie NHS FT UK, Gynaecological Oncology, Manchester, United Kingdom

Aims

to investigate the implications of biopsy taking prior performing identification and excision of inguino-femoral sentinel Lymphnode in vulval cancer, according to ESGO guidelines.

Method

Retrospective study of all patients with presumed stage 1 vulval cancer who underwent identification and excision of inguinal sentinel lymph node in our institute, between 1/3/2015 and 31/1/2017. Data collection included patients demographics, tumour location and characteristics, lymphoscintigraphic and histopathological features, and surgical outcomes.

Results

We identified 30 cases of median age 63.1 years (range 34-92 y.o). Preoperative imaging excluded distance disease. Tumour has been previously excised in 46.7% of the cases. Identification of a both hot and blue lymph node was achieved in 93.3% cases. In 2 (6.7%) cases a sentinel lymph node could not be identified by lymphoscintigraphy and therefore a full lymphadenectomy was performed. Both cases were from the subgroup of patients with previously excised primary tumors, with a failure rate of 14.3% vs 0% of those with incisional biopsies, p<0.05. None of them had final positive lymph nodes. 3 out of 28 (10.7%) sentinel lymph nodes were positive. There were no cases (0%) with groin wound healing problems, lymph cyst or lymphoedema. There were no grade 3-4 complications or deaths (0%). There is no groin recurrence in a median of 11 months follow up (range 1-22).

Conclusion

It is important to counsel patients regarding the failure to surgically identify the sentinel lymph node, in case that an excisional biopsy has been performed, and proceed with full lymphadenectomy.

ESGO7-0520

ROLE OF GLYCOSYLTRANSFERASE C2GNT FOR THE EVASION MECHANISM OF NATURAL KILLER CELL IMMUNITY IN THE CHORIOCARCINOMA CELL

K. Nakamura¹, K. Niimi¹, K. Nishino¹, E. Yamamoto², F. Kikkawa¹
¹Nagoya University Graduate School of Medicine, Obstetrics and Gynecology, Nagoya, Japan
²Nagoya University Graduate School of Medicine, Healthcare Administration, Nagoya, Japan

Aims

The Core2 O-glycan on the certain cancer cell surface is known to be correlated with the metastasis of cancer strongly. We focus on the core2 β1, 6-N acetylglcosaminyl transferase (C2GnT) which forms Core2 O-glycan and examined it about evasion mechanism through the NK cell immunity in the choriocarcinoma cell.

Method

We investigated C2GnT expression in GTDs and placentas by immunohistochemistry. Western blot were performed for expression levels of C2GnT protein in choriocarcinoma cell lines (Jar, BeWo, JEG3), EVT cell line (HTR-8/SVneo), and tissues of hydatidiform mole and placenta of various gestational weeks. We established C2GnT knockout in choriocarcinoma cells in vitro by CRISPR-Cas9 system. (1) We confirmed suppression of C2GnT expression in knockout cells compared to control cells using Western blot. (2) NK cell cytotoxicity against those cells were assayed. (3) Major histocompatibility complex class I-related chain A (MICA) expression were assayed by Western blot. (4) Poly N-acetyllactosamine in core2 branched oligosaccarides were evaluated by Immunoprecipitation.

Results

C2GnT was highly expressed in trophoblasts of choriocarcinoma but not in hydatidiform mole. (1) Expression level of C2GnT protein in knockout cells were significantly reduced compared to controls. (2) C2GnT-knockout cells were more efficiently killed by NK cells than controls at several effector:target ratios. (3) MICA expression were no difference with both cells significantly. (4) MICA in C2GnT knockout cells were less O-glycosylated comopared to control cells.

Conclusion

These findings suggest that the choriocarcinoma cell escaped from NK cell immune system by mechanism of glycosilation for cell surface O-glycan and acquired a high metastaticity.
LAPAROENDOSCOPIC SINGLE SITE SURGERY OF EXTREMELY LARGE OVARIAN CYSTS: USE OF ANGIOCATHETER

S.K. Nam1, Y.S. Lee1, M.J. Song1, E.K. Park1

1College of Medicine- The Catholic University of Korea, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To evaluate the efficiency and feasibility of Laparoendoscopic single site (LESS) surgery using Angiocatheter in patients with palpable large (>15cm) ovarian tumors above umbilicus and report our initial experience.

Method

Retrospective study. Thirty-one patients underwent LESS-surgery with use of angiocatheter for large ovarian tumors between March 2011 and August 2016. Through vertical 1.5-2 cm incision within the umbilicus, the tumor was punctured by angiocatheter and the cystic contents were aspirated by connecting suction. After aspiration the catheter was removed, and a suction tip was put for removal of remnant fluid. Incision seals pulse string. All LESS procedures were performed using a rigid 0°, 5-mm scope and conventional, rigid, straight laparoscopic instruments.

Results

We reviewed the medical records of 31 patients with large ovarian tumors and evaluated the clinical characteristics and operative outcome. The median maximal diameter of preoperative cysts was 18cm. The median operative time was 150mins and median blood loss was 100ml. Three cases (9.7%) were diagnosed as malignant disease and seven cases (22.6%) as borderline disease on frozen sections. Fertility sparing cytoreductive surgery (3 patients) and laparoscopic surgical staging (3 patients) were performed, and one patient was converted to open surgery due to advanced stage. No tumor spillage during use of catheter and no complications were observed, but cyst rupture occurred in 1 case (3.2%). Median follow up period was 22 months and no recurrence was until now.

Conclusion

LESS-surgery using angiocatheter for the management of large ovarian cyst is feasible, with no perioperative complications, faster recovery and better cosmetic results, and is very useful for initial diagnosis for extremely large cyst.
COMBINED RUPIVACAINE PERI-INCISIONAL INJECTION AND INTRAPERITONEAL NEbulization: A NEW EFFECTIVE TOOL IN PAIN CONTROL AFTER LAPAROSCOPIC SURGERY IN GYNECOLOGY: A RANDOMIZED CONTROLLED CLINICAL TRIAL

A. Vitagliano¹, M. Noventa¹, S. Gizzo¹, P.S. Litta¹, S. Borgato¹, V. Bertoldo¹, S. Tosatto¹, M. Palumbo¹, A.S. Laganà², S.G. Vitale², M. Blaganje³, B. Koba³, D.S. Kristina³, A. Lukanovic³, C. Saccardi³

¹University of Padua, Department of Woman and Child Health, Padua, Italy
²University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
³University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubliana, Slovenia

Aims

To evaluate the efficacy of intraoperative topical ropivacaine in the control of post-operative pain in the first 48 h after operative laparoscopy for benign adnexal or uterine pathologies.

Method

We conducted a prospective, randomized, double-blind, placebo-controlled clinical trial. Patients received a standard dose of topical ropivacaine (injected at the three portal sites and atomized in the abdominal cavity) or placebo. We measured the intensity of pain in the first 48 hours using VAS (visual-analogue-scale). Moreover we evaluated shoulder tip pain, the request for rescue analgesics, time to discharge from recovery room, time to mobilizing on the ward and time to return to daily activities. Patients were divided in two groups (Group_A: benign adnexal pathologies; Group_B: benign uterine diseases) and assigned to Subgroup_1 (ropivacaine) and Subgroup_2 (placebo).

Results

A total of 187 women were included: 93 in Group_A and 94 in Group_B. Forty-seven patients entered Subgroup_A1, 46 Subgroup_A2, 48 Subgroup_B1 and 46 Subgroup_B2. Subgroup_A1 experienced lower post-operative pain at 4 (p=0.008) and 6 h (p=0.001) as well as a faster return to daily activities (p=0.01) in comparison with Subgroup_A2. Both Subgroup_A1 and Subgroup_B1 showed lower shoulder tip pain (respectively, p=0.032 and p=0.001) as well as shorter time to mobilizing on the ward after surgery (respectively, p=0.001 and p=0.01). The remaining variables analysis did not show significant results.

Conclusion

Combined topical analgesia with ropivacaine could represent a new safe and effective tool in the control of post-operative pain in gynecological laparoscopic surgery. Given the greater benefits for adnexal surgery, this strategy may be more suitable for this class of patients.

THREE OR MORE PRIMARY MALIGNANCIES INCLUDING THE FEMALE GENITAL TRACT
1 Otsuka T, Matsuura T
1Kameda Medical Center, Gynecology, Kamogawa, Japan

Aims

Objective. To identify clinical features of women who developed three or more primary malignancies including genital tract (GT) cancers.

Method

Methods. We retrospectively studied women with three or more primary malignancies including GT cancer who were treated since 2001 to 2016.

Results

Results. Of the 16 patients, 15 developed triple cancers and 1 quintuple cancers. The most common GT cancer was endometrial cancer (n=13), and 4 of the patients had synchronous ovarian cancer. Cervical and peritoneal cancer were observed in 2 and 1 patient, respectively. Fifteen patients developed non-GT cancer as their first cancer. The age at diagnosis of first cancer ranged 21-69 years (median, 52 years), and the age at diagnosis of the first GT cancer ranged 46-80 years (median, 65 years). The most common non-GT cancer was breast cancer (n=9), followed by colon (n=5), gastric (n=3) and thyroid cancer (n=3). Subsequent non-GT cancers were observed only in endometrial cancer patients (n=5: gastric, breast, lung, pancreas, and external ear). Six patients had a first-degree relative with gastric or colon cancer, and one had a first-degree relative with breast cancer. Two breast cancer patients treated with tamoxifen developed endometrial cancer. Quintuple cancer (esophagus, tongue, breast, cervix, and low-pharynx) developed in an ex-smoker.

Conclusion

Conclusions. The most common GT cancer in patients with three or more primary malignancies was endometrial cancer. Hereditary factors, tamoxifen, and older age appear to be associated with developing these cancers. Smoking and HPV infection seem to be linked with multiple cancers in a cervical cancer patient.
ADENOCARCINOMA NOT OTHERWISE SPECIFIED OF THE SALIVARY GLAND METASTASIS TO A UTERINE LEIOMYOMA

A. Psarris1, N. Koufopoulos2, C. Kalantzis1, F. Antoniadou2, D. Papatheodorou1
1Anticancer Oncologic Hospital “St. Savvas”, Department of Gynecologic Oncology, Athens, Greece
2Anticancer Oncologic Hospital “St. Savvas”, Department of Pathology, Athens, Greece

Aims

We report a case of high grade adenocarcinoma of the parotid gland metastatic to a uterine leiomyoma.

Method

A 68-year-old female with history of high grade adenocarcinoma of her right parotid gland was referred to our department because of a pelvic mass. MRI imaging of the lower abdomen revealed a mass on the posterior uterine wall measuring 7x5cm probably leiomyoma. PET-CT revealed increased 18F-FDG uptake in the uterus (SUVmax 11.1) and multiple nodules in both lungs. A total abdominal hysterectomy and bilateral salpingo-oophorectomy was performed. Macroscopically, the uterus was enlarged with a large leiomyoma located on the posterior uterine wall. On section, a yellowish distinct lesion was noticed at the center of the leiomyoma, measuring 2.8cm.

Results

On microscopic examination the leiomyoma was infiltrated by a high grade adenocarcinoma. Its morphology as well as immunohistochemical study indicate secondary involvement of leiomyoma in the adenocarcinoma otherwise specified (NOS) of the parotid gland.

Conclusion

The diagnosis of secondary involvement of leiomyoma in the adenocarcinoma NOS of the parotid gland. Adenocarcinoma NOS not of the salivary gland is a highly malignant tumor that gives distant metastases to bone, lung, liver and lymph nodes and rarely to skin, brain, thyroid and stomach. Metastasis to uterine leiomyoma is uncommon. The most frequent extragenital tumors that give metastases to leiomyomas are carcinomas of the breast, colon, stomach, pancreas, gallbladder, the lung, thyroid, urinary bladder and melanoma of the skin. To our knowledge no similar case has ever been reported in the English literature.
DIFFERENCES OF C-TYPE LECTIN RECEPTORS AND THEIR ADAPTOR MOLECULES IN THE PERITONEAL FLUID OF PATIENTS WITH ENDOMETRIOSIS AND GYNECOLOGIC CANCERS

D.C. Park¹, S.G. Yeo², Y.I. Kim², J.W. Lee²
¹St. Vincent's Hospital- The Catholic University of Korea, OBGYN, Suwon, Republic of Korea
²Kyung Hee University, Medical Science Research Institute- Kyung Hee University Medical Center, Seoul, Republic of Korea

Aims

Endometriosis, although not malignant, has clinically demonstrated properties of invasiveness and metastasis. The immunological differences between endometriosis and malignant gynecologic tumors were analyzed by assessing C-type lectin receptors and immunoglobulin secretion in peritoneal fluid of these patients.

Method

The levels of expression of C-type lectin receptors mRNAs, including those encoding Dectin-1, MR1, MR2, DC-SIGN, Syk, Card 9, Bcl 10, Malt 1, src, Dec 205, Galectin, Tim 3, Trem 1, and DAP 12, were measured by real time polymerase chain reaction in peritoneal fluid of 43 patients with benign masses (control group), 45 patients with endometriosis, and 44 patients with gynecologic (ovarian, uterine, and cervical) cancers. In addition, the concentrations of IgG, IgA and IgM were measured by enzyme-linked immunosorbent assays (ELISA).

Results

Compared with the gynecologic cancer group, the level of Bcl 10 mRNA was significantly lower, and the levels of MR1, MR2, Syk, Card 9, Malt 1, Dec 205, Tim 3, and DAP 12 mRNAs significantly higher, in the endometriosis group (p<0.05 each). The level of MR2 & DAP 12 mRNA in the endometriosis group was significantly higher than in the control groups (p<0.05), whereas the level of galectin mRNA in the endometriosis group was similar to that in the gynecologic cancer group (p<0.05). IgA and IgG concentrations in peritoneal fluid were significantly lower in the gynecologic cancer than in control group (p<0.05 each).

Conclusion

C-type lectin receptors and immunoglobulins act cooperatively and are closely associated in the pathogenesis of endometriosis and gynecologic cancers.
LAPAROSCOPIC SINGLE-SITE SURGERY(LESS) FOR LARGE SUSPICIOUS MALIGNANT ADNEXAL TUMORS USING SW KIM’S TECHNIQUE: COMPARE TO CONVENTIONAL LAPAROTOMY

S.H. Park1, Y.J. Lee1, J.W. Kim1, J.Y. Lee1, E.J. Nam1, S. Kim1, Y.T. Kim1, S.W. Kim1

1Yonsei Cancer Center- Yonsei University Health System, Department of Obstetrics and Gynecology, SEOUL, Republic of Korea

Aims

To evaluate laparoscopic single-site surgery(LESS) using special technique(SW Kim’s Technique) for large suspicious malignant adnexal tumors and compare the surgical outcomes with laparotomy.

Method

Between January 2013 and December 2016, 40 patients underwent LESS (group A), 27 patients underwent laparotomy (group B). To avoid the specimen being suctioned in abdominal cavity, we used a 30X30cm or 50X50cm sized large LapBag. To remove huge ovarian tumors without spillage, we used SW Kim’s technique (Figure 1).

Results

Patient characteristics and operative time were not significantly different in the two groups. The post-operative hospital stay was significantly shorter for group A than group B [median 2 days (1 – 9) vs. 5 days (3 – 15); P < 0.001]. In terms of intraoperative complications, 1 patient in group A had bleeding. In group B, 1 patient had bowel injury and 2 patients had cyst rupture. The postoperative complications, 1 patient in group A and 1 patient group B had fever. Adnexa tumors in group A included 28 benign (70%), 8 borderline (20%), and 4 malignant (10%; 2 mucinous carcinomas, 1 immature teratoma, 1 clear cell carcinoma) tumors; and in group B included 14 benign (51.85%), 5 borderline (18.52%), and 8 malignancy (29.63%; 3 mucinous carcinomas, 1 immature teratoma, 4 clear cell carcinomas) tumors. There was no recurrence in group A but 1 recurrence in group B.

Conclusion

This study showed LESS was safety and feasible in large suspicious malignant adnexal tumors.
KEystone flap was developed by Felix Behan in 1995, since that time, this technique has been applied in numerous body regions for its several demonstrated advantages.

Aims

Keystone flap was developed by Felix Behan in 1995, since that time, this technique has been applied in numerous body regions for its several demonstrated advantages.

Method

This is the first reported case describing the technique of bilateral Keystone perforator island flaps (KPIF) to close a wide defect after radical vulvectomy in irradiated patient.

Results

A 47 year old nulliparous woman, with a previous history of FIGO Stage IIB squamous cell cervical carcinoma (2012) treated with radical surgery followed by adjuvant chemoradiotherapy. Four years later (2016), she presented a lesion of 3 cm size of the lower right labia majora close to the midline. Punch biopsy was performed which revealed: moderately differentiated squamous cell carcinoma. No inguinal lymphadenopathy was noted and TC scan of the chest and abdomen was negative for distant metastases. The patient underwent radical vulvectomy with bilateral inguinal-femoral lymphadenectomy followed by vulvoplasty using bilateral Keystone island flap (see Fig.1). The KPIF is a curvilinear shaped trapezoidal design flap, which essentially comprises two conjoined V-Y flaps in opposing directions. The surgical wound is measured in two size, and the reconstruction must be elliptic, with the axis parallel to the skin nerves and veins and perforating of the art and the perineum. The long axis is chosen on the orientation of the defect and the tension lines. Therewere no post-operative complications. Aesthetically, the patient was satisfied with the result of surgery. After six months of follow up the patient is free of disease

Conclusion

Keystone flaps seems to be easy to design, elevate, and offer rapid fasciocutaneous closure in wide vulvo-perineal defect after radical vulvectomy.
ROLE OF INTRAOPERATIVE ULTRASOUND TO EXTEND MINIMALLY INVASIVE SURGERY FOR TREATMENT OF RECURRENT GYNECOLOGICAL CANCER

F. Masciilini, F. Moro, L. Quagliozi, M. Maria Cristina, A. Di Siena, R. De Leo, G. Scambia, A.C. Testa, A. Fagotti

1Catholic University of Sacred Heart, Division of Gynecologic Oncology, Rome, Italy
2University of Insubria- Del ponte Hospital, Department of Obstetrics and Gynecology, Varese, Italy

Aims

To describe the potential role of intraoperative ultrasound (US) in the detection and localization of recurrent disease in gynecological cancer patients during minimally invasive surgery (MIS) (either laparoscopy or robotic).

Method

From November 2015 to February 2017, 51 patients with isolated recurrent disease candidate for secondary cytoreductive surgery were treated by MIS in our Institution. Recurrent tumor was preoperatively assessed at clinical examination, transvaginal and transabdominal sonography and radiological evaluation (CT scan/MRI/PET), in all women.

Results

12 of 51 (23%) women needed intraoperative US. Original disease was distributed as follows: 5 (42%) ovarian, 4 (33%) endometrial, 1 (8%) uterine sarcoma, 1 (8%) cervical and 1 (8%) vaginal cancer. Recurrence was localized at vaginal cuff in 5 cases (42%), pelvic lymph nodes in 3 cases (25%), abdominal wall in 2 cases (17%), pelvic peritoneum in 2 cases (17%). Intraoperative US was able to identify the lesion in all women, allowing MIS (83% laparoscopy and 17% robotic) complete cytoreduction, with no conversion to laparotomy. Median operative time was 150 min (range, 77-280) (including US examination). No intraoperative and postoperative complications occurred. Median length of recovery was 2 days (range, 1-4) and median time to start adjuvant treatment (chemo/radiotherapy) was 25 days (range 22-40). Histological examination confirmed the presence of recurrence in 11 of 12 cases (92%), while the remaining case showed inflammatory tissue.

Conclusion

One of four patients (25%) with single gynecological cancer recurrence needs intraoperative ultrasound to benefit from MIS for complete secondary cytoreduction.

IMPLEMENTATION OF AN ENHANCED RECOVERY AFTER SURGERY (ERAS) PROGRAM: THE MD ANDERSON CANCER CENTER EXPERIENCE

G. Salvo¹, L. Meyer¹, J. Lasala¹, M. Iniesta¹, N. Sheth¹, M. Munsell², A. Rodriguez-Restrepo¹, C. Corzo¹, P. Ramirez¹
¹The University of Texas- MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston- TX, USA
²The University of Texas- MD Anderson Cancer Center, Biostatistics, Houston- TX, USA

Aims

To evaluate perioperative outcomes of patients undergoing exploratory laparotomy for gynecologic indications in an Enhance Recovery after Surgery (ERAS) program and compare to those receiving traditional perioperative care (pre-ERAS)

Method

All consecutive patients managed under an ERAS program undergoing exploratory laparotomy between 11/3/2014 and 10/26/2016 were compared to historical controls (May to October, 2014). Interventions included, allowing oral intake of fluids up to 2 hours before induction of anesthesia; perioperative euvolemia as well as opioid-sparing analgesia; and ambulation and regular diet on the day of surgery. Wilcoxon rank-sum and Fisher's exact tests were used

Results

A total of 518 enhanced recovery patients were compared with 74 patients in the control group (pre-ERAS). ERAS resulted in a 1-day reduction in hospital stay (median LOS pre-ERAS: 4 days [range, 2-27] vs. ERAS: 3 days [range, 1-43], p<0.01) with stable readmission rates (pre-ERAS: 14.1% vs. ERAS: 12.9%, p=0.85). ERAS resulted in a 73.6% reduction in median postoperative morphine equivalents during the first 3 days after surgery with no significant difference in mean pain scores between the pre- and post ERAS cohorts. No differences were observed in postoperative complications between pre-ERAS and ERAS groups respectively (29.6% vs. 25.7%, p=0.47; GU: 21.1% vs. 18.3%, p=0.63; Hematologic: 16.9% vs. 11.8%, p=0.25). Overall compliance with all components of the ERAS protocol was 70% (range, 40-85%)

Conclusion

Implementation of an ERAS program was associated with reduced LOS with stable readmission and perioperative complication rates and reduced overall opioid consumption. Further study is warranted to determine impact on progression free survival
AN AUDIT OF THE USE OF INFERIOR VENA CAVA (IVC) FILTERS IN A GYNAECOLOGICAL-ONCOLOGY CENTRE IN ESSEX, UK.

N. Bhagat¹, A. Field¹, D. Kolomainen¹, K. Razvi¹
¹Southend University Hospital NHS Foundation Trust, Obstetrics & Gynaecology, Westcliff on Sea, United Kingdom

Aims

IVC filters are used in GynaeOncology patients who have a current or recent incidence of venous thrombo-embolism. We studied the safety and efficacy of pre operative insertion of IVC Filters in Gynaecological Oncology patients.

Method

A retrospective analysis of IVC Filters use in 27 consecutive patients at the cancer centre at Southend University Hospital during the years 2010-2016. Most individuals had recent or current thromboembolic events or anticoagulation was contraindicated pre-operatively.

Results

Of the 27 patients, 23 were symptomatic with a history of active Venous Thrombo-Embolism(VTE) and 4 had incidental findings of a VTE on imaging during the workup of a cancer diagnosis and treatment planning.

The mean age of the patients was 65 years (49 to 89 years). 63% of patients had ovarian cancer - with 73% being in late stages (3/4), 19% had endometrial cancer, 7% cervical, 4% Fallopian tube and 7% concomitant ovarian and endometrial cancers.

89% patients underwent surgery. The filters were inserted in a median of 5.5 days prior to surgery. There were no filter insertion related complications. There were no episodes of Pulmonary Emboli(PE) or VTE related death in the post operative period(within 30 days of surgery)

Conclusion

IVC Filters are safe to use in Gynae-Oncology patients. They can be inserted within a week prior to surgery without any adverse effects on post operative outcome.
ANALYSIS OF EFFICACY AND SAFETY OF OLARATUMAB + DOXORUBICIN OR DOXORUBICIN ALONE IN PATIENTS WITH UTERINE LEIOMYSARCOMA: RETROSPECTIVE ASSESSMENT OF THE PHASE 1B/2 STUDY JGDG

B.A. Van Tine¹, P. Peterson², A. Shahir³, R. Ilaria Jr.², R.L. Jones⁴
¹Washington University in St. Louis, Medical Department, St. Louis, USA
²Eli Lilly and Company, Diabetes, Indianapolis, USA
³Eli Lilly and Company, Diabetes, Windlesham, United Kingdom
⁴Royal Marsden Hospital, Sarcoma Unit, London, United Kingdom

Aims

Olaratumab (olara), a recombinant human IgG1 monoclonal antibody that specifically inhibits PDGFRα activation, has demonstrated improvement in median overall survival (mOS) in combination with doxorubicin (dox), compared to doxorubicin alone in a Phase 1b/2 Study. Since leiomyosarcoma (LMS) was the most common soft tissue sarcoma (STS) subtype in the study, we sought to characterize the safety and efficacy of olara+dox in the uterine LMS subpopulation.

Method

A retrospective review was performed on the Phase 2 portion of the study to identify patients with uterine LMS. Kaplan-Meier and Cox methods were used for OS and progression-free survival (PFS). Safety was assessed using CTCAE 4.0.

Results

Fifteen patients with uterine LMS (olara+dox N=8, dox N=7) were identified in the intent to treat population. Median OS was 25.0 (95% CI: 4.9, not estimated [n/e]) and 11.4 (3.6, n/e) months for olara+dox and dox (HR [95% CI] 0.61 [0.175, 2.144]), respectively. Median PFS was 2.7 (95% CI: 1.1, 11.0) and 3.6 (1.0, n/e) months for olara+dox and dox (HR [95% CI] 0.93 [0.245, 3.541]), respectively. The grade≥3 adverse events (AE) observed in 2 or more olara+dox treated uterine or non-uterine LMS patients were: anemia, neutropenia, thrombocytopenia, and fatigue. Grade≥3 febrile neutropenia occurred in 3 patients with uterine and in 1 patient with non-uterine LMS.

Conclusion

Although small cohort size limited definitive conclusions, the clinically meaningful improvement in mOS and safety profile in the uterine LMS population with olara+dox versus dox alone is consistent with that previously reported in the overall STS population.
STEREOTACTIC ABLATIVE RADIOThERAPY (SABR) IN PATIENTS WITH GYNAECOLOGICAL CANCERS IN THE WEST OF SCOTLAND

C. Cunningham¹, R. Harrand¹, N. Reed², S. Smith², K. Graham¹, A. Sadozye¹
¹Beatson West of Scotland Cancer Centre, Oncology, Glasgow, United Kingdom
²Beatson West of Scotland Cancer Centre, Oncology, Glasgow, United Kingdom

Aims

To assess safety and efficacy of stereotactic ablative radiotherapy (SABR) for gynaecological cancers in the West of Scotland.

Method

Patients with gynaecological cancers treated with SABR were identified from ARIA database for the period February 2014 to December 2016. Electronic and paper records were scrutinised to record demographic information, indication for treatment, dose and fractionation, toxicities (acute and late), and outcome.

Results

Ten patients were identified, age from 41 to 75 years (median age 52). A total of 12 treatment sites included primary lesions (2 as boost in radical treatment schedule – 1 patient refused brachytherapy, 1 was unfit for Anaesthetic, 1 in metastatic setting for symptom control), central recurrences (2 vaginal, 1 parametrial), and oligometastatic sites (2 pelvic nodes, each treated separately, 1 psoas muscle, 1 abdominal wall lesion, 1 patient with 2 peritoneal deposits, each treated separately). Doses ranged from 1200cGy in 2 fractions (boost in patient who refused a second Brachytherapy insertion) to 3530cGy in 5 fractions.

Four patients had previous radical radiotherapy to Pelvis and SABR was a re-treatment.

Toxicity from this treatment was minimal; there was no G3 toxicity recorded following SABR after a median follow-up of 18 months. Three patients demonstrated excellent clinical or radiological response, 4 demonstrated partial response, and 2 had no response, 4 patients subsequently died, including both where there was no response.

Conclusion

Preliminary results demonstrate the feasibility, tolerability and safety of SABR in Gynaecological malignancies, even in those who have previously received full dose Pelvic radiation.
HUGE PELVIC FIBROMATOSIS DIAGNOSED DURING PREGNANCY

M. Sakinci¹, C. Elteç¹, N.U. Dogan¹, G.A. Ocaş², E. Cobankent², C. Kemaloglu³
¹Akdeniz University School of Medicine, Obstetrics and Gynecology, Antalya, Turkey
²Akdeniz University School of Medicine, Pathology, Antalya, Turkey
³Akdeniz University School of Medicine, Cardiovascular Surgery, Antalya, Turkey

Aims

Cervicovaginal myofibroblastoma is a benign but locally aggressive tumor developing in vulva, vagina or cervix. It is a very rare entity. A case of myofibroblastoma during pregnancy has been described previously; our case is the second in the literature.

Method

A 32 year old patient applied to our clinic during 26th gestational week with the symptoms of pelvic pain, difficulty in urination and defecation. On pelvic examination a large mass beginning from the introitus and filling the deep pelvis had obliterated the vagina totally from the right side. An incisional biopsy of the mass was undertaken and reported as myofibroblastoma by the pathology department. The patient underwent cesarean section at 39 weeks of pregnancy.

Results

After puerperium, two course of embolization treatment was undertaken to reduce tumor tissue and decrease vascularity. Then she was operated. A rigid fixed mass extending to paravaginal, paravesical, pararectal space and ischioanl fossa measuring about 13 cm and filling the ¾ of the true pelvis was observed intraoperatively.
The mass was completely impacted to the true pelvis and interface in between was obliterated. The mass was reduced in size centrally using cold-knife wedge resection. So a dissection plane from the surrounding tissues was created and the mass was excised completely. The final pathology report revealed fibromatosis consisting of myofibroblasts.

Early or late postoperative complications were not observed and radiotherapy and long-term follow-up was planned to prevent recurrence.

Conclusion

Rapid growth of the tumor, direct pressure on the birth canal makes it easier to recognize in pregnant patients but surgery is difficult and complicated, and should be performed in experienced surgical clinics.

METASTATIC NONGESTATIONAL CHORIOCARCINOMA WITH UNKNOWN PRIMARY
M. Sakinci¹, F.C. Guner¹, C. Etlec¹, M. Ozekinci¹, N.U. Dogan¹, S. Sezgin Goksu²
¹Akdeniz University School of Medicine, Obstetrics and Gynecology, Antalya, Turkey
²Akdeniz University School of Medicine, Medical Oncology, Antalya, Turkey

Aims

Nongestational choriocarcinoma is a highly malignant very rare germ cell tumor. Germ cell tumors are mostly located in gonads, however, exceptionally they can be found in other locations. Non gestational choriocarcinoma has been reported in extraplacental and extragonadal sites. The vast majority represents systemic metastases, with the most common sites being lung, liver and brain. Occasionally the primary tumor regresses, leaving only metastatic lesions to be detected on imaging.

Method

A 39-year-old (gravida3,para3) women presented with a three-week history of right upper quadrant pain and nausea. She was on the fifth day of menstrual period and had slight cervical bleeding. Her β-human chorionic gonadotrophin (β-HCG) level was found to be elevated (53,777 mIU/ml). Endometrium was measured 6.7 mm thick and no adnexal pathology found by endovaginal ultrasonography. First diagnosis was unknown location ectopic pregnancy or choriocarcinoma. A diagnostic laparoscopy and endometrial sampling was performed. Both were unremarkable. During the postoperative period, the hCG levels remained progressively increasing (>1,500,000mIU/ml).

Results

To identify occult disease MRI scan of the head, whole body 18 FDG-PET scan were performed, revealing metastatic lesions in frontal cortex, liver and right lung. Ultrasound-guided liver core biopsy was obtained and pathological diagnosis was reported as choriocarcinoma metastasis. EMA-CO chemotherapy regimen (etoposide, methotrexate/leucovorin, and actinomycin-D, followed
a week later by cyclophosphamide and vincristine) was commenced.

Conclusion

Choriocarcinoma is a very aggressive malignancy and death may result from delays in diagnosis. Therefore, early intervention is critical for limiting the progression of disease.

VERY PROLONGED RESPONSE TO TRABECTEDIN AND SURGICAL MANAGEMENT IN REFRACTORY UTERINE LEIOMYOSARCOMA: A CASE REPORT

S. Vanda1, G. Corrado1, M.G. Distefano1, A. Fagotti1, V. Carbone1, G. Scambia1, G. Ferrandina1

1Fondazione Policlinico Universitario A Gemelli, Gynecology Oncology, Rome, Italy

Aims

Uterine leiomyosarcomas (U-LMS) are rare uterine tumors, the prognosis is extremely poor. Total abdominal hysterectomy is the cornerstone of management of early disease, however for recurrent or disseminated U-LMS, cytotoxic chemotherapy remains the mainstay of treatment but with no impact on survival. Trabectedin, a new DNA-damaging agent, is approved in Europe, USA and many other countries worldwide for the treatment of patients with advanced U-LMS after failure of anthracyclines. The role of surgery is unclear in metastatic disease.

Method

We report the case of a 38-year-old woman with peritoneal metastatic uterine leiomyosarcoma refractory to multiple treatments who obtained a prolonged disease control following the treatment with trabectedin and surgery.

Results

The patient received 60 cycles of trabectedin 1.5 mg/m² given as a 24-hour i.v. infusion every three weeks for 6 cycles, reduced for epatotoxicity to 1.1 mg/m² every four week. Trabectedin treatment resulted in a partial response according to RECIST criteria with good and predictable tolerability profile of the regimen. Marked tumor shrinkage allowed a surgical resection that histologically evidenced a complete necrotic response of the pelvic mass and peritoneal carcinosis. After 5 months from surgery patient experimented peritoneal recurrence and was submitted to surgical debulking and Hyperthermic Intraperitoneal Chemotherapy (HIPEC) with doxorubicin. Currently, the patient is alive without evident disease. Molecular characterization pre- and post-trabectedin administration and after recurrence is ongoing.

Conclusion

Trabectedin and surgery represent a feasible option for treatment of metastatic U-LMS; however, further clinical studies are warranted to better understand the mechanism of long-lasting response to trabectedin.
THE BURDEN OF HPV-ASSOCIATED CANCERS IN RUSSIAN FEDERATION

A. Kostin¹, Y. Samsonov¹, O. Gretsova¹

¹Moscow cancer research institute, Russian Center for Informational Technologies and Epidemiological Researches, Moscow, Russia

Aims

To conduct a first analysis of HPV-associated cancers (HPVAC) burden in Russia in 2015.

Method

Statistical data were taken from the State medical statistics report (form #35 "Information on patients with malignancies for 2015"). HPVAC were calculated as a proportion on the basis of world statistics data and extrapolated to the whole country level.

Results

16710 new cases of cervical cancer (CC) were diagnosed in 2015 (63.9% of women in I-II stage, 25.2% in III and 9.4% in IV stage). Mortality within 1 year from the diagnosis was 15.2%. In the total cancer mortality structure in women 15-59 years old the mortality from CC accounted for 10.1%. HPVAC burden in 2015 is presented in Table 1.

Table 1. HPVAC burden in Russia in 2015.

<table>

</table>

Conclusion

Data on HPV-associated cancers burden in Russia were limited. The first analysis shows the estimated number of newly diagnosed HPV-associated cancers was 29867 cases and more than 204,000 patients with HPV-associated cancers registered. Thus, HPV-associated cancers were accounted for more than 6% of the total cancer morbidity in Russia.
MALNUTRITION AND SARCOPENIA: RISK FACTORS FOR SHORTER SURVIVAL IN PATIENTS TREATED WITH PELVIC EXENTERATION FOR RECURRENT GYNECOLOGICAL MALIGNANCY.

V. Seebacher¹, A. Rockall², M. Nobbenhuis³, R.M. Alvarez Lopez⁴, A. Sohaib⁵, T. Knogler⁶, D. Barton⁷

¹Medical University of Vienna, Gynecology and Gynecologic Oncology, Vienna, Austria
²Royal Marsden Hospital, Radiology, London, United Kingdom
³Royal Marsden Hospital, Gynaecology Unit, London, United Kingdom
⁴Medical University of Vienna, Radiology, Vienna, Austria

Aims

Pelvic exenteration is a highly morbid procedure performed as the last option for cure in selected patients with recurrent or persistent gynaecological malignancies. Due to a lack of objective factors predicting outcome, patient selection is in part based on subjective criteria. The aim of the present study was to investigate the prognostic value of malnutrition and sarcopenia on the outcome of patients with recurrent gynaecological malignancies treated by pelvic exenteration.

Method

We retrospectively evaluated muscle body composite measurements based on pre-operative CT scans, pre-operatively filled out questionnaires stratifying the risk for malnutrition, and clinical-pathological parameters in 65 consecutive patients with recurrent gynaecological malignancies treated by pelvic exenteration. Selected parameters were investigated for their predictive value for postoperative morbidity by logistic regression analyses. Relevant parameters were included in uni- and multivariate survival analyses.

Results

In 32 and in 34 patients pre-operative CT scans and questionnaires were available for analyses, respectively. We found (1) low muscle attenuation (MA) – an established factor for muscle depletion – and (2) malnutrition, based on a pre-operative questionnaire, to be independently associated with shorter overall survival \((p=0.006 \text{ and } p=0.008, \text{ respectively})\). Interestingly, MA was significantly lower in overweight and obese patients \((p=0.04)\). We did not find any of the investigated factors to be predictive for post-operative morbidity.

Conclusion

The present study suggests, that pre-operative low MA and malnutrition, based on CT scan and questionnaire, are associated with shorter survival in patients with recurrent gynaecological malignancies treated with pelvic exenteration. Further studies are needed to validate these findings in larger cohorts.
IS NERVE-SPARING SURGERY REALLY NERVE SPARING? A VIDEO OF THE PELVIC NERVOUS SYSTEM AFTER LAPAROSCOPIC DISSECTION OF A THIEL-EMBALMED SPECIMEN TREATED BY A NEW PROCEDURE

F. Siegenthaler¹, S. Imboden¹, S. Mohr¹, N. Boemke², V. Djonov², M.D. Mueller¹
¹Inselspital Bern- University of Bern, Department of Obstetrics and Gynecology, Bern, Switzerland
²Institute of Anatomy, University of Bern, Bern, Switzerland

Aims

The inability to visualize the small caliber nerve fibers makes nerve-sparing surgery very difficult. We demonstrate the anatomic path of the pelvic autonomic nerves by laparoscopic dissection of a female cadaver using a technique that allows advanced description of small nerves.

Method

A Thiel-embalmed female cadaver was dissected laparoscopically. After opening of the retroperitoneal space the pelvis was immersed with nitric acid. This facilitated the dissection of the connective tissue and the subsequent preparation was performed only with rinsing and suction. The autonomous nerves were followed up to the visceral organs. The relationships of the nerves to arteries, viscera and ligaments were documented.

Results

The superior hypogastric plexus was situated anteriorly and below the aortic bifurcation. It branched into the left and right hypogastric nerve connecting the superior to the inferior hypogastric plexus. Other afferences of the inferior hypogastric plexus were the sacral and pelvic splanchnic nerves. We detected an impar hypogastric nerve stretching medially to the mesorectum. Furthermore, we identified a delicate network of nerves originating from the hypogastric nerve and stretching medially towards the rectum.

Conclusion

Precise knowledge of the neuroanatomy of the pelvis is important to reduce morbidity after surgery. Thiel fixation and preparation with nitric acid permitted dissection of the nerves up to the intraorganic branches. With our technique, we demonstrate that the area medially below the superior hypogastric plexus – commonly used as an anatomical cleavage point – isn’t devoid of nerves. This suggests that nerve-sparing surgery may not be as nerve sparing as sometimes presumed.
RECENT ACTIVITIES OF KOREA GYNECOLOGIC CANCER BANK

G.S. Sohn¹, Y.M. Park¹, H.J. Kwon¹, H.Y. Shin¹, E.J. Lee¹, W.K. Yang¹, H.B. Cho¹, D.B. Chay¹, J.H. Kim¹, J.K. Gong¹
¹Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

To develop effective targeted therapy for gynecologic cancer, the need to understand molecular mechanisms related to the tumor generation, metastasis and treatment resistance is increasing. This study seeks to review the current status of the database, the cooperation system with other institutions and to evaluate the utility degree of the stored specimens as research sources of Korea Gynecologic Cancer Bank (KGCB).

Method

Human specimen and data stored in the bank target primary gynecologic cancer cell line, tissue, serum, plasma, lymphocyte, urine, saliva and pelvic ascites. Specimen extraction was administered starting from 2012, and it was administered before or during the treatment using the low-invasive method with the patients agreement. Specimen quality and quantity was identified by classifying specimen by cancer type, acquired year and characteristic.

Results

Currently, specimen and data in the bank numbers total of 49,514. Starting from May 2012 to Mar 2017, 16,757 serum, 13,490 plasma, 3,350 lymphocyte, 2,736 frozen tissue, 5,303 pelvic ascites, 1,081 OCT, 36 HOSE, 3,145 Urine, 350 saliva, 25 whole blood, 1,198 thin-prep, 440 cervicovaginal fluid, 8 TMA and 1,595 paraffin block units were stored. As for the paper using the distribution of research sources, there are 31 papers published on SCI journals from 2012 to 2017.

Conclusion

Resources of gynecologic cancer bank is continuing to grow steadily since 2012, and quality resource is being developed through proper management. Korea Gynecologic Cancer Bank could provide resources actively according to the fair and appropriate procedure of the related research institutions and academic community.
A CASE OF SEPTIC SHOCK COMPLICATED BY INTRAUTERINE NECROSIS OF ADENOMYOSIS

S.K. Lee¹, H.S. Yun¹, H.G. Kim¹, D.H. Lee¹, Y.J. Na¹, O.H. Choi¹, Y.J. Song¹
¹Pusan National University Yangsan Hospital, Obstetrics & Gynecology, Yangsan, Republic of Korea

Aims

Adenomyosis is common benign pathology on women in reproductive age. Dysmenorrhea, heavy menstrual bleeding and chronic pelvic pain are typical symptoms. It is very rare situation for adenomyosis to be complicated by sepsis or septic shock.

Method

A 42-year-old woman complaining of severe pelvic pain, dyspnea and fever visited emergency department. Pelvic computed tomography showed adenomyosis. Her condition was rapidly aggravated to septic shock in spite of antibiotics treatment. There was moderate amount of pus in pelvic cavity.

Results

Total abdominal hysterectomy with both salpingectomy were done emergently. Pathology result was consistent with adenomyosis. After postoperative care at intensive care unit and general ward, she was discharged without any surgical and medical complication.

Conclusion

This case is very rare in representing pelvic abscess formation combined with adenomyosis. Early surgical intervention seems to be beneficial for treatment and diagnosis when medical treatment do not respond promptly.

SOCIAL SUPPORT AND QUALITY OF LIFE IN CERVICAL CANCER PATIENTS AFTER TREATMENT
N. Sriintravanit1, B. Sumdaengrit1
1Faculty of Medicine- Ramathibodi hospital- Mahidol University, Nursing Department, bangkok, Thailand

Aims

Cervical cancer is the second most common cancer in Thai women. In the last ten years, many women can survive from cancer according to advanced treatments. However, these women must to cope with symptom distress from treatment. To promote social support and reduce symptom distress is necessary for the improve quality of life in cervical cancer survivors. Aim of this study was to examine the correlation of these factors and quality of life in cervical cancer patients after treatment.

Method

This study was a descriptive correlational research. Samples included 53 women who visited at outpatient department in university hospital during January – December 2016. The instrument were 1) the personal, disease, and treatment data; 2) Social support; and 3) FACT-Cervix. Data were analyzed by descriptive and Spearman Rank Test.

Results

Results found that age of 53 participants ranged from 30 to 86, mean 55.15 (sd = 10.05). Social Support varied from 29 to 59, mean 48.23 (sd = 6.76). Symptom distress varied from 0 to 9, mean 3.36 (sd = 2.83). In addition Quality of life in these participants varied from 75 to 159, mean 126.02 (sd = 21.09). Results revealed that age and social support had no correlation with the quality of life, however, there was negatively correlation between symptom distress and quality of life with $r = -0.40$ at $p=.003$.

Conclusion

Findings from the study demonstrated that health care providers should focus in reducing symptom distress to improve the quality of life in cervical cancer survivors.

QUALITY OF LIFE IN THAI WOMEN AFTER HYSTERECTOMY

B. Sumdaengrit1, M. Wongrisoontorn2

1Faculty of Medicine Ramathibodi hospital, Ramathibodi School of Nursing, Bangkok, Thailand
2Faculty of Medicine Ramathibodi hospital, Nursing Department, Bangkok, Thailand

Aims

Aims of this research were to examine quality of life and factors related to quality of life in Thai women after hysterectomy in university hospital.

Method

This cross-sectional study was a descriptive and correlational design. Samples included 70 women after hysterectomy in university hospital. Data were collected during January – June 2016. The instruments were (1) the personal disease and treatment data developed by principal investigator, and (2) World Health Organization quality of life – Thai version (WHOQOL-BREF-THAI) developed by WHO. Alpha Cronbach’s coefficient for WHOQOL-BREF-THAI questionnaires was .87. Data were analyzed by descriptive statistics and Spearman Rank Test correlation.

Results

Results found that the average age of participants was 50.91 years (sd=9.29), time after hysterectomy was 28.40 months (sd=10.98). Health status (mean= 3.47, sd= .86, range 2-5) and total quality of life (mean= 3.47, sd= .86, range 3-5) were higher than the average. Majority level of 4 quality of life's domains were moderate as reported; physical (84.3%), psychosocial (74.3%), social (64.3%), environment (60.0%). In addition there were positive correlation between health status and physical, psychosocial, social, environment domain and total quality of life at .05 level, whereas, there was no correlation between age and quality of life in these participants.

Conclusion

Results from this study, health care providers should focus to provide good health status to improve quality of life in Thai women after hysterectomy.
ESTABLISHMENT AND CHARACTERISATION OF PATIENT-DERIVED XENOGRAFT MODELS FOR MALIGNANT GYNECOLOGIC TUMORS

S. Suzuki\textsuperscript{1}, S. Tamauchi\textsuperscript{1}, Y. Shimizu\textsuperscript{1}, M. Yoshihara\textsuperscript{1}, K. Nakamura\textsuperscript{1}, N. Yoshikawa\textsuperscript{1}, H. Kajiyama\textsuperscript{1}, F. Kikkawa\textsuperscript{1}

\textsuperscript{1}Nagoya University Graduate School of Medicine, Obstetrics and Gynecology, Nagoya, Japan

Aims

The patient-derived xenograft (PDX) models have been used in the oncologic field to develop new therapeutic agents, which preserve tumor microenvironment and tumor characteristics, and well reflect patient's histological features. In this study, we attempted to establish PDX models derived from malignant gynecologic tumor patients' surgical specimens implanted into severe immunodeficient mice.

Method

Between April 2016 and March 2017, a total of 15 separate clinical samples (13 malignant ovarian tumors, 1 fallopian tube cancer and 1 uterine carcinosarcoma) were collected and implanted subcutaneously in NSG mice. Surgical tumor tissues were cut into pieces of 2 to 3 mm and transplanted within one day. Three patients had received chemotherapy and/or radiation therapy before surgery.

Results

A total of 8 PDX models (6 malignant ovarian tumors including malignant-transformation of mature cystic teratoma, 1 fallopian tube cancer and 1 uterine carcinosarcoma) were established for a take rate of 53%. The latency time to development of clinically apparent disease from the time of initial implantation varied from 1 to 4 months. Regarding malignant-transformation of mature cystic teratoma, the xenograft tissue was replanted into six nude mice, and after engraftment, two mice were irradiated and other 2 mice were administered cisplatin. Four weeks later, the tumors were sampled and analyzed histologically. Even in nude mice, tumor morphology was maintained. This PDX model's responses to antitumor treatment were similar to those of the patient.

Conclusion

Further evaluation of the PDX models for malignant gynecologic tumors will contribute to the development of treatment strategies.

PRIMARY RETROPERITONEAL MUCINOUS TUMOURS DIAGNOSED IN PREGNANCY – A CASE REPORT AND LITERATURE REVIEW

F. Tahmasebi¹, H. Jamall², N. Deo²
¹, London, United Kingdom
²Whipps Cross Hospital, Obstetrics and Gynaecology, London, United Kingdom

Aims

Primary retroperitoneal mucinous tumours (PRMTs) are extremely rare neoplasm’s occurring almost only in women, with just three cases reported in men. Although PRMTs have been reported in patients of a wide range of ages, they mainly occur in women of reproductive age. They have been categorised into three types consisting of: mucinous cystadenomas (MCs), mucinous borderline tumours or tumours of low malignant potential (MLMP) and mucinous carcinomas (MCas). In many of the cases reported, preoperative diagnosis of these masses is extremely difficult as CT or MRI is unable to differentiate the exact origin of these tumours. As a result of this and due to rare nature of the condition, treatment and prognosis remains controversial and diagnosis is usually made post-operatively after histology. We describe the case of a young female who presented to us with what was found to be a PRMT in pregnancy.

Method

Literature review

Results

NA

Conclusion

PRMT are extremely rare and extremely difficult to diagnose preoperatively due to the asymptomatic presentation. It is not possible to clarify the precise defect in embryologic growth that allows these tumours to develop. The preoperative course of these cysts appears indolent, yet the overall prognosis is poor. The role of chemotherapy in the treatment of these tumours remains undefined. Close follow-up and aggressive management based on histological appearance is indicated to improve the outcome of these patients.
EFFECT OF AGE, RACE, AND STAGE ON SURVIVAL IN GESTATIONAL CHORIOCARCINOMA: A SEER ANALYSIS (1973-2013)
C. Tarney¹, C. Tian², N. Bateman³, T. Conrads³, C. Hamilton¹, L. Maxwell⁴, K. Darcy³
¹Walter Reed National Military Medical Center, Gynecologic Cancer Center of Excellence, Bethesda, USA
²Women's Health Integrated Research Center at Inova, Gynecologic Cancer Center of Excellence, Annandale, USA
³Women’s Health Integrated Research Center at Inova, Gynecologic Cancer Center of Excellence, Annandale, USA
⁴Inova Fairfax Hospital, Obstetrics & Gynecology, Falls Church, USA

Aims

Gestational choriocarcinoma is a malignant form of gestational trophoblastic disease that can occur after any gestational event. Given the rarity of gestational choriocarcinoma, investigations are limited. We evaluated the prognostic effects of age, race, and stage in gestational choriocarcinoma.

Method

Patients diagnosed with gestational choriocarcinoma between 1973-2013 from the Surveillance, Epidemiology, and End Results program were eligible. Relationships with cancer-specific (CSS) and overall survival (OS) were evaluated and adjusted for age, race and stage.

Results

There were 916 patients with gestational choriocarcinoma. Median age at diagnosis was 28 years. Non-Hispanic black (NHB) patients were diagnosed four years younger and Asian/Pacific Islanders were diagnosed six years later than non-Hispanic white (NHW) patients (P=0.0001). Five-year CSS was ≥96% when diagnosed at age <20 years old or with local disease, and dropped to 88% in patients diagnosed ≥40 years old or with distant disease. Adjusted CSS was worse when diagnosed between 20-39 (hazard ratio [HR]=3.60, 95% confidence interval [CI]=1.12-11.53, P=0.031) and ≥40 (HR=5.21, 95% CI=1.50-18.09, P=0.009) compared with <20 years old. Adjusted OS was also worse for those diagnosed ≥20 years old (P<0.001). NHB patients had similar CSS (P=0.119) but worse OS (HR=1.80, 95% CI=1.17-2.77, P=0.008) and more non-cancer deaths than NHW patients. Patients diagnosed with distant disease had worse CSS (HR=2.39, 95% CI=1.33-4.31, P=0.004) and OS (HR=2.56, 95% CI=1.63-4.03, P<0.0001) than those with local disease.

Conclusion

Most patients with gestational choriocarcinoma have excellent prognosis but the subset diagnosed with distant stage or as an adult had significantly worse CSS and OS.
OUR INITIAL EXPERIENCE IN LAPAROSCOPIC MANAGEMENT OF GYNAECOLOGICAL CANCER

T. Theodoridis1, A. Papanikolaou1, D. Tsolakidis1, D. Vavilis1, G. Grimbizis1, L. Zepridis1, M. Kotsailidou1, D. Aivazi1, E. Klonos1, V. Tarlatzis1

1Aristotle University Of Thessaloniki- Greece, 1St Department Of Obstetrics And Gynaecology "Papageorgiou" General Hospital, Thessaloniki, Greece

Aims

To assess the feasibility and safety of laparoscopic management of gynaecological cancer patients

Method

9 patients with endometrial cancer and 10 patients with ovarian cancer underwent laparoscopy as diagnostic or therapeutic method of treatment

Results

Nine patients with endometrial cancer underwent total laparoscopic hysterectomy. In four patients the surgical procedure included pelvic lymphadenectomy (table 1).

Five patients with advanced ovarian cancer were found eligible to for primary debulking surgery, and five patients after initial laparoscopy, were referred for neoadjuvant chemotherapy prior to interval debulking surgery (table 2).

Table 2: laparoscopic management of ovarian cancer

**Conclusion**

Laparoscopic management of gynaecological cancer appears to be feasible and safe method of treatment in selected cases.
AN ALTERNATIVE ROLE FOR A BREAST IMPLANT FOLLOWING TOTAL PELVIC EXENTERATION

C. Thompson¹, F. Abu Saadeh¹
¹St James’s Hospital, Gynaecological Oncology, Dublin, Ireland

Aims

Total Pelvic Exenteration (TPE), is the most destructive of Gynaecological oncology procedures, yet can be curative. Complications of adhesions, radiation enteritis and empty pelvic syndrome, can significantly impact quality of life. This case report describes the use of a breast implant to fill the pelvis, highlighting one potential way of addressing this. A review of other practices will also be discussed.

Method

Case reported and review of all available literature conducted. Keywords applied to searches including PUBMED and MEDLINE.

Results

Case:

66 year old, Stage IIIC High Grade Serous Carcinoma of Ovary diagnosed 2014 with neo adjuvant chemotherapy and interval ovarian debulking. Relapse in 2016, required second surgery due to 8cm penetrating tumour from vagina to anterior rectal wall. Surgery achieved full cytoreduction with TPE. A saline breast implant was used to fill the pelvis. Initially developed subacute bowel obstruction due to small bowel adhesion. Recovered well and to date has had no further episodes of obstruction or evidence of empty pelvic syndrome.

Review:

Although this technique is described there are few gynaecological case reports. Pelvic tissue expanders/prostheses have been described in nongynaecological patients. Issues remain regarding safety, risk of rupture and sepsis, however, these have improved with the use of modern saline implants. Other described methods include: pedicled omental flap, synthetic and biological meshes and myocutaneous flaps. None of which were possible in our patient.

Conclusion

This case highlights an alternative option to fill the pelvis after TPE. Our patient recovered well and to date has had no complications from the pelvic implant.
ACUTE KIDNEY INJURY FOLLOWING GYNAECOLOGICAL ONCOLOGY SURGERY: THE EXPERIENCE OF AN IRISH TERTIARY CENTRE

C. Thompson¹, C. Kelly², N. Gleeson¹
¹St James’s Hospital, Gynaecological Oncology, Dublin, Ireland
²Trinity College Dublin, Obstetrics and Gynaecology, Dublin, Ireland

Aims

Acute Kidney Injury (AKI) is a serious complication which can increased the morbidity and mortality of surgical patients. This audit of AKI in an Irish Gynaecological Oncology Practice aims to highlight the prevalence, identify risk factors in the pre, intra and postoperative periods and assess management set against standards established by the NICE guidelines for AKI. We aim to also highlight factors specific to Gynaecological Oncology and potential methods to reduce risk of AKI in our patient group.

Method

Definition of AKI set in line with RIFLE, AKIN & KDIGO criteria. Retrospective data collection of 300 patients via electronic patient records, laboratory data, surgical and anaesthetic records. Pre defined proforma for data collection.

Results

Overall incidence of AKI 4.3% (13) and all developed within 72 hours of admission. Preoperative risk factors identified: Diabetes Mellitus and Hypertension (p<0.001). Median duration of preoperative fasting was 16 hours. 64% received IV fluids from 6am on day of surgery. Ovarian malignancy was of highest risk group. Episodes of intraoperative hypotension (set as <80 systolic) were recorded in 38% of patients. Postoperative nephrotoxic drugs were implicated in 24% (3) cases. 84% (11) patients had Creatinine levels returned to baseline by Day 4. Remainder all underwent Ultrasound investigation, however, no patient required referral to nephrology.

Conclusion

Our department has a AKI rate OF 4.3% in comparison to other reports (range 6-13%). However, given the high risk group within Gynaecological Oncology care must be given to preoperative fluid administration, avoidance of nephrotoxic drugs and avoidance of acute hypotension intraoperatively.

AWARENESS AND COMPLIANCE WITH PHARMACOVIGILANCE REQUIREMENTS AMONGST UK ONCOLOGY HEALTH CARE PROFESSIONALS

R. Thorne¹, R. Bruggink¹, D. Montgomery¹, S. Payne¹, S. Purcell¹, S. Kelly¹
¹Pfizer Limited, Oncology, Tadworth, United Kingdom

Aims

To explore understanding of and compliance with adverse event (AE) reporting requirements in the real world amongst UK oncology health care professionals

Method

A questionnaire was electronically distributed to oncology pharmacists (P) via British Oncology Pharmacy Association (BOPA), oncologists (O) through Association of Cancer Physicians (ACP) and nurses (N) via UK Oncology Nursing Society (UKONS).

Results

125 (42 O, 61 P, 22 N) clinicians participated in the questionnaire. Definition of black triangle unknown by 26% (55% O, 5% P, 28% N), 54% do not alter their AE reporting in presence of a black triangle. Once a black triangle is removed only 38% were aware which AEs should be reported. 17% have never reported an AE and 7% report over 10 AEs a year. 46% (62% O, 43% P, 25% N) do not report all serious AEs for established medicines, including life-threatening or disabling AEs. Main limitations to underreporting AEs were; decision on what to report (45%); time consumed (41%); perceived not serious enough (35%) and follow up process (23%).

Conclusion

The consistent outcome from the study across all oncology HCPs, was the underreporting of drug related serious AEs. Reasons identified in the study include the time consuming nature of AE reporting and a lack of understanding around the black triangle and AE reporting process. There is a need to further support HCP education on AE reporting coupled with a review of the current reporting process to ensure maximal engagement.
HIGH DEPENDENCY UNIT UTILISATION AFTER GYNAECOLOGICAL ONCOLOGY SURGERY IN SOUTH WEST WALES
A. Tranoulis1, N. Das1, K. Lutchman-Singh1
1Singleton Hospital-NHS Trust Foundation, Gynaecological Oncology, Swansea, United Kingdom

Aims

The aim of this observational cohort study was to calculate the rate of high dependency unit (HDU) admission for patients undergoing gynaecological oncology surgery in a regional centre and to determine risk factors associated with unplanned admission and length of HDU stay respectively.

Method

Data were extracted from a prospectively maintained gynecological oncology surgical database for patients undergoing major surgery between February 2014 and March 2017. Pre- and intra-operative variables were compared between planned and unanticipated admission. In addition, we compared variables affecting length of admission using univariate and multivariate logistic regression analysis including postoperative factors.

Results

A total of 440 patients underwent major surgery in our centre for gynaecological malignancy over this 3-year period. The overall admission rate to HDU was 7.5% (33/440). The planned admission rate was 5.9% (26/440) and the unplanned admission rate was 1.69% (7/440). The mean duration of stay was 3.57 (range 1-12) days. Independent predictors of prolonged admission to HDU included: ovarian origin of tumour (OR=20.7, p-value<0.001), post-op lactate >1.2 mmol/L (OR=20.3, p-value<0.001), and APACHE II score> 15 (OR=17.8, p-value<0.001). Intra-operative transfusion was significantly correlated with unanticipated HDU admission (p-value<0.001).

Conclusion

The rate of planned and unplanned admissions to HDU in our centre was relatively low compared to published guidance. We have identified variables that are potentially predictive of unplanned HDU admission and length of stay respectively. Our future aim to is to establish a risk scoring system so that we can reduce unplanned HDU admission rates further.
Endometriosis-associated malignant transformation in abdominal surgical scar is very rare and aggressive phenomenon. Our review aims to provide a clinical overview, focusing on risk factors affecting survival.

Method

We performed a systematic-review based on prior reviews and case reports regarding the phenomenon published as abstracts in English, since 1980 up to 2016. Overall we identified 47 cases, and we included another case from our institution. We analyzed the data, focusing on risk factors that might affect overall survival.

Results

All the patients reported in the literature, had a uterine surgery, mainly caesarean-section (CS). The average time-lag from first surgery to the diagnosis of cancer was about 19 years. Clear-cell carcinoma was the most prevalent histology (67%), followed by endometrioid adenocarcinoma (15%). Most of the patients were treated by extensive surgery and chemotherapy and/or radiation. Overall 5-years survival was about 40%. The median survival was 42 months. Although our review is currently the largest in the literature, we cannot draw any statistical significant results due to the limited number of patients reported. On multiple logistic-regression model and Cox-regression model we found a tendency towards less favorable prognosis with clear-cell histologic type in the first 3 years (p=0.169) and tumor diameter larger than 8 cm in non-clear-cell histology, 18 months post diagnosis (p=0.06).

Conclusion

Endometriosis-associated malignant transformation in abdominal scar is rare and aggressive. It is mostly related to CS scars, and is diagnosed many years post-surgery. Clear-cell histology tends to endure worse prognosis. The treatment is mainly, extensive surgery and adjuvant chemotherapy and/or radiotherapy.

THE BELGIAN REGISTRY FOR GESTATIONAL TROPHOBLASTIC DISEASES: CENTRAL PATHOLOGICAL REVIEW

A. Vandewal1, K. Delbecque2, P. Moerman3, J.C. Noel4, E. Marbaix5, P. Delvenne2, M. Nisolle5, F. Kridelka6, I. Vergote7, F. Goffin6, S. Han7

1University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium
2University Hospital of Liège, Department of Pathologic Anatomy, Liège, Belgium
3University Hospitals Leuven, Department of Pathologic Anatomy, Leuven, Belgium
4Erasmus Hospital, Department of Pathologic Anatomy, Brussels, Belgium
5University Hospital Saint-Luc, Department of Pathologic Anatomy, Brussels, Belgium
6University Hospital of Liège, Department of Obstetrics and Gynaecology, Liège, Belgium
7Leuven Cancer Institute University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium

Aims

We aimed to compare local pathology reports of gestational trophoblastic diseases (GTD) with central pathological reviews.

Method

This prospective observational study used the data of the Belgian register for GTD between July 2012 and January 2017. We compared pathology reports of local pathologists with the central review by the pathologists of the Belgian Registry. Of a total of 332 patients, 2 were excluded (one with suspicion of mole not otherwise specified and one extra-uterine pregnancy with increased hCG level without proven molar pregnancy), 21 data missing and 6 without pathology. Pathology slides of 303 patients were reread by a central pathologist.

Results

Our data showed a disagreement between local and central pathologist in 66 cases (24%). Downgrading (e.g. complete mole to abortion) was observed in 30 cases (46%), upgrading (e.g. complete mole to choriocarcinoma) was observed in 36 cases (55%). After primary diagnosis of a partial mole or complete mole, rate of agreement was 59.5% and 88.5% respectively. The diagnosis of choriocarcinoma (n = 8) was confirmed in 75%. There was one initial diagnosis of invasive mole, which was downgraded to a complete mole. When the local pathologist diagnosed a placental site trophoblastic tumour, the expert agreed in 2 out of 3 cases. The only epithelioid trophoblastic tumour at initial diagnosis was confirmed by the central pathologist.

Conclusion

A review of the pathology report by a central pathologist changed the diagnosis of patients with GTD in 24%. The revised diagnosis had an important impact on the follow-up and treatment of these patients.
THE BELGIAN REGISTRY FOR GESTATIONAL TROPHOBLASTIC DISEASES: CURATIVE EFFECT OF A SECOND CURETTAGE

1University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium
2University Hospital of Liège, Department of Pathologic Anatomy, Liège, Belgium
3University Hospitals Leuven, Department of Pathologic Anatomy, Leuven, Belgium
4Erasmus Hospital, Department of Pathologic Anatomy, Brussels, Belgium
5University Hospital Saint-Luc, Department of Pathologic Anatomy, Brussels, Belgium
6University Hospital of Liège, Department of Obstetrics and Gynaecology, Liège, Belgium
7Leuven Cancer Institute University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium

Aims

We assessed the curative effect of a second curettage in patients with persistent hCG serum levels after first curettage for a gestational trophoblastic disease (GTD).

Method

This prospective observational study used the data of the Belgian register for GTD between July 2012 and January 2017. We analysed the data of patients who underwent a second curettage. We included 313 patients in the database. Seventeen patients were excluded for various reasons (no pathology report, no information about treatment or lost to follow-up). Primary endpoints were need for second curettage and chemotherapy.

Results

There were 85 partial moles and 147 complete moles diagnosed. Choriocarcinoma and invasive mole was diagnosed in ten and three patients respectively. Placental site trophoblastic tumour and epithelioid trophoblastic tumour was diagnosed each in two patients. Thirty-seven patients of the study population (12%) underwent a second curettage, 21 patients (57%) needed no further treatment afterwards. Sixteen patients (43%) needed postoperatively further chemotherapy. Of these patients 12 (75%) were cured with single-agent chemotherapy and 4 patients (25%) needed multi-agent chemotherapy. Patients with hCG levels below 5000 IU/L undergoing a second curettage were cured without chemotherapy in 65% versus 45% of patients with hCG level more than 5000 IU/L. Of the ten patients with a hCG level below 1000 IU/L, eight were cured without chemotherapy.

Conclusion

Patients with persistent trophoblastic diseases with persistent hCG level can benefit from a second curettage to avoid chemotherapy, especially when the hCG level is lower than 5000 IU/L and even more if hCG level is below 1000 IU/L.
A NATIONAL, PROSPECTIVE OBSERVATIONAL STUDY OF FIRST RECURRENCE AFTER PRIMARY TREATMENT FOR GYNECOLOGICAL CANCER IN NORWAY

Aims

Gynecological cancer patients are routinely followed up for 5 years after primary treatment. However, the value of such follow-up has been debated, as retrospective studies indicate that first recurrence is often symptomatic and occurs within 2-3 years of primary treatment. We prospectively investigated time to first recurrence, symptoms at recurrence, diagnostic procedures, and recurrence treatment in gynecological cancer patients after primary curative treatment.

Method

Clinicians from 21 hospitals in Norway interviewed 680 patients with first recurrence of gynecological cancer (409 ovarian, 213 uterine, and 58 cervical cancer patients) between 2012 and 2016. A standardized questionnaire was used to collect information on self-reported and clinical variables.

Results

Within 2 years of primary treatment, 72% of ovarian, 64% of uterine, and 66% of cervical cancer patients were diagnosed with first recurrence, and 54%, 67%, and 72%, respectively, had symptomatic recurrence. 46% of symptomatic patients failed to make an appointment before their next scheduled follow-up visit.

Conclusion

This is the first prospective, nationwide study to systematically record information on gynecological cancer recurrences. Most recurrences occurred within 2 years of primary treatment; the mean annual incidence rate for years 3-5 after primary treatment was <7%. Sixty percent of patients experienced symptomatic recurrence, but 46% of the symptomatic patients failed to make an appointment earlier than scheduled. Hospital-based follow-up is resource-demanding and may lead to delayed diagnosis of recurrence. Our results imply that shorter hospital-based follow-up should be considered, and patient self-management encouraged.
FACTORS PREDICTING THE QUALITY OF LIFE IN THAI WOMEN AFTER HYSTERECTOMY

M. Wongsrisunthorn1, B. Sumdaengri2
1Faculty of Medicine Ramathibodi Hospital, Nursing Department Mahidol University, Bangkok, Thailand
2Faculty of Medicine Ramathibodi Hospital, Ramathibodi Hospital Mahidol University, Bangkok, Thailand

Aims

Purpose of this study was to study factors predicting the quality of life in Thai women after hysterectomy in Ramathibodi hospital.

Method

This study was cross-sectional research. Participants were 70 women after hysterectomy at Ramathibodi hospital during January – June 2016. The instruments were (1) the personal disease and treatment data developed by principal investigator, and (2) the World Health Organization quality of life – Thai version (WHOQOL-BREF-THAI) developed by WHO. Alpha Cronbach’s coefficient for WHOQOL-BREF-THAI questionnaires in this study was .871. Data were analyzed by descriptive statistics and multiple regression using enter technique.

Results

Results found that health status could predict the quality of life, at .001 level, while education level could predict the quality of life at .05 level. However, age group in reproductive period and partner status could not predict the quality of life in women after hysterectomy. These variables could predict the quality of life in these women 25.8%.

Conclusion

Results from the study can be used as evidence-based to provide and improve quality of life in women after hysterectomy.
THE DISTRIBUTION AND INCIDENCE OF LYMPHOCELES FOLLOWING LYMPHADENECTOMY IN PATIENTS WITH GYNECOLOGIC CANCER

Y.B. Ko¹, S.Y. Song¹
¹Chungnam National University Hospital, Department of Obstetrics & Gynecology, Daejeon, Republic of Korea

Aims

To identify the distribution and incidence of lymphoceles following lymphadenectomy in patients undergoing the pelvic lymphadenectomy or pelvic and paraaortic lymphadenectomy for gynecologic cancer

Method

A total of 86 patients with endometrial, ovarian or cervical cancer underwent pelvic or combined pelvic and paraaortic lymphadenectomy as a primary surgical treatment at single institution from March 2013 to October 2015 and followed up with computed tomography or magnetic resonance imaging. We retrospectively examined the distribution and incidence of lymphoceles after lymphadenectomy.

Results

Four to 8 weeks after operation, 27 cases of lymphocele (33.3%) were detected. The incidence of lymphocele after pelvic and paraaortic lymphadenectomy was higher than that after pelvic lymphadenectomy (81.5% and 18.5%, respectively, p<0.001). The differences of distribution of lymphocyte between pelvic and paraaortic were revealed (75.6% vs 24.4%). We found a statistically significant difference in the incidence of lymphocele between right and left sides (p<0.012). The incidence of lymphocele of left side was higher than that of right side after pelvic lymphadenectomy (30% vs 70%, respectively, p=0.038), however, the incidence of lymphocele between right and left sides were not significantly different after paraaortic lymphadenectomy (32.3% vs 67.7%, p=0.308).

Conclusion

The incidence of lymphocele in pelvic area is higher than that in paraaortic area after lymphadenectomy for gynecologic cancer. The incidence of left side lymphocele is higher than that of right side lymphocele in pelvic area.
Aims

Usual VIN (uVIN), responsible for 20% of the vulvar cancers, is caused by a persistent human papillomavirus (HPV) infection. A better understanding of the microenvironment in relation to lymph node metastasis is essential for the development of effective immunotherapeutic strategies for these tumors.

Method

In the present study, we investigated the microenvironment of tumor-draining lymph nodes of HPV-related vulvar cancer patients, by comprehensive four-color flow cytometry-based phenotyping and enumeration of different T cell subsets by studying expression levels of activation markers (ICOS and HLA-DR), co-inhibitory markers (CTLA-4 and PD-1), and FoxP3+ regulatory T cells (Tregs) levels in tumor-negative (LN-, n=6) versus tumor-positive lymph nodes (LN+, n=5) obtained after surgery as primary treatment.

Results

We found significantly more double-negative CD4-CD8- T cells, significantly more FoxP3+ Tregs, and a lower CD8+ T cell/FoxP3+ Treg ratio in LN+ compared to LN-. Assessment of the expression of the immune checkpoints CTLA-4 and PD-1 on the T cell subsets showed selective up-regulation of CTLA-4+CD4+ T cell rates in LN+ versus LN- (p<0.03).

Conclusion

Higher frequencies of suppressive T cell subsets (CD4-CD8- and FoxP3+ Tregs) and CTLA-4+CD4+ T cells are present in LN+ compared to LN- from patients with HPV-related vulvar cancer. Undoubtedly, the numbers of included samples in this study will have to be increased to obtain higher statistical power, but our preliminary data clearly point to the potential of (local) CTLA-4 blockade in the treatment of early-stage or locally advanced vulvar carcinoma, in order to counter apparent immune suppression.

DIAGNOSTIC DIFFICULTIES OF ASYMPTOMATIC PRIMARY CARCINOID TUMOR OF THE OVARY: CASE REPORT

N. Abdalla1, R. Piorkowski1, A. Timorek1, P. Stanirowski1, K. Cendrowski1, W. Sawicki1

1Medical University of Warsaw, Chair and Department of Obstetrics- Gynecology and Oncology, Warsaw, Poland

Aims

Primary carcinoid tumor of the ovary is a very rare disease. A 59-year-old Caucasian patient was admitted to our Clinic for surgical treatment because of left ovarian tumor.

Method

The patient was asymptomatic. She delivered twice vaginally. She had appendectomy at age of 18 years. The family history of malignancies was nonsignificant. Ultrasound examination showed unilateral irregular cyst wall with a sludge on the internal walls and ground glass appearance of the fluid content suggesting endometriotic cyst. The size of the cyst was 28 mm and the wall had no features of vascularization. Serum level of CA125 was 11 U/ml. The IOTA-ADNEX model showed 97.9% probability of being nonmalignant. The patient underwent laparoscopy with bilateral adnexectomy. Initial intraoperative histopathological assessment of the cyst revealed mature teratoma. The patient was discharged to home in good general condition.

Results

The final histological assessment showed mature teratoma, with cartilage tissues and foci of carcinoid in the tumor. Immunohistochemical staining was positive for chromogranin (+++) and Ki67 (<5%). The patient was admitted again to hospital for further assessment. Computed tomography showed no abnormalities apart from mild osteoarthritic changes of the vertebral column. After discussion with the patient, a staging operation was performed. The excised uterus, cervix, ovaries, oviducts and lymph nodes did not show any malignant changes. The patient was discharged to home on 5th operative day in good general condition.

Conclusion

The rarity of the disease and absence of the symptoms caused ultrasound and pathological assessment difficulties in the assessment of the adnexal tumor.

CA 125, HE4, SMRP, FOLR1 IN PELVIC MASSES

M. Harma¹, R. Başer Açığöz¹, A. Turhan Çakır², T. Zengin², M. Harma¹
¹Bulent Ecevit University, Gynecologic and Obstetric, Zonguldak, Turkey
²Bulent Ecevit University, Gynecologic Oncology, Zonguldak, Turkey

Aims

An adnexal mass is a common gynecologic problem and malignancy must be excluded for any mass that is not clearly benign. Since ovarian cancer is the most common cause of gynecologic cancer death. The differential diagnosis of benign and malignant neoplastic masses is important for referring the patient to the gynecologic oncologist. Use of serum biomarkers for the diagnosis of ovarian cancer is an active area of investigation.

The aim of this study is researching the effectiveness of cancer antigen 125 (CA 125), human epididymis protein (HE4), soluble mesothelin related peptide (SMRP) and folate receptor 1 (FOLR1) to determine malignant ovarian masses.

Method

Our research was performed between September 2014 and January 2017 in our clinic. 95 operated patients because of pelvic masses are included. Preoperatively CA 125, HE4, SMRP, FOLR1 levels are measured for each patient and relationship between tumor marker levels and pathological reports is examined.

Results

HE4 and SMRP levels are found higher in malignant masses significantly. But CA 125 and FOLR1 levels are not related with malignancy.

Conclusion

HE4 and SMRP can be used as a serum biomarker for prediction of ovarian cancer according to our study. However the data should be supported with more studies.

MANAGEMENT OF MALIGNANT INTESTINAL OBSTRUCTION AFTER OVARIAN CANCER SURGERY:
B. Ahmed1, K. Abdelwahab2, I. Abdou1, O. Eldamshety3, H. Nabil4

1Mansoura university-Oncology center, surgical oncology, Mansoura, Egypt
2Oncology Center- Mansoura University, Surgical oncology, Egypt
3Oncology center- Mansoura University, Surgical oncology, Mansoura, Egypt
4Mansoura University Hospitals, Obstetrics and gynaecology, Mansoura, Egypt

Aims

compare the impact of surgical versus medical management on the survival of patients presenting with small bowel obstruction secondary to recurrent ovarian cancer

Method

Review of all patients with SBO due to recurrent ovarian cancer at Oncology center , Mansoura University in between January 2007 , and March 30, 2016. The data abstracted from patient registry included demographics, primary cancer characteristics, detailed clinical information at the time of SBO, management strategy, and outcome

Results

39 patients met our search criteria, 7 were excluded because of a paucity of medical information. O 93% of the patients had stage III/IV ovarian cancer, while 7 % had stage I/II. The median time from tumor recurrence to bowel obstruction was 19 months. 19 (59%) of patients underwent surgery for management of bowel obstruction and the remaining 13 (41%) were managed conservatively with various medical approaches. one year survival for the surgically managed patients was 12 % compared to 14 % for those who received medical treatment . There was no difference in survival for patients based on histology (p = 0.38), grade (p = 0.077), grade of SBO (p = 0.56). Patients with stage I/II had a median survival of 26 months versus stage III/IV at 3 months .

Conclusion

There is a no evidence to show the superiority of surgical management in patients not meeting those criteria.
CHARACTERISTICS OF LGSOC ; A SINGLE CENTER EXPERIENCE
H. Akıllı¹, G. Coban², E. Kocaman³, N. Haberal⁴, A. Ayhan⁵
¹Baskent University School of Medicine, Obstetrics and Gynecology, Ankara, Turkey
²Baskent University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
³Baskent University School of Medicine, Department of Gynecology and Obstetrics, Ankara, Turkey
⁴Baskent University School of Medicine, Pathology, Ankara, Turkey
⁵Baskent University School of Medicine, Obstetrics and Gynecology Division of Gynecologic Oncology, Ankara, Turkey

Aims

The objective of the study is to identify the characteristics of Low grade serous ovarian cancers.

Method

We retrospectively analysed the ovarian cancer patients underwent cytoreductive surgery at Baskent University School of Medicine between the years 2007-2017. All patients received paclitaxel carboplatin based chemotherapy regimen according to their FIGO stages. Statistical analyses were done by using spss package programme.

Results

30 patients met the inclusion criteria. The median age at time of diagnosis was 45.1 years (24-78). Tumor characteristics are given in Table 1. Median PFS was 48.7 (95% CI, 31.2, 66.2). 5-year Median OS was 60.7 (95 CI, 33.6, 87.9). 8 (33%) patients had platinum resistance and platinum resistant patients had lower OS (p=0.033).

Conclusion

LGSOC is very rare and tural characteristics are not very well known. Chemoresistance is one of the strongest factors that affect survival therefore it should be clarified and new agents must be included to chemotherapy regimens.
LAPAROSCOPIC SECONDARY CYTOREDUCTION AND HYPERTHERMIA INTRAPERITONEAL CHEMOTHERAPY FOR RECURRENT OVARIAN CANCER

M.M. Naki¹, E. Karabuk¹, F. Alkhan¹, M. Gungor², M.K. Kose¹
¹Acibadem Atakent University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
²Acibadem Maslak Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

To perform laparoscopic hyperthermic intraperitoneal chemotherapy (HIPEC) after the laparoscopic cytoreduction for a patient with recurrent ovarian cancer.

Method

A 41-year-old woman who had maximal debulking for ovarian serous adenocarcinoma 13 months ago, followed by adjuvant chemotherapy. Local recurrence was detected in PET CT and MRI; there were two nodules (15x10 mm and 10x8 mm) on the mesosigmoid colon found on routine follow up. Secondary cytoreductive surgery with HIPEC was planned. The first 5mm trocar placement was at Palmer point. The procedure continued after abdominopelvic cavity inspection with 5mm scope. Then 10-mm trocar was placed at the level of umbilicus. The 5-mm scope was changed to 10-mm scope. Another 5-mm trocar was placed across the Palmer point, 3 cm under the right rib. And three 5-mm skin incisions were made for accessory lower quadrant trocar placement: 2 lateral, approximately 3 cm medial to the anterior superior iliac spine and 1 suprapubic. Totally 6 trocars were inserted to perform of HIPEC. After the adhesiolysis, the two nodules were found and extracted from abdomen by endobag. A 100 mg/m² (175 mg totally) cisplatin was administered for 90 minutes at a temperature of 42 degrees. Procedure went uneventful.

Results

There was no hepatic, renal or bone marrow toxicity. Patient discharged from the hospital 2nd postoperative day.

Conclusion

Minimally invasive surgical approach and with HIPEC can be performed in selected ovarian cancer patients.

LAPAROSCOPIC PARA-AORTIC LYMPHADENECTOMY IN OVARIAN CANCER

M.M. Naki¹, F. AlKhan², E. Karabuk², M. Gungor³, M.F. Kose²
¹Acibadem Atakent University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
²Acibadem Atakent University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
³Acibadem Maslak Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

To demonstrate step-by-step para-aortic lymphadenectomy

Method

A 31-year-old presented with right ovarian cyst. Patient had one year back laparoscopic right ovarian cystectomy. The histopathology was Sertoli Lydig ovarian tumor. Patient planned for laparoscopic cystectomy and for frozen section in the same session. Patient had right salpingooopherectomy. The specimens sent for frozen section and the result was sex cord stromal ovarian tumor cannot exclude malignancy. Therefore, procedure continued for surgical staging laparoscopically. In this video we demonstrate the para-aortic lymphadenectomy.

Results

The procedure went uneventful. The patient was discharged on 3rd postoperative day. The histopathology result showed Sex Cord Stromal tumor with calcification. Total number of lymph nodes was 45.

Conclusion

Laparoscopic surgical staging for early ovarian cancer is feasible for early ovarian cancers. The number of lymph nodes is similar compared to open surgery.

A CASE OF ADVANCED STAGE OVARIAN CARCINOMA WITH THORACIC SARCOIDOSIS WHICH WAS THOUGHT AS DISTANT METASTASIS

D. Altin¹, A. Usubütün², Ş. Şalvarli³, S. Taşkin¹, F. Ortaç¹
¹Ankara University Faculty of Medicine, Gynecology and Obstetrics, Ankara, Turkey
²Ankara University Faculty of Medicine, Chest Diseases, Ankara, Turkey
³Ankara University Faculty of Medicine, Nuclear Medicine, Ankara, Turkey

Aims

Epithelial ovarian carcinoma is the leading cause of death due to gynecologic malignancies. Most of the patients are diagnosed in advanced stages. Adjuvant taxane + platinum chemotherapy after primary debulking surgery (PDS) or neoadjuvant chemotherapy (NACT) followed by interval debulking surgery (IDS) is chosen according to patients’ and disease’s status. Diagnostic laparoscopy and/or imaging studies can be used to determine if the disease can be optimally debulked or not. PET/CT is a widely used method to identify extend of the disease.

Method

We here present a case of a patient who received neoadjuvant chemotherapy due to her widespread intraabdominal disease. She also had pathologic PET/CT findings in thorax prior to NACT. After 3 cycles of paclitaxel + carboplatin chemotherapy her serum CA 125 level dropped to 22.2 U/ml from 1907.6 U/ml. Her pathological PET/CT findings regressed but thoracic findings were stable. The pathologic examination of thoracic lymph nodes revealed granulomatous lymphadenitis in favor of sarcoidosis. She had undergone IDS and received adjuvant chemotherapy.

Results

not available

Conclusion

PET/CT uses FDG which accumulates in tissues with enhanced glucose metabolism. Therefore, it sometimes cannot categorize benign and malignant lesions accurately. Patients should be evaluated carefully with different modalities and physical examination in order to choose the right approach.

E-CADHERIN AND ITS ROLE IN PATIENTS WITH ADVANCED STAGE SEROUS OVARIAN CANCER

I. Aluloski1, G. Petrusevska2, S. Kunovska2, R. Jovanovic2, T. Mile1

1University Clinic for Obstetrics and Gynecology Skopje, Gynecology Oncology, Skopje, FYR Macedonia
2Institute for Pathology-Medical Faculty Skopje, Institute for Pathology, Skopje, FYR Macedonia

Aims

Ovarian cancer is fifth leading cause of cancer deaths and has the highest mortality rate among gynecologic cancers in women in North America and Europe.

The aim of this study is to analyze the correlation between E-cadherin expression and clinical and pathohistological features and overall survival in advanced-stage serous ovarian carcinoma.

Method

Expression of E-cadherin was examined immunohistochemically in tissue samples from 36 patients with advanced-stage serous ovarian cancer. FIGO Stage of the disease, tumor differentiation, size of the residual tumor, and lymphovascular invasion were included as clinico pathological characteristics. We determined the Overall survival (OS) as the time from surgery to the last follow-up date. Histological samples were retrieved from Institute of Pathology, Medical Faculty Skopje from 2010 to 2013. We examined OS by using Kaplan–Meier method and log-rank test to assess the differences between two E-cadherin groups, positive and negative. Multivariate analyses were done with Cox's model.

Results

Statistical analysis found that E-cadherin immunoreactivity is not in correlation with FIGO stage, tumor grade, residual tumor volume and vascular invasion. Negative E-cadherin expression predicts shorter OS. Multivariate analyses show that negative E-cadherin expression, FIGO stage and residual tumor volume > 1 cm, after primary cytoreductive surgery are predictors of shorter OS.

Conclusion

Negative E-cadherin expression seems to predict unfavorable clinical outcome in patients with advanced serous ovarian cancer, equal to higher FIGO stage and residual tumor volume after primary surgery. Negative E-cadherin expression emerges as a significant independent predictor for poorer OS. We concluded that according to analyses E-cadherin has prognostic value as a marker.
PRIMARY ENDOMETRIOID STROMAL SARCOMA OF THE OVARY - A VERY RARE ONCOLOGICAL DISEASE

S. Alves¹, F. Pereira¹, V. Melo², R. Couto¹, C. Lopes², D. Pereira¹
¹IPO PORTO, MEDICAL ONCOLOGY, OPORTO, PORTUGAL
²IPO PORTO, GYNECOLOGY, OPORTO, PORTUGAL

Aims

Endometrial stromal sarcoma (ESS) is a rare pathology that usually originates in the uterine body, although it may also arise from extra-uterine sites, with the ovary being the most common site. Endometriosis may be the starting point for these neoplasms, although this malignant transformation is even rarer.

We describe a clinical case of a 47-year-old woman, with irrelevant pathological personal antecedents. She was submitted to an exploratory laparotomy to study bilateral adnexal masses (diagnosed on an abdominal computed tomography - CT) on January 2009. Hysterectomy with bilateral adnexectomy, omentectomy and appendicectomy were done. Anatomopathological examination revealed a primary endometrioid stromal sarcoma of the ovary with invasion of the capsule, grafted on lesions of endometriosis. No evidence of disease in staging exams. She was submitted to adjuvant chemotherapy with doxorubicin, 6 cycles, until August 2009. First disease recurrence was diagnosed 1 month after completing adjuvant treatment. During the next 8 years she was submitted to many different recurrence treatments that included: chemotherapy, hormonotherapy, and surgery. Nowadays, she is receiving best supportive care since January 2017, maintaining an Eastern Cooperative Oncology Group Performance Status of 1.

ESS grafted on endometriosis is considered to be an indolent tumor, although late recurrences and distant metastasis may occur. Treatment of metastatic disease is particularly challenging, because of the rarity of these tumors, there is little information in the literature related with the best approach.

A SINGLE INSTITUTION QUALITY ASSURANCE PROGRAM FOR PRIMARY DEBULKING SURGERY IN ADVANCED OVARIAN/TUBAL/PRIMARY PERITONEAL CANCER

E. Araya¹, M. Sundset¹, S. Tingulstad¹, M. Ravlo¹, N. Nordskar¹, J. Kippervik¹, A.K. Engebretsen¹, G. Aune¹, B. Hagen¹

¹St. Olavs University Hospital, Dept. of Obstetrics and Gynecology - Section of Gynecologic Oncology, Trondheim, Norway

Aims

To report initial results following the implementation of prospective registration of surgical procedures and completeness, postoperative complications and postoperative mortality, as part of a single institution quality assurance program in advanced ovarian/tubal/primary peritoneal cancer.

Method

Prospective data from 01.01.2014 to 31.12.2016. Details on surgical procedures categorized into surgical complexity scores (SCS). 3 surgical outcome categories: no gross residual tumor (NGR), gross residual tumor ≤ 1 cm (GR-1) and gross residual tumor > 1 cm (bulky) (GR-B). 30 days postoperative complications according to the Clavien Dindo Classification (CD) and 30 days’ postoperative mortality. Finally, rate of chemotherapy omission and time to initiation of chemotherapy was registered together with recurrences for the calculation of progression-free survival.

Results

Among 153 patients diagnosed, 103 (70%) had stages 3 or 4 of whom 96 underwent primary debulking surgery (PDS). A trend of increasing surgical complexity was observed. The NGR rate was 46 %, 57 % and 73 % in 2014, 2015 and 2016, respectively. Corresponding rates for GR-1 were 18 %, 20 % and 18 %; and for GR-B 36 %, 23 % and 9 %. Corresponding rates of clinically significant complications (CD III-IV) were 29 %, 20 % and 33 %. The rate of postoperative mortality (CD V) for the whole period was 5 %. Median PFS was 16.5 months increasing from 9.9 months for patients with GR-B to 24.0 months for patients with NGR.

Conclusion

Implementation of prospective registration of surgery may improve the surgical outcome in advanced ovarian cancer.

ESGO7-1171

VIMENTINE AS A PREDICTIVE MARKER OF PLATINUM-BASED CHEMOTHERAPY IN OVARIAN CANCER PATIENTS

T. Bogush¹, E. Dudko¹
¹N.N. Blokhin Russian Cancer Research Center, Laboratory of Medical Chemistry, Moscow, Russia

Aims

The epithelial-mesenchymal transition (EMT) is a hallmark of the tumor metastatic potential. EMT can also influence on antitumor drugs activity, however clinical data are controversial. The aim of the study is to assess correlation of expression specific mesenchymal marker vimentine (Vim) in epithelial tumor cells with the progression-free survival (PFS) after completion of the first-line platinum and taxane-based chemotherapy

Method

58 surgical specimens of serous ovarian cancer were analyzed by flow cytometry (double immunofluorescence staining using pan-cytokeratin (CK, MNF116,DAKO) and Vim (SP20,BIOCARE) primary antibodies). All patients received the first-line platinum+taxane chemotherapy. Kaplan-Meier statistics and log-rank tests were used for the analysis.

Results

1. It was revealed significant differences in rate of CK/Vim co-expression in the tumors investigated. Average number of cells co-expressing CK/Vim were 42.9±13.9% (29-57%). 2. High and low EMT rates were defined in accordance to the median level of CK/Vim co-expression (≥ 42%). 3. Significant differences were shown between the groups with high and low rate of EMT: in 40 months after the first-line chemotherapy completion median PFS was 7 vs. 22 months and number of relapses – 71% vs. 50% respectively (p=0.025).

Conclusion

Identified correlation between level of CK/Vim co-expression and both PFS and number of relapses in 40 months after the first line chemotherapy completion indicates a poor prognostic value of EMT to assess in terms of CK/Vim co-expression level in prediction of the first line platinum+taxane chemotherapy efficacy in ovarian cancer patients. Supported by RFBR grants (15-04-06991-a,16-34-01049-mol-a) and President of RF grant-MK-7709.2016.7.

2S.Ü. University Kanuni Sultan Süleyman Education and Research Hospital, Gynecologic Oncology, istanbul, Turkey
3Ege University School of Medicine, Department Of Gynecology and Gynecologic Oncology, İzmir, Turkey
4Zekai Tahir Burak Education and Research Hospital, Department Of Gynecology and Gynecologic Oncology, Ankara, Turkey
5Osmangazi University School of Medicine, Department Of Gynecology and Gynecologic Oncology, Eskişehir, Turkey
6Akdeniz University School of Medicine, Department Of Gynecology and Gynecologic Oncology, Antalya, Turkey
7Dicle University School of Medicine, Department Of Gynecology and Gynecologic Oncology, Diyarbakır, Turkey
8Ankara University School of Medicine, Department Of Gynecology and Gynecologic Oncology, Ankara, Turkey
9Charité Medical University of Berlin, Department of Gynecology with Center for Oncological Surgery, Berlin, Germany

Aims

The purposes of this study were to perform a retrospective assessment of the clinical characteristics, surgical management (especially appendectomy) and surgical outcomes, and to identify variables affecting disease-free survival (DFS) and overall survival (OVS), of patients with mucinous borderline ovarian tumors (mBOTs).

Method

The database of 14 gynecological oncology departments was comprehensively searched for women who underwent primary surgery for an ovarian tumor between January 1, 1998, and December 31, 2015, and whose final diagnosis was mBOT.

Results

A total of 364 patients with mBOT with a median age of 43.1 years were included in the analysis. The median survival time of all patients was 53.1 months. The majority of the staged cases were Stage IA (78.6%). In univariate and multivariate analyses, radical surgery, omentectomy, appendectomy, lymphadenectomy, and receiving adjuvant CT for stage ≥IC tumor were not independent prognostic factors for DFS and OS. Furthermore, FIGO stage (≥IC vs <IC), radical surgery, and staging surgery were not independent risk factors for recurrence of mBOTs. Finally, abnormal macroscopic appendicitis and FIGO stage (≥IC vs <IC) were independent risk factors for appendiceal involvement (P=0.032).

Conclusion

Patients with detailed surgical staging, including lymph node sampling or dissection, appendectomy, and omentectomy do not have lower recurrence rates. Furthermore, survival time is not prolonged. There is insufficient evidence to support a routine appendectomy for patients with a grossly normal appendix in mBOT. Detailed intraoperative exploration of the appendix is important, but appendectomy is only reasonable when the appendix is abnormal.

TP53 DOMAINS’ MUTATIONS ALTER GLYCOLYSIS IN EPITHELIAL OVARIAN CARCINOMA: EX-VIVO AND IN VITRO STUDY

D. Atallah1, S. Antoun2, M. Moubarak3, N. El Kassis3, G. Chahine4, G. Hilal2

1. Obstetrics and Gynecology, Beirut, Lebanon
2. Cancer and metabolism laboratory, Beirut, Lebanon
3. Beirut, Lebanon
4. Oncology, Beirut, Lebanon

Aims

To investigate the effect of TP53 different domain mutations on its transcriptional activity, its ability to induce apoptosis and to regulate glucose consumption and lactate production in epithelial ovarian cancer.

Method

30 ovarian cancer biopsies were characterized. Immunohistochemistry for p53 expression and PCR for exons 2 till 11 were performed, followed by the Single Strand Conformation Polymorphism (SSCP) technique and sequencing. The transcriptional activity of p53 was studied by a qPCR for its target genes p21 and MDM2. Viability and Annexin V tests were performed to study the ability of mutant p53 to induce apoptosis. The expression of the glycolytic enzymes regulated by p53 was quantified by qPCR. SK-OV-3 cell line was transfected by different p53 mutated plasmids, and the same experiments performed on the biopsies were done on transfected cells.

Results

The immunohistochemistry and qPCR showed an approximately 2 folds increase in p53 expression between wild type and mutated cases. The expression of p21 and MDM2 decreased only in DNA binding domain mutated cases and transfected cells, which indicates a decreased transcriptional activity with this type of mutation. The highest increase in apoptosis induction was clear in Sk-Ov-3 cells transfected with WT p53, and p53 proline rich domain mutations decreased the protein’s apoptotic function. Glucose consumption and lactate production increased by mutated cells compared to wild type.

Conclusion

Mutant p53 is overexpressed in ovarian cancer cells. DNA binding domain mutations modify the protein’s transcriptional activity, whereas proline rich domain mutations decrease the protein’s apoptotic activity. Glycolysis is affected differently in both types.

ESGO7-0175

EFFECT OF NEOADJUVANT CHEMOTHERAPY ON CA-125 SECRETION AND TELOMERASE ACTIVITY IN OVARIAN CANCER

D. Atallah¹, S. Antoun², M. Moubarak¹, N. El Kassis¹, G. Chahine³, G. Hila²
¹. Beirut, Lebanon
². Saint Joseph University, Cancer and metabolism laboratory, Beirut, Lebanon
³. Oncology, Beirut, Lebanon

Aims

To evaluate the effect of neoadjuvant chemotherapy and the implication of PI3K/Akt/mTOR pathway on Ca-125 secretion and telomerase expression

Method

Two ovarian cancer cell lines SKOV-3 and IGROV-1 were treated with chemotherapy (Cisplatin CDDP (20 μM) and Paclitaxel PTX (100 nM)) during 48 hours and then 6 weeks. In order to study the presence of relation between these two markers, cell lines OVCAR-3, SK-OV-3 et IGROV-1 were treated with 3 telomerase inhibitors (BIBR-1532, Costunolide et MST-312), and different inhibitors of the PI3K / Akt / mTOR pathway (PI828, wortmanin, GSK692690 and rapamycin).

Results

Treatment of cells with chemotherapy agents during 48 hours has increased significantly the expression of both telomerase and CA125. A longer treatment (6 weeks) has shown an opposite effect. The decrease in serum marker is not only attributed to the diminution of tumor size , but also to the diminution of marker secretion by the cell itself. The three telomerase inhibitors decreased the Ca125 mRNA expression and protein secretion by the three cell lines. The same effect was obtained when cells were treated with hTERT siRNA. The activation of hTERT lead to an increase in Ca125 expression and secretion. Inhibition of PI3K/Akt/mTOR signaling pathway lead to a decrease in Ca125 concentration suggesting the involvement of this pathway in Ca125 regulation.

Conclusion

The inhibition of telomerase and PI3K/Akt /mTOR pathway decreased the Ca-125 secretion. Chemotherapy increase expression of both hTERT and Ca125 on short term treatment, but both parameters are decreased on long term.

MHC I DOWN-REGULATION AND PD-L1 EXPRESSION ARE MUTUALLY EXCLUSIVE IN SEROUS OVARIAN CANCER

S. Aust¹, A. Reinthaller¹, A. Katharina¹, L. Kenner², S. Dekan², C. Grimm³, D. Pils³

¹Medical University of Vienna, Department for Gynecology and Gynecologic Oncology- Gynecologic Cancer Unit- Comprehensive Cancer Centre, Vienna, Austria
²Medical University of Vienna, Department of Pathology, Vienna, Austria
³Medical University of Vienna, Center for Medical Statistics- Informatics- and Intelligent Systems & Dept. of Surgery, Vienna, Austria

Aims

The importance of the tumor immune microenvironment in epithelial ovarian cancer (EOC) has been demonstrated and evokes high expectations for tumor specific immunotherapy. Currently, promising activity of antibodies targeting programmed cell death receptor ligand 1 (PD-L1) across multiple malignancies raise expectations on their role also in EOC. Our aim was to determine the clinical role of PD-L1 as mechanism to escape immune recognition in EOC.

Method

We analyzed PD-L1 expression of primary ovarian and peritoneal tumor tissues together with several other parameters (whole transcriptomes of isolated tumor cells, local and systemic immune cells, systemic cytokines and metabolites) and compared PD-L1 expression between primary tumor and tumor recurrences.

Results

All expressed major histocompatibility complex (MHC) I genes were negatively correlated to PD-L1 abundances on tumor tissues, indicating two mutually exclusive immune-evasion mechanisms in EOC: either down-regulation of T-cell mediated immunity by PD-L1 expression or silencing of self-antigen presentation by down-regulation of the MHC I complex. In our cohort, low PD-L1 expression is associated with unfavorable outcome. Differences in immune cell populations, cytokines, and metabolites suggest the existence of concurrent pathways for progression of this disease. Furthermore, recurrences showed significantly increased PD-L1 expression compared to the primary tumors, supporting trials of checkpoint inhibition in the recurrent setting.

Conclusion

This data shows that targeting immune-escape mechanisms is complex and various pathways have to be considered simultaneously. As data obtained within different cancer types might not apply for all tumor entities we still need to define criteria to guide patient selection for PD-L1 therapy in EOC.
A RARE CASE OF MALIGNANT PERICARDIAL EFFUSION DUE TO OVARIAN ADENOCARCINOMA
H. Ayatollahi¹, S. Faraji², E. Ershadi¹
¹Urmia University of Medical Sciences, Obstetrics & Gynecology, Urmia, Iran
²Urmia medical science university, Obstetrics and gynecology, Uromieh, Iran

Aims
Malignant pericardial effusion with cardiac tamponade is an uncommon metastatic of manifestation gynecologic cancers. There are very few documented cases involving treatment for ovarian cancer metastatic to pericardium.

Method
We describe a 64 years old patient with ovarian cancer who developed pericardial effusion with cardiac tamponade and was successfully treated with pericardiocentesis and additional chemotherapy.

Results
-

Conclusion
There are a limited number of reported cases involving malignant pericardial effusions originated from ovarian adenocarcinoma. Consequently, there is less information documenting successful managment of this disease and patients prognosis.
A HUGUE BORDERLINE BRENNER TUMOUR OF THE OVARY WITH MUCINOUS BORDERLINE COMPONENT

²Akdeniz University, Medical Pathology, Antalya, Turkey
³Akdeniz University, Gynecologic Oncological Surgery, Antalya, Turkey

Aims

Brenner tumors, are rare tumors, representing between 2 and 5% of the ovarian tumors. Mucinous borderline tumors encompass approximately 35% of borderline ovarian tumors. We describe a rare case of a patient diagnosed with two ovarian tumours in the left ovary a huge borderline brenner tumour and a borderline mucinous ovarian tumour.

Method

A 54-year-old woman presented with abdominal pain and abdominal enlargement. Pelvic tomography revealed a bulky abdominopelvic mass that came from the left ovary, measured 25x28 cm. Preoperative tumor marker assays showed a normal CA-125 antigen level. A midline laparotomy was performed. The abdominal exploration confirmed the presence of a bulky tumor of the left ovary. The contralateral ovary appeared normal. Intraoperative frozen section analysis revealed malignant lesion. She underwent surgical staging with total hysterectomy, bilateral salpingo-oophorectomy, bilateral pelvic-paraaortic lymph node dissection, omentectomy, peritoneal cytology, multiple peritoneal biopsies. The final pathology analysis showed a borderline brenner and mucinous of the left ovary, without rupture of the capsule.

Results

Borderline Brenner tumors are rare; they represent only 4–5% of the total of Brenner tumors. 25–36% of the cases, the Brenner tumors coexist with other tumoral lesions, such as cystic mucinous tumor, serous cyst adenoma. Most of the borderline Brenner tumors are detected in the initial stage and have a favorable prognosis after the surgical treatment.

Conclusion

The borderline Brenner tumor diagnosed by us in a 54-year-old patient presented with nonspecific symptoms. The diagnosis was done after surgery by the classical histological examination associated with immunohistochemical examinations.

HOW TO DEAL WITH MICROSCOPIC PERITONEAL METASTASES OF EPITHELIAL OVARIAN CANCER?
H. Azaïs1,2, J.P. Estevez3, Y. Kerbage2,3, S. Mordon2, P. Collinet2,3
1Hôpital de la Pitié-Salpêtrière, Department of gynecologic and breast surgery, PARIS, France
2INSM, U1189 - ONCO-THAI - Image Assisted Laser Therapy for Oncology, Lille, France
3University hospital of Lille, Department of gynecologic surgery, Lille, France

Aims

Despite clinical remission after the completion of complete macroscopic cytoreductive surgery and platinum-based chemotherapy, 60% of patient treated for ovarian cancer will develop peritoneal recurrences. This suggests that microscopic lesions may be present that are not eradicated by conventional surgery, not controlled by systemic chemotherapy and may be part of the mechanisms leading to peritoneal recurrences. We present the results of a review that aim to precise available scientific evidences that deal with microscopic peritoneal metastases and their implications.

Method

Eligible studies related to microscopic peritoneal involvement in patient presenting with ovarian cancer, published from 1980 to June 2016, were retrieved through ClinicalTrials.gov, MEDLINE, Cochrane databases and bibliography searches. To discuss expected benefits of intraperitoneal chemotherapy, fluorescence-guided surgery or intraperitoneal photodynamic therapy, we reviewed most recent and relevant studies. The final reference list was generated based on originality and relevance to the broad scope of this review.

Results

Data concerning early-stage ovarian cancer suggest that occult peritoneal or epiploic metastases are present in 1.2% to 15.1% of cases. In advanced-stage, fluorescence imaging suggests that residual microscopic lesions are ignored by conventional surgery and may represent a relevant surgical therapeutic target. There are very few data in the literature to confirm the link between peritoneal recurrences and microscopic peritoneal metastases at diagnosis

Conclusion

A local therapeutic strategy may contribute to decrease the rate of peritoneal recurrence. Intraperitoneal chemotherapy, and targeted photodynamic therapy could play a role in this new paradigm. The roles of these different options must be defined by future researches.

THE IMPORTANCE OF DNA PLOIDY MEASUREMENT IN FOLLOW UP OF PATIENT WITH MALIGNANT EPITHELIAL OVARIAN TUMORS

S. Babloyan1, G. Beglaryan2, P. Karakitsos3

1Yerevan State Medical University, Erebouni Medical Center, Yerevan, Armenia
2Yerevan State Medical University, OBGYN N1, Yerevan, Armenia
3National University of Athens, Department of Cytolpathology- University Hospital Atticon, Athens, Greece

Aims

The aim of our study was to evaluate the importance of different of DNA ploidy parameters in analysis of survival rate in patients with malignant epithelial ovarian cancer.

Material: Our study was carried out on 105 patients with malignant common epithelial tumors of the ovary in the age ranged from 22 to 70 years (Mean value 45,2, SD=18,35 years)

Method

DNA ploidy measurement in cytological and histologiacal material of tumors was performed. To determine the prognostic significance of various ploidy parameters one-dimensional and multivariate statistical Cox analysis were performed.

Results

Analysis of hyperploidy index (DH) showed that patients with a degree of hyperploidy corresponding to> 3% have a roughly 7-fold greater risk of fatal outcome (Hazard ratio-7.20, p <0.001 , CI: 2.99-17.32) in comparison to patients with degree of hyperploidy below <3%. Analyzing the results of the ploidy balance (PB) shows, that patients with a ploidy balance <70% have a roughly 5 times higher risk of unfavorable prognosis (Hazard ratio-5.16) compared to patients with a balance of ploidy corresponded to > 70%. The result demonstrate that degree of ploidy parameters and aneuploidy in malignant epithelial tumor has important prognostic value.

Conclusion

Cox statistical analysis showed the measurement importance of different ploidy parameters in the overall survival of patients with malignant epithelial ovarian tumors (p <0.001). According to the one-dimensional and multivariate statistical analysis degree of aneuploidy (DA), degree of hyperploidy (DH) and ploidy balance (PB) are important indicators for the general survival rate of patients with malignant epithelial tumours of ovaries (p <0.001).
ISOLATED PELVIC RECURRENCE INVADING THE URINARY BLADDER AFTER SURGICALLY TREATED OVARIAN CANCER

I. Balescu¹, N. Bacalbasa²
¹Ponderas Academic Hospital, Visceral Surgery, Bucharest, Romania
²Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania

Aims

To report the case of a patient who was diagnosed with an isolated pelvic recurrence at 22 months after surgery for stage IIIC epithelial ovarian cancer.

Method

The 42-year-old patient has been submitted to total hysterectomy with bilateral adnexectomy, pelvic and para-aortic lymph node dissection for moderately differentiated epithelial ovarian cancer 22 months before.

Results

Postoperatively the patient was submitted to six cycles of taxanes and platinum based chemotherapy and at one year follow up she presented no sign of recurrence. However ten months later she presented for dysuria and hematuria and was diagnosed with an isolated recurrence in the urinary bladder. The recurrent tumor was successfully resected by performing a partial cystectomy with cystoraphy (Fig.1,2).

At one year follow-up she is free of recurrent disease.

Conclusion

Although is not a common situation, isolated pelvic recurrences after ovarian cancer might develop and are best treated by re-resection.
Aims

To demonstrate the safety and effectiveness of extended left upper abdominal quadrant as part of quaternary cytoreduction for relapsed ovarian cancer.

Method

We report the cases of four patients submitted to extended left upper abdominal quadrant as part of quaternary cytoreduction.

Results

The main visceral resections consisted of splenopancreatectomy – in three cases, partial gastrectomy in two cases, splenectomy in one case, diaphragmatic resections in two cases and left colonic resections in two cases (Figures 1-3).
During the postoperative course a patient developed a pancreatic fistula and necessitating reoperation.

**Conclusion**

Multiple visceral resections in the left upper abdominal quadrant can be safely associated as part of debulking surgery for relapsed ovarian cancer.

DOUGLAS PERITONECTOMY AS PART OF RADICAL PELVIC SURGERY FOR ADVANCED STAGE Ovarian Cancer

N. Bacalbasa¹, I. Balescu²

¹Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania
²Ponderas Academic Hospital, Visceral Surgery, Bucharest, Romania

Aims

To demonstrate the safety and efficacy of Douglas pouch peritonectomy in stage IIIC ovarian cancer.

Method

We present a case series of five patients diagnosed with advanced stage ovarian cancer and Douglas pouch peritoneal carcinomatosis in whom colonic preservation was feasible.

Results

In all cases a total hysterectomy with bilateral adnexectomy, pelvic and para-aortic lymph node dissection, pelvic and parietal peritonectomy were performed. In all cases debulking to no gross residual disease was achieved; in the meantime Douglas peritonectomy was successfully performed, the rectosigmoidian loop being preserved in all cases (Figures 1-3).
There was no postoperative complication related to peritonectomy procedure.

**Conclusion**

Douglas peritonectomy can be safely performed in selected cases presenting peritoneal carcinomatosis with ovarian origin especially if no profound invasion of the digestive segments is encountered.

ESGO7-0565

TOTAL PELVIC EXENTERATION FOR RELAPSED OVARIAN SARCOMA – A CASE REPORT

N. Bacalbasa¹, I. Balescu²
¹Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania
²Ponderas Academic Hospital, Visceral surgery, Bucharest, Romania

Aims

To report a case of relapsed ovarian sarcoma successfully treated by total pelvic exenteration

Method

We present the case of a 67-year-old patient diagnosed with stage I ovarian carcinosarcoma who had been submitted to surgery with radical intent two years before. At that moment a total hysterectomy with bilateral adnexectomy and omentectomy were performed.

Results

At two year follow-up the patient was diagnosed with a pelvic recurrence invading the urinary bladder and the rectum. The patient was resubmitted to surgery, a total infralevator pelvic exenteration being performed (Figures 1, 2).

At one year follow up there are no signs of local or distant recurrence.

Conclusion

Although ovarian sarcomas are aggressive gynecological malignancies with poor outcomes, radical surgery might improve survival even in cases presenting recurrent lesions.
ITERATIVE RIGHT UPPER ABDOMINAL QUADRANT RESECTIONS FOR OVARIAN CANCER

N. Bacalbasa¹, I. Balescu²

¹Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania
²Ponderas Academic Hospital, Visceral surgery, Bucharest, Romania

Aims

To report the case of a 56-year-old patient diagnosed with stage IIIC ovarian cancer submitted to iterative resections in right upper quadrant.

Method

Initially the patient was submitted to total hysterectomy, bilateral adnexectomy, pelvic, para-aortic and upper abdominal lymph node dissection for moderately differentiated epithelial ovarian cancer (Figure 1).

Results

At one year follow-up the patient was diagnosed with disseminated lesions on the right diaphragmatic surface and Glissonian capsule, so she was re-submitted to surgery (Figure 2).
The nodules were removed en bloc with right diaphragmatic peritonectomy and minor liver resection. Two years later the patient was diagnosed with an isolated parenchimatous liver metastasis which was successfully removed (Figure 3).

**Conclusion**

Iterative resections in the upper abdomen for relapsed ovarian cancer might significantly improve survival especially if a R0 resection is achieved.
CENTRAL NERVOUS SYSTEM (CNS) METASTASES IN GYNECOLOGIC MALIGNANCIES

C. Bachmann\textsuperscript{1}, S. Brucker\textsuperscript{1}

\textsuperscript{1}University Hospital Tuebingen, Department of Obstetrics and Gynecology, Tuebingen, Germany

Aims

CNS metastases complicate the course of disease and are rarely reported in gynecologic malignancies (cervical/ endometrial/ ovarian cancer). There are no standardized treatment regimens for patients with CNS metastases from gynecologic malignancies. Due to their poor prognostic impact identification of risk factors and histopathologic parameters for risk stratification should be performed. Objective was to characterize patients with brain metastases from gynecologic malignancies.

Method

In a single center study the data of 28 patients with brain metastases from gynecologic malignancies, treated at the department of gynecology university Tübingen, germany between 2000-2015, were analysed retrospectively.

Results

We identified 18 patients with ovarian cancer, 6 patients with cervical cancer and 4 patients with endometrial cancer. Most common histology subtype was squamous cell carcinoma of the cervix, high-grade serous ovarian cancer and endometrioid endometrial cancer. At diagnosis of brain metastases almost all patients had distant metastases: in 90\% from cervical/ endometrial cancer; in 28\% from ovarian cancer. Patients presented advanced FIGO stages in 61\% and node-positivity in 39\%.

Median interval: first diagnosis to occurrence of CNSmetastases was longer in ovarian cancer (40.22 months (10-98 months) compared to cervical/ endometrial cancer (29.7 months (0-110 months). Median survival after detection of brain metastases was 6.14 months (1-17 months); endometrial/ cervical cancer: median 5.22 month (1-17 months); ovarian cancer: median 6.83 (2-15 months).

Conclusion

Management of these patients is challenging due to lack of effective treatments besides neurosurgical intervention. A risk stratification could be useful to identify risk factors for CNS metastases in gynecologic cancers.

ADULT-TYPE OVARIAN GRANULOSA CELL TUMORS (OGCTS): TREATMENT OUTCOMES FROM A SINGLE INSTITUTIONAL EXPERIENCE

1. King Faisal Specialist hospital, medical oncology, riyadh, Saudi Arabia
2. Lecturer of clinical oncology- Menoufia faculty of medicine, clinical oncology, cairo, Egypt
3. Lecturer of clinical oncology- Ain Shams faculty of medicine, clinical oncology, cairo, Egypt
4. Assistant professor of clinical oncology- Kasr Ailiki faculty of medicine, clinical oncology, cairo, Egypt
5. Lecturer of clinical oncology- Kasr ailiki faculty of medicine, clinical oncology, cairo, Egypt
6. Lecturer of clinical oncology- Zagazig faculty of medicine, clinical oncology, cairo, Egypt
7. Lecturer of clinical oncology- Suez canal faculty of medicine, clinical oncology, eskandera, Egypt
8. Lecturer of clinical oncology- National cancer institute, clinical oncology, cairo, Egypt
9. King Faisal Specialist Hospital- oncology research data analyst, oncology, riyadh, Saudi Arabia

Aims

To report clinical characteristics and long-term outcomes of adult-type OGCTs at our center and to determine prognostic factors affecting relapse and survival.

Method

From 1988 to 2014, we retrospectively reviewed patients with adult-type OGCTs. Baseline characteristics, pathological findings and outcomes were analyzed.

Results

61 patients with adult-type OGCTs were identified with median age of 49 years. Median follow-up was 5.0 years. 74% of patients had FIGO stage I, 7% had stage II, 5% had stage III and unknown in 14%. Most common presenting symptoms included abdominal pain (43%) and vaginal bleeding (43%). Majority of patients (37 patients, 60.7%) were treated with TAH and BSO. 5 (8%) patients received adjuvant chemotherapy. Sixteen patients (26%) relapsed with a median time to relapse of 5.5 years. Half of recurrence (8 patients) occurred after 5 years of diagnosis. Five-year overall survival and disease-free survival were 93% and 84%, respectively. Factors associated with high risk of recurrence were ascites (p=0.000) and elevated preoperative CA 125 (0.048). Overall survival was significantly influenced by menopausal status (premenopausal 100% vs. postmenopausal 84%; p=0.02), preoperative CA 125 (normal 100% vs. elevated 64%; p=0.005), Ascites (present 33% vs. absent 100%; p=0.000), and age (<55 years 100% vs. ≥ 55 years 77%; p= 0.002)

Conclusion

This confirms a good outcome of patients with OGCTs. They require long-time follow-up because recurrence can occur many years after primary therapy. Presence of ascites and elevated preoperative CA 125 were associated with higher risk of recurrence and poor prognosis. Outcome seems not to be affected by fertility-sparing surgery.

RELEVANCE OF CA125, PLATELET COUNT AND NEUTROPHIL TO LYMPHOCYTE RATIO IN THE DIAGNOSIS AND FOLLOW-UP OF OVARIAN CANCER PATIENTS

T. Baert¹,², L. Vanbrabant², A. Laenen³, I. Vergote¹,², ⁴, A. Coosemans¹,²

¹UZ Leuven, Department of Gynecology and Obstetrics- Leuven Cancer Institute, Leuven, Belgium
²KU Leuven, Department of Oncology- Laboratory of Tumor Immunology and Immunotherapy- ImmunOvar Research Group, Leuven, Belgium
³KU Leuven, Biostatistics and Statistical Bioinformatics Center of Leuven, Leuven, Belgium
⁴KU Leuven, Department of Oncology- Laboratory of Gynecologic Oncology, Leuven, Belgium

Aims

It has been shown that the immune system of ovarian cancer patients changes during disease course. Literature has demonstrated correlations between CA125, neutrophil to lymphocyte ratio (NLR), thrombocytosis and survival. This study explored these variables in ovarian cancer patients and whether a correlation exists between these clinical variables and the immune system.

Method

Serum samples of 52 ovarian cancer patients were collected at diagnosis and were retrospectively analysed for clinical characteristics, clinical parameters (NLR, CA125, platelet count, eosinophils, white blood cells (WBC)) and immune profile [IL-4 (interleukin), IL-10, IL-13, IL-17, TGF-β (transforming growth factor), arginase, IFN-γ (interferon gamma), VEGF (vascular endothelial growth factor), Gal-1 (galectin) and CCL-2 (chemokine (C-C) motif ligand 2)].

Results

Increasing NLR (p=0.0113), WBC (p= 0.003) and the absolute number of neutrophils (p=0.0013) were significantly correlated with decreasing overall survival. Increasing platelets were significantly correlated with increased risk of recurrence (p=0.0137). Eosinophil count was not correlated with survival. Platelet count was significantly correlated with IL-10 (p= 0.0001) and TGF-β (p= 0.029), NLR with arginase (p= 0.0482), high levels of CA125 (>105) with IFN-γ (p=0.029) and the percentage of neutrophils with VEGF (p= 0.0104). FIGO stage III and IV were significantly correlated with thrombocytosis (p= 0.034).

Conclusion

NLR, CA125, absolute number of neutrophils and platelet count can be of importance in the diagnosis and follow-up of ovarian cancer patients. Increasing amounts of blood platelets, CA125, NLR and neutrophils seem to be correlated with an inferior immune profile.
Aims

Ovarian cancer (OC) is a silent killer, metastasising throughout the abdomen before causing symptoms. So far, research concerning the immune system has focussed on the intratumoral immune changes. The peripheral immune landscape in OC remains largely undiscovered.

Method

In 39 patients with invasive OC, blood and tumor tissue was sampled at diagnosis. Immunohistochemistry for CD8 and Foxp3 (regulatory T cells (Treg)) was performed on tumor biopsies. Activated CD4 and CD8 T cells, myeloid-derived suppressor cells (MDSC) and Treg were characterized by Fluorescence Activated Cell Sorting (FACS).

Results

In contrast to earlier reports in the literature there was no clear correlation of the expression of Treg, neither in tissue nor in blood, and survival. Overall survival (OS) deteriorated significantly with increasing amount of PDL1-positive monocytic MDSC (mMDSC_PDL1) (p = 0.02) and with increasing amounts of activated CD8+ T cells (p = 0.007). Increasing amounts of CD8+ T cells in tumor tissue (primary tumor + metastasis) were correlated with longer OS (p = 0.062), due to the effect of CD8+ T cells in metastases (p = 0.036), as CD8 infiltration in the primary tumor was not correlated with OS.

Conclusion

This study suggests for the first time the use of immune cells as a possible new biomarker for OC. mMDSC_PDL1 seem to be a major player in immunosuppression. This innate immunosuppression is most probably so overwhelming that an increase in effector cells of the adaptive immune system (CD8) cannot to protect the patient, unless these cells can infiltrate the metastases.
OVARIAN CANCER

ESGO7-0276

HSP90/HER2 AND HSP90/P53 IMMUNOPHENOTYPES AND RESPONSE TO CHEMOTHERAPY IN PATIENTS WITH OVARIAN CARCINOMA

J. Bar¹, A. Lis-Nawara¹, L. Hirnle², M. Jelen³

¹Wroclaw Medical University, Immunopathology and Molecular Biology, Wroclaw, Poland
²Wroclaw Medical University, First Department of Gynecology, Wroclaw, Poland
³Wroclaw Medical University, Department of Pathomorphology and Clinical Oncology, Wroclaw, Poland

Aims

The biological role of parallel expression of HSP90 and HER2 or p53 protein as a target therapy markers have not been established. This study investigates the clinical significance of p53, HER2 and HSP90 co-expression in patients with ovarian cancer who received platinum-based therapy.

Method

P53, HER2 and HSP90 expression was analyzed on 124 malignant ovarian tumors using immunohistochemistry (IHC). The HER2 immunoexpression was confirmed by fluorescence in situ hybridization (FISH) analysis.

Results

p53, HER2 and HSP90 expression was found in 58.9%, 42.2% and 78.9% of ovarian carcinomas respectively. Comparison analysis between the FISH assays for HER2 and corresponding IHC showed 90.0% concordance. p53 overexpression and HER2 expression was associated with high tumor grade (G3) (P=0.04, P=0.03 respectively). p53 and HER2 accumulation showed only borderline association with FIGO stages P=0.07 and P=0.08 respectively. Positive correlation was found between HER2 and HSP90 expression in ovarian carcinomas (P=0.03). Advanced FIGO stage and high expression of HER2 was negatively associated with overall survival time (P=0.01). In the analyzed group of ovarian tumors, the relative risk of recurrence was stronger in HER2 positive than in HER2 negative group of patients (P=0.04). Simultaneous expression of p53, HER2 and HSP90 in ovarian tumor tissue determine shorter overall survival time in patients with ovarian cancer (P= 0.01).

Conclusion

Our study demonstrated that simultaneous expression of HSP90 and HER2 or HSP90 and p53 protein characterize subgroup of patients with worse clinical outcome. HSP90 inhibition might be a promising therapeutic strategy for HER2/HSP90 positive ovarian cancers.

EXPRESSION PATTERN OF P53, BAX PROTEIN AND CANCER STEM CELL MARKERS CD133 AND NOTCH IN OVARIAN CANCERS

J. Bar¹, A. Lis-Nawara¹, L. Hirnle², M. Jelen³

¹Wroclaw Medical University, Immunopathology and Molecular Biology, Wroclaw, Poland
²Wroclaw Medical University, First Department of Gynecology, Wroclaw, Poland
³Wroclaw Medical University, Department of Pathomorphology and Clinical Oncology, Wroclaw, Poland

Aims

Biological heterogeneity of ovarian carcinoma is well documented. Up to now several biological parameters have been analyzed to describe the biological behavior of ovarian carcinoma cells. The aim of the study was to evaluate the expression of stem cells proteins (CD133, Notch1) and p53, Bax protein in ovarian carcinomas in order to establish the biological behavior of ovarian carcinoma.

Method

Stem cells proteins (CD133, Notch1) and p53, Bax proteins expression was analyzed on 104 malignant ovarian tumors using immunohistochemistry (IHC).

Results

P53 protein was found in 39% of ovarian carcinomas and was observed more frequently in advanced stage of disease (FIGO III/IV) (P = 0.04), and poorly differentiated tumors (G3) (P = 0.01). Nuclear accumulation of p53 protein dominated in serous ovarian carcinomas (P = 0.02). Bax protein expression occurred in 42% of ovarian carcinomas and was associated with low stage of disease (FIGO I/II) (P = 0.03). CD133 and Notch expression was observed in 38.0% and 33.0% of ovarian carcinomas respectively. The association between poorly differentiated tumor and Notch1 expression (P = .002) was found. CD133 molecule did not correlate with clinicopathological parameters of ovarian carcinomas. Positive correlation between CD133 and Notch1 was revealed in ovarian carcinomas (P = 0.02). CD133+/Notch1+ immunophenotype dominated in poorly (G3) differentiated ovarian carcinomas.

Conclusion

Our results suggest that parallel expression of CD133 and Notch1 molecules on tumor cells identified subgroup of ovarian carcinomas with high morphological malignancy. Co-expression of CD133 and Notch1 might be associated with redifferentiation of tumor cells.

ESGO7-0334

CLINICAL BENEFIT OF HORMONAL THERAPY IN ADVANCED OVARIAN CANCER
L. Bei1, A.V. Silva1, A. Petiz2, D. Pereira1, J. Savva-Bordalo1
1Instituto Português de Oncologia do Porto, Medical Oncology, Porto, Portugal
2Instituto Português de Oncologia do Porto, Gynaecology, Porto, Portugal

Aims

To evaluate the benefit of hormonal therapy (HT) in advanced ovarian cancer (AOC).

Method

We reviewed the data of patients with AOC who underwent HT between 2009 and 2016. Primary endpoint was clinical benefit (CB). Secondary endpoints were overall survival (OS), progression-free survival (PFS) and toxicity. Descriptive analysis of the main demographic and clinical characteristics was performed. PFS and OS were evaluated using the Kaplan-Meier method.

Results

We identified 47 patients. Median age was 61 years. Serous carcinoma was the main histologic subtype (70%). Clinical stages at presentation were FIGO IIIB (13%), IIIC (55%) and IV (21%). Hormone receptor expression (HRE) was positive in most of the tested patients. Previous to HT, 36% were treated with one regimen of chemotherapy (CT) and 60% with ≥2 regimens. HT was initiated in 34% due to disease progression and the remaining as maintenance therapy. The majority had ECOG ≤1 (70%). Letrozole was the most commonly used (77%), followed by tamoxifen (17%) and megestrol (6%). No relevant toxicity was reported. PFS was 6 months (CI 95% 2.1-9.9) and OS was 22 months (CI 95% 13.0-31.0). Based on imaging response criteria, one patient had complete response, 70% had stable disease and 19% progressed on the first evaluation. Overall CB was 72%.

Conclusion

CB was superior to the reported in the literature, probably related to its maintenance use between CT treatments. More prospective studies are needed to determine the real advantage of HT in AOC vs clinical surveillance in the maintenance setting, as well as its correlation with HRE.

PEMBROLIZUMAB (ANTI-PD-1) IN A PATIENT WITH RECURRENT GRANULOSA CELL TUMOR: A CASE-REPORT
C. Bekos¹, S. Dekan², R. Woitek³, G. Häusler⁴, C. Grimm⁴, A. Reinthaller⁴, S. Polterauer⁵
¹AKH Wien, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria
²Medical University Vienna, Department of Pathology, Vienna, Austria
³Medical University Vienna, Department of Radiology, Vienna, Austria
⁴Medical University Vienna, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria
⁵, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria

Aims

Immunotherapies or Checkpoint inhibitors, targeting programmed cell death protein-1 (PD-1) and cytotoxic t-lymphocyte-associated antigen-4 (CTLA-4), could improve therapeutical outcomes of several malignant diseases. This is a report about the use of an anti-PD-1 antibody in a recurrent and unresectable granulosa cell tumor.

Method

In 2012, when our patient was 35 years old, a suspicious ovarian cancer was diagnosed during pregnancy. An unilateral adnexectomy was performed laparoscopically within the pregnancy. During caesarean section an intraabdominal recurrence was diagnosed. By resection of the spleen, left adrenal gland, both diaphragms, liver segments II, II and part of segment VIII, R0 resection could be achieved. This was followed by four cycles of Bleomycin, Etoposid and Cisplatin. After that there was no more tumor traceable anymore.

In July 2014, a tumor recurrence in the hilum of the liver and peritoneal carcinomatosis was diagnosed. The patient received 33 cycles of anti-VEGF antibody bevacizumab and an anti-hormonal therapy with letrozol.

Results

In September 2016 a new unresectable hepatal relapse was diagnosed. Therefore an off-label therapy with pembrolizumab 200mg dosed every three weeks was initiated.

Diagnostic workup performing CT scans was planned after 3 and 6 months to evaluate therapeutical response. In the first CT scan, three months later, progressive disease according to RECIST criteria was diagnosed. The results from the 6 months follow up will be presented at the conference.

Conclusion

This is the first report about the use of pembrolizumab in recurrent, non-resectable granulosa cell tumor.

COMPARISON OF SYMPTOMS AND QUALITY OF LIFE IN RECURRENT OVARIAN CANCER BY RURAL/URBAN RESIDENCE: ANCILLARY ANALYSIS OF GOG-0259

S.M. Belcher¹, S.M. Sereika¹, M.K. Mattos², T.L. Hagan³, H.S. Donovan¹
¹University of Pittsburgh School of Nursing, Health and Community Systems, Pittsburgh, USA
²University of Virginia School of Nursing, Acute and Specialty Care, Charlottesville, USA
³Massachusetts General Hospital, Harvard Medical School, Boston, USA

Aims

Women with recurrent ovarian cancer (OC) experience a wide range of cancer- and treatment-related symptoms that negatively impact their quality of life (QOL). Research demonstrates that geographic differences in access to high-quality care are associated with healthcare disparities. Our objectives were to evaluate whether rural (versus urban) residence is associated with worse symptoms and poorer QOL in a nationwide sample of women with recurrent OC.

Method

Baseline GOG-0259 data were analyzed. We mapped zip codes to Rural Urban Continuum Code approximations and compared sociodemographic and clinical variables between rural and urban groups using two-sample t and chi-square tests. We used multivariate analysis of covariance to test for associations between residence and symptoms and QOL (FACT-O), controlling for known personal, social, and health risk factors.

Results

Rural (n=75, 15.1%) and urban (n=422, 84.9%) women differed by marital status (83% vs. 70% married), number of concurrent symptoms (16 vs. 14), and overall QOL (107.5 vs. 111) (p<.05). In omnibus multivariate analyses, geographical residence was not associated with either symptoms or QOL. Higher anxiety and lower optimism were associated with worse symptoms. Higher social support, lower depressive symptoms, lower anxiety, and fewer comorbidities were associated with better QOL.

Conclusion

Despite differences in symptoms and QOL by rural/urban residence in bivariate relationships, multi-variate analyses suggest that social and psychological factors may be more important predictors of these outcomes. Future large sample studies should evaluate the interactions between place of residence and social/psychological factors in influencing symptoms and QOL among women with OC.
PREOPERATIVE ULTRASOUND DIAGNOSIS OF DIAPHRAGMATIC SPREAD IN OVARIAN CANCER PATIENTS: TECHNIQUE AND ACCURACY. A PILOT STUDY.

¹Policlinico Umberto I - Sapienza University of Rome, Department of Obstetrical-Gynecological Sciences and Urological Sciences, Roma, Italy

Aims

To evaluate the accuracy of ultrasound in assessing diaphragmatic spread in ovarian cancer (OC) patients and the issues that influencing the performance of ultrasound.

Method

We enrolled consecutive patients with suspected or assessed OC referred to "Sapienza" University of Rome from March 2016 to March 2017. All patient underwent preoperative abdominal and pelvic ultrasound staging examination.

The diaphragm was conventionally divided into 3 parts in according to anatomical reference point: right, central and left diaphragm particularly the lateral, posterior and dome area were examined.

For each area, we record diaphragm thickening, nodules and calcifications.

All patients underwent surgery. The agreement of diaphragmatic spread by ultrasound with the intraoperative and hystopathological findings was evaluated.

Results

We prospectively enrolled 30 patients with primary OC or after neoadjuvant chemotherapy for OC.

The ultrasound staging for right diaphragmatic lesion have a sensivity of 100% and 92.8%, specificity of 61.1% and 53.3%, PPV of 61.1% and 65% and NPV of 100% and 88.8% respectively for nodule and for peritoneal carcinomatosis. For left and central diaphragm ultrasound have high rate of false positives.

Multivariable analysis reported a false positive high rate in patients underwent chemotherapy, in patients with FIGO stage III and sierous hystotype and with ascites.

Conclusion

The ultrasound technique for the assessing of diaphragmatic carcinosis is a simple and accurate method. Preoperative evaluation of right diaphragmatic spread of ovarian cancer is mandatory for optimal surgical plan.

²Gustave Roussy, Anesthésie, Villejuif, France
³Hôpital Marie Lannelongue, Chirurgie Thoracique et Vasculaire, Le Plessis-Robinson, France

Aims

To assess the feasibility of thoracoscopy at the same time of diagnostic laparoscopy by a gynaecologic oncology surgeon and to improve staging in patients with advanced ovarian cancer (AOC).

Method

In 2014 a gynaecologic oncology surgeon of our team had trained in a thoracic surgery unit to learn thoracoscopy. Between April 2015 and January 2017 we assessed the feasibility of thoracoscopy in our institution for patients with AOC, persistent pleural effusion or diaphragm infiltration after neoadjuvant chemotherapy and no contraindication to debulking surgery at laparoscopic exploration.

Results

Sixteen patients met eligibility criteria, with a median age of 62 years (42-74). In 3 cases debulking surgery was contraindicated by the laparoscopic exploration and thoracoscopy was not required. Thirteen right-side thoracoscopy were successfully performed after a median number of chemotherapy cycles of 3 (3-6). Surgery management was changed in six patients with confirmed pleural disease: four patients had extensive pleural disease and were treated only by chemotherapy, two patients presented single-site pleural disease and debulking surgery with pleural resection was performed. Nine patients had no residual disease after debulking.

The median operating time was 63 minutes (45-80).

All patients had chest drainage for one day and median hospital stay was 3 days (2-4). No complications were observed.

Conclusion

We showed that thoracoscopy could be safely performed by a trained gynaecologic oncology surgeon and should be associated with a diagnostic laparoscopy for surgical staging of AOC. In 46% of cases (6/13) therapeutic management was modified based on the thoracoscopy findings.

Aims

To compare oncological outcomes between conservative and radical surgery in the treatment of stage I granulosa cell tumors of the ovary (GCT).

Method

Data from 240 patients with stage I GCT were retrospectively collected among MITO centers (Multicenter Italian Trials in Ovarian cancer and gynecologic malignancies) and analyzed.

Results

Mean age was 48.95 ±15.3 in the entire cohort; 36±12.1 and 56.1 ±11 in the conservative and radical surgery cohorts, respectively (p=0.001). 19 patients were affected by juvenile GCT (7.5%), 222 (92.5%) by adult type GCT. Stage 1A, 1B and 1C were 68%, 2% and 30% respectively. No statistical difference was detected in stage distribution between the two groups. 90 patients (37.5%) underwent conservative surgery (either ovariectomy or cystectomy) while 150 (62.5%) received a radical approach. Five year- disease free survival (DFS)rates in the conservative and radical surgery cohorts were 77% and 83% respectively (p=0.09).

Conclusion

In the present study conservative surgery did not affect the oncological outcome of stage I GCT patients and should therefore be considered the standard of care in patients desiring to retain their fertility.
OPEN VERSUS MINIMALLY INVASIVE SURGERY FOR THE TREATMENT OF GRANULOSA CELL TUMORS OF THE OVARY: RESULTS FROM THE MITO 9 STUDY

Aims

To compare oncological outcomes between laparoscopic and open surgery in the treatment of stage I granulosa cell tumors of the ovary (GCT).

Method

Data from 240 patients with stage I GCT were retrospectively collected among MITO centers (Multicenter Italian Trials in Ovarian cancer and gynecologic malignancies) and analyzed.

Results

19 patients were affected by juvenile GCT (7.5%), 222 (92.5%) by adult type GCT. Stage 1A, 1B and 1C were 68%, 2% and 30% respectively. 138 patients (57.5%) underwent open surgery while 102 (42.5%) laparoscopic surgery. No differences in residual tumor or postoperative complications were detected between the two groups. Five year disease free survival (DFS) rates in the laparoscopic and open-surgery cohorts were 84% and 80% respectively (p=0.3). Median DFS were 228±29 months and 161±18 months, respectively.

Conclusion

In the present study laparoscopy did not affect the oncological outcome of patients affected by GCT, with comparable postoperative outcomes.

J. Zschocke¹, C. Marth¹

¹Med. Universität Innsbruck, Department für Gynäkologie und Geburtshilfe, INNSBRUCK, Austria
²Med. Universität Innsbruck, Devision für Humangenetik, INNSBRUCK, Austria

Aims

p53 is the most frequently mutated gene in cancer. There are conflicting results in literature regarding TP53 mutations and survival in ovarian cancer (OC) patients. Therefore we analyzed the TP53 mutational status in a well-defined patient-cohort.

Method

Samples from 199 ovarian cancer patients diagnosed at our Department between 1989 and 2014 were analysed. After DNA extraction the TP53 mutational status was determined by Next generation sequencing using the TruSight Cancer Sequencing Panel. Results were correlated with clinicopathologic features using the chi-square test. Survival probabilities were calculated according to the Kaplan Meier method and the multivariate Cox regression model.

Results

TP53 mutations were detected in 59% (118/199) and unclassified TP53 variants (UVs) in 15% (29/199) of ovarian carcinomas. TP53 mutant tumours were significantly associated with adverse tumor grade and high-grade serous OC (HGSOC; p<0.001). Patients with TP53 mutant OC showed a significantly impaired overall survival (OS; 3.4 vs 8.2 years; p=0.004) as did the subgroup of 127 HGSOC patients (3.3 vs. 5.8 years; p=0.005). Interestingly all the TP53 UVs identified in this study were also associated with poor OS in the whole cohort (p=0.001) and the subgroup of HGSOC patients (p=0.002).

In the multivariate analysis the TP53 mutational status was confirmed as a prognostic marker in all OC patients (p=0.019) and the subgroup of HGSOC patients (p=0.001).

Conclusion

We demonstrated that the TP53 mutational status is an independent marker for poor OS in HGSOC. TP53 UVs identified within this study showed the same prognostic relevance as the verified mutations.

6 University of Brescia, Clinical and Experimental Sciences, Brescia, Italy
7 ASST Spedali Civili di Brescia, Obstetrics and Gynecology, Brescia, Italy
8 University of Ferrara, DEpartment of Morphology - Surgery and Experimental Medicine, Ferrara, Italy

Aims

High-grade serous ovarian carcinoma (HGSOC) is the most lethal gynecologic neoplasm, with five-year survival rate below 30%. Early disease detection is of utmost importance to improve HGSOC cure rate. The focus of this study was the detection of the levels of circulating miRNAs in tissues and sera from patients with HGSOC as a first step in the evaluation process of their role as diagnostic biomarkers.

Method

Sera from 168 HGSOC patients and 65 healthy controls were gathered together from two independent collections and stratified into a training set, for miRNA marker identification, and a validation set, for data validation. An innovative statistical approach for microarray data normalization was developed to identify differentially expressed miRNAs. Signature validation in both the training and validation sets was performed by quantitative Real Time PCR (RT-qPCR) and droplet digital PCR (ddPCR).

Results

In both the training and validation sets, miR-1246, miR-595 and miR-2278 emerged significantly over expressed in the sera of HGSOC patients compared to healthy controls. Receiver Operating Characteristic curve analysis revealed miR-1246 as the best diagnostic biomarker, with a sensitivity of 87%, a specificity of 77% and an accuracy of 84%.

Conclusion

This study is the first step in the identification of circulating miRNAs with diagnostic relevance for HGSOC. According to its specificity and sensitivity, circulating miR-1246 levels are worthy to be further investigated as potential diagnostic biomarker for HGSOC.

Volume 27, Supplement 4 1439
Aims

The lack of information on the molecular etiology of ovarian cancer (OVCA) makes it a lethal malignancy. Longstanding unresolved stress and persistent high levels of circulating follicle stimulating hormone (FSH) are characteristic features in the postmenopausal ovary. The goal of this study was to examine whether chronic unresolved stress is associated with malignant development and if high levels of FSH is associated with ovarian chronic stress in postmenopausal women.

Method

Ovarian tissues from healthy per-and post-menopausal subjects, BRCA1+ subjects and patients with early and late stage OVCA were examined for the expression of markers of chronic stress including glucose regulator protein 78 (GRP78, a maker of endoplasmic reticular stress), OGG1 (a marker of DNA-damage repair mechanism) and FSH receptor (FSHR) using immunohistochemistry, proteomics and gene expression studies. Changes in the intensity of expression of markers by ovarian surface epithelium (OSE) and inclusion cysts as well as malignant cells were determined and compared among normal and different pathological groups.

Results

Compared with OSE, the intensity of GRP78, OGG1 and FSHR expression was significantly higher in ovarian malignant cells. Similarly, inclusion cysts (potential premalignant lesions) in postmenopausal ovaries and fimbrial epithelium of the fallopian tube in BRCA1+ showed significantly higher intensities than the OSE. The expression of these markers were positively associated with FSHR expression.

Conclusion

The results of this study suggest that increased expression of FSHR is associated with ovarian chronic stress in postmenopausal subjects, and may be involved in malignant transformation in the ovary. Support: NIHR01 CA210370-01

SPLENECTOMY IN CYTOREDUCTIVE SURGERY FOR ADVANCED OVARIAN CANCER: HIGHER INVOLVEMENT RATE THAN EXPECTED?

N. Bizzarri1, P. Korompelis1, V. Ghirardi1, R.L. O’Donnell1, S. Rundle1, I.C. Kotsopoulos1, A. Kucukmetin1, C. Ang1, A. Fisher1, N. Ratnavelu1, C.W. Helm2, R. Naik1

1Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom
2Royal Cornwall Hospitals Trust, Gynaecological Oncology, Truro, United Kingdom

Aims

Complete surgical resection (CSR) to no macroscopic residual disease (RD) is the most important prognostic factor in advanced ovarian cancer (AOC). To achieve CSR it is often necessary to perform a splenectomy. The aim of this study is to correlate intraoperative and histological findings of patients with AOC undergoing splenectomy.

Method

All consecutive patients with AOC undergoing primary, interval or secondary cytoreductive surgery and who underwent splenectomy between 01/2010 and 03/2017 at the NGOC (Gateshead, UK) were included. Demographic and surgico-pathological data were extracted from medical records.

Results

Of 129 patients, 73 (56.6%) underwent primary, 44 (34.1%) interval and 12 (9.3%) secondary cytoreductive surgery. Median age was 65 years (24-91) and median Surgical Complexity Score (Aletti) 8 (4-15). Cytoreduction to RD<1cm was obtained in 116 (89.9%). Indication for splenectomy was: direct involvement by tumor in 97 (75.2%), preoperative radiological involvement of spleen in 4 (3.1%), intra-operative splenic capsule injury in 15 (11.6%), to facilitate en-bloc resection of peri-splenic disease in 13 (10.1%). Histologically, 84 (65.1%) had hilum, 80 (62.0%) had capsule and 27 (20.9%) had parenchyma involvement. 10/15 (66.7%) spleens removed for intra-operative injury had positive histological involvement (60% hilum, 60% capsule and 10% parenchyma).

Conclusion

Splenectomy is an important procedure in the surgical management of AOC. Intra-operative detection of spleen involvement is not always reliable and this may be due to adhesions/poor access preventing adequate assessment. A low threshold for removal is required if there is suspicion of splenic disease in a patient where CSR is to be achieved.
PERITONEAL CARCINOMATOSIS FROM PRIMARY MALIGNANT OVARIAN PARAGANGLIOMA: A CHALLENGING MANAGEMENT OF AN EXTREMELY RARE CASE

⁶IRCCS AOU San Martino - IST- University of Genoa, Pathology Unit- Department of Surgical Sciences and Integrated Diagnostics DISC, Genoa, Italy

Aims

Paraganglioma is one of the rarest neoplasms involving the ovary, with only 7 previous reports. We present the case of a patient with peritoneal carcinomatosis from ovarian paraganglioma (OP) and a systematic review of the literature.

Method

Clinical information was retrieved from medical records and a systematic review was performed.

Results

A 33-year-old woman presented with a 12-month history of hypertension and weight loss. CT-scan showed bilateral complex ovarian masses, para-aortic lymphadenopathy and IVC-wall infiltration, no parenchymal organs involvement. Laparoscopic biopsy showed a Sertoli-Leydig ovarian tumor (SLOT). After 3-cycles of bleomycin+etoposide+cisplatin she had stable disease and underwent laparotomy with extensive debulking surgery also involving recto-sigmoidectomy with primary anastomosis (no macroscopic residual disease). Histology reported a solid cordonal neoplasm with neuroendocrine immunophenotype consistent with SLOT with neuroendocrine differentiation (FIGO-stage IIIC).

Postoperative course was complicated by anastomosis dehiscence (re-operated) and pulmonary sepsis. 6-months after surgery a CT-scan showed recurrent disease in abdomen and chest. Subsequent clinical-pathological review reported the case as malignant OP with unusual features. Somatostatin-analogue was started. Following further disease-progression with bone metastases (treated with palliative radiotherapy) a trial with Sunitinib was started. Patient died 30-months after initial diagnosis. Of the 7 cases reported to date, one had peritoneal metastasis at presentation; as in our case, this was initially misdiagnosed as SLOT.

Conclusion

OP is extremely rare. Clinico-pathological correlation and wide immunohistochemical panel are important to avoid misdiagnosis. Due to its rarity, a standard treatment is not recommended, but cytoreductive surgery to no residual disease seems to be a favorable approach.
Aims

Background

In 2014, data from the Danish Gynecological Cancer Group (DGCD), showed that cancer patients were mobilized 45% of the recommended within the first 2 days after surgery.

Objective

Optimizing extent and way of mobilizing patients.

Method

Literature search was conducted in PubMed, CINAHL, and Embase in the subject of early mobilization, the benefit of this as well as consequences and reasons of postoperative immobility. In collaboration with a physiotherapist a flowchart were made to clarify the optimal mobilization including alternative mobilization, if the patient had well known postoperative difficulties as low blood pressure, nausea etc. Care staff were educated in optimizing the mobilization to reduce surgical stress response. Additionally focus on sufficient medication of nausea and pain to permit mobilization.

A pulpit and a walker were acquired to help patients with poor balance or dizziness

Patients and relatives were informed preoperatively in speech as well as in writing of the importance and focus of mobilization.

The aesthetic environment were changed to be more inviting to patients by adding glass art, paintings, flowers, new magazines, games, and knitting to the common areas.

Results

The nurse’s attitude were changed about mobilization. There is commitment and focus among the nurses to optimize mobilization regarding the individual resources of the patient. The tools are diligently being used. Patient satisfaction has increased in our ongoing questionnaire. DGCD reveals an increased mobilization in our unit to about 70% of the recommended.

Conclusion

We believe the results will improve in time as this new culture develops even more into everyday practice.

THE SHORT-TERM IMPROVEMENT IN THE TREATMENT OUTCOMES AMONG PATIENTS WITH ADVANCED OVARIAN CANCER AFTER "THE SHIFT" FROM CONSERVATIVE TO MULTIVISCERAL SURGERY

P. Blecharz1, M. Janeczek1, A. Komorowski2, M. Jasiowka1, W. Szatkowski1, K. Karolewski1

1Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology - Cracow, Gynecologic Oncology, Kraków, Poland
2Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology - Cracow, Surgical Oncology, Kraków, Poland

Aims

Cytoreductive surgery for AOC results in considerable toxicity •Experience of multidisciplinary team seems to be crucial for achieving survival improvement. „The shift” from conservative (pelvis/omentum) to multivisceral procedures is a challenge and seems to be difficult for introducing. Time to gain the experience, skills and survival benefit of AOC patients is not clearly recognized.

The aim of the analysis was to analyze short-term differences in survival among AOC patients, after incorporation of multivisceral, cytoreductive surgery (MCRS) to the common clinical practice and to compare it to the historical cohort of „conservative” surgeries (CS) and to analyze the prognostic factors in this group of patients.

Method

Prospective analysis of patients treated with the MCRS, 2015–2016 and comparing them with historical cohort of patients treated with CS, 2010-2014. PFS was calculated for both groups (K-M method). Prognostic factors for MCRS group (multivariate Cox analysis).

Results

The group of 52 consecutive pts with AOC (FIGO III/IV) treated 2015-2016 and historical cohort of 110 consecutive pts with AOC, treated 2010-2014 were identified.

The PFS curves are presented on the picture 1. Table 1 presents the 1- and 2-year PFS rate and the HR for progression for
Both groups. The independent prognostic factor for PFS was residual disease (Table 2.)

THE ROLE OF PI3K/PTEN/AKT/MTOR PATHWAY IN ADVANCED OVARIAN CANCER PATIENTS RECEIVING PLATINUM-BASED NEOADJUVANT CHEMOTHERAPY.

M. Jesiotr1, C. Szczepan1, K. Robert1, A. Gasowska-Bodnar2, B. Lubomir3
1Military Institute of Medicine, Department of Pathology, Warsaw, Poland
2Military Institute of Medicine, Department of Gynecology Oncology, Warsaw, Poland
3Military Institute of Medicine, Department of Oncology, Warsaw, Poland

Aims

The aims of this study were analysis of associations between genetic variations and the expression of selected proteins of the PI3K/AKT/mTOR pathway on the effects of neoadjuvant chemotherapy (NACT), based on platinum analogues in patients with advanced ovarian cancer (AOC).

Method

Retrospectively, 67 consecutive patients were evaluated with AOC (FIGO stage IIIC-IV) treated with NACT. Thirteen tagging SNPs in four core genes (PIK3CA, AKT1, AKT2, and FRAP1) and the expression of PI3KCA, PTEN, pAKT473, mTOR and p70S6K were assessed immunohistochemically according to the H-score method.

Results

After NACT, a significant decrease of expression in the AOC of PI3KCA (p=0.0002; T=24.5; Z=3.71) and p70S6K (p=0.0299; T=12.5; Z=2.17) was observed. No significant difference was found in IHC expression before or after NACT and other analysed proteins. In multivariate analysis it was found that the lack of an optimal range of IDS and a decrease of the p70S6K expression were independent adverse predictive factors for PFS (respectively, HR=5.33 (95%CI; 2.76-10.27, p<0.0001 and HR=1.90 (95%CI; 1.06–3.39, p=0.0308). We observed that the high expression of mTOR [HR=2.39 (1.31–4.37), p=0.0208] had an adverse impact on OS. We identified that any from analysed SNPs in four genes had no significantly impact on PFS and OS.

Conclusion

The study provides evidence that variations within the PI3K/PTEN/AKT/mTOR signaling pathway are associated with variation in clinical outcomes of AOC patients.
Aims

The process of epithelial-mesenchymal transition (EMT) has been implicated in many cancers, including ovarian, enabling epithelial cells to acquire motile and invasive characteristics which are essential for metastatic spread. We aimed to investigate the role of caldesmon (CALD1) gene, which encodes an important regulator protein of microfilament network, in epithelial ovarian cancer (EOC) pathogenesis.

Method

Reverse transcription quantitative real-time PCR (RT-qPCR) was used to determine CALD1 expression levels in 48 EOC and 19 benign ovarian formalin fixed paraffin embedded (FFPE) specimens. The median patients’ age in both groups was 57 years. The differences in CALD1 gene expression between these two subgroups and its association with various clinicopathological features were assessed by Mann-Whitney test and Spearman’s rank correlation test. P value <0.05 was considered significant.

Results

We found that CALD1 expression levels were lower in malignant compared to benign ovarian tissue (p<0.0001), while CALD1 gene was also significantly lower expressed in high vs. low-grade ovarian carcinomas (p=0.0440). Lower CALD1 expression was observed in higher FIGO stage, tumors with metastases and ascites, as well as in tumors from patients who relapsed, although without statistical significance.

Conclusion

Study findings suggest that CALD1 gene, an important regulator of cell motility, could be a potential biomarker in the prognosis of ovarian tumors.

Aims

MITO (multicenter-Italian-trials-in-ovarian-cancer) 21 is a retrospective observational study aimed at exploring genotype-phenotype correlations in a cohort of BRCA mutation-carrying ovarian cancer (OC) patients. We present an ad interim analysis that characterizes the breast and ovarian cancer (BOC) subgroup and investigates if breast cancer (BC) co-occurrence affects prognosis compared to OC alone.

Method

Fifteen Italian centers participated in the study. Retrospective chart review was used to identify patients carrying a BRCA mutation who were diagnosed with OC between 1995 and 2016 and to collect relating clinical data.

Results

Of the 319 patients included in the study, 72 (23%) were diagnosed with BOC and 247 (77%) with OC only. In the BOC sub-cohort, BC and OC were the first malignancy in 56 (78%) and 16 (22%) cases, respectively. Median age at diagnosis was 50yr (range 32-81yr) for BC and 57yr (range 42-84yr) for OC. The median interval between first and second primary cancer was shorter when BC followed OC than when it preceded it (31m vs. 100m). Forty-seven (65%) patients carried a BRCA1 mutation and 25 (35%) a BRCA2 mutation--mostly frameshift mutations causing a premature stop. Overall survival (OS) did not depend on the mutated gene and was longer in the BOC group compared to the OC only group (168m vs. 65m, p<0.00001).

Conclusion

We describe the largest Italian cohort of BRCA mutation carriers with BOC. Most patients carried a BRCA1 mutation. BC more often preceded OC diagnosis. OS analysis suggests that patients with BOC live longer.
Cisplatin hyperthermic intraperitoneal chemotherapy (HIPEC) has been evaluated in the first phase-I dose escalation trial (CHIPASTIN, NCT02217956) to identify the recommended dose of cisplatin for HIPEC at complete cytoreductive surgery after neoadjuvant carboplatin-paclitaxel. The observed cisplatin-related renal toxicity has raised the questions of the choice of cisplatin. The aim of this study was to evaluate pharmacokinetic factors that could be used to predict renal toxicities after HIPEC.
The clinical and pharmacokinetic characteristics of patients are summarized in Table 1.

<table>

<td>Clearance IP (L/h)</td>
<td>4.53 (2.51 - 21.00)</td>
</tr>
</tbody>
</table>

Table 1. AUC: area under the curve (mg of platin.L/h).

The 8-week creatinine clearance was significantly associated with its baseline value (p=0.015) and the diuresis before HIPEC (p=0.013). No pharmacokinetic factors have been kept in the final multivariate model.

Conclusion

Our results suggest that cisplatin-related renal toxicities can’t be predicted by pharmacokinetics and support to avoid cisplatin in HIPEC for ovarian cancer.
OVARIAN CANCER

ESGO7-1112

CLINICAL SIGNIFICANCE OF CA125 VALUES AFTER PRIMARY TREATMENT IN SURVIVAL OF PATIENTS WITH OVARIAN CANCER

S.W. Byun¹, H.K. Jang², T.C. Park¹
¹Uijeongbu St Mary’s hospital - Catholic University Medical College, obstetrics and gynecology, Uijeongbu-si- Gyeonggi-do, Republic of Korea
²National Cancer Center Korea, obstetrics and gynecology, Goyang-si Gyeonggi-do, Republic of Korea

Aims

To determine cancer antigen 125 (CA125)-related prognostic factors for epithelial ovarian cancer (EOC) and to identify cut-off values that distinguish patients with poor prognosis from those with a good prognosis.

Method

We included 166 patients who received staging laparotomy and were diagnosed with stage I–IV serous EOC at a single institution from 2009 to 2015. Multivariate Cox regression analysis was used to determine the prognostic significance of serum CA125 after the third and sixth cycles of chemotherapy; relative percentage change in CA125 levels after the third and six cycles of chemotherapy compared to baseline CA125; and the total sum of CA125 levels after each chemotherapy cycle after adjusting for clinicopathological variables.

Results

CA125 level <35 U/mL \( (p = 0.0136) \) after three cycles of chemotherapy was an independent predictor of overall survival (OS). The total sum \( (p = 0.0162) \) of CA125 levels after each chemotherapy cycle was an independent predictor of progression-free survival (PFS). CA125 level <7 U/mL after the sixth chemotherapy cycle was an independent prognostic factor for OS \( (p = 0.016) \) and PFS \( (p = 0.0004) \).

Conclusion

CA125 level <7 U/mL after the sixth chemotherapy cycle was a significant predictor of both OS and PFS independent of stage, cell type, grade, or baseline CA125 level.

M2 PYRUVATE KINASE EXPRESSION IN OVARIAN CANCER
F.J. Candido dos Reis¹, A. Poersch², C.B. de Sousa¹, A.C. Marchessini de Camargo¹, D.G. Tiezzi¹, V.M. Faça³, J.M. de Andrade¹
¹Ribeirão Preto Medical School, Gynecology and Obstetrics, Ribeirão Preto, Brazil
²Ribeirão Preto Medical School, Biochemistry, Ribeirão Preto, Brazil
³Ribeirão Preto Medical School, Biochemistry, Ribeirão Preto, Brazil

Aims

Our aim is to describe the identification of M2 pyruvate kinase (M2PK) in high grade serous ovarian cancer (HGSOC) through differential proteomic analysis.

Method

We performed proteomic analysis in a pool of HGSOC tumor fluid (n=10) and in a pool of benign ovarian serous cystadenoma fluid (n=10). After, we validated the M2PK expression by ELISA EDTA-Plasma Test (ScheBo® Biotech AG) in HGSOC fluids (n=14) and serous cystadenoma (n=13), and by immunohistochemistry in 87 serous ovarian malignant tumors.

Results

Nineteen percent of M2PK cover sequence was identified in the proteomic analysis of HGSOC tumor fluid pool. In ELISA test, M2PK concentration was 169.4 UI (27.78 - 206.44) in malignant fluids and 25.82 UI (1.27 - 164.0) in benign ones (p<0.0001). In the IHC analysis, cytoplasmic positivity of M2PK was higher than 10% in 91% of serous ovarian tumors (Figure 1).

Conclusion

Differential proteomic analysis allowed the identification of M2PK as a highly expressed protein in serous ovarian cancer. This data warrants further investigation of metabolic pathways as potential target for treatment of women with HGSOC.

PERFORMANCE OF HE4, CA-125, ROMA, IOTA-LR2, ANDEX, RMI AND COPENHAGEN INDEX TO DETERMINE RISK OF MALIGNANCY OF ADNEXAL MASSES

N. Carreras Diéguez¹, M. Ángeles¹, P. Fusté¹, B. Gil¹, M. del Pino¹, P. Jaume¹, R. Molina², A. Torné¹
¹Hospital Clínic de Barcelona, Gynecology-Obstetrics and Neonatology, Barcelona, Spain
²Hospital Clínic de Barcelona, Biomedical Diagnostic Center, Barcelona, Spain

Aims

To study the diagnostic accuracy of several models (ROMA, IOTA-LR2, ADNEX, RMI, Copenhagen) and biomarkers (CA-125, HE4) to assess the risk of malignancy of adnexal masses.

Method

Retrospective study including a cohort of women who underwent surgery for adnexal masses in our centre. Patient data (age, menopausal status, ultrasound features, serum markers) was collected to calculate studied indexes. According to histological findings, the main outcome was defined as presence of malignant tissue in removed masses. We plotted ROC curves and AUC for CA-125, HE4, ROMA, IOTA-LR2, ADNEX, RMI and Copenhagen. Sensitivity and specificity for such indexes were calculated for different cutoff points, as for a combination of ROMA and IOTA-LR2 models (considering high risk of malignancy patients with ROMA>15 or IOTA-LR2>15).

Results

835 patients were included: 674 women had benign or borderline masses, while 161 had malignant disease. Isolated ADNEX and IOTA-LR2 models showed higher AUC (table 1) and sensitivity (92.5%, 95%CI: 87.1-95.8% and 94.5%, 95%CI: 89.5-97.2% respectively), but higher specificity was found for RMI (96.3%, 95%CI: 94.3-97.5%) and HE4 (95.5%, 95%CI: 93.4-96.9%, at cutoff 120). When combining IOTA-LR2 and ROMA, maximum sensitivity was achieved (96.2%, 95%CI: 91.9-98.2%).

MIRNA181A-5P EXPRESSION AS A BIOMARKER OF TGFβ PATHWAY ACTIVATION ASSOCIATED WITH ONCOLOGIC OUTCOME AND TUMOR DIFFUSION IN HIGH GRADE SEROUS EPITHELIAL OVARIAN CANCER

L. Ceppi1,2, S. Palazzi1, C. Romualdi2, P. Dilorenzo1,2, T. Grassi1,2, E. Biagioli3, L. Paracchini4, R. Milani1,2, A. Buda2, M. D’Incalci4, S. Marchini4, R. Fruscio1,2

1University of Milano-Bicocca, Department of Medicine and Surgery, Piazza dell’Ateneo Nuovo 1- 20126 Milan, Italy
2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33- 20900 Monza, Italy
3University of Padova, Department of Biology, Via U. Bassi 58/b- 35121 Padova, Italy
4Istituto di Ricerche Farmacologiche “Mario Negri” - IRCCS, Department of Oncology, Via La Masa 19- 20156 Milan, Italy

Aims

activation of TGFβ pathway in advanced epithelial ovarian cancer has been found to be a predictor of residual tumor and survival. miRNA181a-5p expression in EOC has been identified as a stable readout of TGFβ activation, here further analyzed as outcome biomarker.

Method

a consecutive series of high grade serous EOC (HGSEOC) from the snap-frozen ‘Pandora’ tumor tissue biorepository (2004-2012) has been included for miRNA analysis with relative real time-PCR. Tumor diffusion was categorized using an established semi-quantitative disease score (DS). The prognostic value of miRNA181a-5p was analyzed using a Cox proportional-hazards regression model; non parametric tests to analyze the association between mRNA 181a-5p and clinical features were used.

Results

84 HGSEOC patients with a median follow-up of 50.7 months entered the study. Using Cox proportional-hazards regression model an optimized threshold of miR181a-5p expression to group patients according to their prognosis was identified (miR-low and miR-high), with progression free survival (PFS) of 20.9 v. 9.6months[Hazard Ratio(HR)=2.451 (1.454-4.133), p:0.0008] and overall survival (OS) of 60.3 v. 23.3months[Hazard Ratio(HR)= 2.812 (1.632 - 4.847), p:0.0008], respectively. High DS grouped the highest miRNA181a-5p expressors. Residual tumor >1cm was significantly related to high miRNA181a-5p expression (p:0.041, p:0.029).

In multivariate Cox proportional-hazards regression models DS high and miR-high were related to worse PFS[HR2.95 (95%CI1.65-5.29), p=0.0002];[HR=2.31 (95%CI1.05-5.13), p=0.036]; miR-high also negatively affected OS [HR=2.18 (95%CI1.22-3.89), p=0.007].

Conclusion

miR181a-5p confirms to be a reliable prognostic biomarker associated to PFS and OS in HGSEOC. Thus, a prospective validation of its role is urgently needed. A translational ancillary study has been designed to the TRUST trial (NCT # 02828618).

ESGO7-0028

adolescent ovarian epithelial cancer

N. Mondal, T. Chatterjee, R. Roychowdhuri, B. Chakraborti

1SGCC&RI, Gyne-oncology, kolkata, India

Aims

Aim is to assess the prevalence of ovarian epithelial cancer in adolescents & analyse the epidemiology, clinical features, histopathology, treatment & disease free survival.

Method

Retrospective study of hospital records of a tertiary oncology centre from 1996-2015. Total gynecologic new registration was 17020.

Ovarian malignancy was 2008 (11.7%). 94 cases were between 0-19 yrs (4.6%), 83 were between 10-19 yrs. 17 cases of ovarian epithelial malignancy were in adolescents (20.48%).

Epidemiology eg. age, religion, education, socio-economic status, age of menarche, geographical region, nutrition, clinical features, imaging, markers, histopathology, treatment offered were analysed.

Results

Epidemiology:

a) Age: 10-14 yrs = 4 cases, 15-19 yrs = 13 cases.
b) Religion: Hindu = 10 cases, Muslim = 6 cases, Buddhist = 1 case.
c) Menarche was normal in all cases.
d) Education: Illiterate = 3 cases, 10 yrs or below = 9 cases, 10-12 yrs = 4 cases, 12-14 yrs = 1 case.
e) Nutrition: All in low socio-economic group with poor nutrition.
f) Geographical area: Local = 3 cases, Adjacent districts = 6 cases, International = 5.

Clinical features: Pain & abdominal swelling were the commonest features with palpable abdominal mass.

There was concomitant tuberculosis in 2 cases. Only 3 cases had USG & CT scan possible. 9 cases had CA125 done, it was raised in 4, but normal in 5.

Treatment: 13 patients had surgery, fertility preserving in 9 & radical surgery in 4 cases. 11 had adjuvant chemotherapy.

Histology:

Papillary serous = 8 cases, Mucinous adenocarcinoma = 7, Borderline = 1, Clear cell = 1.

Conclusion

Ovarian malignancy is a disease of the elderly and is epithelial in almost 90%, of which 60% is highly aggressive serous papillary variety. In adolescents most ovarian malignant tumours are Germ cell tumours. Epithelial malignancy is rare before menarche & only 20% is in adolescents. Papillary & mucinous are almost in equal proportions. Primary surgery is usually recommended but fertility preservation needs serious consideration.

Selection of chemotherapy is also important, aiming to preserve ovarian reserve. Most of the patients being students fail to come for follow up if they are well. We lost 1 case of generalised carcinomatosis (clear cell type) 18 months after laparotomy. Parents refused chemotherapy. 3 patients came for follow-up, 1 alive & well for 16 yrs, 1 for 5 yrs & 1 for 2 yrs.

9Gynaekologische Onkologie, Gynäkologisches Zentrum, Bonn, Germany
10Onkologische Tagesklinik und Ambulanz, Department of Gynecology- University Hospital, Tuebingen, Germany
11Department of Gynecology, University of Dresden, Dresden, Germany

Aims

For ovarian cancer (OC) patients with platinum-sensitive recurrence the addition of new biologic agents to chemotherapy may improve survival. Panitumumab is a fully human monoclonal antibody specific to the epidermal growth factor receptor (EGFR). The purpose of this trial was to investigate the therapeutic efficacy of panitumumab in the combination with carboplatin-based chemotherapy in relation to the respective standard combination in patients with a KRAS wildtype with platinum-sensitive recurrent ovarian cancer (NCT01388621).

Method

Only patients with platinum-sensitive epithelial ovarian/ fallopian/ peritoneal cancer, measurable disease or elevated CA125 and with KRAS wild type and no more than 2 prior treatments were registered for this study. Therapy included Carboplatin AUC4/Gemcitabine 1000 mg/m² or Carboplatin AUC5/PLD 40 mg/m² and randomized to panitumumab 6 mg/kg day 1 and day 15, every 3 or 4 weeks. Tumor assessment was performed at baseline and at every third cycle according to CT-scan and CA-125 criteria.

Results

In this multi-institutional phase II trial 102 patients were randomized and 96 enrolled for the final analysis. Progression-free survival in the intention-to-treat population (N=96) was 9.5 vs. 10.7 months (HR 0.829, 95%CI of 8.5-11.6 months vs 8.5-13.1 months) for the experimental vs. standard arm, p=0.45. Data of overall survival are not yet evaluable. The most common treatment related grade 3+ toxicities included hematologic toxicity (54%), skin reactions (18%) and gastrointestinal events (16%).

Conclusion

Addition of panitumumab to platinum-based chemotherapy for recurrent ovarian cancer does not influence efficacy and progression-free survival in platinum sensitive patients, while no new additional toxicity aspects for panitumumab were evaluated.

²Department of Gynecology, Städtisches Klinikum, Karlsruhe, Germany
³Onkologische, Gemeinschaftspraxis, Nordhorn, Germany
⁴Department of Gynecology, Klinikum Kassel, Kassel, Germany
⁵Onkologische, Praxis, Stolberg, Germany
⁶Onkologische, Praxis, Leer, Germany
⁷Department of Gynecology, Friedrich Schiller University, Jena, Germany

Aims

Ovarian cancer (OC) is one of the most deadly cancers affecting women. Evidence about optimal treatment strategies in recurrent disease, is limited. According to experience in late therapy lines, the sensitivity of the tumor to chemotherapy decreases, but an efficient therapy is strongly related to a good tolerability of the treatment and a high patient compliance. Therefore it is essential to investigate any parameters that might lead to an early treatment discontinuation in order to support a better compliance and patient outcome even in late lines and under real life conditions.

Method

The primary objective of this non-interventional study is to identify parameters related to non-compliance in Treosulfan therapy (p.o. or i.v.) and to calculate a predictive score for non-compliance. Patients of all ages and with different co-morbidities could be included. Secondary end-points are preference (p.o. or i.v.), efficacy and tolerability. The question, if compliance is influenced by the decision maker of i.v or p.o. application – patients themselves, physician or both together – is of special interest. Clinical examinations will be done in the daily practice of the center and additional questionnaires concerning experiences with former therapies, disease specific symptoms (MOST questionnaire), and questions concerning belief in alternative medicine and complementary therapy.

Results

The study initiated in late 2016 will report first preliminary results.

Conclusion

There is an essential interest to investigate any parameters that might lead to an early treatment discontinuation in order to support a better compliance and patient outcome even in late lines and under real life conditions.

MELATONIN SUPPRESSES THE GROWTH OF OVARIAN CANCER CELL LINES (OVCAR-429 AND PA-1) AND POTENTIATES THE EFFECT OF G1 ARREST BY TARGETING CDKS

Y.C. Chen¹, C.J. Shen¹, W. Ching-Hu²
¹Kaohsiung Medical University Hospital, Gynecology/Obstetrics, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Medical University Hospital, Gynecology and Obstetrics, Kaohsiung, Taiwan R.O.C.

Aims

Melatonin is found in animals as well as plants. In animals, it is a hormone that anticipates the daily onset of darkness and regulates physiological functions, such as sleep timing, blood pressure, and reproduction. Melatonin has also been found to have anti-tumor properties. Malignant cancers are the most common cause of death, and the mortality rate of ovarian tumor is the highest among gynecological diseases.

Method

This study investigated the anti-tumor effects including cell proliferation, apoptosis and cell cycle of melatonin on the ovarian cancer lines, OVCAR-429 and PA-1.

Results

We observed the accumulation of melatonin-treated cells in the G₁ phase due to the down-regulation of CDK 2 and 4. Our results suggest that in addition to the known effects on prevention, melatonin may also provide anti-tumor activity in established ovarian cancer.

Conclusion

Our findings highlight the role of melatonin in the inhibition of tumor growth through the delay of G1/S through the down-regulation of CDK2 and 4 in OVCAR-429 and PA-1 cell lines. This is the first study to demonstrate that the down-regulation of CDKs may at least partly explain the anti-cancer effects of melatonin against human ovarian cancer. This study provides one possible therapeutic strategy for the treatment of advanced ovarian cancer.

EXPLOITING VULNERABILITIES IN OVARIAN CANCER BY TARGETING PROTEIN HOMEOSTASIS

J. Chien¹

¹University Of Kansas Medical Center, Cancer Biology, Kansas City, USA

Aims

Recent genome-wide shRNA screens identified Valosin-containing protein (VCP) or p97 as an ovarian cancer lineage-specific essential gene. p97 is an AAA-ATPase protein and regulates protein homeostasis. The aims of this study is to evaluate the therapeutic potential of targeting p97 in ovarian cancer.

Method

Cytotoxicity assays, immunoblots, and caspase activity were used to assess the cytotoxic effect and signal transduction induced by p97 inhibitors DBeQ, ML240, and CB-5083.

Results

We show that all three inhibitors induce cytotoxicity in high-grade serous or clear cell ovarian cancer cell lines. These agents induce unfolded protein response (UPR), cell cycle arrest at G1, and subsequent cell death mediated by both intrinsic and extrinsic apoptotic pathways. The effect of p97 inhibitors can be enhanced by salubrinal, a compound that inhibits GADD34 and disrupts adaptive UPR. The effect of these inhibitors can also be enhanced by mifepristone, a steroidal antagonist to progesterone that induce ER stress. Finally, we generated CB-5083 resistant cell lines, and DNA sequence analysis indicates resistant cells harbor mutations in p97, demonstrating the target specificity of CB-5083. However, these cells are sensitive to another p97 inhibitor, ML240. Molecular docking analysis indicates CB-5083 and ML-240 bind to different regions in p97 and that mutations found in CB-5083 resistant cells potential disrupt the binding of CB-5083 but not ML-240.

Conclusion

p97 inhibitors represent novel therapeutic candidates in ovarian cancer. Mutations in p97 result in resistance to p97 inhibitors. However, resistance to a specific p97 inhibitor could be overcome by another p97 inhibitor.

THE ROLE OF USP10 IN EPITHELIAL OVARIAN TUMORS
H. Cho1, D.B. Chay2, J.Y. Chung3, S.M. Hewitt4, J.H. Kim1
1Gangnam Severance Hospital - Yonsei University College of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
2Yongin Severance Hospital, Department of Obstetrics and Gynecology, Yongin, Republic of Korea
3National Institutes of Health, Laboratory of Pathology, Bethesda, USA

Aims

Ubiquitin-specific protease 10 (USP10), a deubiquitinating enzyme, has been pronounced in malignancies. However, the role of USP10 in epithelial ovarian cancer has not been elucidated yet. Here, we investigated the expression and clinical significance of USP10 in ovarian cancer.

Method

Immunohistochemical analyses of USP10 and p14ARF were performed using tissue microarray analysis of 336 ovarian tumors and compared the data with clinicopathologic variables, including the survival of ovarian cancer patients. We also examined USP10 and p14ARF methylation near the putative transcriptional start site (TSS) in the 5' CpG islands of the genes in ovarian cancer cells and fresh frozen tissues.

Results

USP10 and p14ARF expression was significantly decreased in ovarian cancer than normal ovarian epithelium (both \( p<0.001 \)). Immunoreactivity significantly correlated with tumor stage (USP10, \( p<0.001 \)) and tumor grade (p14ARF, \( p=0.007 \)). USP10 expression showed strong positive correlation with that of p14ARF (Spearman's rho = 0.430, \( p < 0.001 \)) in cancer patients. Using cox proportional hazards model, low USP10 expression [HR=3.77 (95% CI, 1.65–8.60), \( p=0.002 \)] and a combined USP10-/p14ARF- expression [HR=4.35 (95% CI, 1.58–11.90), \( p = 0.005 \)] were the independent prognostic factors. Methylation specific PCR analysis showed that the USP10 and p14ARF CpG island was highly methylated in cancer tissues (62% and 87%, respectively) and cells (both 95%) and at lower percentages in normal tissues (3% and 13%, respectively).

Conclusion

Low expression of USP10 or combined USP10/p14ARF is an indicator of bad prognosis in ovarian cancer, suggesting their potential utility as prognostic tests in clinical assessment.
COMPARISON OF HE4, CA125, AND RISK OF OVARIAN MALIGNANCY ALGORITHM IN THE PREDICTION OF OVARIAN CANCER IN KOREAN WOMEN

H.Y. Cho1, P. Sung-ho2

1Dongtan Sacred-heart Hospital, Obstetrics and Gynecology, Hwasung, Republic of Korea
2Kangnam Sacred Heart Hospital, OBGY, Seoul, Republic of Korea

Aims

This study is a multi-center clinical study, which aimed to compare CA125, HE4, and risk of ovarian malignancy algorithm (ROMA) in predicting epithelial ovarian cancer of Asian women with a pelvic mass.

Method

Prospectively, serum from 90 Korean women with ovarian mass was obtained prior to surgery. For control group, serum from 79 normal populations without ovarian mass was also obtained. The HE4 and CA125 data were registered and evaluated separately and ROMA was calculated for each sample.

Results

Total 67 benign tumors and 23 ovarian cancers were evaluated. Median serum levels of HE4 and CA125, and ROMA score were significantly higher in patients with ovarian cancer than those with benign ovarian tumor and normal population (P < 0.0001). In ROC curve analysis for women with a pelvic mass, area under the curve (AUC) for HE4 and ROMA was higher than CA125. Statistical differences in each study compared to CA125 were marginal (P compared to CA125; 0.0818 for HE4 and 0.0690 for ROMA). Sub-analysis revealed that AUC for HE4 and ROMA was higher than AUC for CA125 in post-menopausal women with a pelvic mass, but there were no statistically significant differences (P compared to CA125; 0.1598 for HE4 and 0.1273 for ROMA).

Conclusion

Our data suggested that both HE4 and ROMA score showed better performance than CA125 for the detection of ovarian cancer in women with a pelvic mass. HE4 and ROMA can be a useful independent diagnostic marker for epithelial ovarian cancer in Korean women.
EXPRESSION PATTERNS OF NRF2 AND KEAP1 IN OVARIAN CANCER CELLS AND THEIR PROGNOSTIC ROLE IN DISEASE RECURRENCE AND PATIENT SURVIVAL

H.Y. Cho

1Dongtan Sacred-heart Hospital, Obstetrics and Gynecology, Hwasung, Republic of Korea

Aims

This study evaluated the expression patterns of nuclear factor erythroid 2-related factor 2 (Nrf2) and Kelch-like ECH-associated protein 1 (Keap1), and assessed their clinical value as prognostic indicators in ovarian cancer.

Method

The expression patterns of Nrf2 and Keap1 were determined in 100 epithelial ovarian cancers by immunohistochemistry analyses. The associations of Nrf2 and Keap1 expression with clinicopathological characteristics of patients were evaluated. All patients received platinum-based chemotherapy. Chemoresistance was defined as recurrence within 6 months of first-line chemotherapy.

Results

Cytoplasmic expression of Nrf2 and Keap1 was observed in 95% and 72%, respectively, of all 100 epithelial ovarian cancers examined. Low Keap1 expression (intensity<1) was strongly associated with disease recurrence ($P=0.046$) and death ($P=0.002$). Chemoresistance was associated with high Nrf2 expression (intensity=3) ($P=0.833$, HR 1.202, 95% CI 0.217-6.667) and low Keap1 expression ($P=0.862$, HR 0.899, 95% CI 0.270-2.994). However, these associations were not statistically significant. Survival analysis indicated that high Keap1 expression (intensity≥1) was strongly predictive of better overall survival ($P=0.049$) and disease-free survival ($P=0.004$). Cox’s regression analysis indicated that Keap1 expression was an independent prognostic factor for overall survival ($P=0.012$, HR 0.349, 95% CI 0.153-0.797). Although patients with high Nrf2 expression displayed better overall survival and disease-free survival, the association was not statistically significant.

Conclusion

High cytoplasmic Keap1 expression, which might prevent nuclear translocation of Nrf2 in ovarian cancer cells, was associated with lower disease recurrence and death rate. Survival analysis suggested a probable role of Keap1 expression in predicting the prognosis of ovarian cancer.
A TAILORED STRATEGY USING CA125 AND HE4 STRATIFIED BY MENOPAUSAL STATUS FOR DIFFERENTIATING BENIGN AND MALIGNANT ADNEXAL TUMORS

B.G. Kim1, H.J. Choi1, D.S. Bae1

1Samsung medical center, Obstetrics and gynecology, Seoul, Republic of Korea

Aims

This study aimed to compare the diagnostic performances between CA125 alone and a combination of CA125 and HE4, and to tailor the combination method using CA125 and HE4 for Korean women with ovarian tumors.

Method

We enrolled 327 epithelial ovarian cancer (EOC) patients and 322 benign ovarian tumor patients. In this study, we used the risk of ovarian malignancy algorithm (ROMA) and the simple dual-marker method (DualM) as combination methods. DualM identified a result as positive when either CA125 or HE4 was higher than the cut-off. Optimized cut-off values for tumor markers were evaluated according to patient menopausal status.

Results

The optimized cut-off values of CA125, HE4, and ROMA were 89.6 U/ml, 53.7 pmol/L, and 11.1% in premenopausal women (PreMP) respectively. In PreMP, DualM and ROMA yielded higher sensitivity (SN) than CA125, but the opposite trend was seen for specificity (SP) (CA125: SN=61.3% and SP=94.7%, DualM: SN=78.7% and SP=88.9%, ROMA: SN=70.7% and SP=92.2%). In PostMP patients, the optimized cut-off values for CA125, HE4, and ROMA were 23.4 U/ml, 64.3 pmol/L, and 25.3%, respectively. DualM yielded improved SN without decreasing SP in PostMP compared with CA125 alone. ROMA did not yield improved performance compared with CA125 alone (CA125: SN=85.3% and SP=94.9%, DualM: SN=90.5% and SP=88.5%, ROMA: SN=85.3% and SP=97.4%).

Conclusion

DualM performed better than CA125 alone in PostMP patients by increasing sensitivity via optimized cut-off values.

PULMONARY TYPE SMALL CELL CARCINOMA ARISING IN A MATURE CYSTIC TERATOMA OF THE OVARY: A CASE REPORT

K.U. Choi1, Y.K. Kim1, S.J. Lee1, A. Kim1, D.Y. Park1, G.Y. Huh1, C.H. Lee1

1Pusan National University Hospital, Pathology, Busan, Republic of Korea

Aims

Small cell carcinoma arising from a mature cystic teratoma (MCT) in ovary is extremely rare.

Method

A 74-year-old woman had a large ovarian cystic mass incidentally discovered by abdomen ultrasonography. An investigation of her tumor marker levels showed that serum CA125 level was slightly elevated. Bilateral salpingo-oophorectomy, total hysterectomy and omentectomy were performed.

Results

The resected ovarian mass showed a multilocular cystic lesion, measuring 14x13x10 cm and containing sebum and dark brown fluid. At the periphery, a 4.7x4.5 cm solid nodule was noted. Histologically, the tumor cells were closely packed and displayed neuroendocrine morphologies in a solid nodule and MCT was observed in the background. Immunohistochemical staining revealed positive staining for EMA, CDS6 and synaptophysin, focal positive staining for pan-cytokeratin and WT1, but negative for TTF-1, CK20, a-inhibin and chromogranin A.

Conclusion

The tumor was compatible with pulmonary type small cell carcinoma arising in a MCT presented as stage IA with 51 months survival after surgery.
HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC) A PROMISING TREATMENT FOR RELAPSED INTRAPERITONEAL OVARIAN CANCER. CHIPOR AN ONGOING PHASE III, EUROPEAN MULTICENTRIC RANDOMIZED TRIAL.

14Institut Bergonié, Surgery, Bordeaux, France
15Centre Hospitalier Universitaire, Surgery, Clermond Ferrand, France
16Centre Hospitalier Universitaire Hospices Civils, Surgery, Lyon, France

Aims

OBJECTIVE:

The majority of patients with advanced ovarian cancer relapse, often evolving towards peritoneal carcinosis. Prospective series of secondary surgery with Hyperthermic Intraperitoneal Chemotherapy (HIPEC) have shown an increase in overall survival. HIPEC requires scientific validation in a randomized trial. CHIPOR (Chemotherapy and HIPEC for Ovarian cancer Relapse) aims to assess HIPEC impact on OS in patients with ovarian cancer first relapse.

Method

This prospective multicentric randomized phase III trial compares SCS with or without HIPEC (cisplatinum, 75mg/m², 42°C during 1 h), after at least 6 cycles of second-line platinum based chemotherapy. Patients are randomized during surgery. Primary objective is to improve OS by one year, which requires 444 patients. A pharmacokinetic study will allow the first comparison of open to closed HIPEC techniques.

MAIN INCLUSION CRITERIA

- Patient with intraperitoneal first epithelial ovarian cancer relapse (more than 6 months after the end of the initial treatment), resectable without distant metastasis
- Second-line platinum-based pre-operative chemotherapy
- Complete cytoreductive surgery

MAIN NON-INCLUSION CRITERIA

- Known hypersensitivity to cisplatin,
- More than 2 segmental digestive resections concomitant to HIPEC,
- Any progressive disease during the second-line chemotherapy),
- Patient who has already been treated by HIPEC

Results

Currently 22 sites are open in France, 1 in Spain and 1 in Belgium. 10 Institutions have included more than 10 patients. At the end of April 2017, 265 patients had been included.

Conclusion
CHIPOR is an innovative ongoing European trial aiming to assess the impact of HIPEC on overall survival, for patients with a first relapsed ovarian cancer.
Aims

To evaluate the differences in clinical presentation, treatment and prognosis in patients affected by ovarian cancer, based on the presence or absence of the germ-line BRCA mutation.

Method

Retrospective study on 204 patients treated for ovarian epithelial cancer between 2010 - 2015. The variables were: germline BRCA mutation, histology, FIGO stage, primary treatment, response to neoadjuvant chemotherapy (NACT), disease free interval (ILT), and overall survival (OS).

Two cohorts based on the presence of mutation: BRCA (n = 34) and NON - BRCA (n = 170) with statistical study to assess differences.

Results

The BRCA group showed a higher frequency of serous type, and incipient stages at diagnosis, without significance.

Differences were observed in primary treatment and overall survival between both groups. The BRCA group was treated with primary surgery (p = 0.001) and presented significantly higher OS (p = 0.02).

Considering only advanced stages (III - IV), the serous type was equalized in both groups, constituting 95% of the cases. Significant differences were maintained in primary surgical treatment (p = 0.001) and OS (p = 0.011).

Evaluation of patients undergoing NACT showed a significantly higher pathological response in the BRCA group (p = 0.025).

Lower percentage of relapses in BRCA group, but ILT no differences in both groups.

Conclusion

In our sample, we verified that patients with germ-line BRCA mutation-bearing ovarian cancer are operated primarily, have a better response to NACT and greater OS than non-mutated ones.
CLEAR CELL CARCINOMA: IS STAGING SURGERY NECESSARY?
M.T. Climent¹, M.D. Martí Cardona¹, M. Barahona Orpinell¹, M.J. Pla Farnós¹, J. Rovira Montane¹, J. Ponce Sebastià¹
¹Bellvitge University Hospital, Gynecology, Barcelona, Spain

Aims
To determine the impact of staging surgery on clear cell tumors clinically and radiologically limited to ovaries.

Method
Retrospective study of 63 cases of ovarian cancer (18.2% of all ovarian cancers) treated in our center over a period of 15 years.
The variables evaluated: Peritoneal extension of the disease, lymph node involvement, global survival (OS) and type of relapse.

Results
In our sample, 57.1% (n = 36) presented clinically a disease limited to the ovaries (classification TNM: T1). A 42.9% were classified as T2 and T3.

Lymph node involvement was detected in 3 cases (9.1%) in T1 patients, increasing in T2 and T3 to 50% with significant differences (p = 0.002).

The classification of patients in T1 presented a greater correlation with the overall survival (p < 0.0001), against patient in T2 and T3. The detection of nodal involvement in these patients (T1) shows no change in overall survival.

Patients with nodal involvement are not correlated with type of relapse.

Conclusion
In our sample, it is evident that in patients with clear ovarian cell tumor limited to one or two ovaries (T1), staging surgery does not modify subsequent treatment or OS. Therefore, the possibility of not performing staging surgery in T1 patients, currently accepted by extrapolation of the results obtained from serous ovarian cancer, is considered.

RANDOMIZED, NON-COMPARATIVE, PHASE II TRIAL OF BEVACIZUMAB AND TRABECTEDIN WITH OR WITHOUT CARBOPLATIN IN PARTIALLY PLATINUM-SENSITIVE OVARIAN CANCER (ROC) WOMEN

N. Colombo¹, M.O. Nicoletto², A. Lissoni³, G. Scambia⁴, G. Tognon⁵, E. Negrif, F. Gallif, E. Biagioli⁶, E. Rulli⁶, R. Fossatif, M. D’Incalci⁶

¹IEO - European Institute Of Oncology, Gynecologic Oncology, Milano, Italy
²Instituto Oncologico Veneto- IOV-IRCCS, Oncology, Padova, Italy
³Ospedale S. Gerardo, Oncology, Monza, Italy
⁴Ospedale Policlinico Gemelli, Oncology, Roma, Italy
⁵Università' degli Studi di Brescia, Oncology, Brescia, Italy
⁶IRCCS Istituto di ricerche farmacologiche Mario Negri, Oncology, Milan, Italy

Aims

Trabectedin interferes with cancer cells division and decreases the number/function of tumor-associated macrophages (TAMs). Since TAMs produce several angiogenic factors, trabectedin might be synergistic with bevacizumab.

Method

Women with disease progression between 6-12 months since the last 1st/2nd line platinum-based therapy were randomized to Arm-A (trabectedin 1.1 mg/m² and bevacizumab 15 mg/kg q3w) or Arm-B (carboplatin AUC-4 plus trabectedin 0.8 mg/m² and bevacizumab 10 mg/kg q4w). In both arms responding patients from Cycle 7 onward could continue with trabectedin and bevacizumab until progression as in Arm-A. The study would open to the second-stage accrual if 7 and 13 of the first 17 patients in Arm-A and 8 and 13 patients in Arm-B remain progression-free at 6 months and without severe toxicities (primary end-points), respectively.

Results

In Arm-A and Arm-B, 11/17 and 14/17 patients remained progression-free at 6 months and achieved a median PFS of 9.4 and 23.1 months, respectively. At 6 months, 14 patients in Arm-A and 11 patients in Arm-B remain without severe toxicities. In Arm-B, 4 patients had grade 4 thrombocytopenia, 2 had grade 4 neutropenia, and 5 had hypersensitivity reaction to carboplatin. Despite this severe myelotoxicity, 11/12 patients without hypersensitivity reaction were able to complete 6 cycles after dose adjustment.

Conclusion

The combination of trabectedin/bevacizumab+carboplatin is highly effective in ROC. Arm-A completed second-stage accrual and the mature results on safety and efficacy will be presented. Arm-B did not meet the toxicity criteria to access second-stage accrual, but its remarkable median PFS of 23.1 months warrants further study with adapted schedules.

SYSTEMATIC PELVIC AND PARA AORTIC LYMPHADENECTOMY IN ADVANCED EPITHELIAL OVARIAN CARCINOMA: EXPERIENCE FROM A TERTIARY REFERRAL CENTRE IN EASTERN INDIA

R. Dasgupta 1, J. Bhaumik 1, B. Chakraborti 1, A. Ghosh 1, A. Mukhopadhyay 1

1 Tata Medical Centre, Gynaecological Oncology, Kolkata, India

Aims

To analyse the rate of lymph node positivity in advanced EOC patients undergoing Primary (PDS) and Interval (IDS) debulking surgery and correlate with disease recurrence.

Method

Retrospective observational study, carried out at Tata Medical Centre between September 2011 to December 2016. Demographic data was obtained from the Redcap database and hospital electronic medical records. Systematic pelvic and para aortic node dissection was carried out in all cases.

All patients were followed up until April 2017.

Results

221 patients with advanced EOC underwent PDS (n=70) or IDS (n=151). Demographic characteristics of the study population were as follows: median age 52yrs (20-71), BMI 24.8, high grade serous histology 193/221 (87.3%), median CA125 at presentation 856 IU/L (4-40,000), FIGO stage III (76.9%), FIGO stage IV (23.07%). Optimal cytoreduction was achieved in 90.82% patients.

Any lymph node positivity was observed in 44/70 (62.8%) cases of PDS and 56/151 (37%) cases of IDS. Table 1 illustrates the detailed distribution.

<table>
<thead>
<tr>
<th>NODAL SITE</th>
<th>PDS (node positive)</th>
<th>IDS (node positive)</th>
<th>Median No. of nodes retrieved</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pelvic</td>
<td>37/68 (54.4%)</td>
<td>57/144 (39.5%)</td>
<td>7 (0-30)</td>
</tr>
<tr>
<td>Para aortic</td>
<td>32/65 (49.2%)</td>
<td>71/143 (49.6%)</td>
<td>8 (0-34)</td>
</tr>
<tr>
<td>Any node positive</td>
<td>44/70 (62.8%)</td>
<td>56/151 (37%)</td>
<td></td>
</tr>
</tbody>
</table>

Complications related to lymph node dissection were as follows: vascular injury 11 (4.9%), lymphocele 6 (2.7%), chylous ascites 3 (1.3%).

Disease recurrence within 6 months of completion of primary treatment (platinum resistance) was seen in 20.4% (18/88) of node positive patients compared to 9.7% (11/113) in node negative patients who completed follow up.

Conclusion

Significant proportion of advanced stage EOC patients have lymph node involvement which persists even after neoadjuvant chemotherapy and is associated with higher incidence of platinum resistant recurrence.

ESGO7-0881

SURVIVAL IMPACT OF SURGICAL STRATEGY IN STAGE III OR IV EPITHELIAL OVARIAN CANCER

B. Delga¹, E. Lambaudie¹, G. Houvenaeghel², N. Andrieux², J.M. Classe²

¹Institut Paoli Calmettes, Department of Surgical Oncology, Marseille, France
²Institut de Cancerologie de l'Ouest, Department of Surgical Oncology - Centre René Gauducheau, Saint-Herblain, France

Aims

To evaluate the evolution of practices and the influence of surgical strategy on survival for patients with stage III or IV epithelial ovarian cancer (EOC).

Method

Prospective data collection in two french national cancer centers. Our analysis concerned clinicals information, completeness of surgery, definitive pathology, Overall Survival (OS) and Disease Free Survival (DFS). Three surgicals strategies were compared: Primary Debulking Surgery (PDS), Interval Debulking Surgery (IDS) after 3 courses of neoadjuvant chemotherapy and Final Debulking Surgery (FDS) after at least 6 chemotherapy’s courses. We analysed 4 periods: <2000, 2000-2004, 2005-2009 and >2009.

Results

Median age at diagnosis was 61 (17-94). 1473 patients managed for FIGO stage III (80%) or IV (20%) EOC between 1985 and 2015 were included. We compared the 4 periods: The rate of non-operated patients increased (10,1% vs 22,6% p<0,001) between first and last period. Neoadjuvant chemotherapy increased from 20,1% to 52,2% (p<0,001). Complete resection rate increased from 37% to 66,2% (p<0,001).

For patients who underwent surgery, OS increased in case of complete resection (HR=2,123 CI95% [1,816 - 2,481] p<0,001) but time of surgery didn’t impact median OS (month): PDS 44,9; IDS 50,3; FDS 42 (p=0,410).

For patients with complete surgery, DFS was significantly shorter of 3 months in case of FDS compared to PDS (p<0,001).

Conclusion

A significative improvement of OS and DFS has been observed during our study in relation with complete resection rate. We did not observe any difference between PDS, IDS and FDS in term of OS but a reduction of DFS for FDS.
CARCINOID TUMOR OF THE OVARY: A CLINICOPATHOLOGIC STUDY OF 67 CASES
L. Deligdisch¹, D. Feingold², A. Mares³, M. Shafir²
¹Icahn School of Medicine at Mount Sinai,
Department of Pathology- Department of Obstetrics- Gynecology and Reproductive Science, New York, USA
²Icahn School of Medicine at Mount Sinai, Department of Surgery- Division of Surgical Oncology, New York, USA
³New York Medical College, Department of Pathology, Valhalla, USA

Aims
To correlate tumors’ pathological characteristics with clinical behavior and survival of patients diagnosed with ovarian carcinoid tumors, a rare group of ovarian neoplasms.

Method
Histologic slides of 67 cases of ovarian carcinoid tumors diagnosed at the Mount Sinai Hospital between 1994 and 2015, were reviewed and correlated with clinical outcomes.

Results
Of 67 patients, 29 had primary and 38 had metastatic carcinoids to the ovary. Primary tumors were unilateral in 93% cases, 66% were associated with ovarian teratoma, 22% were malignant (3 mucinous, 1 insular, 2 undifferentiated). Mean age was 48.7 years, overall survival was 86%. Carcinoid syndrome was present in one patient with malignant tumor. Metastatic tumors were bilateral in 72% cases, 82% were of gastrointestinal primary, of which 52% were from small bowel. Mean age was 53, overall survival was 50%. Carcinoid syndrome was present in 45%. Surgery was performed in 95% cases and 74% had adjuvant treatments. For the entire cohort, histologically severe cellular atypia was present in only 6 cases; immunoreactivity was positive for neurosecretory granules in all cases, p53 positive in one metastatic tumor, and Ki67 was relatively low in most cases.

Conclusion
The natural history of ovarian carcinoid (neuroendocrine tumors) is different, being more indolent than the common ovarian carcinomas. Carcinoid syndrome was far more common in the metastatic cases. The rather low-grade histologic features of carcinoid do not always correlate with the metastatic potential of the tumors and patients’ survival, requiring personalized therapeutic strategies.

MUCINOUS OVARIAN CANCER (MOC) : WHAT IS THE REPRODUCIBILITY OF THE WHO CLASSIFICATION?

C. Genestie1, A. Auguste2, S. Gouy3, P. Pautier4, A. Leary4, P. Morice5, M. Devouassoux-Shisheboran5

1Gustave Roussy Cancer Campus, Department of Pathology, Villejuif, France
2Gustave Roussy Cancer Campus, INSERM 981, Villejuif, France
3Gustave Roussy Cancer Campus, Department of Surgery, Villejuif, France
4Gustave Roussy Cancer Campus, Department of Medicine, Villejuif, France
5Hospices Civils de Lyon, Department of Pathology, Lyon, France

Aims

The WHO 2014 classification redefined the diagnostic classification of ovarian mucinous tumors: borderline mucinous tumor (BOM) and mucinous expansive (EA) and infiltrative (IA) adenocarcinoma.

Method

Retrospective study of 95 patients referred to the IGR for a borderline or malignant ovarian mucinous tumor from 1999 to 2016. All cases were reviewed by two gynecological pathologists (CG and MDS). Each pathologist interpreted the set of slides (from 1 to 4 HES per case) independently and was blinded to the interpretation of the other and to the clinical outcome of the patient.

Three types of pathological diagnoses were rendered: BOM, EA et IA. Grade of nuclear atypia and the presence of microinvasion were noted.

Results

Diagnosis was concordant between the 2 blinded independent pathologists for 87% of cases. Inter-observer diagnostic discordance was noted in 8 cases, mainly attributed to disagreement on IA vs EA with severe atypia (6/8). In 2 cases there was discordance on EA vs BOM.

Conclusion

The classification of mucinous tumors according to the WHO 2014 is difficult even for expert pathologists. The major difficulties are seen in separation of BOM from expansile adenocarcinoma. Also, the presence of severe atypia in an otherwise expansile type of invasion is interpreted differently between two pathologists (EA versus IA).

Nevertheless, it seems important to define more reproducible histological criteria for distinction of mucinous ovarian tumors between borderline and expansive adenocarcinomas in one hand and expansive and invasive adenocarcinomas in the other hand. This study is underway in the TMRO network organized in France.

A RARE CASE OF PRIMARY PERITONEAL AMYLOIDOSIS MIMICKING PRIMARY PERITONEAL CARCINOMA WITH MASSIVE ASCITES

M. Dolanbay¹, S. Daglitunçezdi¹, C.R. Cündübey¹, M. Ak¹, B. Özcelik¹, I.S. Serin¹
¹Erciyes University, Obstetrics and gynecology, Kayseri, Turkey

Aims

Amyloidosis is a rare systemic disease that occurs via extracellular deposition of insoluble protein (amyloid) in healthy tissues or organs, leading to their dysfunction. The clinical manifestations of amyloidosis depend on the type of insoluble protein as well as the location of amyloid deposits in tissues or organs. In the gastrointestinal tract, the small intestine is the most common site of amyloid deposits, whereas peritoneal involvement and ascites are rare.

Method

We report on a case of ascites and peritoneal thickening due to peritoneal amyloidosis. A 75-year-old patient was admitted to our institution due to abdominal massive ascites, peritoneal thickening, pulmonary congestion and respiratory distress mimicking primary peritoneal carcinoma. Due to the lack of ovarian mass we thought to perform primary diagnosis with peritoneal sampling and give neo-adjuvant chemotherapy according to histopathological examination. We drained peritoneal-pleural ascites by way of peritoneal cannula and directed patient to the internal medicine unit for the treatment.

Results

The biopsies revealed primary peritoneal amyloidosis. (Figure1.)

Conclusion

Amyloidosis is rare in the peritoneum and is usually asymptomatic. Ascites occurs in only 20% of patients with peritoneal amyloidosis. To date, there is no specific treatment for peritoneal amyloidosis. In the cases of ascites and peritoneal thickening without ovarian mass, amyloidosis must be kept in mind.

THE EFFECTS OF ESTROGEN AND PROGESTERONE RECEPTOR POSITIVENESS TO PATIENTS OVERALL SURVEY IN SEROUS OVARIAN CARCINOMA

S. Bakkaloglu¹, M. Dolanbay¹, İ.S. Serin¹
¹Erciyes University, Obstetrics and gynecology, Kayseri, Turkey

Aims

To investigate the effects of estrogen and progesterone receptor positiveness to patients overall survey in serous ovarian carcinoma.

Method

Patients preparations with serous ovarian carcinoma that operated in Erciyes University were detected retrospectively. Receptor status of patients determined by the way oh Immunohistochemical staining. Tumor stage and grade determined. The average duration for the survey was taken 5 years. 119 patients were divided into 4 groups: ER (+) PR (+), ER (-) PR (-), ER (+) PR (-) and ER (-) PR (+). The numbers of patients in the groups were 34, 23, 41 and 21 respectively.

Results

There was no significant association between ER and PR positivity with tumor grade or stage (p>0.05). ER positivity was not significantly contributing to the surveillance of patients (p <0.247) and the PR positivity is associated with longer surveillance (p <0.006). The longest surveillance have seen in the combination of ER (-) PR (+) (9.526 ± 1.039 years) (p <0.049).

Conclusion

The findings of this study have potentially important implications for the clinical management of patients with ovarian cancer. Especially in serous carcinomas, PR and ER expression status may give an idea about the prognosis of the patients to the physicians. In addition this may help to distinguish patients who need aggressive chemotherapy from those who may benefit from less toxic endocrine therapy.
LOW GRADE SEROUS OVARIAN CARCINOMA IN A HETEROGENOUS SOUTHEAST ASIAN SETTING

T.X. Ee¹, Y.K.T. Lim², I.M. Aggarwal², W.L. Wong²
¹KK Women's and Children's Hospital - Singapore, Department of Obstetrics and Gynaecology, Singapore, Singapore
²KK Women's and Children's Hospital - Singapore, Department of Gynaeoncology, Singapore, Singapore

Aims

It has now been established that low grade serous carcinoma of the ovary is a distinct entity by itself distancing itself from the high grade serous carcinomas in many aspects. Being in a unique heterogenous Southeast Asian country where the population comprises of 4 different races namely, Chinese, Malay, Indian and Eurasian, we examined the characteristics of the low grade serous ovarian carcinomas in our institution.

Method

Data was collected retrospectively from the KK Gynaecologic oncologic database from the KK Women’s and Children’s hospital, the biggest women’s tertiary hospital in Singapore. The data of 34 patients with confirmed low grade serous carcinoma of the ovary was collected from 1991 – 2015. The data analysed using SPSS system software.

Results

A total of 34 patients were analysed with low grade serous carcinoma. The patients’ ages ranged from 23 – 84.8 years. The mean age was 47.9 years. Majority (55.9%) of patients presented as stage 3 disease, 29.4% of patients presented as stage 1 disease, 8.8% as stage 3 disease and 2.9 % as stage 2 and unstaged. Overall survival was 182 months for all stages. The 5 years survival rate was 68.8% and 10 years survival rate, 62.3%. There was no significant difference between patients receiving chemotherapy and overall survival, $p = 0.58$.

Conclusion

Similar to the Caucasian population, low grade serous carcinoma in a heterogenous Asian population also appears to present earlier, are fairly resistant to conventional chemotherapy. Hence, more needs to be done to elucidate this distinct entity of ovarian serous carcinoma.

ESGO7-0021

LAPAROSCOPIC SCORING FOR ADVANCED OVARIAN TUMORS: A WAY FOR PREDICTION OF OPTIMAL CYTOREDUCTIVE SURGERY

A. El-Agwany¹

¹Faculty of Medicine, Obstetrics and Gynecology, Alexandria, Egypt

Aims

CT imaging and staging laparotomy are used to assess feasibility for optimal cytoreduction. We evaluated the role of laparoscopic scoring in assessing operability for optimal cytoreduction in advanced ovarian tumors.

Method

From 6/2016 to 12/2016, 15 patients were recruited. Inclusion criterion were Patients diagnosed with advanced ovarian cancers who were planned for primary reduction surgery were included in this study. The diagnosis of ovarian cancer was mainly clinical and CT based corroborated with CA 125 levels. All patients underwent three port laparoscopy. Thorough exploration of 8 sites at ovarian mass, peritoneal deposits, omental cake, mesenteric retraction by no free mobility of intestine, intestinal infiltration not surface implants, stomach infiltration not surface implants, liver and diaphragmatic infiltration. Each has a score of 0 if negative and 2 if positive for all sites except ovarian mass. If score of <8 this mean optimal for cytoreduction. No attempts were made to perform sub optimal cytoreduction in score of >=8 and interval cytoreduction would be planned after 3-4 cycles of upfront platinum based chemotherapy.

Results

6 of total cases underwent neoadjuvant chemotherapy with hepatic and diaphragmatic deposits and 9 underwent cytoreductive surgery. 12 patients had mesentery, omental cake and peritoneal deposits. No patients with gastric or intestinal infiltration were detected. Peritoneal deposits, mesenteric retraction were not detected on CT but were detected during laparoscopy. Intestinal infiltration were falsely detected on CT.

Conclusion

Laparoscopy could diagnose mesenteric, small bowel deposits, omental, stomach, liver and peritoneal deposits better than CT.

RE-APPRAISAL OF THE ROLE OF DELAYED DEBULKING SURGERY IN PATIENTS WITH STAGE 3C/4 EPITHELIAL OVARIAN CANCER AFTER 6 CYCLES OF UPFRONT CHEMOTHERAPY

S. Elorbany1, R. Tozzi2, D. Barton3

1St George's University Hospital, Obstetrics and Gynaecology, London, United Kingdom
2Oxford University, Obstetrics and Gynaecology, Oxford, United Kingdom
3Royal Marsden Hospital and St George 's University Hospital, Obstetrics and Gynaecology department, London, United Kingdom

Aims

The aim of the study is to evaluate the feasibility and the outcomes of cytoreductive surgery in a particular group of stage 3C/4 Epithelial ovarian cancer patients who received up to 6 cycles of chemotherapy rather than the traditional 3-4 cycles of neoadjuvant chemotherapy.

Method

This is a retrospective service evaluation (observational) study that included 182 patients who received their treatment in Oxford University hospital NHS trust from 2009 till 2015. 88 patients had 6 cycles of chemotherapy followed by delayed debulking surgery (group 1) and 94 patients had only 6 cycles of chemotherapy (group 2). Patients who had <6 cycles of chemotherapy due to progressive disease where excluded from the study

Results

Group 1 had significantly higher overall survival compared to Group 2; 34 months (95% CI: 21m-46m) and 17 months (95% CI: 15-19m) respectively. Progression free survival was also significantly higher in group 1; 16 months (95% CI: 10.7m-17m) and 10 months (95% CI: 9 m-11m) respectively. Complete cytoreduction was feasible in 75% of the patients eligible for surgery and residual disease of <1cm was achievable in 88.6% of those patients. The main reason for not proceeding with surgery was unresectable disease by CT scan +/- diagnostic laparoscopy. Diagnostic laparoscopy in patients with stable disease by CT scan improved the selection of patients for surgery.

Conclusion

Surgery still provides significant survival benefit and should still be offered to all suitable candidates. Diagnostic laparoscopy improved the selection of patients for surgery and reduced the number of futile laparotomies.

IDENTIFYING THE PLATINUM-SENSITIVE HIGH GRADE SEROUS OVARIAN CANCER; THE SYNERGY BETWEEN HOMOLOGOUS RECOMBINATION AND NUCLEOTIDE EXCISION REPAIR

Z.F. Faraahi1, S. Tyagi1, N. Gavrielides1, M. Price1, A. McCormick2, L. Woodhouse2, E. Crosbie1, R. Edmondson1

1The University of Manchester, Molecular & Clinical Cancer Sciences, Manchester, United Kingdom
2Newcastle University, Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom

Aims

There is strong evidence that abrogation of nucleotide excision repair (NER) and homologous recombination repair (HR) correlates with platinum-sensitivity and relapse in high-grade serous ovarian cancer (HGSOC). We aimed to develop clinically feasible assays to determine the functional NER and HR status of HGSOC and to identify any link between NER, HR and platinum response.

Method

Functional NER capacity (NERC) was determined by measuring benzopyrene (BPDE)-induced single-stranded DNA damage and repair using an alkaline comet assay. HR status was determined by a two-fold increase in Rad51 foci following UV-C induced double strand DNA damage. We assessed the correlation between NERC, HR and cell survival following carboplatin treatment in HGSOC cell lines and patient samples. The effect of inhibiting pivotal NER genes (ERCC1, ERCC5 and XPA) on NERC was assessed by siRNA knockdown.

Results

Comet analysis showed 70% of HGSOC patient sample were NER defective (n=35) and these tumours were more sensitive to carboplatin (p=0.03). Platinum-resistant PEO4 cells (I) had increased NERC compared to the platinum-sensitive PEO14 (IC50=23µM vs 125µM, p=0.002). NER/HR-competent HGSOC cells had decreased carboplatin-sensitivity compared to NER/HR-defective cells (p=0.016). Furthermore, knockdown of XPA, ERCC1 and ERCC5 inhibited NER function and increased carbo-sensitivity in PEO4 but not NER-defective PEO14 cells.

Conclusion

NER/HR-competent HGSOC are less sensitive to carboplatin compared to NER/HR-defective HGSOC. Our functional NER and HR data support the clinical need for determining DNA repair status to improve prediction of response and resistance to chemotherapy. Further data is required to establish clinical correlations between NER status and platinum sensitivity.
RESECTABILITY IN ADVANCED OVARIAN CANCER, OUR RESULTS
F. Fargas Fabregas¹, C. Blancafort Casabón¹, R. Fabregas Xaudaró²
¹Hospital Universitari Quiron-Dexeus, Gynecology Oncology, Barcelona, Spain
²Hospital Universitari Quiron-Dexeus, Gynecology Oncology, Barcelona, Spain

Aims
In the period from January 2011 to December 2016, a total of 38 patients with an advanced ovarian cancer were operated in our center (stage III-IV). We have done a descriptive analysis of our results of the last 6 years. In the literature is reported that approximately 30% of patients undergoing cytoreductive surgery do not achieve 0 residual disease at the first surgical procedure, and in some groups this percentage amounts to 60%.

Method
As part of a good surgical team, a good preoperative study of the patients is essential to be able to carry out a correct planning of the treatment to the patients. Our preoperative analysis consists of a blood analysis with tumor markers, a transvaginal ultrasound, a CT scan, and usually a diagnostic laparoscopy for resectability assessment.

Results
In our hospital, of the total of the surgeries practiced (36/38), complete surgery has been achieved in 94.4% of the cases. Of these surgeries, 4 have been after neoadjuvant chemotherapy, and only 2 have not been achieved a complete cytoreduction. Two other patients only received chemotherapy, with progression during the treatment. Analyzing the two specific cases, in which complete surgery was not achieved, one of them presented a Sugar Baker index of 28 pre-chemotherapy, which fell to 8 after the treatment. And the other case, was a mistake in the diagnosis by image, in which it was not detected that there was affection of the mesenteric vessels, and a primary surgery was tried.

Conclusion
Nowadays, we have introduced diagnostic laparoscopy as an obligatory part in the pre-surgical evaluation of the patients. As always, a very good multidisciplinary team is required, including specialists radiologists in gynecology-oncology, specialized surgeons and oncologists.

2Shahid Beheshti University of Medical Sciences, Virology Research Center- National Research Institute of Tuberculosis and Lung Diseases NRITLD, Tehran, Iran
3Shahid Beheshti University of Medical Sciences, Pathology Department, Tehran, Iran
4Shahid Beheshti University of Medical Sciences, R&D Center- Imam Hossein Hospital, Tehran, Iran

Aims

Ovarian epithelial tumor is one of the most common gynecological tumors; we evaluated the presence of HPV in benign and malignant epithelial ovarian tumors.

Method

In presented cross-sectional study the records of 105 patients with epithelial ovarian tumors (benign and malignant) referred to Imam Hossein University Hospital from 2012 to 2015 were evaluated along with assessing the presence of the HPV infection in their ovarian tumors using PCR

Results

Among 105 patients including 26 (24.8%) with malignant and 79 (75.2%) benign ovarian epithelial tumors, the factors impact on the malignancy were age at diagnosis, the age of the first pregnancy, the number of pregnancy and hormonal status, however, the malignancy was not related to the abortion, late menopause, and early menarche. In all of the ovarian tissues (benign and malignant tumors) removed from 105 patients, the HPV DNA was not found.

Conclusion

In this study the HPV DNA could not be found in any epithelial ovarian tumors (benign and malignant) removed from 105 women; more studies in larger sample size are needed to have the better conclusion.

IMMUNONUTRITION: A NEW TOOL IN THE MANAGEMENT OF OVARIAN CANCER?
V. Marola1, M. Geuna2, L. Fuso3, D. Vassallo4, N. Santoro2, G. Menato1, A. Ferrero1
1Mauriziano Hospital, Academic Division of Gynaecology and Obstetrics- University of Turin, Turin, Italy
2Mauriziano Hospital, Laboratory of Immunopathology- Division of Pathology, Turin, Italy
3Mauriziano Hospital, Academic Division of Gynaecology and Obstetrics- University of Turin, Turin, Italy
4Mauriziano Hospital, Division of Dietetics, Turin, Italy

Aims

Immunonutrition has been proved to stimulate the immunological, inflammatory and nutritional response in different tumours, decreasing postoperative mortality and morbidity. Alterations in lymphocyte subpopulations, particularly the Treg cell subpopulation and the expression of PD1, could be a key factor in determining the status of tumour microenvironment. Patients with ovarian cancer are most effectively treated by radical surgery, that carries a high risk of postoperative complications. The aim of this study is to evaluate the effects of preoperative immunonutrition on patients with ovarian cancer undergoing surgery.

Method

Our pilot study involved 11 patients with ovarian cancer who underwent primary debulking surgery between 2016 and 2017. Enteral immunonutrition was prescribed for 5 to 7 days preoperatively. The following parameters were evaluated before and after immunonutrition: monocytes, granulocytes, lymphocyte subpopulations (CD3+/4+/5+/8+/19+/20+/25+/56+), prealbumin, serum total protein, C-reactive protein (CRP), creatinine, length of hospital stay (LOS) and postoperative complications. The expression of PD1 was assessed on CD4+, CD8+ and Treg cell subpopulations.

Results

After immunonutrition, granulocytes and lymphocytes B CD19+ were significantly increased (p<0.05). CD3+ and CD8+ T cell subpopulations showed an increasing trend (p>0.05). The expression of PD1 on CD8+ cell subpopulation decreased (p>0.05). CRP and creatinine significantly decreased (p<0.05), while prealbumin significantly increased (p<0.05). In comparison with patients with ovarian cancer who underwent surgery between 2013 and 2016 without preoperative immunonutrition, LOS and the G2-G3 postoperative complications were reduced, (8 vs 6.9 p>0.05) and (40.0% vs 9.1%, p=0.04) respectively.

Conclusion

Preoperative immunonutrition may represent a promising approach in the management of ovarian cancer.

A PROVEN MODEL FOR IMPROVEMENT IN GENETIC COUNSELING REFERRALS FOR OVARIAN CANCER PATIENTS IN A COMMUNITY HOSPITAL CANCER CENTER

G. Cantuaria1, K. Lang2, B. Benigno1, G. Feuer1, S. Yap1, M. Burrell1, M. Jones3, D. Hayes4, P. Huggins4, P. Owens4

1Northside Hospital Cancer Institute, Gynecologic Oncology, Atlanta, USA
2Northside Hospital Cancer Institute, Genetics, Atlanta, USA
3Northside Hospital Cancer Institute, Oncology Analytics, Atlanta, USA
4Northside Hospital Cancer Institute, Cancer Institute, Atlanta, USA

Aims

Despite guidelines recommending genetic counseling (GC) referrals for ovarian cancer patients, rates within US academic centers (15-30%) and worldwide (15-20%) remain low. While most US cancer patients receive treatment at community centers, there is little research on genetics referrals in this setting. With changes to clinical pathways in 2013, our goal was 100% referral rate to GC within 1 year from diagnosis.

Method

In October 2013, the Gynecologic Oncology Steering Committee (GOSC) implemented a multidisciplinary approach to improve education, communication, and care integration for ovarian referrals to GC. Compliance was monitored and reported. Missing referral notifications were sent regularly and status presented bi-monthly at GOSC for two years. Baseline 2013 referrals were compared to those in 2014 and 2015.

Results

In 2013, 35% (41/116) of ovarian patients were referred. In 2014, 90% (71/79) of eligible ovarian patients received GC and testing. Sixty-four (81%) of these were in-house referrals, 4 patients were seen at an outside institution, and 3 were tested through a clinical trial. The 8 (10%) missed referrals were due to 2 deaths, 2 lost to follow-up, and 4 were never referred. This demonstrates a 157% increase over baseline. In 2015, in-house referrals remained high at 73% (72/99).

Conclusion

Improvement in ovarian genetics referrals can be sustained in community setting through a multidisciplinary approach and regular reporting. Physician engagement and accountability are key to success. Our impressive growth in GC referrals within a large community cancer center benefits patients and can serve as a model for guideline compliance.
COMPARATIVE STUDY OF SURVIVAL OUTCOMES FOLLOWING ROBOTIC-ASSISTED LAPAROSCOPIC VERSUS ABDOMINAL SURGERY IN THE MANAGEMENT OF OVARIAN CANCER

G. Feuer1, S. Salmeri1, M. Berrell2, N. Lakhi2,3

1Northside Hospital, Gynecologic Oncology, Atlanta, USA
2Richmond University Medical Center- New York Medical College, Gynecologic Oncology, Staten Island- New York, USA
3New York Medical College, Department of Obstetrics and Gynecology, Valhalla- New York, USA

Aims

To compare survival outcomes following robotic-assisted and abdominal surgery in patients with ovarian cancer.

Method

Retrospective analysis of consecutive ovarian cancer patients seen by a single surgeon between January 2008-March 2016. Intention-to-treat analysis was conducted using chi-square and t-test with significance <0.05. Kaplan-Meier survival curves were compared using the Mantel-Cox-log-rank test.

Results

Robotic-assisted cases were (n=122) were similar to abdominal surgery (n=49) on age, BMI, uterine weight, parity, prior pelvic surgery and intra-and post-operative complications (p>0.05). More robotic-assisted cases (vs. abdominal) had neoadjuvant chemotherapy (47.5% vs. 24.5%, p=0.004), were stage I (37.7% vs. 20.4%, p=0.03) and had no evidence of disease after surgery (79.5% vs. 40.8%, p<0.001). In early stage cancer (I/II), optimal debulking (<0.5 cm residual disease) was achieved in 98.1% and 80.0% of robotic-assisted vs. abdominal surgeries respectively (p=0.27). In advanced cases (III/IV), optimal debulking was attained in significantly more in robotic than abdominal surgeries (85.3% vs. 61.8%, p=0.009).

Survival distributions showed robotic surgery patients had better overall survival (p=0.02), but only for early stage cancers (p=0.003) and not advanced cancers (p=0.38) (Figure 1). There were no differences in progression-free survival by surgical approach either overall (p=0.56) or by early (p=0.63) or advanced stage (p=0.73) disease.

Conclusion

Overall and progression-free survival were at least as good in patients who underwent robotic-assisted compared to abdominal procedures, at all stages of ovarian cancer.

⁴Masaryk University, Institute of Biostatistics and Analysis, Brno, Czech Republic
⁵First Faculty of Medicine- Charles University and General University Hospital in Prague, Department of Radiology, Prague, Czech Republic

Aims

To compare the diagnostic accuracy of ultrasound, CT, and MRI in ovarian cancer staging.

Method

Patients planned for ovarian cancer surgery were enrolled. They underwent preoperative staging with ultrasound, CT, and MRI, following evaluation form. Findings were compared to intraoperative and histopathological evaluation forms. The evaluation assessed peritoneal spread in 17 sites and metastatic lymph nodes in 7 sites.

Results

Twenty-one patients were enrolled between March and August 2016. Ultrasound showed the best results in detection of pelvic carcinomatosis and depth of rectosigmoid infiltration, followed by MRI and CT (AUC 0.85, 0.79, and 0.72). In the abdomen, ultrasound had the best results in the detection of peritoneal carcinomatosis in the upper abdomen (spleen, liver, lesser omentum) and in greater omentum (AUC of 0.82 and 1.00), in contrast with MRI (AUC 0.73 and 0.93) and CT (AUC 0.71 and 0.88). Ultrasound also reached the highest AUC in the detection of bowel mesentery (AUC 0.78) compared to MRI and CT (AUC 0.66 and 0.62) and was comparable to MRI in the assessment of bowel surface (AUC 0.76), followed by CT (0.73). Ultrasound had the lowest AUC in detection of parietal carcinomatosis (diaphragm, paracolic gutters, anterior abdominal wall) in comparison to MRI and CT (AUC 0.72, 0.86, and 0.78). In the assessment of retroperitoneal lymph nodes, all three methods showed similar results (AUC of 0.80).

Conclusion

This is the first prospective study to date documenting the potential role of ultrasound in ovarian cancer staging, compared to the method of choice (CT) and a novel technique (WB-DWI/MRI).

ESGO7-1061

COMPLETE GROSS RESECTION AT PRIMARY VERSUS INTERVAL SURGERY FOR ADVANCED OVARIAN CANCER IMPROVES PROGRESSION-FREE SURVIVAL

N. Fleming1, S. Westin1, R. Coleman1, P. Soliman1, K. Schmeler1, B. Fellman2, P. Ramirez1, K. Lu1, A. Sood1

1MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA
2MD Anderson Cancer Center, Biostatistics, Houston, USA

Aims

To determine effect of complete gross surgical resection (R0) of tumor on progression-free survival at primary versus interval tumor reductive surgery in advanced ovarian cancer.

Method

We prospectively triaged patients from April 2013 to December 2016 with suspected advanced stage ovarian cancer to laparoscopic scoring assessment to determine primary resectability. Medically inoperable or those with distant metastatic disease received neoadjuvant chemotherapy (NACT). 20 gynecologic oncologists from a single institution performed all scoring. Predictive index value (PIV) scores <8 were dispositioned to primary surgery and ≥8 to NACT. Clinicopathologic and adjuvant treatment data was collected prospectively. Univariate and multivariate analysis was performed for effects on progression-free survival (PFS).

Results

658 patients presented with presumed advanced ovarian cancer. 488 patients were found to have pathologically confirmed stage II-IVB high-grade epithelial ovarian cancer and triaged to NACT/no scope (n=243), NACT/scope (n=105), and primary surgery (n=138). Patients undergoing primary surgery had improved PFS (HR=0.52, 95% CI 0.31-0.85, p=0.02) compared to interval surgery after NACT. Patients undergoing R0 resection at primary surgery had significant improved PFS compared to those undergoing R0 resection at interval surgery (23.5 vs. 12 months, p<0.001). On multivariate analysis, ECOG performance status (p=0.03), R0 resection (p=0.01), and primary surgery (p=0.01) had significant effects on PFS.

Conclusion

Complete surgical resection at primary surgery in advanced ovarian cancer is associated with superior progression-free survival compared to NACT and interval surgery. Laparoscopic scoring assessment allows for appropriate triage of patients to primary surgery.

ESGO7-1378

IMPLEMENTATION OF A LAPAROSCOPIC SCORING ALGORITHM PRIOR TO CYTOREDUCTIVE SURGERY IN PATIENTS WITH ADVANCED OVARIAN CANCER

N. Fleming1, P. Ramirez1, S. Westin1, R. Coleman1, P. Soliman1, L. Meyer1, K. Schmeler1, K. Lu1, A. Sood1

1MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA

Aims

To determine the surgical outcomes and concordance rates of patients undergoing laparoscopic scoring assessment for presumed advanced stage ovarian cancer.

Method

We prospectively triaged patients from April 2013 to April 2017 with suspected advanced stage ovarian cancer to laparoscopic scoring assessment to determine primary resectability. Medically inoperable or those with distant metastatic disease received neoadjuvant chemotherapy (NACT). 20 gynecologic oncologists from a single institution performed all scoring. Predictive index value (PIV) scores <8 were dispositioned to primary surgery and ≥8 to NACT. Two surgeons scored each patient in a blinded fashion, and a third surgeon score was available to assess cases with a discrepancy. Descriptive statistics were used to report surgical and scoring outcomes.

Results

672 patients presented with presumed advanced ovarian cancer and 292 patients underwent laparoscopic scoring assessment. 21 patients (3%) were diagnosed with a non-ovarian primary malignancy. Surgical complications included GI trocar injury (n=6, 2%), port site metastasis (n=12, 4%), and wound infection (n=9, 3%). 184 patients (63%) had a PIV<8 and 100 patients (34%) a PIV ≥8. PIV score could not be determined in 8 patients (3%). Two-surgeon scoring (n=200) resulted in qualitative agreement in 94% of cases, and a third surgeon was called in 10 cases (5%). The third surgeon agreed with the second surgeon in 4 cases, giving a discordance rate of 2%.

Conclusion

Laparoscopic scoring assessment in presumed advanced stage ovarian cancer is associated with acceptable surgical outcomes and low complication rates. Concordance is high amongst surgeons experienced with the scoring algorithm.
Aims

CT images can be quantitatively analysed to describe intuitive features such as shape and texture. The features generated from such analyses (i.e. texture analysis or radiomic data) have been associated with prognosis and cellular pathways in many cancer types. The non-invasive and cost-effective nature of radiomic data make it a promising biomarker candidate for cancer patients. In this study, we aimed to investigate the clinical value of radiomic data as a potential biomarker in serous ovarian cancer.

Method

Here, we developed texture analysis software in-house and extracted 657 features from each CT scan. We collected radiomic data and comprehensive molecular information including copy number profile, proteomic and molecular subtype for over 200 primary serous ovarian tumours.

Results

We found that radiomic features of primary ovarian tumours closely correlated with ovarian cancer stage, grade and survival. Furthermore, we discovered that a subset of radiomic features correlated with molecular subtypes and PI3K pathways.

Conclusion

In summary, we demonstrated that radiomic data could be a potential diagnostic and prognostic biomarker to guide future therapy.

DOES MENOPAUSAL STATUS OF OVARIAN CANCER PATIENTS INFLUENCE MESOTHELIN EXPRESSION IN PRIMARY TUMOR AND INTRAPERITONEAL METASTASES?
K. Frąszczak\textsuperscript{1}, B. Barczyński\textsuperscript{1}, G. Polak\textsuperscript{1}, R. Tarkowski\textsuperscript{1}, K. Kułak\textsuperscript{1}, M. Sobsty\textsuperscript{2}, P. Ziobro-Malinowska\textsuperscript{1}, I. Wertel\textsuperscript{1}, W. Bednarek\textsuperscript{1}, J. Kotarski\textsuperscript{1}
\textsuperscript{1}Medical University of Lublin, I Klinika Ginekologii Onkologicznej i Ginekologii, Lublin, Poland
\textsuperscript{2}Medical University of Lublin, Department of Endocrinology and Gynaecological Endocrinology, Lublin, Poland

Aims

Epidemiological data confirm a link between reproductive factors and the risk of ovarian cancer. An increase in ovarian cancer risk occurs in perimenopausal and immediate postmenopausal periods, and continues to rise as the ovary ages. The majority of sporadic ovarian cancers are diagnosed in postmenopausal women, with an average age of approximately 63 years. Mesothelin is suggested to be one of the proteins facilitating intraperitoneal metastazing in ovarian cancer. The aim of the study was immunohistochemical analysis of mesothelin expression in primary epithelial ovarian tumors and intraperitoneal metastases in relation to menopausal status of patients.

Method

The study included 47 patients with histopathologically confirmed ovarian cancer, who were retrospectively allocated by menopausal status into two groups: premenopausal and postmenopausal women. To evaluate mesothelin expression in both groups biopsies of primary and peritoneal metastases, commercially available Novocastra NCL-L-Meso antibodies were used. For the purpose of analyses, mesothelin expression was classified into two groups of strong (SE group) (>10% of cells) and weak (WE group) (<10% of cells) expression.

Results

55% of primary tumors were classified into SE group, and 45% into WE group, whereas 26% of ovarian metastases were classified into SE group, and 74% into WE group. There was no significant correlation between general mesothelin primary tumors and metastases expression in relation to menopausal status (p>0.05).

Conclusion

Mesothelin expression in primary ovarian tumor and intraperitoneal metastases is not correlated with patients’ menopausal status. Menopausal status probably does not influence formation of peritoneal metastases in ovarian cancer patients.

HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC) IN GYNECOLOGICAL MALIGNANCIES
M. Friedrich¹, C. Altgassen², A. Terjung²
¹HELIOS Hospital, Department of Gynecology, Krefeld, Germany
²HELIOS Klinikum, Department of Gynecology, Krefeld, Germany

Aims

Peritoneal carcinomatosis is a sign of advanced disease of carcinoma of the ovary and fallopian tube, but also of primary peritoneal carcinomas. Meanwhile it could be shown that the prognosis is significantly improved after cytoreductive surgery. If it is possible to achieve a complete tumor free situation, HIPEC should further improve the prognosis.

Method

Patients with peritoneal malignancies underwent a cytoreductive surgery. In 40 patients we could achieve an optimal tumor resection so that HIPEC with a cisplatin solution (50mg/m²) at 41°C could be performed. Adverse events were recorded after the Clavien-Dindo classification especially by evaluating grade III and IV side effects.

Results

The mean age was 59.8 years. The Peritoneal Cancer Index was between 3 and 18. The CC-0-rate was 68%, the CC-1 rate was 32%. More than 20 anastomoses had been performed without any insufficiencies. We counted 13 adverse events in 8 patients. The only grade III toxicity was a temporary renal failure, the remaining adverse events were only grade I or II side effects. The postoperative systemic treatment with carboplatin and paclitaxel was not postponed. The median follow up was 1.25 years. The recurrence free survival will be presented.

Conclusion

HIPEC with 50 mg/m2 cisplatin seems to be feasible in gynecologic malignancies without inducing severe adverse events. Thus, we believe HIPEC is another important component of the treatment of peritoneal malignancy.

11Iwate Medical University, Department of Obstetrics and Gynecology, Iwate, Japan
12Kosei Hospital, Department of Obstetrics and Gynecology, Tokyo, Japan
13Tohoku University School of Medicine, Department of Obstetrics and Gynecology, Miyagi, Japan

Aims

To compare the efficacy, safety and tolerability profiles of pegylated liposomal doxorubicin and carboplatin (PLD-C) with those of gemcitabine and carboplatin (GC) for the treatment of patients with platinum-sensitive recurrent ovarian cancer (PSROC).

Method

Patients with histologically proven ovarian cancer with recurrence >6 months after first-line platinum and taxane-based therapies were randomly assigned to PLD-C (PLD 30 mg/m² plus carboplatin area under the curve [AUC] 5 on day 1) every 4 weeks or GC (gemcitabine 1,000mg/m² on day 1 and 8 plus carboplatin AUC 4 on day 1) every 3 weeks for at least 6 cycles. The primary endpoint was progression-free survival (PFS), with overall response rate, overall survival, toxicity and dose administration as secondary endpoints.

Results

One hundred patients (49 PLD-C; 51GC) were randomly assigned. With a median follow-up of 27 months, the median PFS was 12.0 months (95%CI, 9.2 to 15.0) for PLD-C and 9.8 months (95%CI, 8.9 to 12.3) for GC. The overall survival data are immature. Response rate was 57.1% (95%CI, 41.0 to 72.3) for PLD-C and 56.4% (95%CI, 39.6 to 72.2) for GC. No obvious differences in toxicity (G3/4) were noted between arms. Treatment completion rate for 6 cycles was higher for PLD-C (63.3%;95%CI, 48.3 to 76.6) than for GC (31.4%;95%CI, 19.1 to 45.9).

Conclusion

PLD-C and GC are both good treatment candidates for PSROC patients; however, the dose intensity was lower for GC than for PLD-C. PLD-C seems to have a more favorable risk-benefit profile than does GC for the patients in this study.
THE ASSOCIATION BETWEEN EXPRESSION OF TBX2 AND SENSITIVITY TO PLATINUM-BASED CHEMOTHERAPY FOR OVARIAN SEROUS CARCINOMA

P. Tasaka¹, T. Fukuda¹, Y. Inoue¹, M. Shimomura¹, H. Matsubara¹, T. Wada¹, M. Kawanishi¹, T. Yasui¹, T. Sumi¹
¹Osaka City University Graduate School of Medicine, Obstetrics and Gynecology, Osaka, Japan

Aims

We examined the correlation between TBX2 (T-box2) expression and the sensitivity to platinum-based chemotherapy for ovarian serous carcinoma.

Method

We reviewed 54 cases of ovarian serous carcinoma stage III-IV from 2005 to 2013. Cases were divided into two groups: one group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and did not recur within 6 months after initialization of chemotherapy (group A; n=27), and another group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and recur within 6 months (group B; n=27). TBX2 expression was examined immunohistochemically in paraffin-embedded sections using the avidin-biotin peroxidase complex method. This study was approved by the institutional review board in our facility.

Results

The expression of TBX2 was significantly higher in the group B than in the group A (p=0.005). Cases were divided into two groups: one group in which TBX2 expression was low level (weighted score ≤6, n=44), and another group in which TBX2 expression was high level (weighted score ≥8, n=10). Low TBX2 expression group might be sensitive to platinum-based chemotherapy than high expression group (p=0.02). The overall survival of Low TBX2 expression group was significantly longer than High TBX2 expression group (p=0.023).

Conclusion

It is suggested that the expression of TBX2 might be associated with sensitivity to platinum-based chemotherapy and predictor of prognosis of advanced ovarian serous carcinoma.

¹Osaka City University Graduate School of Medicine, Obstetrics and Gynecology, Osaka, Japan

Aims

We examined the correlation between UCP2 (uncoupling protein 2) expression and the sensitivity to platinum-based chemotherapy for ovarian serous carcinoma.

Method

We reviewed 51 cases of ovarian serous carcinoma stage III-IV from 2005 to 2012. Cases were divided into two groups: one group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and did not recur within 6 months after initialization of chemotherapy (group A; n=26), and another group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and recur within 6 months (group B; n=25). UCP2 expression was examined immunohistochemically in paraffin-embedded sections using the avidin-biotin peroxidase complex method. This study was approved by the institutional review board in our facility.

Results

The expression of UCP2 was significantly higher in the group B than in the group A (p=0.027). Cases were divided into two groups: one group in which UCP2 expression was low level (weighted score≤6, n=24), and another group in which UCP2 expression was high level (weighted score≥8, n=27). Low UCP2 expression group might be sensitive to platinum-based chemotherapy than high expression group (p=0.007). The overall survival of Low UCP2 expression group was significantly longer than High UCP2 expression group (p=0.006).

Conclusion

It is suggested that the expression of UCP2 might be associated with sensitivity to platinum-based chemotherapy and predictor of prognosis of advanced ovarian serous carcinoma.

OVARIAN GASTROINTESTINAL STROMAL TUMOR: DOES THIS DIAGNOSIS EXIST
K.M. Gaballa¹, I.H. Metwally¹, B. Refky¹, M. Abdelkhalek¹, S. Saleh¹, A.M. Abdelaziz², M. Arafà³
¹Oncology Center Mansoura University, Surgical oncology, Mansoura, Egypt
²Mansoura University Hospitals, Surgical oncology, Mansoura, Egypt
³Oncology Center Mansoura University, Pathology, Mansoura, Egypt

Aims

Gastrointestinal stromal tumors (GISTs) are rare gastrointestinal (GI) tract tumors. Those tumors rarely arise extra-intestinally; within omentum, mesentery, and rarely uterus. We report a case of myxoid variant of GIST arising in the ovary with no evidence of a primary tumor in the GI tract. Surgeons as well as gynecologists should bear this possibility in mind when managing pelvic masses.

Method

In the present case report, We present a unique case of GIST arising from the ovary with no evidence of other primary with endoscopy, radiology, and exploration.

Results

Also in this case, a rare pathological type (myxoid variant) was detected with a very aggressive course and poor response to imatinib. We claim that GISTs can arise from the ovary primarily supported by the two published reports by Agaimy et al. recording presence of interstitial cells of Cajal in an ovarian teratoma in one case and recording coexistence of Cajal cell hyperplasia with teratoma in another case also supported by the presence of pleuripotent stem cells within the ovary.

Conclusion

GISTs can arise within the ovary either as a primary tumor or metastatic from GI site with great difficulty in differentiation between both. Surgical treatment and adjuvant therapy with imatinib is still the main line of treatment of GISTs, even for those arising in rare sites. Myxoid variant of GIST may present with a very aggressive course and its response to imatinib is questionable.

MINIMALLY INVASIVE SURGERY FOR THE MANAGEMENT OF OVARIAN EPITHELIAL CANCER: FEASIBILITY, MORBIDITY AND SURVIVAL

A. Gabrielle¹, L. Lecointre¹, T. Boisramé¹, C.Y. Akladios¹
¹Hopitaux Universitaires de Strasbourg, Gynecological Surgery, Strasbourg, France

Aims

Laparoscopy is becoming the gold standard in gynecological oncologic surgery, but it remains controversial for the management of ovarian carcinomas. The aim of this study is to evaluate laparoscopy for management of both early and advanced stages of ovarian epithelial cancer.

Method

We performed a single institution retrospective study. All patients who underwent a laparoscopic surgery for primary ovarian cancer between the 1st January 2010 and the 31st December 2016 were included in the study. Standard surgical procedures were performed according to national guidelines. Neo-adjuvant chemotherapy was administered when indicated. Preoperative clinical data, perioperative data and survival outcomes were analyzed.

Results

Fifty patients were included. Forty one (82%) were successfully managed by laparoscopy without conversion to laparotomy. Absence of residual tumor was achieved for all cases (100%). Three intraoperative complications (7.3%) occurred, all resolved laparoscopically. Median length of stay was five days. Seven patients (17%) had postoperative complications but only one (2.4%) was grade 3. Median time to start adjuvant chemotherapy was 27 days. For a median follow-up of 18 months, twenty nine patients (71%) are still alive with no recurrence, ten relapsed (24%). Median overall survival was 64 months and median progression-free survival was 38 months.

Conclusion

Minimally invasive surgery may represent a valuable surgical alternative for management of ovarian epithelial cancer in selected cases, with a low morbidity rate and no impact on progression free survival. A prospective multicentric study for laparoscopic management of advanced stages is currently under evaluation in our department.

PRIMARY OVARIAN LARGE B-CELL LYMPHOMA
H. Mansouri1, S. Gadria1, M.A. Ayadi1, I. Ben Safta1, A. Chabchoub1, L. Charfi2, M. Hechiche1, J. Ben Hassouna1, K. Rahal1
1Salah Azaiz Institute, surgical oncology department, Tunis, Tunisia
2Salah Azaiz Institute, Pathology department, tunis, Tunisia

Aims

Primary ovarian non-Hodgkin’s lymphoma (NHL) is a rare disease accounting for 0.5% of all NHLs and 1.5% of all malignant ovarian neoplasms. Primary ovarian NHL arises from hilar lymphoid tissue or teratoma in the ovary. The most common histological subtype is diffuse large B-cell lymphoma.

Method

We describe clinical, histological and therapeutic feature of a case of primary ovarian NHL.

Results

A 44-years old woman, without medical history, presented with symptoms of abdominal distension, dysuria and constipation worsening over four months. Physical examination revealed an ill-defined lump in the lower abdomen. The ultrasound examination and the computed tomography (CT) scan of the abdomen and pelvis showed an irregular, heterogenous and hypervascular lesion arising from the left ovary measuring 17x10x8 cm. The tumor involved the right parametrium and repulsed the uterus and the bladder. No lymph nodes or distant metastases were detected. The CA-125 tumor marker level was normal. The patient underwent a total abdominal hysterectomy with bilateral salpingo-oophorectomy and pelvic lymph node dissection. The histology on frozen section was malignant and suspicious for sarcoma. The final pathologic diagnosis after immunostaining was diffuse large B-cell malignant lymphoma arising from the right adnexa. The patient received post operative chematherapy with CHOP regimen. She remains in remission for 36 months.

Conclusion

Primary ovarian lymphoma is a rare disease diagnosed generally after surgery using immunohistochemistry. Its treatment is essentially based on chemotherapy.

IMMUNE RESPONSE TO CHEMOTHERAPY-ASSOCIATED ANTIGENS AS PREOPERATIVE PREDICTOR OF ONCOLOGIC OUTCOME IN OVARIAN CANCER PATIENTS: A PILOT STUDY

M.L. Gasparri¹, C. Focaccetti², M. Paroli², F. Palombo², A.R. Besharat¹, C. Marchetti¹, M. Fischetti³, V. Barnaba², P. Benedetti Panici¹

¹Sapienza University of Rome, Gynecology and Obstetrics, Rome, Italy
²Sapienza University of Rome, Laboratory of Cellular and Molecular Immunology and Laboratory of Proteomics- Department of Internal Medicine, Rome, Italy
³Sapienza University or Rome, Department of Medical-Surgical Sciences and Biotechnologies, Rome, Italy
⁴Sapienza University of Rome, Gynecology and Obstetrics, Rome, Italy

Aims

Chemotherapy is able to induce the release of tumor antigens from dying ovarian cancer (OC) cells (chemotherapy-associated antigens [CAAs]). T-lymphocytes recognize CAAs derived from apoptotic OC cells and generate an immune response, through INF-γ and IL-17 production. Aim of the study is to correlate the amount of INF-γ and IL-17 produced by T-lymphocytes upon stimulation with CAAs with long-term survival in OC patients.

Method

Immune response was evaluated at the time of diagnosis. A correlation between INF-γ and IL-17 production with OS was performed in a cohort of OC patients, in whom the correlation between memory T-cell responses to CAAs and platinum sensitivity was previously investigated.

Results

T-cells from advanced OC patients, previously interrogated for their capacity to respond to CAAs, were correlated with survival data (Pearson r of 0.85, p 0.14). Mean of INF-γ and IL-17 produced by T-cells from 12 selected patients (379.5 spots/10⁶ cells ± 495) defines the cut-off between an high and low immune response. The median survival was 101 and 45 months for patients with high and low immune response, respectively (p 0.34). Mean OS (60 months) defines the cut-off between long and short survivors. The amount of INF-γ and IL-17 spots produced by T-cells from each patient in response to CAAs, was significantly higher in the group of longer survivors (mean 1043 ± 288.4) than in the group of shorter survivors (mean 262.4 ± 36.1) (p 0.003).

Conclusion

T-cell responses to CAAs seem to play a role in determining survival in OC patients.

CLINICAL EFFECT OF LIVER TRANSAMINASE ABNORMALITIES AFTER ABLATION OF OVARIAN CANCER

J. Geisler¹, K. Manahan¹

¹CTCA, Newnan, USA

Aims

Patients with ovarian cancer often have disease involving the liver (surface or parenchyma). The object of this study was to 1) see the difference in liver transaminases in women getting tumor ablation involving the liver compared to women undergoing tumor ablation not involving the liver and to 2) see if any differences had a noticeable clinical effect.

Method

Twenty women with ovarian cancer undergoing primary cytoreduction with tumor ablation involving the liver were compared to twenty women with ovarian cancer undergoing primary cytoreduction and tumor ablation without involvement of the liver. The data were compared with Fisher’s exact, Chi-square or Mann-Whitney U as appropriate.

Results

Women undergoing tumor ablation involving the liver compared with women undergoing tumor ablation not involving the liver had significantly elevated AST and ALT levels the first day after surgery (p = 0.002; 0.002, respectively). There were no significant differences in age, operative blood loss, need for transfusion, or postoperative stay (p=0.24; 0.065; 0.33; 0.49, respectively). The mean time for resolution of the elevations of AST and ALT was 2.5 days (95% CI = 1.8-3.2) for AST and 2.8 days (95% CI = 2.0-3.6) for ALT. The mean postoperative stay was 3.4 days (95% CI = 2.2-4.6) for those without ablation involving the liver and 3.6 (95% CI = 2.7-4.5).

Conclusion

Significant elevations in AST and ALT occur when tumor involving the liver is ablated in women undergoing debulking. These elevations do not increase operative blood loss, need for transfusion or postoperative stay.

CORRELATION BETWEEN FINDINGS AT ROBOTIC DEBULKING AND SUBSEQUENT LAPAROTOMY

J. Geisler\textsuperscript{1}, K. Manahan\textsuperscript{1}
\textsuperscript{1}CTCA, Newnan, USA

\textbf{Aims}

The purpose was to determine whether the reported findings at time of robotic debunking correlated with reported findings at time of subsequent laparotomy.

\textbf{Method}

Patients with stage IIIc or IV ovarian carcinoma who presented for second opinions after primary robotical surgery were offered a laparotomy and complete cytoreduction within 6 weeks of initial surgery.

\textbf{Results}

The median age of the 19 patients was 51 years (mean 51.4, 95\% CI 47.3-55.5). Thirteen were said to have no residual disease while 6 patients were declared optimally cytoreduced robotically. Significant differences in reported levels of debulking were found in 15 of 19 patients at time of laparotomy (P=0.028)(Kappa correlation -0.498 (95\% CI -0.974 to -0.022; poor correlation)). All 13 patients were found to have residual disease with 9 of them having disease greater than >1 cm and four of them with visible disease <1 cm. Of the six patients optimally robotically debulked, four had disease <1 cm and two had gross disease >1 cm. All were able to be debulked to no residual. Overall, fifteen patients had residual disease after robotic debulking in the upper abdomen (diaphragm, liver, infragastric omentum), thirteen had residual disease on bowel mesentery or surface, and nine had residual disease in the pelvis. The median hospital stay was 3 days (mean 3.53, 95\% CI 3.02-4.04).

\textbf{Conclusion}

It appears to be very difficult to accurately assess the level of cytoreduction at time of robotic surgery (k correlation -0.498). Open cytoreduction can achieve no visible or palpable residual disease after a robotic surgery.

APPROPRIATE TUMOR MARKERS FOR PREMENOPAUSAL WOMEN WITH AN OVARIAN MASS: A COST EFFECTIVENESS ANALYSIS

J. Geisler¹, A. Apoian², K. Manahan¹
¹CTCA, Newnan, USA
²UTMC, Ob/Gyn, Toledo, USA

Aims

To determine which tumor markers are cost effective to order in a premenopausal woman with a complex adnexal mass.

Method

A decision analytic model was performed using the following tumor markers: quantitative bhCG, AFP, LDH, neuron enolase, inhibin B, CEA, CA 125, and prealbumin. Incidence rates in the reference population were determined from literature. Costs were determined from CMS.

Results

Due to extremely low incidence rates, even if bhCG, AFP, LDH, neuron enolase, and inhibin B were positive in 100% of their respective tumors they are not cost effective to order. Only the non-proprietary ovarian cancer risk assessment score (OCRA) which is a combination of CA 125 and prealbumin is cost effective. It would take ordering hundreds of tests to find one using all the other aforementioned tumor markers.

Conclusion

In premenopausal women with a pelvic mass, only the combination of CA 125 and prealbumin is cost effective to order.
INCREASE IN GENETIC TESTING IN OVARIAN CANCER (OC) PATIENTS AFTER IMPLEMENTATION OF A FACILITATED REFERRAL SYSTEM

D. Gerber1, K. Musselman2, M.K. Frey3, J. Lee1, J. Martineau4, S. Asgari4, A. Cantor4, J.Y. Chern1, B. Pothuri5, S.V. Blank6

1NYU School of Medicine, Gynecologic Oncology, New York, USA
2NYU School of Medicine, Obstetrics and Gynecology, New York, USA
3Weill Cornell Medicine, Gynecologic Oncology, New York, USA
4New York University Langone Medical Center, Cancer Genetics Program, New York, USA
5New York University Langone Medical Center, Gynecologic Oncology, New York, USA
6Icahn School of Medicine at Mount Sinai, Gynecologic Oncology, New York, USA

Aims

It's recommended that all women with OC undergo genetic counseling (GC) and consider testing (GT). Universal referral was endorsed by SGO in 2014. However, rates of referral to GC are 15-30%. Since 10/2015, women newly diagnosed at our institution have been offered GC through a facilitated referral pathway (FRP). Our objective is to examine differences in GC and GT since implementation of FRP.

Method

Patients with new diagnosis of OC were retrospectively evaluated from 2012-9/2015 and prospectively since. Through FRP, patients are contacted by a genetics-navigator to schedule GC and communication between patient, physician and genetic counselor are facilitated. Chi-square and Mann-Whitney tests were used.

Results

There were 216 women diagnosed with OC who hadn't undergone previous GT identified between 2/2012-10/2016, of which 61 (28%) were in FRP and 154 (72%) weren't. Patients in the FRP were significantly more likely to obtain GC than non-FRP patients, and similarly, GT was obtained more often in the FRP group. There were 10 (21%) patients in the FRP and 21 (23%) in the non-FRP group found to have at least one deleterious mutation (p=0.98).

Conclusion

Implementation of FRP has resulted in a significant increase in GT, with a rate >80% among women with newly diagnosed OC with similar mutation rates in both groups. Although historically uptake of GT has been low, this study highlights the effectiveness of FRP. The implications of increased GT are profound; targeted therapies are now FDA-approved for BRCA1/2 mutation carriers. GT can result in increased screening/risk-reducing measures and allows for cascade testing.

EFFICACY AND OUTCOMES OF MINIMAL ACCESS SURGERY (MAS) VERSUS LAPAROTOMY (LAP) IN RE-STAGING OF APPARENT EARLY-STAGE OVARIAN AND FALLOPIAN TUBE CARCINOMA

A.G. Eriksson¹, Y. Wang¹, G. Falhaas Dahl¹, B. Eyjolfsdottir¹
¹Oslo University Hospital- The Norwegian Radium Hospital, Department of Gynecologic Oncology, Oslo, Norway

Aims

To compare efficacy and outcomes of MAS to LAP in re-staging of epithelial ovarian or fallopian tube carcinoma.

Method

All cases with presumed early-stage adnexal carcinoma referred to our institution for re-staging were identified from 02/2006-02/2017. Patient and tumor characteristics, operative findings, complications and recurrences were documented. Appropriate statistical tests were applied.

Results

Among 98 cases, 53 (54%) underwent LAP and 45 (46%) MAS; 29 (64%) robotic, 16 (36%) laparoscopic. When comparing the LAP and MAS groups, there was similar age, body mass index, stage, histologic subtypes, number of patients who underwent omentectomy and hysterectomy, number of pelvic lymph nodes removed, omental weight, detection of nodal and omental metastasis, number of patients who were upstaged, and number and sites of recurrences. Mean estimated blood loss (287ml±208 vs 76ml±58, p<0.001) and hospital stay (7.4 days ±3.2 vs 3.9 ±2.8, p<0.001) were lower for MAS, operative time (162minutes ±49 vs 216minutes ±69, p<0.001) was longer. Mean number of para-aortic nodes removed was 4.7±4.4 (LAP) versus 8.7±5.9 (MAS) (p=0.005) respectively. There were similar operative- and 30-day complication rates for both groups. Mean time from re-staging until initiation of adjuvant therapy was 40.5 days (± 62.4) in the LAP group and 21.3 days (± 11.2) in the MAS group (p=0.064). There was no difference in PFS or OS between groups.

Conclusion

Re-staging of adnexal carcinoma by MAS is feasible and safe without compromising efficacy or oncologic outcome. Time from re-staging to initiation of adjuvant chemotherapy trended towards being shorter in patients operated by MAS.
TOP2A OVER-EXPRESSION AS MARKER OF RESPONSE TO PEGYLATED LYPOSOMAL DOXORUBICIN (PLD) IN EPITHELIAL OVARIAN CANCERS

E. Ghisoni1, F. Maggiorotto2, G. Mittica1, G. Giannone1, A. Sciarrillo3, F. Borella4, A. Ferrero5, S. Genta1, I. Sarotto6, D. Katsaros7, G. Valabrega1

2Candiolo Cancer Institute-FPO-IRCCS, Gynecologic Oncology, Candiolo, Italy
3AOU Città della Salute- Turin- Italy., Department of Surgical Sciences- Gynecology, Turin, Italy
4AOU Città della Salute- Torino- Italy, Department of Surgical Sciences- Gynecology, Turin, Italy
5Mauriziano Hospital- University of Turin, Academic Division of Gynaecology and Obstetrics-, Turin, Italy
6Candiolo Cancer Institute-FPO-IRCCS, Unit of Pathology, Candiolo, Italy
7AOU Citta della Salute-Turin- Italy., Department of Surgical Sciences- Gynecology, Turin, Italy

Aims

Relapsed epithelial ovarian cancer (EOC) is frequently treated with pegylated liposomal doxorubicin (PLD). Unfortunately, most patients do not benefit from treatment. To optimize the use of PLD and avoid unnecessary toxicities, prediction of response is crucial. We aimed at assessing the value of topoisomerase II alpha (TOP2A) expression as predictive marker of response to PLD-based therapy in patients with relapsed EOCs.

Method

We retrospectively analyzed Formalin fixed paraffin Embedded tissues from 94 patients with platinum resistant (PR)/partially platinum-sensitive (PPS) EOCs treated with PLD-based chemotherapy beyond second line in three different institutions between January 2010 and December 2016. TOP2A expression was measured by immunohistochemistry (IHC) in paraffin-embedded tumor material. Images of each sample were acquired by optical microscope and analyzed by using automatic counter software. Correlation between TOP2A expression and response to PLD was assessed. Because no cut-off for positivity has been validated, we dichotomized TOP2A expression based on a cut-off of 18% (mean value in this study).

Results

TOP2A expression beyond cut-off was associated with a higher probability of response to PLD, unless not statistically significant (p=0.085). No difference was observed between PR and PPS groups (p=0.445 and p=0.185, respectively). Patients with TOP2A over-expression treated with PLD monotherapy achieved a longer time to progression (TTP) compared with PLD-doublet therapy (p=0.035).

Conclusion

Our data suggest that TOP2A increased expression might predict activity of PLD in patients with PR/PPS EOCs.
NEOADJUVANT CHEMOTHERAPY VERSUS PRIMARY DEBULKING SURGERY IN ADVANCED HIGH GRADE OVARIAN CANCER PATIENTS: A COHORT STUDY

N. Girard1, J. Asmar2, B. Rance2, A.S. Bats2, M. Delomenie1, L. Rossi1, M. Gosset1, F. Lecuru1, C. Ngo1

1Hôpital Européen Georges Pompidou, Chirurgie Oncologique Gynécologique et Sénologique, Paris, France
2Hôpital Européen Georges Pompidou, Informatique Médicale et Santé Publique, Paris, France

Aims

Main objective was to report survival outcomes in advanced ovarian cancer patients treated with neoadjuvant chemotherapy (NACT) or primary debulking surgery (PDS).

Method

A retrospective cohort study was conducted. Patients included had stage IIb to IV high-grade ovarian carcinoma diagnosed between January 1, 2011 and March 31, 2016, treated either by NACT or PDS. Overall survival (OS) and progression free survival (PFS) analysis were performed using log-rank tests and adjusted Cox proportional hazards models.

Results

213 patients were eligible. 116 patients (55%) received NACT, 97 patients (45%) underwent PDS. Median OS was 24 months. 123 patients (62%) had disease recurrence, 65 (32%) had died at study census. Patients who underwent PDS were younger, had a lower initial peritoneal cancer index (PCI) and less advanced disease. Optimal cytoreduction was obtained for 179 patients (84%). On univariate analysis, older age at diagnosis, higher initial PCI, NACT and incomplete surgical cytoreduction were associated with decreased OS and PFS. On multivariate analysis, only incomplete cytoreduction remained associated with decreased OS and PFS (respectively, adjusted HR 3.80 95%CI 1.94-7.44 and HR 2.03 95%CI 1.03-4.01). High initial PCI was also associated with decreased PFS (HR 1.05 for each additional unit of PCI) but not OS. Similar results were observed when excluding platinum resistant patients.

Conclusion

Our findings suggest that survival does not depend on initial strategy of management. PDS is not associated with post-operative complications or less complete resection. NACT might be reserved for women who are not appropriate candidates for PDS for institutional or individual reasons.

ADVANCED OVARIAN CANCER: ARE WE UNDERSTAGING OUR PATIENTS? THE ROLE OF FDG-PET/CT BEFORE PRIMARY TREATMENT

A. G. Glickman1, B. Gil Ibañez1, P. Paredes2, L. Buñesch3, M. C. Sebastià1, I. Nicolas1, A. Rodríguez-Trujillo1, M. Munmany1, M. Del Pino1, P. Fuste1, J. Pahisa1, A. Torne1

1Hospital Clinic de Barcelona, Gynaecology Oncology Unit, Barcelona, Spain
2Hospital Clinic de Barcelona, Nuclear Medicine Department, Barcelona, Spain
3Hospital Clinic de Barcelona, Radiodiagnóstics Department, Barcelona, Spain

Aims

FDG-PET/CT has been suggested as a feasible but not yet broadly recommended tool to workup epithelial ovarian cancer (EOC) before primary treatment. The aim of this study was to evaluate the rate of upstaging introduced by the use of FDG-PET/CT for the initial assessment of suspected advanced EOC.

Method

Between 08/2012 and 07/2016, 48 patients presented, according to abdomino-pelvic CT and confirmed by histology, advanced EOC and were evaluated with whole-body FDG-PET/CT. Patient data were collected before primary treatment.

Results

The median age at diagnosis was 60 years (range 38-83). The median CA125 value was 1161.7 U/mL and median HE4 was 845.5 pmol/L. 60.4% showed moderate or massive ascites.

When evaluated using standard abdomino-pelvic CT we found 36 cases of suspected stage III (75%) and 12 suspected stage IV patients (25%). After FDG-PET/CT we identified that 19 patients were upstaged (39.6%), finding 21 stage III cases (43.8%) and 27 stage IV cases (56.3%). FDG-PET/CT detected patients with either cardiophrenic, internal mammary, mediastinal, supraclavicular, submandibular or axillary FDG-avid lymph nodes and patients with either pleural, splenic, adrenal and/or hepatic FDG-avid nodes suggestive of metastasis. None of these had been found by standard abdomino-pelvic CT.

Conclusion

More than one third of advanced EOC patients were upstaged by the use of FDG-PET/CT. Randomized studies should be used to clarify the role of FDG-PET/CT in the preoperative assessment of advanced EOC. We should discuss if we are staging advanced EOC patients correctly and therefore providing them with an accurate treatment.
Aims

Ever since their discovery microRNAs are in the focus of scientific research. These small epigenetic regulators act as tumor suppressor or onco-miRs during carcinogenesis. Due to their high stability in tissue and serum and characteristic expression patterns indicative not only of cancer type but also disease development and progression we aimed to determine the set of miRNAs that show unique expression changes during the course of disease progression in women diagnosed with ovarian cancer at the Department of Obstetrics and Gynaecology (University of Pécs, Medical School).

Method

A total of 25 patients were enrolled and their serum samples were prospectively collected at regular time intervals with the simultaneous registration of clinical status. Samples were stored at -70°C before microRNA isolation and SYBR-green Fluorescence based real-time relative quantification using qRT-PCR (LightCycler 480). Housekeeping and interrun calibrators were added to the runs that were repeated 3times and averaged. LighCycler Software 4.0 and SPSS Version 23 were used for quantification and data analysis.

Results

We are trying to determine the expression changes of the selected panel of microRNAs. Data assessment and evaluation in conjunction with patient characteristics and clinical status are still ongoing. Finding the right combination of miRNAs can increase significance and relevance. We are assessing our data to determine the most effective combination of miRNAs for risk assessment. Final results are due by the end of June.

Conclusion

Based on our results changes in miRNA expressions can be informative and have clinical utility. Based on sufficient evidence miRNAs are potential biomarkers in ovarian cancer.

CHANGES IN THE MANAGEMENT OF OVARIAN CANCER DUE TO THE NEW FIGO AND WHO CLASSIFICATIONS:A CASE SERIES OBSERVATIONAL DESCRIPTIVE STUDY. SEVEN YEARS OF FOLLOW UP

M. GOMES FERREIRA1, R. GONZALEZ2, M.J. DOYAGUE SÁNCHEZ3
1Hospital Clínico Universitario de Salamanca, Obstetrics and Gynecology, Salamanca, Spain
2IBSAL - Institute for Biomedical Research of Salamanca, DIRECTOR, SALAMANCA, Spain
3Hospital Clínico Universitario de Salamanca, Obstetrics and Gynecology, Salamanca, Spain

Aims

Ovarian cancer is the deadliest of gynecologic cancers. Therefore, FIGO and the WHO classifications were revised. Both classifications are essential criteria for the treatment decision. We sought 1) to compare the major changes between the both classifications; 2) to examine the effects on the therapeutic and prognosis of the Ovarian, Fallopian Tubes and Peritoneum cancer in our sample.

Method

We performed a case series observational descriptive study of 210 patients who have been diagnosed with and/or treated for a malignant ovarian tumor at University Clinic Hospital of Salamanca from 2010-2016.

Results

According to the new FIGO subdivision of stage IC, we obtained 2.52% in substage IC2. The vast majority of ovarian cancer cases are in III FIGO stage. In the new WHO classification, the main change to the Serous group was the increase in the HGSC percentage. In the previous classification we had 6.48% of endometrioid malignant tumor and in the new classification this rate has decreased to 2.78%. Concerning Serous tumors, the separating line between adenomas and borderline tumors (SBOT) has been refined in the current WHO classification. In our study, the HGSC has reached 55.56% in the new WHO classification thanks to the incorporation of serous malignant adenocarcinoma (1988 WHO classification). We found 1.85% of Seromucinous Borderline Tumors. We found that 4.2% of the previous Stage IIIC patients have changed to stage IIIA2 or stage IIIB and this group of patients has a better prognosis and a superior survival rate.

Conclusion

This study demonstrated that the new-created WHO and FIGO classifications have improved the ability to predict the prognosis and consequently to change the therapeutic managements in Ovarian cancer patients.

16Arizona Oncology US Oncology Network- University of Arizona College of Medicine- Creighton University School of Medicine at St. Joseph's Hospital, Gynecologic Oncology, Phoenix- AZ, USA

Aims

Niraparib (ZEJULA™) is a selective poly (ADP-ribose) polymerase (PARP) 1/2 inhibitor. The ENGOT-OV16/NOVA trial demonstrated the clinical efficacy of niraparib in patients with recurrent ovarian cancer (OC) who are in complete or partial response (CR or PR) to platinum-based chemotherapy, regardless of their germline BRCA mutation (gBRCAmut) or homologous recombination deficiency (HRD) status. The primary objective of this trial is to measure the efficacy of niraparib maintenance in patients with advanced OC with a CR or PR to front-line platinum-based chemotherapy.

Method

This multicenter international trial is enrolling ≈330 patients with ovarian, fallopian tube, or peritoneal cancer. Eligibility criteria includes all patients with stage IV disease, and patients with stage III disease who were treated with neoadjuvant chemotherapy followed by interval debulking surgery, or who have either inoperable disease or visible residual disease after primary debulking surgery. Patients must have had a CR or PR to front-line platinum-based chemotherapy. Stratification factors include neoadjuvant chemotherapy (yes/no), best response to platinum therapy (CR or PR), and HRD status (HRD positive, including the known deleterious BRCA mutations gBRCAmut or somatic BRCAmut, or HRD negative). Patients are randomized 2:1 to receive either oral niraparib (300 mg) or matched placebo once daily in 28-day cycles. Tumors are assessed every 12 weeks per RECIST v1.1. The primary endpoint is progression-free survival, assessed by RECIST criteria and clinical criteria using blinded central review. Secondary endpoints include overall survival, patient-reported outcomes, safety and tolerability, and time to progression on next therapy.

OVARIAN SCLEROSING STROMAL TUMOR. A RARE OVARIAN ENTITY

C. Goudeli1, N. Koufopoulos2, F. Antoniadou2, E. Terzakis1

1Hellenic Anticancer Hospital- "Saint Savvas", Gynecology, Athens, Greece
2Hellenic Anticancer Hospital- "Saint Savvas", Pathology, Athens, Greece

Aims

We report a case of sclerosing stromal tumor (SST) of the ovary a rare, benign sex cord stromal ovarian tumor occurring predominantly in the second and third decade of life.

Method

A 44-year-old patient was admitted to the Gynecology Department due to a solid tumor of the right ovary that was an incidental finding on routine US examination. US also revealed a fibromyomatous uterus. The patient had a history of hypermenorrhea for the last five years and menstrual irregularity in the last 12 months. Physical examination revealed a palpable abdominal mass. MRI confirmed the US examination results finding a stromal tumor of the right ovary measuring 47x34x28mm probably of the sclerosing stromal tumor type. Hysterectomy and bilateral adnexectomy was performed.

Results

On gross examination the tumor was circumscribed, solid measuring 47x34x28 mm. Microscopic examination revealed a pseudolobular pattern of growth with cellular areas forming nodules separated by less cellular edematous areas, numerous thin-walled blood vessels, a cell population consisting of an admixture of fibroblasts and rounded to oval vacuolated cells some of them with a signet-ring cell like appearance. There was no atypia in either cellular component. Mitoses were not identified. Immunohistochemical analysis revealed positive staining for Vimentin, Inhibin and Smooth Muscle Actin while AE-1/AE-3, Estrogen and Progesterone Receptors were negative.

Conclusion

The diagnosis of SST of the ovary was made. SST is a rare sex cord stromal tumor with unique clinicopathological and histological characteristics.

STAGING SURGERY IN EARLY-STAGE OVARIAN MUCINOUS TUMORS ACCORDING TO EXPANSILE AND INFILTRATIVE TYPES

S. Gouy1, S. Marine1, E. Bentivegna1, S. Bach-Hambâ2, A. Maulard1, A. Leary2, P. Pautier2, M. Devouassoux-Shisheboran3, C. Genestie4, P. Morice1

2Gustave Roussy, Oncology, Villejuif, France
3Hospices Civils de Lyon, Pathology, Lyon, France
4Gustave Roussy, Pathology, Villejuif, France

Aims

To determine the value of surgical staging for the two histologic types (expansile or infiltrative) of apparent stage I mucinous ovarian carcinoma.

Method

We retrospectively analyzed patients treated from 1976 and 2016 for apparent macroscopic stage I ovarian mucinous carcinoma. Extra-ovarian disease and tumors that metastasized to the ovaries were excluded. Two expert pathologists performed pathologic reviews of tumor data, according to 2014 WHO classification criteria. Tumors were typed as expansile or infiltrative and clinical and histologic characteristics were studied. The value of staging procedures (peritoneal and nodal) was based on the rate of microscopic involvement in macroscopically normal specimens.

Results

Of 114 cases reviewed, 46 were excluded (26 with macroscopic stage >I; 20 inaccessible for pathologic review). Of 68 patients included, 29 had expansile and 39 had infiltrative types. 27 patients received one-step surgery and 41 received restaging surgery. 52 patients received “complete” peritoneal surgical staging (including cytology, peritoneal biopsies, and an omentectomy or large omental biopsies). 24 underwent appendectomies and 31 underwent lymphadenectomies (8 expansile and 23 infiltrative). Before histologic analyses of staging specimens, 35 had “initial” stage IA and 33 had IC disease. After histologic analyses of lymph nodes, 4 cases (17%, all infiltrative) had nodal involvement, and 2 showed microscopic peritoneal disease (1 omentum and 1 right diaphragm peritoneum). Three patients were upstaged based on isolated positive peritoneal cytology.

Conclusion

Peritoneal staging procedures are required for both types of mucinous ovarian carcinoma. Lymphadenectomy could be omitted in expansile, but required in infiltrative type.
EVALUATION OF OLAPARIB SERUM CONCENTRATIONS IN PATIENT WITH TERMINAL RENAL INSUFFICIENCY AND DIALYSIS TREATED FOR PLATIN-SENSITIVE RECURRENT BRCA POSITIVE HIGH GRADE SEROUS OVARIAN CANCER.

J.P. Grabowski¹, J. Glajzer¹, R. Richter¹, D. Zickler², J. Sehouli¹

¹Charité - Universitätsmedizin Berlin, Department of Gynecology- European Competence Center for Ovarian Cancer, Berlin, Germany
²Charité - Universitätsmedizin Berlin, Department of Nephrology and Internal Intensive Medicine, Berlin, Germany

Aims

Olaparib, a PARP inhibitor, is a recommended maintenance therapy in BRCA mutated patients with relapsed, platinum sensitive high-grade serous ovarian cancer. Until now, there are lacking data of olaparib in patients with terminal renal failure (GFR< 30 ml/min) and dialysis.

Method

The serum concentrations of olaparib in a 75 year old patient with platin-sensitive recurrent high-grade ovarian cancer and terminal renal insufficiency (GFR< 15 ml/min) were measured systematically. The blood samples were taken prior, 1, 1.5, 2, 3, 4 and 6 hours after medication intake on a dialysis- and a non-dialysis day. Subsequently, the serum concentrations were analyzed.

Results

The patient is under olaparib therapy since March 2016 in a reduced dose of 200mg daily. She suffered from terminal renal insufficiency due to postoperative kidney failure after primary cytoreductive surgery by initial FIGO IIIC stage. Mild nausea and fatigue were present at the beginning of the therapy and released after few weeks. The patient is after a follow up of 14 months in a complete remission. The analysis revealed a median olaparib serum concentration of 1.46 µg/ml on dialysis and 2.93 µg/ml on non-dialysis day. No statistical significant difference between concentrations variations on these days was found (p=0.200; Mann-Whitney- U- Test).

Conclusion

To our knowledge, this is the first report evaluating olaparib serum concentration in terminal renal insufficiency and dialysis situation. Our analysis shows olaparib therapy as feasible and safe in those patients. Given to no concentrations variations differences on both days, the elimination seems to be independent from dialysis.

Aims

To evaluate the impact of tertiary cytoreductive surgery (TCS) on survival in recurrent epithelial ovarian cancer (EOC), and to determine predictors of complete surgical cytoreduction.

Method

A multi-institutional retrospective study was conducted within the MITO Group on a 5-year observation period. Patients were considered eligible if they met the criteria listed in Table 1.

<table>
<thead>
<tr>
<th>Inclusion criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age ≤75 years</td>
</tr>
<tr>
<td>Performance status (ECOG) 0–1</td>
</tr>
<tr>
<td>≥6 month TFI at the time of each recurrence</td>

</tr>
<tr>
<td>Patients with second malignancies who had been treated by laparotomy or who had a therapy that could interfere with the treatment of ROC</td>
</tr>
</tbody>
</table>

Table 1. Enrollment criteria.

Results

A total of 103 EOC patients undergoing TCS were included (Table 2). Complete cytoreduction was achieved in 71 patients (68.9%), with severe post-operative complications in 9.7%, and no 30-day operative mortality. Multivariate analysis identified the complete tertiary cytoreduction as the most potent predictor of survival followed by FIGO stage I-II at initial diagnosis; exclusive retroperitoneal recurrence; TCS performed ≥3 years after primary diagnosis (Table 3). Patients with complete tertiary cytoreduction had a significantly longer overall survival (median OS: 43 mos, 95% CI 31 – 58) compared to those with residual
tumor (median OS: 33 mos, 95% CI 28 – 46; \( p < 0.001 \)). After multivariate adjustment, the following variables were the most significant predictors of complete surgical cytoreduction: single lesion; good performance status (ECOG 0) (Table 3).

### Conclusion

Only one further large retrospective study on TCS has been published so far. The achievement of postoperative no residual disease is confirmed as the primary objective also in a TCS setting, when considering surgical efforts aiming at improvement of survival, with acceptable morbidity. Accurate patient selection is of utmost importance to have the best chance of complete cytoreduction.
FACTORS ASSOCIATED WITH A DEVIATION FROM STANDARD SURGICAL TREATMENT IN ELDERLY PATIENTS TREATED FOR OVARIAN TUMOR.

G. Babin¹, D. Querleu¹, F. Lecuru², A.S. Bats², G. Cordeiro Vidal¹

¹Institut Bergonié, Surgery, Bordeaux, France
²Hôpital Européen Georges Pompidou, Surgery, Paris, France

Aims

To compare two groups of elderly patients treated for an epithelial ovarian cancer, to understand the outcomes leading to a deviation to standard therapy and to isolate predicting factors of this outcome.

Method

It's a retrospective, bi-centric study, about all patients over 70 years old treated for an epithelial ovarian cancer between January 2005 and January 2014. We studied the pre therapeutic data of the patients, their treatment and the outcome of it depending on the standard treatment for ovarian cancer.

Results

222 patients were included. 93 patients received a complete standard treatment and 129 had a deviation to standard therapy. The encountered causes of deviation were: the spreading of the disease in 87 cases (67.4 %), a medical refusal due to co-morbidities in 36 cases (27.9 %), surgical complications in 19 cases. An oncogeriatric analysis was performed in 22% of the cases in the group with standard therapy and in 38% in the group with deviation p = 0.02. When the oncogeriatric analysis did not promote a standard therapy, no patient had a standard treatment. There weren't more complication in surgery despite a more aggressive surgery in the group with standard treatment. Patients without deviation had an extended, survival hazard ratio 0.23 (0.14-0.39), p < 0.001.

Conclusion

Standard management of advanced EOC is associated with a substantial survival benefit in the elderly patient when it can be achieved. The main obstacle to complete a standard treatment remains the spread of the disease and the impact of aggressive surgery in frail patients.
OVARIAN CANCER

SYNCHRONOUS PRIMARY OVARIAN AND ENDOMETRIAL CANCERS: A SERIES OF CASES AND A REVIEW OF LITERATURE

S. Haddad¹, F. Tekari², M. Bouhani¹, R. Doghrî², M. Slimene¹, M. Driss², K. Ben Mrad³, M. Hechiche¹, J. Ben Hassouna¹, K. Ben Rahal⁴

¹Salah Azaiez Institute, Surgery, Tunis, Tunisia
²Salah Azaiez Institute, Anatomy and Cytology, Tunis, Tunisia

Aims

Synchronous primary cancers of the female genital tract occurs in only 0.5-1.7% cases. In those patients, the most common combination is synchronous primary endometrial and ovarian cancers. cases of metastasis from an ovarian and endometrial cancer should be distinguished from synchronous cancer. we aim to highlight the morphological, immunohistochemical and molecular features in order to distinguish synchronous carcinoma from metastatic ones.

Method

The clinical data of 12 patients with synchronous primary cancers of the endometrium and ovary were retrospectively reviewed. Clinical and pathologic information was obtained from medical records.

Results

Median age at diagnosis was 46.8 years. almost half of the women were premenopausal and 33% were nulliparous. The most common presenting symptom was abnormal vaginal bleeding. Ovarian cancer was bilateral in 4 cases. Sixty-eight percent of patients had endometrioid histology of both their endometrial and ovarian cancers. Patients with early stage ovarian cancer tended to have a more favorable prognosis than those with advanced stage disease (median survival not reached in stage I and II versus 66 months in stage III and IV, P = 0.06). Patients with concordant endometrioid histology had a favorable prognosis (median survival 119 versus 48 months in all other groups, P = 0.02).

Conclusion

Synchronous ovarian and endometrial cancers are usually diagnosed at an earlier stage, have lower histological grade and better prognosis than single cancers.
OVARIAN CANCER

ESGO7-1161

EXPRESSION OF ACID CERAMIDASE (ASAH1) AS A PROGNOSTIC FACTOR IN OVARIAN CANCER

1University Lübeck, Gynecology and Obstetrics, Lübeck, Germany
2Tübingen University Hospital, Department of Women’s Health, Tübingen, Germany
3Goethe University Frankfurt, Department of Obstetrics and Gynecology, Frankfurt, Germany
4Bethesda Hospital, Department of Gynecology, Mönchengladbach, Germany
5BCCA Cancer Research Centre, Department of Molecular Oncology, Vancouver, Canada
6University Hospital Bonn, Institute of Pathology, Bonn, Germany

Aims

Acid ceramidase (AC), encoded by the ASAH1 gene, is a key enzyme of sphingolipid metabolism and frequently overexpressed in a variety of cancer types. In the present study, we investigated the expression of AC and its prognostic impact in ovarian cancers.

Method

Tissue micro arrays constructed using formalin-fixed paraffin-embedded tissue of primary ovarian cancers (n = 789) were obtained. Immunohistochemical analysis of AC was performed, and the results were correlated with clinico-pathological characteristics and survival.

Results

High AC expression was shown to significantly correlate with optimal tumour resection (p < 0.001). Kaplan-Meier analysis further revealed that low AC levels were associated with reduced progression-free survival (PFS; 44.82 months [95% confidence interval (CI): 32.21-55.43] vs. 86.49 months [95%CI: 63.01-109.97], p < 0.001) and overall-survival (OS; 68.25 months [95%CI: 59.14-77.35] vs. 108.69 months [95%CI: 85.79-131.58], p < 0.001). Subsequently, the prognostic value of AC expression together with clinical factors (i.e. FIGO stage, age, and residual tumour burden after surgery) was substantiated in univariate Cox regression analysis (PFS: hazard ratio (HR) = 1.36 [95%CI: 1.15-1.63], p < 0.001; OS: HR = 1.4 [95%CI: 1.7-1.68], p < 0.001).

Conclusion

Our results suggest that AC expression is a prognostic factor in ovarian cancer, and that low AC expression might be associated with cancer progression and suboptimal tumour debulking. To corroborate these findings, however, our results need to be validated in an independent patient cohort.
INCIDENCE AND PREDICTORS FOR CHEMOTHERAPY MODIFICATIONS AND THEIR IMPACT ON THE OUTCOME OF OVARIAN CANCER PATIENTS

S. Hatsy1, C. Brambs1, M. Kiechle1

1Technical University Munich, Gynecology and Obstetrics, Munich, Germany

Aims

Chemotherapy (CTX) is an important part of the treatment strategy of stage II-IV ovarian cancer. Chemotherapy modifications, such as delay, dose reduction or premature termination might have a negative impact on overall survival (OS) and progression free survival (PFS). The goal of this study was to determine the incidence and predictors of chemotherapy modifications and their influence on survival in an ovarian cancer cohort of a DKG* certified gynecological cancer centre.

Method

An observational retrospective cohort analysis of ovarian cancer patients who received care according to national guidelines (AGO**) was performed including 219 ovarian cancer patients from 2009 to 2013. An association of patient and disease characteristics with a chemotherapy delay, dose reduction and premature termination will be tested with multivariate logistic regression. Overall survival and progression free survival will be estimated by Kaplan-Meier analysis.

Results

39.3% (86/219) received a modification of chemotherapy. 33.7% (29/86) of women stopped chemotherapy prematurely, 20.9% (18/86) experienced a chemotherapy delay, 23.3% (20/86) had a dose reduction and 12.8% (11/86) had both a delay and a dose modification. In 9.3% (8/86) the dose needed to be split. Survival data for patients with chemotherapy modifications as well as predictors will be presented.

Conclusion

Compared to earlier studies, we detected a lower incidence of dose reduction or delay of CTX (80.9% in N. Joseph et al., Gynecologic Oncology 137 (2015), versus 39.3% in our study). This might be due to the fact that patients were treated within a comprehensive cancer centre.

*DKG = Deutsche Krebs Gesellschaft
**AGO = Arbeitsgemeinschaft Gynäkologische Onkologie
A RETROSPECTIVE ANALYSIS OF IMMUNOHISTOCHEMICAL DETERMINED IRF4 (INTERFERON REGULATING FACTOR 4) EXPRESSION IN A CONSECUTIVE COHORT OF 114 OVARIAN CANCER PATIENTS

A.S. Heimes¹, M. Schmidt¹, J. Jaekel², K. Almstedt¹, S. Gebhard¹, V. Weyer-Elbereich³, T. Elger¹, S. Krajnak¹, W. Brenner¹, A. Hasenburg¹, M.J. Battista¹

¹University Medical Center, Department of Gynecology and Obstetrics, Mainz, Germany
²University Medical Center, Institute of Pathology, Mainz, Germany
³University Medical Center, Institute of Medical Biostatistics-Epidemiology and Informatics IMBEI, Mainz, Germany

Aims

Tumor-infiltrating lymphocytes (TILs) influence the prognosis of solid tumors, including ovarian cancer (OC). The immunoregulatory transcription factor (IRF4) is mainly expressed in plasma cells and regulates immunoglobulin class switch recombination as well as plasma cell differentiation. Therefore, we analyzed the impact IRF4 expression in a consecutive cohort of OC patients.

Method

IRF4 expression was evaluated by immunostaining. Differences in IRF4 expression among subgroups of established clinical-pathological features like age, histological subtype, tumor stage, histological grading, postoperative tumor burden and completeness of chemotherapy were determined by x² test. The impact of IRF4 expression on progression free survival (PFS) and overall survival (OS) was examined by univariate and multivariate Cox analysis adjusted for established clinical-pathological factors and Kaplan-Meier survival analysis.

Results

114 patients entered this study. IRF4 was expressed in 51.7% of the entire cohort. 72.3% patients with high-grade serous OC showed IRF4 expression compared to 37.3% patients with a non high-grade serous OC (p<0.001). Univariate Cox-Regression analysis revealed no prognostic impact of IRF4 expression in terms of PFS (p=0.35) and OS (p=0.98). Kaplan-Meier plots failed to show any prognostic impact for PFS (p=0.35) and OS (p=0.98), too. Established clinicopathological factors retained their prognostic impact as tumor stage in terms of PFS (<0.001) and as postoperative residual tumor burden (p=0.04), tumor stage (<0.001), histological grade (p=0.02) and completeness of chemotherapy (p<0.001) in terms of OS, respectively.

Conclusion

Immunohistochemically determined IRF4 expression correlated with high-grade serous OC. However, it failed to show to any prognostic impact in this cohort of 114 patients.
DETECTION AND CHARACTERIZATION OF P53 PRIONS IN HIGH-GRADE SEROUS OVARIAN CANCER

6KU Leuven, Division of Gynecological Oncology, Leuven, Belgium
7University Medical Center Hamburg-Eppendorf, Department of Gynecology, Hamburg, Germany
8Ludwig-Maximilian University of Munich, Department of Gynecology and Obstetrics, Munich, Germany

Aims

About 96% of high-grade serous ovarian cancers (HGSOC) harbor TP53 mutations. Recent evidence showed that several TP53 mutations lead to aggregation into prion-like amyloids, resulting in dominant-negative activity and oncogenic gain-of-function. This process could be involved in HGSOC initiation, progression and platinum-resistance. An ELISA-based technique was applied to detect p53 prions and to evaluate their prevalence and clinical relevance.

Method

Fresh-frozen tumour tissue of 123 HGSOC patients from the OVCAD study (at least five years follow-up) was analysed. An ELISA previously applied in the diagnosis of mad cow disease was optimized for the analysis of p53 prions. Data were analysed using Kaplan-Meier curves and Log-rank test.

Results

Samples carrying TP53 missense mutations showed a significantly higher prion signal compared to wild-type or frameshift mutated samples. In 37/46 (80.4%) of missense mutated cancers a p53 prion specific signal was detected. The ELISA results varied significantly between different tumours carrying the same missense mutation. A significantly diminished overall survival was observed for patients with moderate aggregation compared to patients with no p53 prions (p=0.031). In contrast, extensive p53 aggregation resulted in a prolonged overall (p=0.025) and progression-free survival (p=0.014).

Conclusion

We demonstrated the validity of the established ELISA in detecting p53 prions and their high abundance in HGSOC. Our data indicate that missense mutations alone are not sufficient and other cofactors are involved in the formation of prions. The significant correlation between survival and p53 prion levels demonstrates that the understanding of the biology of p53 prions is of high importance.
LSR PROMOTES LIPID UPTAKE, BETA-OXIDATION AND SUBSEQUENT TUMOR GROWTH IN OVARIAN CANCER

K. Hiramatsu¹, S. Serada¹, T. Sugase¹, S. Nakagawa¹, M. Fujimoto¹, S. Matsuzaki², Y. Ueda², K. Yoshino², T. Kimura², T. Naka¹
¹Kochi University, Immuno Disease Center, Kochi, Japan
²Osaka University, Obstetrics and Gynecology, Osaka, Japan

Aims

Previously we demonstrated that high expression of lipolysis-stimulated lipoprotein receptor (LSR) was poor prognostic factor in ovarian cancer. However, the pathophysiological role of LSR in the progression of ovarian cancer remains unclear. We aimed to reveal the function of LSR in lipid metabolism and develop a new anti-tumor monoclonal antibody against ovarian cancer.

Method

In terms of lipid metabolism, we investigated the function of LSR in ovarian cancer. We treated LSR-positive ovarian cancer cell lines with VLDL and analyzed cell proliferation. Moreover, we also analyzed the expression of beta-oxidation related proteins and cell cycle regulation by flow cytometry.

Results

LSR cDNA transfected cells significantly increased uptake of VLDL (p<0.05) and reserved lipid metabolite (p<0.01). In high glucose medium, LSR promoted cell cycle via peroxisome proliferator-activated receptor (p<0.05). On the other hand, in low glucose medium, LSR promoted beta-oxidation and subsequent cell proliferation (p<0.05). Our newly developed anti-LSR monoclonal antibody inhibited these processes (p<0.05).

Conclusion

LSR promoted lipid uptake and subsequent tumor growth in ovarian cancer. Especially LSR increased beta-oxidation and promoted cell cycle. These data shows that LSR is a promising target for ovarian cancer treatment.

PREOPERATIVE LYMPHOCYTE-MONOCYTE RATIO IS A PREDICTOR OF SUBOPTIMAL CYTOREDUCTION IN STAGE III-IV EPITHELIAL OVARIAN CANCER

K. Hong Bae

1Hallym University Hospital, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

To determine whether the preoperative lymphocyte-monocyte ratio (LMR) is a predictor of suboptimal cytoreduction in advanced-stage epithelial ovarian cancer (EOC).

Method

Preoperative clinico-pathologic and hematologic parameters were reviewed in a total of 154 patients with EOC submitted to primary cytoreductive surgery. Patients were categorized into two different groups according to the results of cytoreductive surgery: optimal and suboptimal cytoreduction. Continuous variables were categorized into two groups using the best cutoff points selected on the receiver operating characteristics (ROC) curve for suboptimal cytoreduction.

Results

Based on data collected from the 154 patients, 133 (86.4%) and 21 (13.6%) patients presented with stage III and IV disease, respectively. One hundred seventeen (76%) patients had serous adenocarcinoma, and 92 (59.7%) had histologic tumor grade 3. The optimal and suboptimal cytoreduction groups included 96 (62.3%) and 58 patients (37.7%), respectively. The best LMR cutoff point for suboptimal cytoreduction was 3.75. On multivariate logistic regression analysis, age, cancer antigen 125, white blood cell count and LMR were found to be the strongest predictors for suboptimal cytoreduction (P = 0.0037, 0.0249, and 0.0015, respectively).

Conclusion

Preoperative LMR is an independent predictor of suboptimal cytoreduction. It provides additional prognostic information beyond the biological parameters of the tumor.
INHIBITION OF HISTOLOGY-SPECIFIC EXPRESSION OF HOX GENES FOR OVERCOMING PLATINUM RESISTANCE IN EPITHELIAL OVARIAN CANCER

D.H. Hong

Seoul National University Bundang Hospital, Gynecology Office, Bundang-gu- Seongnam-si, Republic of Korea

Aims

Expression of HOX genes in epithelial ovarian cancer (EOC) was known to be histology-specific. Purposes of this study was to explore the expression level of HOX genes in EOC cell lines and finding tailored strategy of inhibiting histology-specific expression pattern of HOX genes for overcoming platinum-resistance in EOC.

Method

Eleven HOX genes were tested for identifying the histology-specific expression of HOX genes in this study. SKOV-3 and RMUG-S was selected for serous and mucinous type EOC cell lines. Cell viability after treatment of 10 μM cisplatin over 72 hours with or without 50 nM siRNA of HOX were examined using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Signaling pathways for apoptosis, cell proliferation, and epithelial-mesenchymal transition were evaluated before and after the treatment.

Results

HOXA10 and HOXB9 showed high expression in SKOV-3 and RMUG-S. After cisplatin treatment, 91.3%±0.9% of RMUG-S and 46.5%±0.5% of SKOV-3 survived. However, co-treatment of HOXB9 siRNA with cisplatin reduced cell viability of RMUG-S to 64.9%±0.2%. HOX10 siRNA treatment decreased cell viability of SKOV-3, but not RMUG-S. By contrast, HOXB9 siRNA treatment decreased cell viability of RMUG-S, but not SKOV-3. HOX10 siRNA and HOXB9 siRNA treatments: increased the expression level of cleaved PARP and caspase-3 in SKOV-3 and RMUG-S; expression of vimentin was decreased while expression of E-cadherin was increased; SOX-2, Nanog, and Oct-4 decreased in both cell lines after siRNA treatment.

Conclusion

Our findings suggested that platinum-resistance of mucinous cell line might be defeated by inhibiting highly-expressed HOXB9, which could be a target of tailored strategy for overcoming the platinum-resistance in EOC.

**INTERACTION BETWEEN TWIST1 EXPRESSION AND TUMOR MICROENVIRONMENT FOR ANGIOGENESIS IN OVARIAN CARCINOMA**

J.H. Hong¹, Y.T. Ouh¹, H.W. Cho¹, J.K. Lee¹

¹Guro Hospital Korea University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

**Aims**

Twist1 is a transcription factor that is involved in cancer metastasis and recurrence, but little is known about the mechanisms underlying these processes. This study aimed to investigate the role of Twist1 in tumor angiogenesis in epithelial ovarian cancer (EOC) and to identify key molecules involved in the Twist1 pathway.

**Method**

A Twist1 siRNA was transfected into the EOC cell line that showed the highest expression to silence the gene, while a cDNA vector was transfected into human ovarian surface epithelial cells to generate a Twist1-overexpressing cell line. To evaluate the change in angiogenesis, HUVEC tube formation assays were performed using the control and the transfected cell lines. In addition, a cytokine array was used to determine the molecules involved in Twist1-mediated angiogenesis.

**Results**

After Twist1 knockdown in A2780 cells, the number of tubes formed by HUVECs significantly decreased. In a cytokine array, Twist1 downregulation inhibited the expression of the CXC chemokine ligand 11 (CXCL11), which was confirmed by both an enzyme-linked immunosorbent assay and a western blot assay. In contrast, Twist1 overexpression increased the secretion of CXCL11. Furthermore, the ability of Twist1-expressing A2780 cells to induce angiogenesis was inhibited after CXCL11 knockdown by CXCL11-siRNA in a tube formation assay. Conversely, CXCL11 downregulation did not inhibit Twist1 expression.

**Conclusion**

Our findings demonstrate that Twist1 plays an important role in angiogenesis in EOC and is mediated by a novel pro-angiogenic factor, CXCL11. Downregulation of CXCL11 can inhibit tumor angiogenesis, suggesting that an anti-CXCL11 therapy may offer an alternative treatment strategy for Twist1-positive ovarian cancer.
EXTERNAL MULTICENTRIC VALIDATION OF TWO SCORES PREDICTING THE RISK OF RELAPSE IN PATIENTS WITH BORDERLINE OVARIAN TUMORS: NOMOGRAM OF BENDIFALLAH AND SCORE OF OULDAMER

P. Pais1, C. Huchon1, A. Chevrot1, A. Fauconnier1, R. Rouzier2, M. Mimouni1

1 CHI Poissy-Saint-Germain, Gynecology, POISSY, France
2 Hôpital René Huguenin, Gynecology, Saint Cloud, France

Aims

Borderline ovarian tumors are rare and can occur in young women. For this patients, a fertility sparing surgery should be discussed. Two predicting borderline ovarian tumor relapse risk models were developed in 2014 (Nomogramm of Bendifallah) and 2017 (Score of Ouldamer). This study aimed to valid in an external poplulation this two scores using a multi-institutional Borderline Ovarian Tumor database.

Method

In this bicentric and retrospective study, all consecutive patients comprising the variable nomogram documented treated between January 2006 and December 2012 for Bordeline Ovarian Tumor in Centre Hospitalier de Poissy-Saint-Germain and Hôpital René Huguenin were included. A ROC model was etablished for each predicting scores.

Results

Sixty-five patients were included in the study. Twelve patients showed a recurrence (19%), three of them experienced an infiltrative cancer (5%). The median time of recurrence was 25 months (range: 8-115). The concordance index for the Nomogramm of Bendifallah and the Score of Ouldamer were 0.88 ([IC95%] 0.78-0.98) and 0.87 ([IC95%] 0.77-0.96) respectively.

Conclusion

This study from an independant population valid the Bendifallah nomogram and Ouldamer score for clinical use in predicting borderline ovarian recurrence.
FRIED FRAILTY SCORE IS A POSSIBLE PREDICTOR FOR POSTOPERATIVE COMPLICATIONS IN GYNECOLOGIC CANCER PATIENTS: RESULTS OF A PROSPECTIVE STUDY IN 237 PATIENTS

G. Inci¹, L. Anders¹, R. richter¹, Z. Muallem¹, R. Chekerov¹, J. Sehouli¹
¹Charité - Universitätsmedizin Berlin, Gynecologic Oncology, Berlin, Germany

Aims

Physicians need to risk-stratify their patients preoperatively to adjust the radicality of surgery. Aim of this study is to evaluate the predictive ability of fried frailty score for surgical outcomes after gynecologic cancer surgery.

Method

This is a prospective cohort study of patients undergoing gynecologic cancer surgery at a tertiary care academic center from October 2015 through January 2017. At baseline, we classified frailty as proposed by Fried. Surgical complications were graded using validated Clavien-Dindo criteria. Using ROC Analysis and logistic regression, we identified demographic and predictive clinical characters for postoperative complications.

Results

Out of the 237 enrolled patients the median age was 59 years. The overall prevalence of frailty based on the presence of 3 or more frailty criteria was 16.4%, the presence of 2 frailty criteria was classified as prefrail with 16% and without any presence as robust with 67.6%. Within 30 days of surgery, 9 (3.8%) patients have died and 41 (17.3%) experienced a grade≥3b complication. 12 (33.3%) of the frail patients, 10 (28.6%) of the prefrail patients and 16 (10.8%) of the robust patients developed severe complications (P=0.001). Age (p=0.34, OR 1.01, 95% CI 0.98-1.03) showed no association for postoperative complications. The logistic regression shows that prefrail patients (P=0.009, OR 3.30, 95% CI 1.34-8.10) and frail patients (P=0.001, OR 4.12, 95% CI 1.73-9.80) had a significant higher risk for postoperative complications.

Conclusion

Frailty is associated with severe postoperative complications in patients undergoing gynecologic surgery. Fried frailty score could help the surgeon to estimate the risk for postoperative complication.

ESGO7-0049

A CASE OF PORT SITE METASTASIS AFTER LAPAROSCOPIC SURGERY FOR OVARIAN CARCINOSARCOMA
1Sapporo Medical University, Department of Obstetrics and Gynecology, Sapporo, Japan

Aims

Port site metastasis after laparoscopic surgery for ovarian carcinosarcoma is a rare phenomenon.

Method

We present a case report of umbilical port site metastasis from primary carcinosarcoma of the left ovary 2 months after laparoscopic surgery.

Results

A 56-year-old woman underwent abdominal hysterectomy, right salpingo-oophorectomy and suboptimal excision of tumor following laparoscopic surgery for uterine leiomyoma. The histopathologic examination of the tumor revealed stageIIB ovarian carcinosarcoma. After that, she hoped to change hospitals and receive additional treatment in our hospital. She underwent excision of the residual tumor, sigmoidectomy, left ureterectomy, omentectomy, resection of a 1.5-cm umbilical metastatic tumor involving the trocar tract and pelvic-paraaortic lymphadenectomy. Peritoneal washing cytology proved negative for malignant cells. Lymph nodes, omentum and the other lower three port-sites proved no metastasis. One month after she was treated with 6 cycles of adjuvant chemotherapy, she underwent resection of recurrent tumor of right cardinal ligament, ureteral anastomosis following right ureterectomy. Five months after she was treated with 3 cycles of adjuvant chemotherapy, she still proves no recurrence.

Conclusion

Port-site metastasis after laparoscopic surgery is usually associated with poor outcome. Further investigations are necessary to reveal the mechanisms and management to prevent this serious complication as laparoscopic surgery become more common.

MORBIDITY AND SURVIVAL OF PATIENTS TREATED FOR AN ADVANCED OVARIAN CANCER BY RETROPERITONEAL LYMPHADENECTOMY: CARACO, A FRENCH RANDOMIZED TRIAL

I. Jaffré1, F. Lecuru2, G. Houvenaeghel3, E. Lambaudie4, I. Vergote5, P. Harter6, J.M. Classe7

1Institut Cancérologie de l'Ouest, Surgery, Nantes, France
2HEGP, Surgery, Paris, France
3IPC, Surgery, Marseille, France
4CJP, Surgery, Clermont Ferrand, France
5UZ Leuven, Surgery, Leuven, Belgium
6Kliniken Essen mitte, Surgery, Essen, Germany
7Institut Cancérologie de l'Ouest, Surgery, Nantes, France

Aims

The objectives of this study are to evaluate the impact of systematic pelvic and para-aortic lymphadenectomy on advanced ovarian cancer patient survival, postoperative complications and quality of life.

Method

CARACO is an ongoing French randomized multicentric and prospective study initiated in December 2008. Patients with epithelial ovarian cancer FIGO stages IIIB and IIIC with optimally debulked surgery are eligible for participation in the study.

The main endpoint is survival.

We have calculated that with a type I error limited to 0.05, a total of 450 patients would need to be accrued to afford 80% statistical power to reveal a 10% increase in the 5-year survival rate in the systematic lymphadenectomy arm.

Patients are randomized during surgery between lymphadenectomy or no lymphadenectomy.

There are three possible options in timing of surgery and inclusion. (1) Inclusion at primary debulking surgery (PDS). (2) Interval debulking surgery after neoadjuvant chemotherapy (3 or 4 courses). (3) After neoadjuvant chemotherapy (6 courses).

Results

To date, 372 patients have been enrolled, 326 were eligible for this intermediate analysis. According to the MSKCC secondary events grading system, we reported a low rate of minor and major complications (15.6% and 3%, respectively). Neither blood transfusion nor other postoperative complications significantly differed between the two groups.

Patients submitted to systematic lymphadenectomy showed a statistically longer median operative time (318.3 min vs 240.9, p<0.0001).

Conclusion

The CARACO study is ongoing, and requires a substantial effort to recruit new patients for inclusion as well as new clinical European teams in this randomized and prospective study.

ESGO7-0866

HIGH SERUM SVCAM-1 CONCENTRATIONS MIGHT BE PREDICTIVE FOR EARLY OVARIAN CANCER RECURRENCE
M. Jakimovska Stefanovska1, B. Kobal2, K. Černe3, I. Verdenik4
1University Clinical Center Ljubljana, Department of Gynecology, Ljubljana, Slovenia
2University Clinical Center Ljubljana, Department of Gynecology, Ljubljana, Slovenia
3Institute of Pharmacology and Experimental Toxicology, Department of Pharmacology, Ljubljana, Slovenia
4University Clinical Centre- Ljubljana, Department of gynecology, Ljubljana, Slovenia

Aims

High levels of soluble vascular cell adhesion molecule1 (sVCAM1) are associated with cancer progression. The aim of our study was to analyze serum levels of sVCAM-1 in advanced ovarian cancer, the correlation with disease treatment and recurrence and its applicability as a tumor marker for ovarian cancer.

Method

Thirty-seven patients with advanced ovarian cancer and seventy-four controls were included. Serum samples were obtained prior to surgery, 7-10 days after the cytoreductive surgery and 6 months after the treatment was completed. sVCAM-1 concentrations were analysed by flow cytometric bead-based assay.

Results

Serum concentrations of sVCAM-1 are significantly higher in patients with ovarian cancer. There was a correlation but not significant difference between a serum sVCAM-1 at time of ovarian cancer diagnosis with serum sVCAM-1 after cytoreductive surgery (p=0.24) and after the treatment was completed (p=0.08). We have defined 1269 ng/ml as a cut-off value for serum sVCAM-1 with 84% sensitivity and 77% specificity for ovarian malignancy. Patients with sVCAM-1 concentration higher than cut-off value at diagnosis had significantly lower concentration after the treatment (p=0.04). Higher sVCAM-1 concentrations at diagnosis were associated with cancer progression or recurrence in the period of 12 months after the treatment was completed. sVCAM-1 can be satisfactory tumor marker for ovarian cancer diagnosis when compared to Ca125.

Conclusion

Increased sVCAM-1 in serum is connected with the presence of advance ovarian cancer and might be predictive for early ovarian cancer relapse. Serum sVCAM-1 can be potential tumor marker for ovarian cancer diagnosis and follow-up.
OVARIAN CANCER

ESGO7-0457

FDG-PET/CT IN THE PRE-OPERATIVE EVALUATION OF WOMEN WITH OVARIAN CANCER - EXPERIENCES WITH INCIDENTAL FINDINGS
S.E. Sponholtz¹, O. Mogensen², M.G. Hildebrandt³, P.T. Jensen¹
¹Odense University Hospital, Department of Gynecology and Obstetrics, Odense, Denmark
²Karolinska University Hospital, Department of Gynecology and Obstetrics, Stockholm, Sweden
³Odense University Hospital, Department of Nuclear Medicine, Odense, Denmark

Aims

To assess the clinical impact of pre-operative FDG-PET/CT in women with ovarian, fallopian tube, or peritoneal cancer (OC) with special focus on consequences of incidental findings.

Method

Pre-operative FDG-PET/CT scans in the initial staging of women with OC performed from January 2011 - December 2012 were reviewed to evaluate the impact of incidental findings on additional examinations and the delay and change in planned treatment of OC. All incidental findings and decisions regarding further examination were registered at the first succeeding multidisciplinary team conference. Subsequent procedures were tracked via medical records.

Results

Of 209 included women, 44 (21.1%) presented with one or several incidental findings. Further examination was performed in 35 (79.5%). Malignancy was identified in 15/35 (42.9%), revealing metastases from OC (11), a synchronous primary cancer (3) and one recurrence of a previous cancer. The OC metastases were localized in the lungs, uterus, colon, vagina, and breasts. The remaining 20 women with incidental findings had two benign lesions and one pre-malignant lesion identified whereas no abnormality was found in 17 patients. A significant delay in time until treatment of median four days (range 1-83) was found when an incidental finding was further examined (p < 0.004).

Conclusion

In the present setting, with fast track access to additional diagnostics, further examinations of incidental findings by FDG-PET/CT delayed time to treatment of OC by median four days. The clinical implications of this must be balanced against the gain of detecting unrecognized malignancy in 15 of 209 patients (7.2%).
Aims

It is difficult to estimate carcinomatosis in ovarian cancer and identify inoperable patients. The purpose of this study was to evaluate the ability of integrated PET-MRI and MRI alone in estimating carcinomatosis using peritoneal cancer index (PCI) with the surgical PCI as gold standard.

Method

Whole-body PET-MRI was performed on 24 patients with presumed carcinomatosis of a gynecologic origin, planned for surgery. The radiologist evaluated PCI on MRI (including DWI) and PET-MRI scans separately. The surgeon estimated PCI intraoperatively. The radiologist and the surgeon were blinded to each other results.

Results

The median total PCI was 16.5 for MRI (p = 0.01), 22 for PET-MRI (p = 0.725) and 24 for surgery. Bias between radiologic and surgical PCI was for MRI 4.96±6.15 (p = 0.73) and for PET-MRI 0.04 ± 4.71 (p = 0.32). The sensitivity calculated for each region ranged from 36.8-87.5% for MRI and 53.3-95.8% for PET-MRI. In the four inoperable patients the estimated median PCI for region 9-12 (small bowel, max score 12) was 3.5 for MRI and 10 for PET-MRI respectively, surgical PCI being 9.5.
Conclusion

PET-MRI and MRI have a good ability evaluating carcinomatosis, PET-MRI slightly exceeding MRI. Possibly the most interesting finding is the indication of better sensitivity of PET-MRI to detect carcinomatosis in the small bowel, which is crucial in deciding operability.
OVARIAN CANCER

ESGO7-0333

CLINICAL ANALYSIS OF ENDOMETRIOID AND CLEAR CELL CARCINOMA OF THE OVARY WITH OR WITHOUT ENDOMETRIOSIS

S. Kim¹, U. Ju¹, W. Kang¹
¹Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Aims

We investigated the cases of endometriosis-associated ovarian cancers (EAOC) and analyzed outcome of endometrioid carcinoma (EC) and clear cell carcinoma (CCC) with or without endometriosis.

Method

Among 678 patients, received treatments for ovarian cancer from 2004 to 2015, 126 were identified to had EC (n=70) and CCC (n=56). They divided into two groups according to the presence of endometriosis or not (n=27 and n=99, respectively).

Results

38 patients (5.6%) had EAOC; 15 (39.5%) of EC, 12 (31.6%) of CCC, 7 (18.4%) of mucinous carcinoma, 3 (7.9%) of serous carcinoma, and one (2.6%) of endometrial stromal sarcoma. The frequency of coexistence of endometriosis was 21.4% (15/70) for EC and 21.4% (12/56) for CCC. FIGO stage were not significantly different between two groups of EC and CCC with or without endometriosis. 18 at I (66.7%), 7 at II (25.9%), and 2 at III (7.4%) vs. 69 at I (69.7%), 18 at II (18.2%), 10 at III (10.1%), and 2 at IV (2.0%). There was no difference in the rate of optimal cytoreduction and response to chemotherapy. During a median follow-up of 44 months (range, 14-156), 7 cases (25.9%) in group with endometriosis had a recurrence, while 36 (36.4%) in control group (p=0.038). The 5-year disease-free survival (DFS) and overall survival (OS) of patients with endometriosis vs. without endometriosis were 75% vs. 64% (p=0.030) and 86% vs. 80% (p=0.084), respectively.

Conclusion

EC and CCC with endometriosis had the lower recurrence rate and more improved 5-year DFS. However, the coexistence of endometriosis did not affect 5-year OS.
A CASE OF PRIMARY PERITONEAL CARCINOSARCOMA

J. Leese1, J. Garvican2, K. Galaal3, D. Byrne4, S. Julian4
1Royal Cornwall Hospitals NHS Trust, Obstetrics and Gynaecology, Truro, United Kingdom
2Royal Cornwall Hospitals Trust, Department of Pathology, Truro, United Kingdom
3Royal Cornwall Hospital Trust, Obstetrics and Gynaecology, Truro, United Kingdom
4Royal Cornwall Hospital Trust, Obstetrics and Gynaecology, Truro, United Kingdom

Aims

We present a case of primary peritoneal carcinosarcoma and a literature review.

Method

A 43 year old woman presented with severe right iliac fossa pain. CT scanning revealed right ureteric obstruction with no obvious cause. Despite placing a retrograde ureteric stent, her pain worsened. MRI demonstrated an ill-defined 4cm soft tissue mass in the right adnexa, separate from the uterus, ovary and bowel. A working diagnosis of endometriosis was made and laparoscopy was undertaken. Biopsies from the mass showed primary peritoneal carcinosarcoma/malignant mixed mullerian tumour (MMMT). She underwent complete cytoreductive surgery and is receiving adjuvant chemotherapy.

A Pubmed search was performed using key words including “primary peritoneal carcinosarcoma” and “MMMT”

Results

Primary peritoneal carcinosarcoma is rare, especially in this age group.

Only 35 cases have been reported since the first in 1955 by Ober and Black. Seven cases describe resection from the rectosigmoid peritoneum. The longest disease free period in the literature is 60 months. Unfortunately most patients die within one year, with a median postoperative survival of 14 months. 34 patients had surgery, one had a diagnostic biopsy only, 19 received chemotherapy and 4 had radiotherapy.

Conclusion

As primary peritoneal carcinosarcoma is rare there is little evidence on which to base management. The mainstay of treatment is surgical resection and adjuvant chemotherapy, usually cisplatin and ifosfamide; other agents are associated with reduced overall survival. BRCA mutations and endometriosis may predispose to this condition.
Aims

The aim of this study is to describe the clinical pathological and prognostic features of the ovarian Sertoli Leydig cell tumors (SLCT) in Tunisian women.

Method

We collected 13 cases of ovarian SLCT, all diagnosed at the Gynecological Obstetrics Department and at the Anatomopathology Laboratory of the Farhat Hached Hospital of Sousse Tunisia between 2004 and 2016.

Results

The incidence of all ovarian cancers in our center was 4.7 new cases per year. Similarly, SLCT accounted for 1.5% of all our malignant ovarian tumors. The age at onset of the illness varied from 14 years to 79 years with a median age of 30 years. The median consultation period was 6 months. Endocrine signs were present in 76.92% of cases. Surgical exploration found a solid mass in 5 patients, a solido-cystic mass in 7 patients and no purely cystic mass. A peritoneal invasion was present in 5 patients. 15.4% of the patients were stage IA, 61.5% stage IC and 23% in stage IIIC. The slightly differentiated tumors represented 61.5% of the cases. Only one patient had a recurrence of her tumor two years later. Four patients developed metastasis and accounted for 30.76% of the cases. The overall survival rate at 10 years was 39.46%.

Conclusion

Sertoli Leydig cell tumors of the ovary represent a rare histological entity. They belong to the group of tumors of the sexual cords and of the gonadal stroma. The diagnosis is usually earlier than other ovarian tumors because of their endocrine clinical signs.
FEASIBILITY OF THE DIAGNOSTIC LAPAROSCOPIC SURGERY FOR CARCINOMATOUS PERITONITIS
N. Kado¹, N. Takahashi¹, Y. Kasamatsu¹, E. Yoshioka¹, A. Mochizuki¹, M. Abe¹, M. Takekuma¹, Y. Hirashima¹
¹Shizuoka Cancer Center, Gynecology, Nagaizumi town, Japan

Aims
The surgery by laparotomy for advanced ovarian cancer has been carried out in Japan. Recently, laparoscopic surgery has also been available in some institutes. The purpose of the present study was to investigate the feasibility of the diagnostic laparoscopic surgery for carcinomatous peritonitis.

Method
Fifty-nine patients with carcinomatous peritonitis of epithelial ovarian/tubal/peritoneal cancer were evaluated from January 2010 to March 2017. In the preoperative assessments, exploratory laparotomy was supposed for all patients. They were divided into laparotomy group (N=36) and laparoscopy group (N=23). Characteristics, complications of surgery, time to start chemotherapy and hospital stay of both groups were investigated.

Results
There were no significant differences in the characteristics and operation time between two groups. Significant differences were found in blood loss (g) (laparotomy group 33.5±70.9 vs. laparoscopy group 0.78±2.86; p<0.01), the increase of WBC (/mm³) (7940±1510 vs. 6800±2140, respectively; p=0.02), C-reactive protein (mg/dl) (6.23±3.65 vs. 3.50±3.09, respectively; p<0.01). The incidence of ileus after surgery was more in laparotomy group than in laparoscopy group, though the differences were not statistically significant (13.9% vs. 4.3%, respectively; p=0.389). There were no significant differences in period to start chemotherapy and hospital stay between two groups.

Conclusion
Diagnostic laparoscopic surgery for carcinomatous peritonitis is supposed to be less invasive than laparotomy. Further follow-up is required in order to confirm complications in a long term.
Aims

Ovarian cancer (OC) is the second commonest gynaecological cancer, characterized by patients’ diversity to treatment and high mortality rate. Usually presents late in advanced stage which pose challenges to management. Recently, better understanding of the disease biology and application of aggressive surgery to achieve no visible residual has led to longer survival amongst these patients. Purpose of our study is to examine the clinical and demographic characteristics, surgical morbidity and outcomes of patients undergoing radical surgery for OC.

Method

A retrospective cohort study of women undertaking debulking surgery for OC between February 2014 and September 2016 at Aberdeen Royal Infirmary (ARI).

Results

121 women in total had debulking surgery for OC. 43 (35.6%) were stage I, 20 (25.7%) stage II, 53 (43.8%) stage III and 5 (4.1%) were stage IV. 78 (64.5%) women had radical surgery. Of these, 40 (51.3%) women had primary vs. 38 (48.7%) women who had interval debulking surgery. Commonest procedures that were performed as part of radical surgery include rectosigmoid resection (n=20, 25.6%), small bowel resection (n=10, 12.8%), splenectomy (n=9, 11.5%). Commonest morbidity outcomes included blood loss >1.5 lt. (n=17, 21.8%), hospitalization >7days (n=40, 51.2%), sepsis (n=14, 17.9%). Surgery outcomes were: no macroscopic residual disease (n=61, 78.2%), ≤10mm disease (n=6, 7.7%), and ≥10mm disease (n=8, 10.3%).

Conclusion

Identification of patients who will benefit from radical surgery avoiding unnecessary morbidity and mortality is a real challenge. We suggest that radical surgery for OC is related to acceptable morbidity after careful case selection.

ASSESSING THE RISK OF PELVIC AND PARA-AORTIC NODAL INVOLVEMENT IN APPARENT EARLY-STAGE OVARIAN CANCER: A PREDICTORS- AND NOMOGRAM-BASED ANALYSES

G. Bogani¹, A. Ditto¹, M. Signorelli¹, F. Martinelli¹, U. Leone Roberti Maggiore¹, V. Chiappa¹, E. Tagliabue¹, D. Lorusso¹, F. Raspagliesi¹, H.J. Kang¹

¹National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

Lymphadenectomy is a crucial surgical step to assess lymphatic dissemination in apparent early-stage ovarian cancer (eEOC). However, the choice to perform or not nodal dissection in eEOC is still object of debate. Here, we sought to estimate the prevalence of nodal involvement according to various disease characteristics in order to assess the prognostic advantages to have nodal dissection in eEOC

Method

Data of consecutive patients undergoing comprehensive staging for eEOC were retrospectively evaluated. Logistic regression and a nomogram-based analysis were used to assess the risk of nodal involvement

Results

Overall 377 patients were included. All patients had nodal dissection including pelvic and para-aortic lymphadenectomy in 366 and 370 cases, respectively. Forty-four (11.7%) were upstaged due to nodal involvement. Pelvic and para-aortic nodal metastases were observed in 32/366 (8.7%) and 42/370 (11.3%) patients, respectively. Nodal involvement was observed in 46/136 (33.8%), 8/24 (33.3%), 15/94 (15.9%), 4/42 (9.5%) and 1/81 (1.2%) patients with serous, undifferentiated, endometrioid, clear cell, and mucinous histology. Via multivariate analysis, we observed that poor differentiated tumor, (FIGO grade 3), serous histology and bilateral tumors were independently associated with both pelvic and para-aortic nodal involvement (p<0.01). A normogram displaying the risk of nodal involvement is reported in Figure 1

Conclusion

Our data suggested that FIGO grade 3, serous and bilateral eEOC are at high risk of having disease harboring in the lymph nodes. After receiving external validation, our data will help to identify patients deserving comprehensive retroperitoneal staging.

ULTRARADICAL OVARIAN CANCER SURGERY IN KUOPIO UNIVERSITY HOSPITAL 2013-2016
H. Kärkkäinen¹, M.L. Eloranta¹, M. Anttila¹
¹Kuopio University Hospital, Gynecologic Oncology, Kuopio, Finland

Aims

The size of the residual tumor is the most important prognostic factor in ovarian cancer. The aim was to evaluate the quality of our ovarian cancer surgery as more radical upper abdomen surgery is now routinely involved in our debulking surgery procedures.

Method

All the primary ovarian, tubal or primary peritoneal cancer patients operated in Kuopio University Hospital during years 2013-2016, N = 156, were analyzed. Stage was III-IV in 81% of patients, N=126.

Results

Ultraradical surgery was needed in 61 (49%) of the patients. During the study period, cytoreduction to no residual tumor was achieved in 49%, less than 1 cm in 28%, and more than 1 cm in 23% of the cases. Significantly more patients would have had suboptimal cytoreduction without ultraradical surgery (p<0.0005).

Conclusion

To improve the results of cytoreductive surgery and to meet the quality standards of ovarian cancer surgery set by ESGO, upper abdominal and other ultraradical procedures are obviously needed.

CAN COPENHAGEN INDEX REPLACE RISK OF OVARIAN MALIGNANCY ALGORITHM (ROMA) IN A TRIAGE OF PATIENTS WITH PELVIC MASS?

M. Katsyuba\(^1\), R. Khasanov\(^1\), G. Usmanova\(^2\), E. Ratner\(^3\), G. Muratova\(^4\), N. Nigmatulina\(^5\)

\(^1\)Kazan State Medical Academy, oncology, Kazan, Russia
\(^2\)Tatarstan Regional Clinical Cancer Center, laboratory, Kazan, Russia
\(^3\)Tatarstan Regional Clinical Cancer Center, oncology, Kazan, Russia
\(^4\)Kazan Federal University, Physics and mathematics, Kazan, Russia
\(^5\)Kazan Federal University, Fundamental Medicine and Biology, Kazan, Russia

Aims

to comprehensively compare two algorithms, predicting ovarian cancer in patients with pelvic mass: Copenhagen index (CPH-I) and Risk of Ovarian Malignancy Algorithm (ROMA).

Method

We prospectively enrolled 320 patients with pelvic mass, which were consecutively scheduled for surgery in a single institution. Prediction results by ROMA and CPH-I, obtained before surgery, were compared to final histological diagnoses.

Results

Histological analysis revealed 26 epithelial ovarian cancers (EOC), 15 borderline ovarian tumors, 8 non-epithelial malignancies, 2 cases of ovarian metastases and 260 benign diseases. On comparing ROC-AUC, CPH-I was not inferior to ROMA neither in pre- nor in postmenopausal patients. At standard cut-off points ROMA provides a tailored specificity of about 90% in all subgroups (89.6 and 89.7% in pre- and post-menopause, respectively), whereas CPH-I in premenopausal patients demonstrated an extremely high specificity of 96.3% (95%CI: 91.6-98.4) to the detriment of sensitivity. The sensitivity of CPH-I and ROMA for EOC was 87.5% and 100%, respectively, in premenopausal patients; 92.9% and 96.4%, respectively in postmenopausal patients; and 91.7% and 97.2%, respectively.

Conclusion

Both CPH-I and ROMA are excellent algorithms for triaging patients, diagnosed with pelvic mass, with the aim of referring high-risk patients to a tertiary centers. Non-inferiority of CPH-I’s ROC-AUC relative to ROMA’s is not to be doubted. However, when using standard cut-off points, ROMA was slightly superior to CPH-I and showed more balanced specificity and sensitivity. Thus, more research aimed at a thorough validation of CPH-I’s standard cut-off level is still needed for the widespread introduction of CPH-I into clinical practice.
OPTIMIZATION OF SURGICAL TREATMENT OF PATIENTS WITH RECURRENT OVARIAN CANCER

K. Kharchenko¹, V. Boyko², A. Kliysov³

¹Kyiv City Clinical Oncology Center, oncogynecology department, Kyiv, Ukraine
²SI "V.T. Zaitsev IGUS NAMS", Head of the Institute, Kharkiv, Ukraine
³Kyiv City Clinical Oncology Center, Head of the Center, Kyiv, Ukraine

Aims

Treatment of patients with recurrent ovarian cancer is an actual problem of modern oncology. Involvement of the main vessels into neoplastic process often causes poor results of the surgical treatment of patients with recurrent ovarian cancer. The purpose of our research is improvement of immediate and long-term results of surgical treatment of patients with recurrent ovarian cancer.

Method

We analyzed the results of surgical treatment of 18 patients with recurrent ovarian cancer. Optimal cytoreductive resection were performed in all cases.

Results

Invasion of the major vessels with ovarian tumor intraoperatively was interpreted as an indication to the combined resection. All patients were underwent combined surgeries. Prosthetics of arteria iliaca externa were performed in 11 (61.11 %) cases: 8 (44.44%) of them were with autovenous prosthetics. Wedge resection of main veins (vena cava inferior, vena iliaca) were performed in 7 (38.9%) cases. Routine pathohistomorphological research confirmed the true invasion of the vessel wall only in 4 (22.22%) cases. Postoperative complications occurred in 3 (16.7%) cases. Median survival was 18 ± 3 months. (P <0.05).

Conclusion

Involvement of 1/3 of the diameter of main vessel is an indication for boundary resection. Involvement of 1/2 of the diameter of main vessel is an indication for segmental resection with prosthetics. Combined angioplasty leads to increase in median survival and it can be possible in case of complete or optimal cytoreductive surgery. Experience of cytoreductive surgeries with combined angioplasty in patients with recurrent ovarian cancer demonstrates possibility of successful results and improvement of life quality.

THE SIGNIFICANCE OF PREOPERATIVE SERUM CANCER ANTIGEN 125 IN MALIGNANT OVARIAN GERM CELL TUMORS

J.Y. Park¹, J.H. Kim¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam²

¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea
²Asan Medical Center, Seoul, Korea, Republic of Korea

Aims

To determine the prognostic value of preoperative serum cancer antigen 125 (CA 125) in malignant ovarian germ cell tumors (MOGCTs).

Method

Using information from medical databases, we investigated 161 patients with histologically diagnosed MOGCTs between 1993 and 2014. We chose the optimal cut-off value of CA 125 by using a receiver operating characteristic (ROC) curve.

Results

The median patient age was 24 years (range, 6-52 years). The most common histologic type was immature teratoma. Forty-eight patients had a normal range of serum preoperative CA 125 (<35 U/mL). Most patients had stage I disease. Fertility-sparing surgery was performed for 138 patients, and staging surgery in 118 patients. The median tumor size was 15 cm. Ninety-four patients had ascites at surgery. Spillage of the tumor was observed in 51 patients. Fourteen patients had positive cytology, 12 had lymph node metastasis, and 61 patients had ovarian surface involvement. Six patients had residual tumors. We determined the reference level of CA 125 (>78 U/mL) using a ROC curve. On univariate analysis, lymph node metastasis, positive cytology, ascites, ovarian surface involvement, tumor rupture, age, tumor size, and stage were significantly associated with elevated serum preoperative CA 125 levels (>78 U/mL). Patients with an elevated serum preoperative CA 125 level (>78 U/mL) had poorer disease-free survival, but this was not statistically significant. However, elevated preoperative CA 125 (>78 U/mL) was significantly associated with poorer overall survival.

Conclusion

Elevated preoperative serum CA 125 is associated with poorer prognostic factors and may have prognostic value in patients with MOGCTs.

SINGLE PORT GASEOUS LAPAROSCOPY-ASSISTED MINI-LAPAROTOMIC OVARIAN RESECTION (SP-GLAMOR): REASONABLE TREATMENT FOR OVARIAN MALIGNANCY

S.I. Kim1, J.H. Ahn1, M.J. Song2, S.J. Lee1, J. Yoon1
1St. Vincent's Hospital- College of Medicine- The Catholic University of Korea, Department of Obstetrics and Gynecology, Suwon-si- Gyeonggi-do, Republic of Korea
2Daejeon St. Mary’s Hospital - College of Medicine- the Catholic University of Korea, Department of Obstetrics and Gynecology, Daejeon, Republic of Korea

Aims

Recent improvements to both optical and laparoscopic tools have enabled the use of single port laparoscopic surgery for gynecological procedures as opposed to laparotomic operation. However, laparoscopic access has several potential limitations, including tumor rupture, spillage, incomplete resection of lesions, and trocar insertion site metastasis. Here, we report a case series of ovarian cancers that were successfully removed by Single Port Gaseous Laparoscopy Assisted Mini-laparotomic Ovarian Resection (SP-GLAMOR).

Method

We reviewed the medical records of 8 women who visited St. Vincent Hospital from December 2011 until April 2017 and were diagnosed as malignant ovarian cancer with suspicion of malignancy based on imaging studies and tumor markers. After diagnosis, all of the women underwent SP-GLAMOR.

Results

The median maximal diameter of cancer mass, median umbilical skin incision size, median surgical duration and median volume of blood loss were 6.9 cm (range 4.3-8.5 cm), 2.5 cm (range 2.5-4cm), 310 minutes (range 270-420 minutes) and 800 mL (range 650-1200mL), respectively. All of 8 cases were diagnosed as epithelial ovarian cancer on frozen sections obtained during the operation. In only 2 cases, we converted them to open surgery. No major complications were observed. All patients also underwent adjuvant chemotherapy. All patients were followed up to the time of this report.

Conclusion

The results of our study suggest that the SP-GLAMOR procedure in cytoreduction of ovarian cancer is feasible, with potentially decreased perioperative abdominal wound problem and faster recovery.

ENGRAFTMENT OPTIMIZATION, CHARACTERIZATION AND TUMOR SPREAD TRACKING BY PRECLINICAL IMAGING IN OVARIAN CANCER PATIENT DERIVED XENOGRAFT MODELS
K. Kleinmanns1, S. Anandan1,2, K. Bischof1,2, I. Tveit Karlson1, M. Popa1, E. Mc Cormack1,3, L. Bjørge1,2
1University of Bergen, Clinical Science, Bergen, Norway
2Haukeland University Hospital, Obstetrics and Gynecology, Bergen, Norway
3Haukeland University Hospital, Internal Medicine, Bergen, Norway

Aims

As PDX models of high grade serous ovarian cancer (HGSOC) conserve the genetic, phenotypic and functional characteristics of the primary tumor, we aim to use them to identify new biomarkers and improve image-guided surgery techniques. But insufficient engraftment rates and tumor progression monitoring hinder the use of PDX models. Therefore, firstly we optimized the tumor cell isolation from the heterogeneous tumor tissues. Secondly, we developed HGSOC xenograft models representing patient disease progression to establish molecular imaging techniques.

Method

Tissues samples from HGSOC patients undergoing debulking surgery were processed with 8 differential enzymatic cocktails. Cells were characterized in 2D and 3D cultures for cell viability, growth and cell composition. Patient derived cells and HGSOC cell lines were injected intraperitoneally and orthotopically, followed by molecular imaging.

Results

Dependent on the macroscopic characteristics of the tumor, Collagenase II for soft tumors and the Miltenyi enzyme mix for fibrotic tumors resulted in the best dissociation efficiency. Further, the combined use of calcium chloride and TrypLE enhances cell viability and fitness in both tissue categories. 3D organoids were developed and maintained for up to 10 weeks.

The developing tumors in the xenograft and PDX models were detected with high sensitivity and specificity by molecular imaging. We found that the engraftment and growth rates were different between intraperitoneally and orthotopically injected mice.

Conclusion

By optimizing the tumor dissociation, we increased the number of living cells for xenografting. The PDX model combined with the optical imaging approach should be further developed to optimize debulking surgery.
TOWARD OPERATIVE FLUORESCENCE IMAGING OF C-MET FOR PERSONALISED THERAPY IN OVARIAN CANCER

D.M. Klotz1, P. Wimberger1, A. Ahmed2
1University Hospital / TU-Dresden, Gynaecology and Obstetrics, Dresden, Germany
2University of Oxford, Weatherall Institute of Molecular Medicine and Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom

Aims

Despite an initial therapeutic response with optimal surgical debulking, most women diagnosed with ovarian cancer will experience a recurrence, typically with peritoneal metastases. To develop novel targeted therapies, biomarker selection is a key criterion.

Method

We studied the expression of the c-Met oncogene in ovarian cancer. We stained tissue microarrays generated from individual 40 high-grade and 40 low-grade serous ovarian cancers (Gynecological Oncology Targeted Therapy Study 01). A modified cyanine 5–tagged peptide, GE137, with a high in vitro affinity for the human c-Met protein, was tested in ovarian cancer cell lines. Finally, the feasibility of detecting peritoneal metastases in vivo was tested through the intravenous injection of GE137 into mice with tumour xenografts.

Results

The histopathological analysis revealed a differential expression pattern of c-Met, indicating the importance of tumour heterogeneity for patient selection. Importantly, c-Met expression was also significantly increased in peritoneal tumour deposits compared to normal peritoneum. Next, we showed that GE137 co-localises to c-Met in SKOv3 (ovarian cancer) cells without activating downstream c-Met signalling pathways, such as AKT phosphorylation. After intravenous injection of GE137, tumour xenografts were readily detectable at a sub-millimeter resolution with the fluorescent signal being maintained for at least 8 hours.

Conclusion

This study established the expression of c-Met as biomarker in ovarian cancer and peritoneal deposits, providing a proof-of-concept of c-Met-targeted therapeutic strategies. This suggests that intraoperative optical imaging could provide a new paradigm for selecting cancer patients suitable for appropriate targeted therapies.
SHOULD AROMATASE INHIBITORS BE USED AS MAINTENANCE TREATMENT IN HIGH-GRADE SEROUS OVARIAN CANCER PATIENTS?

V. Heinzelmann-Schwarz¹, A.M. Knipprath-Mészáros¹, J. Francis², S. Stadlmann³, F. Vigo¹, A. Schoetzau², G. Singer³, M. Vetter¹

¹University Hospital Basel, Gynecological Cancer Center, Basel, Switzerland
²Ovarian Cancer Research Center, Department of Biomedicine, Basel, Switzerland
³Cantonal Hospital Baden, Institute of Pathology, Baden, Switzerland

Aims

Endocrine therapy is used in ER positive breast cancer and has been proposed as effective treatment in G1 serous ovarian cancer. The aim of this study was to determine the expression rate of ER in a high-grade advanced stage serous ovarian cancer cohort (HGSOC) and whether a maintenance antihormonal therapy adds a benefit in relation to the time of recurrence.

Method

We retrospectively examined ESR1 expression in breast and ovarian cancer as well as ER expression in a cohort of HGSOC. In addition, matched primary and recurrent HGSOC samples collected between 1985-2003 were inserted in a Tissue Microarray and IHC for ER expression. Furthermore, newly diagnosed HGSOC FIGO III/IV since 2013 were assessed prospectively for ER expression and when positive, offered a maintenance therapy with Letrozole 2.5mg/d in an off-label fashion. We assessed the time of first recurrence in correlation with the use or not of Letrozole using Kaplan-Meier analysis.

Results

ESR1 was strongly expressed in similar levels in HGSOC as in breast cancer. Strong ER expression in HGSOC is similar in chemotherapy-resistant primary tumors as in their recurrent counterparts. The use of Letrozole as maintenance treatment was associated with a significant prolonged recurrence free interval, with 75% of patients recurrence free after 24 months when taking Letrozole vs 40% in the control group (p= 0.01).

Conclusion

Primary HGSOC have a high ESR1 and ER expression which is similar to breast cancer where Aromatase inhibitor maintenance is routine for decades. Here we demonstrate evidence for the usefulness of a similar rationale in HGSOC.
ROLE OF INITIAL SURGERY IN MALIGNANT OVARIAN GERM CELL TUMORS

E. Kocaman¹, G. Coban¹, H. Sahin², H. Akillili¹, H. Celik¹, E. Kuscu¹, A. Ayhan¹
¹Baskent University, Department of Gynecology and Oncology, Ankara, Turkey
²Zekai Tahir Burak Education and Training Hospital, Department of Gynecology and Oncology, Ankara, Turkey

Aims

To determine the role of initial surgery type in malignant ovarian germ cell tumor (MOGCT).

Method

Medical records of 59 MOGCT patients that underwent surgery in our department of gynecology and oncology between April 2007-2017 were retrospectively reviewed. The patients divided into three groups depending on the initial surgery type. Complete surgical staging (Group 1; defined as unilateral or bilateral salpingo-oophorectomy+bilateral pelvic and paraaortic lymphadenectomy+ cytological washing+ omentectomy±appendectomy±total abdominal hysterectomy), incomplete surgical staging (Group 2; defined as cystectomy±unilateral pelvic and paraaortic lymphadenectomy± omentectomy±appendectomy) and complementary surgery groups (Group 3; defined as the same surgery as Group 1 of referred patients after the first diagnosis by an ovarian biopsy or cystectomy).

Results

The median age was 22 years (range 12-47 years). The most common two histopathology of the tumors were immature teratoma (23 patients, 39.0%) and dysgerminoma (14 patients, 23.7%). The stage distribution was 66.1% for stage I, 5.1% for stage II and 28.6% for stage III. There were 36 (61%) patients in Group 1, 13 (22%) in Group 2 and 10 (16.9%) in Group 3. Median follow-up time was 35 months (range 1-96 months). 5-years of disease free survival was 41.8%, 69.2% and 70% (p=0.45) and 5-years of overall survival was 92.6%, 65.6% and 76.2% (p=0.46), in Group 1, 2 and 3, respectively (p=0.45).

Conclusion

In our small sample size study of this rare ovarian tumor, type of initial surgery does not appear to effect survival outcomes and further studies are needed.

17The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Department of Medical Oncology, Amsterdam, The Netherlands

Aims

In the OVHIPEC study (NCT00426257), the addition of HIPEC to interval cytoreductive surgery (CRS) significantly improved recurrence-free (HR 0.68, 95% CI 0.51-0.89) and overall survival (HR 0.67, 95% CI 0.48-0.94) in patients with stage III ovarian cancer. We analysed adverse events (AEs) in OVHIPEC, the first randomized study that evaluated HIPEC in primary ovarian cancer.

Method

We randomly assigned patients who showed at least stable disease after 3 cycles of carboplatin (area under the curve 6) and paclitaxel (175 mg/m²) to receive interval CRS with (n=122) or without (n=123) HIPEC using cisplatin (100 mg/m²). Patients in both arms received 3 additional cycles of carboplatin/paclitaxel post-operatively. We describe AEs graded by CTCAE v4.0 occurring up to first follow-up, defined as 6 weeks after the end of treatment.

Results

Over 95% of patients in both arms experienced at least one AE of any grade. The number of patients with grade 3-5 AEs was 30 (24%) without HIPEC and 34 (28%) with HIPEC (p=0.71). The most common grade 3-5 AEs after HIPEC were pulmonary events, infections, abdominal pain, and ileus, all occurring in less than 10% of patients (table). Three patients died within 6 weeks after the end of treatment, 1 was treatment related (CRS only arm) and 2 were due to rapid disease progression (1 in
HIPEC arm and 1 in CRS only arm).

SPONTANEOUS RUPTURE OF ENDOMETRIOMA ASSOCIATED ENDOMETRIOID ADENOCARCINOMA CAUSING ACUTE ABDOMEN

N. Kosić¹, I. Babić¹, P. Planinić¹, F. Grgić¹
¹Clinical Hospital Centre Zagreb, Obstetrics and Gynaecology, Zagreb, Croatia

Aims

Epithelial ovarian cancer is the most lethal gynaecological cancer, with the majority of patients (>75%) being diagnosed at the advanced stage of peritoneal metastatic disease. Although most ovarian cancers (OC) have an insidious course with patients having abdominal discomfort when the disease has already spread, we report here a patient with early stage endometrioid adenocarcinoma presenting with acute abdomen secondary to spontaneous rupture.

Method

This is a case report of a 27-year-old woman that presented at our emergency department with acute abdominal pain.

Results

The patient presented with lower abdominal pain and vomiting. Her abdomen was diffusely tender with localized guarding. The laboratory findings showed elevated white blood cells and C-reactive protein. Ultrasonography detected a cystic-solid mass of the left ovary with a moderate amount of pelvic fluid. With clinical features indicating peritonitis, the patient underwent emergent laparoscopy which revealed a ruptured ovarian mass. The histopathologic finding of the excised tissue returned as ovarian endometrioma malignantly transformed into differentiated endometrioid adenocarcinoma. The patient underwent restaging laparotomy.

Conclusion

Since the early phase of OC is mostly asymptomatic, the disease is usually detected either incidentally or in the advanced symptomatic phase of peritoneal carcinomatosis. In our patient, however, OC has become symptomatic at an early stage due to its spontaneous rupture. Furthermore, this case supports the role of endometriosis in OC pathogenesis emphasizing the importance of close monitoring of these patients. Most importantly, if they develop signs of rupture and acute abdomen, as our patient did, the occurrence of malignant transformation has to be suspected.
NOTCH 2 AS A POTENTIAL SIGNALLING PATHWAY FOR TARGETED THERAPIES IN OVARIAN CANCER

⁴Institute of Applied Biosciences, Center of Research and Technology, Thessaloniki, Greece
⁵Cytology Department, Theagenio Cancer Hospital, Thessaloniki, Greece

Aims
Notch receptors and the related signalling pathways are involved in multiple physiological cellular processes while deviation of their expression is related to carcinogenesis. While Notch 3 over-expression has been confirmed in ovarian cancer, the study of Notch 2 expression is very limited. The aim is to study the gene expression of Notch 2 in comparison to Notch 3 with a view to explore potential targeted therapies related to the former.

Method
Tissues specimens from the primary ovarian tumour and the paired metastatic intra-abdominal sites were collected from seventeen patients, during the cytoreductive surgery. For the gene expression of Notch 2 and Notch 3, qRT-PCR was used while Comparative C₅ Method (ΔΔCt Method) was used for the analysis of the results.

Results
In both primary and metastatic sites, Notch 2 is equally high expressed compared to Notch 3.

Conclusion
Inhibition of Notch 3 by g-secretase inhibitors (GSI) or siRNA was found to cause reduced cellular proliferation and induced apoptosis. The equally high expression of Notch 2 render this signalling pathway a potential candidate for targeted therapies in ovarian cancer. More studies concerning the protein expression as well as in vitro treatment response are needed.
ASPIRIN USE AND RISK OF OVARIAN CANCER AMONG BRCA1 AND BRCA2 MUTATION CARRIERS

⁸Women's College Research Institute, Dalla Lana School of Public Health, Toronto, Canada

Aims

Epidemiologic evidence suggests that aspirin use is associated with a reduction in the risk of developing ovarian cancer among women in the general population. No studies that evaluated this relationship among high-risk women. We evaluated the relationship between aspirin use and BRCA-associated ovarian cancer.

Method

We conducted a matched case-control study which included 986 cases of ovarian cancer and 3,069 controls with a BRCA1 or BRCA2 mutation. Detailed information regarding lifetime medication use (prescriptions and over-the-counter) was collected from a routinely administered questionnaire. Conditional logistic regression was used to evaluate the association between ever aspirin use, as well as, cumulative duration of aspirin use and the risk of developing ovarian cancer.

Results

Among BRCA1 and BRCA2 mutation carriers, aspirin use was not associated with the risk of developing ovarian cancer (odds ratio [OR] for ever vs. never use = 1.19; 95% confidence intervals [CI] 0.56-2.50; P = 0.65). Among women with a history of aspirin use, the risk of developing ovarian cancer associated with lifetime aspirin use for less than one year was 0.50 (95%CI 0.06-4.23) and was 1.45 (95%CI 0.65-3.24) for lifetime use of more than one year. Findings did not vary by BRCA mutation type.

Conclusion

Our findings do not support a role of aspirin for the prevention of ovarian cancer among women carrying BRCA mutations. Prophylactic bilateral salpingo-oophorectomy is the most effective primary prevention strategy for this high-risk population.
P53 PROTEINS ARE ABLE TO EXHIBIT PRION-LIKE BEHAVIOUR - A STUDY TO ESTABLISH RELIABLE DETECTION TECHNIQUES IN OVARIAN TUMOURS

K. Koziel1, E. Maritschnegg2, E. Pechriggl3, M. Bitsche3, A. Berger1, A. Zeimet1, R. Zeillinger2, N. Concin1

1Innsbruck Medical University, Department of Gynaecology and Obstetrics, Innsbruck, Austria
2Medical University of Vienna, Department of Obstetrics and Gynaecology, Vienna, Austria
3Innsbruck Medical University, Division of Clinical and Functional Anatomy - Department of Anatomy- Histology and Embryology, Innsbruck, Austria

Aims

The recently discovered propensity of p53 proteins to exhibit prion-like behaviour may play an important role in initiation and progression of ovarian cancer. The aim of the present study was to establish reliable methodology to detect p53 prion-like aggregates in ovarian tumours.

Method

Three techniques to analyse p53 prion-like protein aggregates were established, i.e. immunofluorescence co-localization and co-immunoprecipitation based on 1) anti-aggregates antibodies and 2) on Seprion methodology. In a first step 10 ovarian cancer cell lines were tested, followed by analysis in tissues of patients with borderline tumours and malignant ovarian carcinomas (OC) of different histological subtypes. This included paraffin-embedded tissues (n=77) and a subset of fresh frozen tissues (n=30).

Results

p53 prion-like aggregates were found in 5/10 ovarian cancer cell lines consistently with all 3 different techniques. All positive cell lines harboured p53 missense mutations. With respect to patients samples, 3/11(27%) borderline tumours were positive for p53 prion-like aggregates and 34/66(52%) invasive OCs. 30/34(88%) positive OCs harboured p53 missense mutations, 1 showed a frameshift mutation and 3 were p53 wild-type. In the big majority of tissue samples consistency between the 3 techniques was found.

Conclusion

We demonstrated a high prevalence of p53 prion-like aggregates among the spectrum of different ovarian tumours, mainly associated with p53 missense mutations. High consistency and therewith reliability of the 3 established techniques was achieved. In a next step we plan to investigate the clinical relevance of p53 prion-like aggregates in a large homogenous cohort of prospectively collected high-grade serous OC cases.

16Princess Margaret Cancer Centre- University Health Network, Department of Obstetrics and Gynecology, Toronto- ON, Canada

Aims

The poly(ADP-ribose) polymerase (PARP) inhibitor rucaparib is approved in the US for treatment of patients with deleterious BRCA mutation (germline and/or somatic) associated advanced OC who have been treated with ≥2 chemotherapies. Data are limited that compare PARP inhibitors to standard of care (SOC) treatment for relapsed OC. ARIEL4 (NCT02855944) is evaluating rucaparib vs SOC chemotherapy as treatment for patients with relapsed, high-grade OC (regardless of histology) and a deleterious germline or somatic BRCA1 or BRCA2 mutation who have received ≥2 prior chemotherapy regimens.

Method

Patients (n=345) stratified by progression-free interval after their most recent platinum regimen will be randomised 2:1 to receive rucaparib 600 mg BID or chemotherapy. Patients with platinum-resistant (progressive disease [PD] ≥1 to <6 months after last platinum) or partially platinum-sensitive disease (PD ≥6 to <12 months after last platinum) will receive rucaparib or weekly paclitaxel; patients with platinum-sensitive disease (PD ≥12 months after last platinum) will receive rucaparib or investigator’s choice of platinum-based therapy (single-agent or doublet). Patients receiving chemotherapy may cross over to rucaparib upon radiographic disease progression. The primary endpoint is investigator-assessed progression-free survival (RECIST v1.1). Secondary endpoints include overall survival, investigator-assessed objective response rate (ORR) by RECIST, ORR by RECIST/CA-125 criteria, duration of response, and patient-reported outcomes. Safety will be summarised descriptively using standard AE reporting.

Results

ARIEL4 is actively recruiting patients.

Conclusion

Randomised studies such as ARIEL4 are needed to assess the benefit-risk profile of PARP inhibitors vs SOC as treatment for relapsed, high-grade OC.
OVARIAN CANCER

IMMUNOHISTOCHEMICAL EXPRESSION OF NIDOGEN-1 PROTEIN IN OVARIAN CANCER TISSUES
K. Kułak¹, A. Kułak¹, P. Ziober - Malinowska¹, M. Mazurek - Kociubowska¹, I. Werte³, R. Tarkowski³, J. Kotarski³
¹Medical University of Lublin, I Chair and Clinic of Gynaecological Oncology, Lublin, Poland

Aims

Late diagnosis of ovarian diagnosis is often due to the lack of sensitivity and specificity of available diagnostic methods. Protein nidogen-1 is being suggested as a potential new bio-marker for ovarian cancer. Nidogen-1 is a crucial component of basement membrane. The aim of the study was to rate the cytoplasm, intracellular and nuclear expression of Nidogen-1 in comparison to a control non malignant ovarian tissues.

Method

20 ovarian tissue samples from epithelial ovarian cancer (EOC) patients and 15 samples from healthy patients with confirmed BRCA (BRCA-1 or BRCA-2) mutations were collected. Paraffin-embedded samples and monoclonal mouse antibody against nidogen-1 were used for detect nidogen-1. Immunochemistry reaction was analyzed via light microscopes. Cytoplasmic reaction, intracellular reaction and the lack of reaction were observed and evaluated. The number of nucleus affected by the reaction was calculated. The results were compared with a group of counterparts with benign ovarian tumors (N=20). Statistical analysis were performed with "Statistica" Software.

Results

Stronger cytoplasmic reaction was detected in EOC patients comparing to intercellular reaction (p<0.001). In healthy patients with BRCA mutation most-commonly detected was intercellular reaction (p<0.001), followed by the lack of reaction. The lack of reaction was observed inmost of the patients with benign tumors (p<0.001). Nucleus was affected more frequently in the EOC group comparing to other groups.

Conclusion

Based on analysis it was concluded that nidogen-1 expression in ovarian tissues is higher in patients with EOC comparing to both healthy patients with BRCA-1 or BRCA-2 mutation and patient with benign ovarian tumors.

CYTOREDUCTIVE SURGERY WITH HYPERThERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC) FOR EPITHELIAL OVARIAN CARCINOMA: PRELIMINARY RESULTS

A.A. Labrecque1, L. De Guerké1, S. Lucas2, D. Pierre3, C. Alexis-Simoin2, D. Pierre3, S. Fortin1

1Hôpital Maisonneuve-Rosemont, Gynaecology-Oncology, Montreal, Canada
2Hôpital Maisonneuve-Rosemont, Surgical Oncology, Montreal, Canada
3Hôpital Maisonneuve-Rosemont, Anesthesiology, Montreal, Canada

Aims

The aim of this study was to present preliminary results in terms of morbidity and survival of cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC) for advanced epithelial ovarian carcinoma (EOC) in a tertiary care center in Canada.

Method

Patients treated for primary or recurrent EOC with CRS + HIPEC between March 2011 and February 2016 were included. All patients received perioperative platinum and/or taxane-based systemic chemotherapy. Postoperative morbidity and mortality was assessed with the Dindo-Clavien classification, and were categorized as minor (grade I and II) or severe (grade III and IV). Overall and disease-free survival calculations started at the end of adjuvant chemotherapy after CRS + HIPEC.

Results

Twenty-one patients with FIGO stage IIIB or C epithelial ovarian cancer were identified. 86% of patients (18/21) had primary EOC and 14% (3/21) had recurrent disease. The mean age at time of HIPEC was 57.8 years. CRS was complete (CC-0) in 86% (18/21) of patients and optimal (CC-1) in 14% (3/21) of patients. Nine patients (42.9%) had severe complications, 11 patients (52.4%) had minor complications and one patient (4.8%) had no complication. At a median follow-up of 23 months (range 3-39 months), 3 patients had died, 11 were disease-free and 9 were alive with disease. The median disease free interval post adjuvant chemotherapy after HIPEC was 13 months.

Conclusion

This therapeutic approach seems both feasible and safe in select patients. Preliminary survival results are encouraging but prospective studies are needed.

GHOST ILEOSTOMY IN THE MANAGEMENT OF MODIFIED POSTERIOR EXENTERATION: A RELIABLE OPTION IN OVARIAN CANCER

V. Lago Leal1, L. Matute Tobias1, S. Domingo Del Pozo1, P. Padilla Iserte1, M. Gurrea Soteras1, C. Díaz García1

1Hospital Universitario y Politecnico La Fe, Gynecologic Oncology, Valencia, Spain

Aims

Our objective was to determine the usefulness of the ghost ileostomy associated with sequential postoperative rectoscopy (SPR) in patients in which modified posterior exenteration was performed due to ovarian cancer.

Method

After modified posterior exenteration (MPE) and colorectal anastomosis were performed, a loop ileostomy was created to minimize the clinical impact of colorectal anastomotic leak instead of a real ileostomy. A SPR was performed in 4º-5º postoperative (PO) day. CRP and Procalcitonin serum levels were also monitored in 1º and 3º PO day. When anastomotic leakage was suspected, the ghost ileostomy was converted into a defunctioning ileostomy. In case of uncomplicated PO course, the loop was removed before discharge.

Results

Between January 2015 and April 2017, 139 cytoreductive procedures due to ovarian cancer were performed. In 30 out of 48 cases of MPE, a ghost ileostomy was created. SPR, CRP and Procalcitonin levels were found normal except in one patient (1/30; 3.3%). In this single case anastomotic leakage was confirmed in SPR. In consequence, real defunctioning ileostomy was created with an uncomplicated PO course.

Conclusion

Not only ghost ileostomy prevents all the complications related to defunctioning ileostomy but also presents its advantages in case of anastomotic leakage.

SENTOV I: TAILORING CLINICAL FEASIBILITY OF SENTINEL LYMPH NODE TECHNIQUE IN EARLY OVARIAN CANCER

V. Lago Leal1, S. Domingo Del Pozo1, L. Matute Tobias1, P. Padilla Iserte1, M. Gurrea Soteras1, C. Díaz García1

1Hospital Universitario y Politecnico La Fe, Gynecologic Oncology, Valencia, Spain

Aims

To determine the intraoperative detection of ovarian sentinel nodes in patients with confirmed ovarian cancer after removal of the adnexal mass.

Method

Patients scheduled for surgical staging due to epithelial ovarian cancer (EOC) after diagnosis in previous anexectomy or with intraoperative confirmation of malignancy were included.

Both laparotomy or laparoscopy, radioisotope and indocyanine green were injected under the serosa of the infundibulopelvic and ovarian ligament stump. 30 min after injection, migration of SLN were checked. A Large Field-of-View Portable Gamma camera device, a “SPIE®” camera and a gamma probe were used for the search.

Results

The recruitment began in April 2017: 2 patients met inclusion criteria and were included.

#1: 37 years old. A right anexectomy was previously performed. High grade serous ovarian tumor Stage IIA was confirmed. 2 SLN were identified (ipsilateral) in the obturator fossa and 3 in the para caval-inframesenteric region. Final study confirmed the initial Stage. Including SLN, all the nodes were negative (Pelvic: 7+9; Para-aortic: 17).

#2: 63 years. A total hysterectomy and bilateral salpingo-oophorectomy was previously performed. A high grade left serous ovarian tumor Stage IA was shown. The ovarian ligament stump could not be identified for obvious reasons. 2 SLN were identified (ipsilateral) in the para aortic-inframesenteric region. Final study confirmed the initial Stage. Including SLN, all the nodes were negative (Pelvic: 11+11; Para-aortic: 23).

Conclusion

This is the first ongoing study with clinical application of SLN technique. The cases performed showed the apparent feasibility of the procedure. Further recruitment is needed for conclusions.

NEUTROPHIL TO LYMPHOCYTE RATIO AND PLATELET TO LYMPHOCYTE RATIO IN OVARIAN MALIGNANCY

B. Laihad¹, F. Utama¹, H. Tendean¹, G.I. Rambert²
¹R.D. Kandou General Hospital, Oncology Division Department of Obstetric and Gynecology, Manado, Indonesia
²Medical Faculty Sam Ratulangi University, Clinical Pathology, Manado, Indonesia

Aims

To determine the sensitivity and specificity of neutrophil - lymphocyte ratio compared to platelet - lymphocyte ratio in predicting ovarian malignancies

Method

This research is an observational analytic study with diagnostic tests design on 37 patients with ovarian tumors which are planned to laparotomy in Prof. Dr. R. D. Kandou Hospital Manado and networks hospitals in Manado from March to May 2016. 3 cc Intra venous blood samples were taken through and then do a complete blood count.

Results

During the defined periods, we obtained a mean age of patients was 28.13 years (range 18-71 years). A total of 13 samples had malignancy with most histopathological types are cystadenocarcinoma muscinosum (27 %). Sensitivity and specificity value of neutrophil - lymphocyte ratio was 92.3 % and 95.8 % with cut off point of 2.47 and platelet - lymphocyte ratio was 61.5 % and the 75 % with cut off point 152.8.

Conclusion

Neutrophil-lymphocyte ratio and platelet-lymphocyte ratio associated with ovarian malignancy. The sensitivity and specificity of neutrophil - platelet ratio has better performance in predicting ovarian malignancies.

AGE IS NOT AN INDEPENDENT PROGNOSTIC FACTOR IN OPERATED STAGE III-IV EPITHELIAL OVARIAN CARCINOMA

A. De Nonville¹, B. Delga², R. Sabatier¹, F. Rousseau¹, P. Viens¹, G. Houvenaeghe², J.M. Classe³, E. Lambaudie²

¹Institut Paoli-Calmettes- Aix-Marseille Univ- CNRS- INSERM- CRCM, Department of Medical Oncology, Marseille, France
²Institut Paoli-Calmettes- Aix-Marseille Univ- CNRS- INSERM- CRCM, Department of Surgical Oncology, Marseille, France
³Institut René Gauducheau, Department of Surgical Oncology, St Herblain, France

Aims

Recent data shows that older women are less likely to have complete surgery for stage III-IV ovarian Carcinoma. Moreover, this undertreatment has been linked to higher rates of mortality. Many publications have suggested that age may be a prognostic factor in ovarian carcinoma. Most of them are old and extrapolated overall survival data instead considering ovarian cancer-specific survival (OC-SV). The objective of this study was to evaluate if age is an independent prognostic factor in stage III-IV operated epithelial ovarian carcinoma.

Method

A total of 1,259 patients who underwent surgery at 2 French centres between 1985 and 2015 were identified. The primary endpoint was OC-SV. A multivariate Cox model was built including age, FIGO stage, CA125 level, surgery and chemotherapy.

Results

Median follow-up was 33 months. Median age at diagnosis was 60 (17-90). 242 (19%) patients were over 70 years of age. Patient characteristics were as follows (≥70 vs. <70y): proportions of FIGO IV were 23 vs. 17% (p=0.042), CA125>500: 55 vs. 58% (p=0.54), incomplete surgery: 42 vs. 27% (p<0.001) and 5 vs. 1% didn't had chemotherapy (p<0.001). Age<70y, FIGO III, CA125<500, complete surgery and chemotherapy were significantly associated with a better OC-SV in univariate analysis (p<0.05, Log-rank test). Only age>70y was not an independent prognostic factor of OC-SV in multivariate analysis (Hazard Ratio=1.16; 95%CI [0.84,1.6]; p=0.372).

Conclusion

This study did not identify age ≥70y as an independent prognosis factor in this population. Our results suggest that age related poor prognosis is more link to suboptimal treatment of elderly patients.

PROGNOSTIC SIGNIFICANCE OF ENDOMETRIOD OVARIAN CANCER SUBTYPE: RESULTS OF AN INTERNATIONAL MULTI-INSTITUTIONAL RETROSPECTIVE STUDY

A. de Nonneville1,2, E. Lambaudie2,3, F. Cannone4, G. Houvenaeghe2,3, R. Sabatier1,2

1Institut Paoli-Calmettes, Department of Medical Oncology, Marseille, France
2Aix Marseille Univ, CNRS U7258- INSERM U1068- Institut Paoli-Calmettes - CRCM, Marseille, France
3Institut Paoli-Calmettes, Department of Surgical Oncology, Marseille, France
4Garibaldi Nesima Hospital, Department of Obstetrics and Gynecology, Catania, Italy

Aims

The prognostic significance of endometrioid ovarian cancer (OvC) subtype is unclear. We compared histoclinical characteristic of patients with OvC by pathological subtype and correlate them with overall survival (OS).

Method

Patients with endometrioid or serous OvC diagnosed in two cancer center in Italy and France between 2000 and 2016 were retrospectively identified. Data were collected in a systematic manner. A multivariate Cox model was built, including age, year of diagnosis, surgery, FIGO stage and adjuvant treatment, to determine the impact of pathological subtype on OS.

Results

Six hundred and sixty-eight cases were retrieved including 86 (12.9%) endometrioid carcinoma and 582 (87.1%) serous controls. Women with endometrioid cancer were younger (median age 55.9 vs. 61.6 years; p<0.001), had less aggressive tumors (64.5% of grades I or II vs. 28.9%; p<0.001), less advanced stage (III-IV) cancers (47.9 vs. 84.2%; p<0.001) and were less likely to receive chemotherapy (87 vs. 96.5%; p=0.001). No significant difference for complete surgery or year of diagnosis were found. Five-year OS rates were 60% in the endometrioid group and 45% in the serous group, respectively (p=0.001). In multivariate analysis, the lower risk of death from endometrioid cancer compared to serous ovarian cancer was no longer significant [HR=0.957 (IC95:0.612-1.494); p=0.846].

Conclusion

In this large cohort, the better clinical baselines characteristic seem to explain the better survival of endometrioid OvC cases. The endometrioid subtype is not an independent prognostic factor. Further analyses are needed to understand why endometrioid OvC patients are diagnosed at a younger age and at earlier stage.
OVARIAN CANCER

ESGO7-0101

STRATIFICATION BY FAGOTTI SCORE FOR PRIMARY CYTOREDUCTIVE SURGERY IN ADVANCED OVARIAN CANCER. PRELIMINARY EXPERIENCE AT A UNIVERSITY HOSPITAL IN URUGUAY

J. Laufer¹, S. Scasso¹, I. Alonso², J. Silvera²
¹Centro Hospitalario Pereira Rossell. ASSE. Department of Gynecology- University of Uruguay- School of Medicine, Montevideo, Montevideo, Uruguay
²Centro Hospitalario Pereira Rossell. ASSE. Department of Medical Oncology, Montevideo, Montevideo, Uruguay

Aims

To implement an initial laparoscopic diagnosis with Fagotti score to select primary cytoreductive surgery in patients with suspected advanced ovarian cancer.

Method

From January 2016 to January 2017, 14 patients with suspected advanced stage ovarian cancer were prospectively included in this case series. Laparoscopy and Fagotti Score were used to confirm diagnosis and to guide the primary treatment: either primary cytoreductive surgery followed by chemotherapy or neoadjuvant chemotherapy followed by interval cytoreductive surgery.

Results

Three of the 14 patients were diagnosed with another malignancy at laparoscopy and referred for appropriate treatment. In the remaining group (n=11) seven patients were candidates for primary cytoreductive surgery based on a Fagotti score Predictive Index Value (PIV) <8, but one of them had an ECOG score 3 and was assigned to the chemotherapy arm. Before this patient could begin neoadjuvant chemotherapy, she suffered a fatal pulmonary embolus. Hence, 6 patients were candidates for primary cytoreductive surgery and 4 patients underwent neoadjuvant chemotherapy. Three of the four patients that underwent neoadjuvant chemotherapy had biomarker and radiologic response and consequently submitted to interval surgery. After a median follow up of 12 months, 10 patients with diagnosis of ovarian cancer remained alive with one recurrence in the patient that received chemotherapy alone.

Conclusion

Selecting patients for primary cytoreductive surgery using laparoscopy and Fagotti Score seems to be a safe and reproducible approach in developing countries, thereby avoiding unnecessary laparotomies. This may be a promising triage strategy, but further research is necessary to validate our preliminary findings.
MORBIDITY OF RECTOSIGMOID RESECTION IN CYTOREDUCTIVE SURGERY FOR OVARIAN CANCER. RISK FACTOR ANALYSIS

C. Huchon¹, A.S. Bats², A. Berger³, F. Lecuru², M. Fournier²
¹Hopital Poissy, Gynecology, Poissy, France
²HEGP, Gynecology, Paris, France
³HEGP, General Surgery, Paris, France

Aim: Rectosigmoid resection is often performed during cytoreductive surgery for ovarian cancer, to achieve the goal of no residual tumour. Here, we evaluated the morbidity associated with rectosigmoid resection and the underlying risk factors.

Method: We retrospectively assessed consecutive patients managed with rectosigmoid resection during cytoreductive surgery for ovarian cancer at our centre in Paris, France, between 2005 and 2013. All previously identified risk factors were analysed. Major complications were defined as grade III-IV in the Clavien-Dindo classification.

Results: Of 228 patients, 116 had primary and 112 interval surgery; 43/228 [18.9%] experienced major complications, and these were more common after primary surgery [24.1% vs. 13.4%, p=0.04]. The 69 patients who had rectosigmoid resection [33 primary vs. 36 interval surgery, p=0.32] had a higher morbidity rate compared to the other patients [30.4% vs. 14.6%, p=0.006]. The anastomotic leakage rate was 2.89%. By multivariate logistic regression, independent risk factors for morbidity were postmenopausal status [adjusted odds ratio (aOR), 13.7; 95% confidence interval (95%CI), 1.2;161.9], surgery after neoadjuvant chemotherapy [aOR, 4.4; 95%CI, 1.1;18.8], and peritoneal stripping of the left paracolic gutter [aOR, 11.3; 95%CI, 2.3;54.3].

Conclusion: The morbidity of rectosigmoid resection during cytoreductive surgery for ovarian cancer seems acceptable. Ileostomy does not seem associated with a lower risk of major complications or adjuvant bevacizumab with a higher complication rate.
PROGNOSTIC IMPACT OF THE TIME INTERVAL BETWEEN PRIMARY SURGERY AND CHEMOTHERAPY IN THE TREATMENT OF EPITHELIAL OVARIAN CANCER

M. Fournier1, C. Huchon2, A.S. Bats1, F. Lecuru1

1HEGP, Gynecology, Paris, France
2Hopital Poissy, Gynecology, Poissy, France

Aims

Complete surgical debulking followed by platinum-taxane is the standard therapy for epithelial ovarian cancer. The aim of this study is to assess whether the interval from primary surgical debulking to initiation of chemotherapy has an impact on progression free survival (PFS) and overall survival (OS) in ovarian cancer.

Method

One hundred and seventy eight patients underwent debulking surgery for epithelial ovarian cancer between 1/2005 and 12/2012 followed by chemotherapy. Only patients with primary surgery and advanced FIGO stage were included. We collected individual datas for these patients. Logrank test was performed to determine the effect of the time to chemotherapy (TTC) on PFS and OS.

Results

60 patients met our inclusion criteria. The median interval from surgery to chemotherapy was 35 days [Min=10; Max=115]. Median follow-up for OS was 2.77 years and 17 patients died. No statistical difference was found on OS between patient who underwent chemotherapy in the 35 first days (HR 1.49 [0.5: 4.15]). Median follow-up for PFS was 1.61 years and 37 patients had progression of disease. No statistical difference was found on OS between patient who underwent chemotherapy in the 35 first days (HR 1,29 [0,63 :2,66]). No risk factors were correlated with interval from surgery to chemotherapy.

Conclusion

The time interval between surgery and chemotherapy seems to have no impact on prognosis in epithelial ovarian cancer. However a study with a larger effective could provide more informations

ONCOLOGIC AND OBSTETRIC OUTCOMES OF CONSERVATIVE SURGERY FOR BORDERLINE OVARIAN TUMORS IN WOMEN OF REPRODUCTIVE AGE.
C. Lee1, S.Y. Lee1, K. Bo Ram1, C. Min Chul1, J. Sang GUN1, S. Seung Hun1, H. Park1, J. Won Duk1, L. Je Ho1

1CHA Bundang Medical Center- CHA University, Comprehensive Gynecologic Cancer Center, Seongnam, Republic of Korea

Aims

To compare the oncologic and obstetric outcomes in reproductive-age females with borderline ovarian tumors (BOTs) treated with cyst enucleation (CE) or unilateral salpingo-oophorectomy (USO).

Method

The medical records of patients with BOTs treated between 1998 and 2014 were retrospectively reviewed. The recurrence rates in the USO and CE groups were compared, and the postoperative obstetric outcomes were assessed via telephone survey.

Results

Eighty-nine patients with BOTs underwent USO, and 19 underwent CE. Of these, six patients had recurrent BOTs. The recurrence rate was significantly lower in the USO group (3/89, 3.4%) than in the CE group (3/19, 15.8%) (P=0.032).

All patients with recurrent disease were successfully treated with further surgery. Of the 76 patients interviewed by telephone, 71 (93.4%) resumed regular menstruation after surgery. Twenty-six of the 32 patients (81.3%) who attempted to conceive had successful pregnancies. USO (19/24, 79.2%), like CE (7/8, 87.5%), resulted in favorable pregnancy rates for patients with BOTs.

Conclusion

USO is a suitable fertility-preserving surgery for women with BOTs. CE is also an acceptable option for select patients.

POST-DEBULKING CIRCULATING TUMOR CELL AS A POOR PROGNOSTIC MARKER IN ADVANCED STAGE OVARIAN CANCER

1Soon Chun Hyang University Hospital, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
2Seoul National University Bundang Hospital, Department of Obstetrics and Gynecology, Seongnam, Republic of Korea
3Korea Advanced Institute of Science and Technology KAIST, Department of Bio and Brain Engineering, Daejeon, Republic of Korea

Aims

To evaluate the association between the presence of perioperative circulating tumor cell (CTC) and clinical outcomes of ovarian cancer.

Method

In 30 patients who were going to undergo staging operation for ovarian cancer, peripheral blood samples were collected before and after primary debulking surgery. CTC was isolated using the tapered-slit filter (TSF) platform. Association between the presence of CTC and tumor characteristics was evaluated. The impact of the presence of perioperative CTC on progression-free survival (PFS) outcomes was also analyzed.

Results

The median age at diagnosis was 58 years (range, 24-77 years), and the median follow-up period was 15 months (range, 0-21 months). Overall, CTC positive rate was not different between pre- and post-operative peripheral blood samples (23/30 [76.7%] vs. 16/28 [57.1%], p=0.673). The presence of preoperative (6-month PFS rate, 90.5% vs. 83.3%, p=0.216) and postoperative CTC (6-month PFS rate, 80.0% vs. 100%, p=0.121) was not significantly associated with PFS outcomes. In a subgroup analysis of advanced stage, however, patients with postoperative CTC had significantly poorer PFS outcome than those without (6-month PFS rate, 75.0% vs. 100%, p=0.031). In this group of patients with advanced stage disease, postoperative CTC was more frequently detected in patients who had lymph node metastasis than those who did not (7/7 [100%] vs. 3/10 [30.0%], p=0.010).

Conclusion

The presence of postoperative CTC on the TSF platform might be associated with poorer PFS outcome in patients with advanced stage ovarian cancer. Further study with larger number of patients is needed to confirm our study results.
CHANGES OF SURVIVAL FOR OVARIAN CANCER OVER 20 YEARS IN KOREA

J.Y. Lee¹, J.W. Kim², M.C. Lim³, Y.J. Won⁴, J.A. Noh¹

¹Yonsei University Health System, OBGYN, Seoul, Republic of Korea
²Seoul National University, OBGYN, Seoul, Republic of Korea
³National Cancer Center, OBGYN, Republic of Korea
⁴National Cancer Center, National Cancer Center, Seoul, Republic of Korea

Aims

To estimate the change in survival rates of women with ovarian cancer during the past 20 years in Korea

Method

Data were obtained from the Korea Central Cancer Registry for patients who were diagnosed with epithelial ovarian cancer between 1995 and 2014. Demographic and clinicopathologic factors, and survival outcomes were extracted and analyzed using Kaplan-Meier and Cox regression models.

Results

A total of 22,830 women were diagnosed with epithelial ovarian cancer. The 5-year relative survival rate across 1995-1999 and 2010-2014 improved from 57.2% to 63.8% (P<0.001). Regarding histology, the survival outcomes increased gradually for serous carcinoma type during past 20 years. However, significant improvements were not observed in those with mucinous, endometrioid, and clear cell carcinoma type. Multivariate analysis showed that younger age, early-stage, favorable histologic subtypes, standard surgery, and recent time interval from 2010-2014 were independent favorable prognostic factors.

Conclusion

Although the survival of epithelial ovarian cancer has improved over 20 years, clinical unmet needs are found for advanced-stage and non-serous carcinoma types. New treatment strategies are urgently required for this disease subset.
THE EXPRESSION OF PD-Ls AND PROGNOSIS OF OVARIAN CANCER: A META-ANALYSIS

M. Lee¹, H.S. Kim¹, S.I. Kim¹
¹Seoul National University, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To evaluate the effect of the expression of PD-Ls on the prognosis of ovarian cancer.

Method

A comprehensive literature search was carried out 19 articles that compare PD-Ls expression and prognosis of patients with ovarian cancer. We performed a meta-analysis using 5 cohort studies published to December 2016 after a literature review.

Results

We analyzed 5 studies comprising 853 patients. The combined hazard ratio (HR) of the overall survival was 1.10 (95% confidence interval (CI) 0.91-1.33, P=0.33), the HR of the progression free survival was 1.10 (95% CI 0.92-1.33, P=0.29) for patients with tumors exhibiting PD-Ls overexpression. Moreover, the included studies have no public bias.

Conclusion

Our findings show that the expression of PD-Ls did not affect the prognosis of ovarian cancer patients.

BEVACIZUMAB ASSOCIATED DIAPHRAGM RUPTURE IN PATIENTS WITH OVARIAN CACNER
H.S. Yun1, S.K. Lee1, B.S. Kwon1, D.S. Suh1, K.H. Kim1, D.H. Kim2, Y.J. Song1
1Pusan National University School of Medicine, Obstetrics and Gynecology, Yangsan, Republic of Korea
2Pusan National University Yangsan Hospital, Cardiovascular and Thoracic Surgery, Yangsan, Republic of Korea

Aims

Bevacizumab is an angiogenesis inhibitor used for adjuvant chemotherapy and maintenance therapy after cytoreductive surgery for advanced ovarian cancer patients. Various adverse effects are encountered in the treatment of bevacizumab, which include gastrointestinal perforation, delayed wound healing, proteinuria, hypertension, congestive heart failure, nasal septal fistula. However, bevacizumab associated diaphragm rupture is a rare entity. We herein report a case of diaphragm rupture, which is the first reported complication of bevacizumab in ovarian cancer to our knowledge.

Method

A 54-year-old woman was treated with cytoreductive surgery for advanced ovarian cancer, followed by 6 cycles of paclitaxel and carboplatin combined with 5 cycles of bevacizumab, because largest diameter of residual disease was 1.5 cm. The response evaluation of adjuvant chemotherapy was complete remission. After 1 cycle of bevacizumab maintenance, she visited the emergency room with uncontrolled epigastric and chest pain. Abdomen computed tomography revealed diaphragmatic hernia with stomach herniation by diaphragm rupture.

Results

Diaphragmatic hernia was repaired by thoracic surgeon.

Conclusion

Diaphragmatic rupture is a serious complication that may occur during the use of bevacizumab in the treatment of ovarian cancer.

IMPACT OF TIME INTERVAL BETWEEN COMPLETION OF NEOADJUVANT CHEMOTHERAPY AND THE INITIATION FOR POSTOPERATIVE ADJUVANT CHEMOTHERAPY IN ADVANCED OVARIAN CANCER

Y.J. Lee¹, Y.S. Chung¹, J.Y. Lee¹, E.J. Nam¹, S.W. Kim¹, S. Kim¹, Y.T. Kim¹
¹Yonsei University College of Medicine - Women’s Life Medical Science, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The aim of our study was to investigate the relationships between the time interval from the end of neoadjuvant chemotherapy (NAC) to initiation of postoperative adjuvant chemotherapy (POAC) and survival outcomes benefit.

Method

We retrospectively investigated 224 patients with pathologically confirmed epithelial ovarian cancer who received NAC at Yonsei Cancer Hospital between 2006 and 2016. Time interval was defined as the time from completion of NAC to initiation of POAC, in days. According to time interval all patients were divided into two groups: 43 days or fewer and longer than 43 days.

Results

Median time interval was 43 (range 22-201) days; 103 patients (54.2 %) had POAC within 43 days of their last dose of NAC, 87 patients (45.8 %) after more than 43 days. Patients who underwent POAC more than 43 days after NAC had poorer overall survival (OS) than patients underwent POAC within 43 days (p=0.004). There was no difference in progression free survival (PFS) between two groups (p=0.129).

Conclusion

The findings from this study suggest that OS may be significantly lower in patients who undergo POAC later than 43 days after NAC.

ASSOCIATION BETWEEN OVARIAN OR EXTRA-OVARIAN ENDOMETRIOSIS AND CANCER IN PELVIC MRI: CLINICAL CASES

G. Levy¹, S. Taieb¹, L. Ceugnart¹, N. Rocourt¹, T. Boulangert¹, H. Jarraya¹, A. Lemair², L. Bresson³, T. Dennis³, F. Narducci³, E. Léblanc³, A. Chevalier³, E. Vanlerenberge³, A. Lesoin⁴

¹Centre Oscar Lambret, Imaging, Lille, France
²Centre Oscar Lambret, Anatomopathology, Lille, France
³Centre Oscar Lambret, Gynaecological surgery, Lille, France
⁴Centre Oscar Lambret, Oncology, Lille, France

Aims

1. Discuss the epidemiology of endometriosis description as a risk factor for epithelial ovarian cancer (more commonly endometrioid or clear cell carcinoma).
2. Review the MRI findings of malignant degeneration, more often arising in an ovarian endometriotic cyst, but also in deep pelvic or parietal pelvic endometriosis lesions (all endometriosis sites are possible).
3. Explain endometriosis-associated ovarian and extra-ovarian cancers is rare, but it must be recognized in pelvic MRI. Atypical endometriosis imaging or suggesting malignancy (whether adnexal, deep pelvic or parietal) should be suspected preoperatively by pelvic MRI (excluding the context of endometriosal decidualization during pregnancy).
4. Remember the differential diagnosis of atypical parietal endometriosis remains the sarcomatous or desmoid tumor pathology justifying histological evidence by biopsy.

Method

Epidemiology of endometriosis-associated cancers.

Review of clinical cases (MRI and pathologic correlation).

Results

MRI findings from atypical imaging to malignant transformation and pathologic correlation:

- in ovarian endometriomas.

![Image of MRI results]
Conclusion

In case of atypical endometriotic imaging (ovarian, deep pelvic or parietal), the objective of the radiologist is to optimize MRI protocol in order to orient the surgeon to a borderline or malignant pathology.

CD-147 AND CA-9 ARE OVER-EXPRESSED IN SPHEROIDS OBTAINED FROM SEROUS OVARIAN CANCERS

O. Elyashiv¹, M. Singh², D. Landesman-Milo², D. Peer², T. Levy¹
¹Wolfson Medical Center, Gynecologic Oncology, Holon, Israel
²Tel Aviv University, Cell Research and Immunology, Tel Aviv, Israel

Aims

In recent years, accumulating evidence suggests that the presence of cancer stem cells (CSCs) in epithelial ovarian cancer (EOC) has a role in chemo-resistance and relapse. Identification of these cells by CSC-markers can serve for the development of novel CSC-targeted personal precision nanomedicine. The aim of the present study was to characterize and compare different EOC cells by molecular stem cell markers.

Method

Cells were obtained from 5 serous EOC established cell lines (NAR, CAOV-3, OVCAR-8, OVCAR-3 and A2780) and from 16 patients with primary and recurrent serous EOC. Cells forming non-adherent spheroids were considered as CSCs. Known CSCs surface markers such as CD44, CCR5, CD117, CD133, and CD326 were analyzed by flow cytometry. In addition, RNA expression of stem cell marker genes, such as: Nanog, nestin, CD133, CD117, CD147, oct-4, CA-9, and ABCB1 were evaluated by quantitative PCR (qPCR).

Results

All 5 cell lines grew stable spheres while <50% of the patient samples (cells obtained from tumors or ascites) were capable of forming self-renewing spheres. Spheroids were CD44+ in the cell lines and in cells obtained from patients. We found that CD147, a transmembrane glycoprotein, involved in cell adhesion, invasion and metastases and CA-9 which is an enzyme induced by hypoxia and related to chemo-resistance were significantly expressed in spheroids obtained from patients' specimens.

Conclusion

The over expression of CD-147 and CA-9, might have clinical implications for targeted and tailored therapy against these highly expressed stem cells molecules through personalized precision medicine.

EFFECTS OF SC-560 IN COMBINATION WITH TAXOL OR CIS-PLATIN ON EXPRESSION OF CYCLIN D1, APOPTOSIS AND KI-67 OF OVARIAN CANCER IN VIVO

W. Jane¹
¹Nanjing Medical University of Hangzhou Hospital, Department of Gynecology, Hangzhou, China

Aims

To evaluate the effects of SC-560 (a COX-1 selective inhibitor) combined with taxol or cisplatin on the expression of cyclin D1, apoptosis and cell proliferation in human ovarian SKOV-3 carcinoma cells xenograft-bearing mice.

Method

Mice were treated with intraperitoneal (i.p.) injections of SC-560 6 mg/kg/day, i.p. injections of cisplatin 3 mg/kg every other day and i.p. injections of taxol 20 mg/kg once a week for 21 days. Expression of cyclin D1 and the index of Ki-67 in tumor tissues were determined by immunohistochemistry. The apoptotic index was detected by the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick end labeling (TUNEL) method.

Results

Downregulated cyclin D1 expression and cell proliferation were statistically significant, while the apoptotic index was notably increased in the drug-treated groups (all \( p < 0.05 \) compared with the control group). SC-560/taxol combination therapy demonstrated a synergistic effect than SC-560 or taxol alone on the inhibition of cyclin D1 expression and the quantification of the Ki-67 positive cells (all \( p < 0.05 \)), and promoting cell apoptosis (\( p < 0.05 \)).

Conclusion

This study suggests that the combination of SC-560 and taxol have a synergistic effect on suppressing cyclin D1 expression, cell proliferation and promoting cell apoptosis in human ovarian cancer xenografts.

CLINICAL SIGNIFICANCE OF C-MET AND PHOPHO-C-MET IN OVARIAN CANCER

L. Lim¹, C.C. Wu², Y.T. Hsu², C.L. Chang¹,²,³
¹MacKay Memorial Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.
²MacKay Memorial Hospital, Department of Medical Research, New Taipei City, Taiwan R.O.C.
³MacKay Memorial Hospital, Department of Medicine, New Taipei City, Taiwan R.O.C.

Aims

C-Met is expressed in human ovarian cancer tissues and phosphorylation of c-Met activates signaling cascades that might affect the behavior of cancer cells. C-Met inhibitors are now under investigation. In this project, we evaluate the clinical significance of c-Met and phospho-c-Met in ovarian cancer.

Method

Tissue arrays consist of archived ovarian cancer tissues from 269 patients were stained with anti-Met mAb and anti-phospho-Met (Tyr1234/1235) mAb. The stainings were scored on a scale of 0 to 3+. High expression was defined as over 50% of moderate and intense staining. Patients’ charts were reviewed until April 2017 for analysis.

Results

Patients with late stage had significant increased lower expression in both c-Met and phospho-c-Met (P=0.0016 and 0.0037). Besides, low expression of c-Met also correlated with higher histological grade (P<0.0001). Lower progression-free survival were found in low expression of c-Met and phospho-c-Met (P=0.0024 and 0.0163) despite no significant difference in overall survival (P=0.1308 and P=0.5351).

Conclusion

High expression of c-Met and phospho-c-Met are associated with better progression-free survival.
DIFFERENT TUMOR BEHAVIOR OF SEROUS AND NON-SEROUS OVARIAN CARCINOMA, FOCUS ON DISTRIBUTION OF STAGE, LATERALITY AND SURVIVAL

Y.C. Ou¹, S.C. Liu¹, C.H. Wu¹, H. Lin¹
¹Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.

Aims

To determine if ovarian serous carcinoma had different tumor behavior compared to non-serous ovarian cancer.

Method

We retrospectively collects the medical records of patients with ovarian cancer in our hospital during Jan, 2010 to Dec, 2015. We analyzed the distribution of laterality, pathological stage and survival. Chi-square test was used for analysis of distribution of category variables. Kaplan-Meier method and Cox regression were used for analysis of survival outcomes.

Results

There were 268 patients were included in this study. The percentage of serous carcinoma was 38.1% which is much lower compared to general data.

The patient with serous carcinoma had more frequency of advanced disease included extra-ovarian disease (89.2% vs. 34.3%, p=0.000), abdominal disease (69.6% vs. 22.9%, p=0.000), lymph node metastasis (39.2% vs. 14.4%, p=0.000), para-aortic lymph node involvement (17.7% vs. 5.4%, p=0.000) and FIGO stage III and IV disease (78.4% vs. 28.3%, p=0.000). Also, serous carcinoma tends to involve bilateral ovaries (65.7% vs. 22.3%, p=0.000) in all patients and in patient with FIGO stage I and II disease (31.8% vs. 7.6 %, p=0.001).

Although serous carcinoma presented as advanced disease more, it seems had similar overall survival compared to non-serous carcinoma (5-year overall survival 62.2% vs. 77.9%, p=0.062). In addition, patient with serous carcinoma had better overall survival in advanced stage (HR 0.557, 95% CI=0.318-0.978, p=0.042), especial in stage III disease (HR 0.406, 95% CI=0.215-0.767, p=0.005).

Conclusion

Ovarian serous carcinoma presented as advanced disease more but tends to have better outcome compared to non-serous carcinoma.

RETROSPECTIVE ANALYSIS OF THE IMPACT OF PLATINUM DOSE MODIFICATIONS ON THE OUTCOMES OF STAGE I-IV OVARIAN CANCER PATIENTS

S. Liutkauskiene¹, M. Ilekis², K. Jureniene³, S. Grižas⁴, E. Juozaitytė⁵

¹Hospital of Lithuanian University of Health Science, Oncology and hematology department, Kaunas, Lithuania
²Lithuanian University of Health Sciences, Medicine Faculty, Kaunas, Lithuania
³Lithuanian University of Health Sciences, Institute of Biomedical Sciences, Kaunas, Lithuania
⁴Affiliate of Lithuanian University of Health Sciences Kaunas Oncology Hospital, Surgery department, Kaunas, Lithuania
⁵Lithuanian University of Health Sciences, Oncology and hematology department, Kaunas, Lithuania

Aims

The objective of this study was to evaluate the impact of platinum dose reduction and delays on progression free survival (PFS) and overall survival (OS) in patients with stage I-IV ovarian cancer.

Method

Medical records of patients with FIGO stage I-IV ovarian cancer were reviewed. PFS was calculated as the time from surgery until the date of progression or death, OS from surgery until the date of death. Last follow up was on 2016-05-30.

Results

Patients were divided into four platinum response status groups: 1) platinum refractory (N=19), OS 17 months (95% CI: 2.4-31.5); 2) platinum resistant (N=26), OS 20 months (95% CI: 15.1-24.8); 3) partially platinum sensitive (N=16 patients), OS 33 months (95% CI: 19.8-46.1); 4) platinum sensitive (N=39), OS not reached (Figure 1), P<0.0001.

Patients were divide into four chemotherapy delay/platinum reduction groups. 38 patients experienced no dose delay or reductions, OS was 40 months (95% CI: 23.8-56.1); 12 patients had a dose reduction, OS was 21 months (95% CI: 15.6-26.3); 38 patients had a delay, OS was 45 months (95% CI: 17.5-72.4); 12 patients had both schedule and dose modifications, OS was 33 months (95% CI: 29.8-36.2), P>0.05 (Figure 2). The main reason of chemotherapy modification was neutropenia (52%) (Figure 3).

Conclusion

There were no statistically significant OS differences the the four groups of chemotherapy modifications. Neutropenia is the most common side effect affecting dose modifications.
Aims

Primary mucinous ovarian tumours and mucinous ovarian metastases of the gastrointestinal (GI) tract can be difficult to differentiate, especially in the presence of pseudomyxoma peritonei (PMP). We evaluated whether this differentiation is relevant for treatment and chance of recurrence.

Method

In this single-centre, retrospective study, 94 patients diagnosed with a mucinous ovarian tumour with or without PMP between January 2000 and February 2017 were reviewed. Demographics, clinical data, histological data and follow-up data were collected and analysed.

Results

Sixty-six (70%) mucinous tumours originated in the ovary, 23 (25%) were metastases from the GI tract and 5 (5%) had an unknown origin. PMP occurred significantly more often in patients with metastases (70%) compared to patients with primary ovarian tumours (17%, p<0.05). Results of immunostaining, serum tumour marker measurements and treatment are shown in Table 1. There was no significance difference in the incident of recurrence between patients with primary ovarian tumours (33%) and patients with metastases (32%, p=0.930) and between patients with PMP (22%) and patients without PMP (39%, p=0.150). Follow up ranged from 3 months–12 years.

Conclusion

No serum tumour marker or immunostaining can differentiate with certainty between primary ovarian tumours and metastases from the GI tract. The incidence of recurrence is independent of the origin and of the presence of PMP, suggesting that both origins have similar biological behaviour and require similar diagnostic work up and treatment protocols.

BORDERLINE EPITHELIAL OVARIAN TUMORS: CLINICAL FEATURES, DIAGNOSIS AND TREATMENT

1Hospital universitario materno infantil de Canarias, Department of Obstetrics and Gynecology, Las Palmas de Gran Canaria, Spain
2Las Palmas University, Department of Obstetrics and Gynecology, Las Palmas de Gran Canaria, Spain
3Hospital Dr Negrin, Department of Medical Oncology, Las Palmas de Gran Canaria, Spain
4Hospital universitario materno infantil de Canarias, Department of Medical Oncology, Las Palmas de Gran Canaria, Spain

Aims

To evaluate the clinical outcome and pathological features of patients with borderline ovarian tumors (BOT) with special emphasis on serous and mucinous histology.

Method

A retrospective study of patients diagnosed with borderline ovarian tumor between January 2000 and December 2013 was performed. The follow-up consisted of clinical assessment, determination of tumor markers and ultrasound control. Survival rates were analyzed using the Kaplan Meier curves.

Results

A total of 202 patients are included, with a mean age of 50 years. The serous tumor was present in 104 patients and the mucosa in 88. 89.9% of the patients with mucosal tumor presented clinic at the time of diagnosis, compared to 68.3% of serous patients (p <0.0001). 86.1% of patients had stage I of FIGO at the time of diagnosis, 2% had stage II and 11.9%, stage III. Disease-free survival at 2 and 5 years was 99.5% and 89.6%, respectively. There were 17 relapses, two of which died. Finally, overall survival at 2 and 5 years was 99% and 96.7%, respectively.

Conclusion

Younger patients are those with serous tumor, with a mean of 43.24 years. More clinical symptomatology appears and a greater number of laparotomies are performed on mucosal tumors. Surgical staging is performed more frequently in the serous type, therefore a greater number of stage III tumors is observed in this histological type and a larger number of stages I in mucosal type tumors. Finally, serosal recurrence is more frequent, but there are no significant differences in mortality between the two groups.

ESGO7-1032

ANALYSIS OF MIR-196A, MIR-146A AND TWO MIR193B SINGLE NUCLEOTIDE POLYMORPHISM IN OVARIAN CANCER PATIENTS

J. Lukacs1, B. Soltesz2, B. Nagy2, R. Poka1
1University of Debrecen Faculty of Medicine, Department of Obstetrics and Gynecology, Debrecen, Hungary
2University of Debrecen Faculty of Medicine, Department of Human Genetics, Debrecen, Hungary

Aims

Some polymorphisms of microRNAs were found to be associated with development of ovarian cancer. Analysis of these polymorphisms might help in indispensable early diagnosis. We aimed to determine miR-196a rs11614913, mir-146a rs2910164, miR-193b rs30236 and rs1649942 polymorphisms in ovarian cancer patients and controls.

Method

75 ovarian cancer patients, 75 controls were recruited. 15-16 ml EDTA anti-coagulated blood was drawn; DNA was isolated with silica adsorption method. LightSnip kits were used for detection of rs11614913, rs2910164, rs1649942 and rs30236 polymorphisms. Melting temperatures of PCR fragments were determined by LightCycler96 instrument and melting curve analysis was used for allele classification. Allele and genotype frequencies were calculated and chi-square test was used for statistics.

Results

Based on the melting curve analysis of miR-196a rs11614913 we found 32.67% T allele frequency in patient and 40.67% in control group. In case of mir-146a rs2910164 we found 18% C allele frequency in patient and 27.33% in control group. During the analysis of mir-193b rs30236 T allele was found in 28.29% in patient group and 37.83% in controls. In case of mir-193b rs1649942 the T allele was present in 69.74% in patient group and 78.00% in controls. Statistical analysis showed marginal significance in alterations of studied polymorphisms.

Conclusion

Determining the above mentioned polymorphisms in a group of Hungarian ovarian cancer patients and healthy controls differences of marginal significance were found in genotype frequencies. We plan to collect more samples to continue the determination of polymorphisms and find out the exact role of these SNPs in development of ovarian cancer.

ESGO7-0324

ROLE OF TUMOR MARKERS IN CLINICAL RESPONSE TO THERAPY IN PATIENTS WITH EPITHELIAL OVARIAN CANCER (EOC)

C. Macchi¹, F. Calavita¹, P. Danna¹, M. Mitidieri¹, D. De Ruvo¹, E. Male¹, P. Zola¹
¹S. Anna Hospital, Obstetrics and Gynecology - Department of Surgical Sciences - University of Turin, Turin, Italy

Aims

Overall survival at 5 years of epithelial ovarian cancer (EOC) is 41% and most of EOC recur several time, so it’s important to have a tool to predict the response to chemotherapy. The aim of the study is to evaluate the role of biomarkers as predictive factors for the patients with EOC, treated with chemotherapy.

Method

CA-125 and HE4 values were determined for each cycle of chemotherapy in 41 patients aged ≥18 with EOC and ≥3 cycles. The average value, the slope of the straight line passing through the values of the first and third cycle (point 1 and point 3) and the half-life of the markers were analyzed through univaried analysis and correlated with response according to RECIST criteria. To calculate p values, T student test was used. For the analysis of the curves a generalized linear model was used for repeated measures.

Results

The curves plotted with average of HE4 and CA-125 show a statistically significant difference between responders (RR) and non-responders (NN) groups (CA-125: p=0.008; HE4: p=0.005). Comparing HE4 (RR=46.5 die, NN=79.3 die; p=0.005) and CA-125 (RR=28.8 die, NN=53.8 die; p=0.004) half-lives, these results are independent predictors for response to chemotherapy. The slope of the curve passing through the points 1 and 3 is different for CA-125 (RR=-132.175; NN=-53.14) and HE4 (RR=-141.625; NN=-3.5).

Conclusion

In conclusion, serum levels of CA-125 and HE4 and their half-lives can predict the clinical response to chemotherapy, in patients treated for EOC.
A COST-EFFECTIVENESS STUDY OF A NOVEL SURGICAL DEVICE USING NEUTRAL ARGON PLASMA (PLASMAJET) IN GYNAECOLOGICAL ONCOLOGY

T.K. Madhuri¹, S. Butler-Manuel¹, A. Tailor¹, J. Davies²
¹Royal Surrey County Hospital NHS Foundation Trust and University of Surrey, Department of Gynaecological Oncology, Guildford, United Kingdom
²Royal Surrey County Hospital NHS Foundation Trust, Department of Finance, Guildford, United Kingdom

Aims

Principle behind the surgical management of epithelial ovarian cancer (EOC) is to achieve nil macroscopic residual disease. This often comes at the cost of bowel surgery and stomas, bleeding and results in intensive care admissions and delayed discharges.

The aim of this study is to evaluate if the use of the PlasmaJet(PJ) device is cost effective in comparison to standard surgical technique(SST).

Method

Retrospective data collection on 10 patients (PJ=5, SST=5) with Stage 3/4 epithelial EOC undergoing primary/interval debulking surgery. Each patient was matched to one of five criteria (large bowel resection, large/small bowel resection, body mass index over 30, length of hospital stay over 10 days, none of the above). Comparisons were made directly between participants within each criteria. Estimates of medical expenditures were obtained from the finance department of a tertiary oncology centre. Quality of life (QoL) analysis was conducted by evaluation of two (EORTC) questionnaires completed by each patient at various stages.

Results

Preliminary results suggest PJ is more cost-effective than SST with mean cost of admissions being £8,654.20 and £14,195.22 respectively. LOS was generally lower in PJ arm compared with SST. Analysis of QoL scores suggests significant improvement in QoL scores in the PJ arm.

Conclusion

This is the first cost-effectiveness study of PlasmaJet™ suggesting it is more cost-effective than SST although studies with a larger sample size are required in the form of a health economics evaluation reporting quality-adjusted life-years (QALYs) and incremental cost-effectiveness ratio (ICER) to determine the relationship between QoL and use of PlasmaJet™.
RESULTS ON FEASIBILITY RCT ON USE OF (PLASMAJET) TO ACHIEVE COMPLETE CYTOREDUCTION DURING DEBULキング FOR EPITHELIAL OVARIAN CANCER

T.K. Madhuri¹, S. Butler-Manuel¹, P. Ellis¹, A. Tailor¹, P. Williams²
¹Royal Surrey County Hospital NHS Foundation Trust and University of Surrey, Department of Gynaecological Oncology, Guildford, United Kingdom
²University of Surrey, Department of Maths and Statistics, Guildford, United Kingdom

Aims

Epithelial ovarian cancer (EOC) is the 2nd common gynaecological cancer and is the commonest cause of death. Standard treatment of EOC is combination of cytoreductive surgery and chemotherapy.

Recent studies (EORTC 55971 and CHORUS) suggest that complete cytoreduction should remain the objective when surgery undertaken.

The primary aim of this study is to evaluate if the use of the PlasmaJet(PJ) device enables increased cytoreduction rates in comparison to standard surgical technique(SST).

Secondary aims include morbidity and mortality data, Quality of life (QoL) and survival.

Method

Following ethics approval and clinical trials registration (NCT02376231 & ISRCTN26261491), patients recruited when discussing surgery after consent obtained, patient blinded randomised controlled trial, Baseline Qol and at various timepoints collected, Randomisation performed in theatre and patient blinded, Operative details and post op data collected.

Results

110 patients recruited with nearly half in each arm. 8 adverse events. Results suggest decreased bowel resection rate in PJ arm (p<0.05), reduced stoma rates despite higher cytoreduction rate (p, 0.05) and higher diaphragm stripping (p<0.05) rates.

LOS was generally lower in PJ arm compared with SST. Analysis of QoL scores suggests significant improvement in QoL scores in the PJ arm.

Conclusion

This is the first RCT of PlasmaJet™ suggesting it may play a role in improving debulking rates while reducing morbidity. A larger multicentre RCT is being recruited to for further evaluation of the reduced stoma rates. Translational work is ongoing with the samples collected at the time of surgery to evaluate reasons behind the response in the PJ arm.

MAINTENANCE TREATMENT WITH OLAPARIB IN BRCA-MUTATED HIGH GRADE SEROUS OVARIAN CANCER (HGSOC): OUR EXPERIENCE IN A CASE REPORT

A. Mainella¹, N. Giacomi¹, F. Marmisolle¹, S. Vigo¹, P. Price¹, M. Sansano¹, M.L. Lujan¹, G. Zapata Caamaño¹, P. Dominguez¹
¹Policlinica Privada SITE La Plata, La Plata, Buenos Aires, Argentina

Aims

We report the first case of a patient with BRCA-mutated high grade serous ovarian cancer (HGSOC) who received Olaparib to treat advanced disease platinum-sensitive relapsed.

Method

A 48 year old commenced in August 2010 with abdominal distension, pain and asthenia. Familiar history of ovarian and breast cancer. CT scan was performed: great left ovarian mass behind the uterus. September 18th, 2010: Surgery: Oophorectomy + hysterectomy + omentectomy + multiple peritoneal biopsies: high grade serous papillary bilateral ovarian cancer with capsule infiltration. Cytokeratin 7 +, CK20 -, WT1 +. CA125: 7.8 (35).

She completed chemotherapy with Carboplatin AUC5 and Paclitaxel 175mg/m2 (6 cycles from November 2010 to February 2011) and continued surveillance with CT scan in March 2010 no evidence of residual disease.

Results

She consulted in June 2015 with abdominal distension and pain. US was performed: ascites and multiple abdominal and pelvic nodules. Ca 125: 312 (35). PET Scan: multiple hypermetabolic nodules in abdominal and pelvic cavity and free liquid.

The patient started chemotherapy with Carboplatin AUC5 + Paclitaxel 175mg/m2 + Bevacizumab 15mg/kg. She completed 3 cycles with clinical improvement. CA 125: 45,20 (35). In October 2015: the patient completed 6 cycles. CA 125 response: 18,82 (35). PET scan: reduction in number, size and metabolism of abdominal nodules. She completed 2 cycles more without Bevacizumab. BRCA mutation assessment: BRCA1 mutation +.

January 2016: the patient started Olaparib 800mg/daily. CT Scan in July 2016: reduction of peritoneum nodules.

Conclusion

The patient is undergoing treatment with Olaparib since January 2016, with acceptable tolerance and still no relapse.

ESGO7-0018

IT’S COMPLICATED: A CASE REPORT OF MALIGNANT PERITONEAL MESOTHELIOMA PRESENTING AS OVARIAN NEW GROWTH

R.G. Mallari¹
¹University of Santo Tomas Hospital, Obstetrics and Gynecology, Manila, Philippines

Aims

To present a case of a 25 year old nulligravid with a 2 month history of abdominal enlargement.

Method

Imaging studies to evaluate the cause of abdominal enlargement such as ultrasound and CT scan. Tumor markers like CA-125, CA 19-9, LDH and CEA can be done however not specific. Surgery is the definitive management and chemotherapy for palliative care. Immunohistochemical staining for differentiation and identification of histologic type.

Results

Ultrasound showed ascites, inflammatory versus neoplastic hence paracentesis and tumor markers were requested which all showed normal results. CT scan revealed a suspicious complex mass on the right adnexa. Patient underwent pelvic laparotomy which revealed multiple implants, yellowish to pinkish necrotic and friable masses scattered over the bowel loops, omentum, peritoneal surface, right adnexa, posterior cul de sac, liver surface and subdiaphragmatic area. Histopathologic diagnosis was atypical papillary structures, reactive versus neoplastic. Immunohistochemical staining was positive to Calretinin and Epithelial membrane antigen favoring Malignant peritoneal mesothelioma.

Conclusion

Peritoneal mesothelioma is a very rare disease with an incidence of 1 case per 4-5 million of the population and accounts for 20-30% of all mesothelioma type cancers. Early diagnosis of mesothelioma is often difficult since symptoms are usually atypical or nonspecific such as abdominal enlargement present in the patient. It may be mistaken as being a disease of the gastrointestinal tract or reproductive tract. Therefore, diagnosis often occurs at an advanced stage when it is widespread throughout the peritoneal cavity. Treatment approaches ranges from palliative surgery, systemic chemotherapy like Cisplatin to aggressive cytoreductive surgery and perioperative intraperitoneal chemotherapy.

PROGNOSTIC VALUE OF HISTOLOGIC PATTERN IN ADULT GRANULOSA CELL TUMORS

H. Mantoan¹, L. De Broº, L.Y. Kumagai¹, L. Badiglian-Filho¹, C.C. Faloppa¹, A.A.B.A. da Costa³, E.M. Fukazawa¹, G. Baiocchi¹
¹Ac Camargo Cancer Center, Gynecology Oncology, São Paulo, Brazil
²Ac Camargo Cancer Center, Pathology, São Paulo, Brazil
³Ac Camargo Cancer Center, Clinical Oncology, São Paulo, Brazil

Aims

Adult granulosa cell tumors (AGCT) are rare neoplasms, corresponding for about 5% of all ovarian neoplasms. They are known for their indolent behavior, often with initial disease at diagnosis. However, a significant group of patients, independent of clinical stage, may experience disease recurrence, often years after diagnosis. To date, no data correlated histological pattern and survival. Our aim was to analyze the prognostic value of histological pattern in AGCT.

Method

We retrospectively analyzed a series of 60 patients treated at A.C. Camargo Cancer Center from April 1980 to August 2015. Of these, the histological pattern data was available in 41 cases.

Results

Median age was 51 years (range, 23-84). Median follow-up time was 48 months (range 1-272 months). Ten (16.7%) patients had fertility sparing surgeries. Of the 41 cases with histological pattern retrieved, most presented with diffuse tumors (37 cases; 90.2%). Micronodular pattern was found in 14 cases (34.9%), usually along with diffuse pattern. In univariate analysis, the presence of micronodular pattern showed worse disease free survival (56.1% vs. 95.5%; p=0.044), with retained as significant in multivariate analysis (HR: 10.79; CI95%: 1.19 – 97.48; p= 0.034). Yet, there was no difference on overall survival (91.7% vs. 96%; p=0.952).

Conclusion

Our data suggest that micronodular pattern has worse disease free survival in patients with AGCT.

**SQUAMOUS CELL CARCINOMA ARISING IN A MATURE CYSTIC TERATOMA: TWO CASE REPORTS**

Z. Marchocki, S. McDonnell, C. Thompson, W. Kamran, F. Abu Saadeh

1St. James’s Hospital, Department of Gynaecologic Oncology, Dublin, Ireland

**Aims**

Mature Cystic Teratoma (MCT) is the most common benign Germ cell tumours (GCT). Malignant transformation is rare and occurs in up to 2% of cases with squamous-cell carcinoma (SCC) being the most frequent histological type.

**Method**

We present two cases of SCC arising on the background of MCT.

**Results**

First patient was a 36 year old women who presented with abdominal pain. Abdominal ultrasound and MRI showed ovarian mass suggestive of MCT with features concerning for malignancy (solid component with intrinsic T1 high signal). A unilateral salpingo-oophorectomy and subsequent histopathological analysis revealed an invasive poorly differentiated SCC arising in a MCT. Staging CT demonstrated para-aortic lymphadenopathy and biopsy of it confirmed the presence of metastases and FIGO stage IIIC disease. She underwent completion surgery followed by adjuvant chemotherapy and radiotherapy. She is well with no evidence of recurrence 12 months after treatment completion.

Second patient was a 83 year old women who was diagnosed with left ovarian mass suggesting MCT. Due to her multiple medical comorbidities she was managed conservatively. She presented 2 years later with worsening left sided abdominal pain and incidental finding of pulmonary embolism. MRI showed increased in size MCT with features suggestive of malignant transformation. She underwent cytoreductive surgery with excision of sigmoid and rectum. Histological examination revealed poorly differentiated SCC arising on a background of a teratoma giving FIGO stage IIIC. Sadly she deteriorated after surgery and passed away 12 days later.

**Conclusion**

Malignant transformation in MCT remains low. Clinicians should be aware of this possibility and should remain vigilant when treating patients with suspected MCT. Certain features on MRI could help in diagnosing malignant teratoma.

CANCER-RELATED SEVERE HYPERCALCEMIA IN OVARIAN ADENOSARCOMA – A CASE REPORT

Z. Marchocki1, C. O’Rlair2, C. Thompson1, F. Abu Saadeh1
1St. James’s Hospital, Department of Gynaecologic Oncology, Dublin, Ireland
2St. James’s Hospital, Histopathology Department, Dublin, Ireland

Aims

Hypercalcemia affects up to 44.1% of cancer patients and cancer is the leading cause of hypercalcemia in hospitalised patients. Unfortunately cancer-related hypercalcemia carries a very poor prognosis, as it is often associated with advanced disease stage.

Method

We report a case of 59 year old women with severe cancer related hypercalcemia secondary to ovarian adenosarcoma.

Results

She initially presented to our Emergency Department with a large pelvic mass, anaemia and incidental pulmonary embolism. Laparotomy revealed 30cm left ovarian cyst, morbidly adherent to the small bowel mesentery, sigmoid and pelvic side wall. There was evidence of old endometriosis. Optimal debulking surgery was performed. Histological examination showed ovarian adenosarcoma associated with grade 1 uterine endometrioid adenocarcinoma, FIGO stage IIIB. Due to rarity of the condition, a second opinion sought and confirm the diagnosis. Our patient made a good recovery and was discharged home 12 days later. She represented 4 weeks post-surgery with: nausea, constipation, poor appetite, lack of energy and confusion. On examination the patient appeared severely dehydrated and lethargic. Her abdomen was distended and she had reduced muscle power. Labolatory results showed severe hypercalcemia (corrected calcium 4.91), signs of acute kidney injury (creatinine 267, GFR 16) and low parathormone level (9.6). Abdominal imagining demonstrated multiple soft tissue masses (largest 12.7cmx6cm), ascites and peritoneal nodularity consistent with recurrent disease. During the inpatient stay she developed a new pulmonary emboli and a heart failure. Sadly she passed away few days later.

Conclusion

Cancer-related hypercalcemia has a poor prognosis. Ovarian small cell carcinoma should be always considered in differential diagnosis. This should be taken into account when counselling the patient and the family regarding the goals of care and disease prognosis.
OLAPARIB IN GERMAN ROUTINE CLINICAL PRACTICE – INTERIM RESULTS OF THE NON-INTERVENTIONAL STUDY C-PATROL

F. Marme¹, J. Sehouli², M. Welslau³, T. Schinkoethe⁴, A. El-Balat⁵, P.A. Fasching⁶, R. Glowik⁷, F. Hilpert⁸
¹National Center for Tumor Diseases, Gynecologic Oncology, Heidelberg, Germany
²Charité Medical University, Department of Gynecology, Berlin, Germany
³Medical office for hemato-oncology, Oncology, Aschaffenburg, Germany
⁴CANKADO, CANKADO, Kirchheim, Germany
⁵Goethe University Frankfurt, Department of Obstetrics and Gynecology, Frankfurt, Germany
⁶University Erlangen-Nuremberg, Department of Gynecology and Obstetrics, Nuremberg, Germany
⁷AstraZeneca Germany, Medical Affairs - Oncology, Wedel, Germany
⁸Jerusalem Hospital Hamburg, Oncology Centre - Mammazentrum, Hamburg, Germany

Aims

The PARP inhibitor olaparib is approved in the EU for maintenance therapy of BRCA-mutated (BRCAm+) platinum-sensitive relapsed ovarian cancer patients who are in response to their most recent platinum-based chemotherapy. So far, only limited data on real-world olaparib treatment are available.

Method

The German prospective, non-interventional study C-PATROL (NCT02503436) collects real-world clinical and patient-reported outcome data in BRCAm+ platinum-sensitive relapsed ovarian cancer patients treated with olaparib according to label. This first preplanned interim analysis (cut-off date: 06 April, 2017) provides data on safety and dosing under real-life conditions. Data were analyzed by descriptive statistics.

Results

This interim analysis comprises the first 75 patients (median age 61 [45 to 80] years; ECOG ≤1: 93.3%; patients with ≥2 relapses: 49.3%, patients with ≥3 prior platinum-based chemotherapeutic regimens: 53.3%) with ≥3 months observation after start of olaparib therapy. Patients started with a median daily dose of 800 [300 to 800] mg olaparib. For 70.7% of patients no dose reduction was reported. For 29.3% of patients dose interruptions (median duration 10.0 [2 to 51] days) were documented. Olaparib therapy was permanently stopped due to an adverse event in 3 patients. Treatment-emergent adverse events (all grades) were documented for 85.3% of patients. Anemia (34.7% of all patients), nausea (29.3%) and fatigue (26.7%) were the most common ones.

Conclusion

The current interim analysis indicates that under routine conditions olaparib is well tolerated with a manageable toxicity profile. The toxicity profile is in line with the results of the clinical trial program of olaparib.

MOVING BEYOND THE MICROSCOPE AND INTO PRECISION MEDICINE: ESTABLISHING PROOF-OF-PRINCIPLE FOR A “MOLECULAR” SECOND LOOK SURGERY IN OVARIAN CANCER
J. Martignetti1, M. Schwartz2, O. Camacho-Vanegas1, A. Wood3, M. Dashkoff1, C. Whitelock1, T. Harkins3, A.M. Beddoe2, P. Dottino2
1Icahn School of Medicine at Mount Sinai, Genetics & Genomic Sciences, New York, USA
2Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology- and Reproductive Sciences, New York, USA
3Swift Biosciences, -, Ann Arbor- MI, USA

Aims

Ovarian cancer (OvCa) survival has not improved over 4 decades nor has our ability to identify true treatment responders. We hypothesized that coupling ultra-deep sequencing technology to the theoretically powerful technique of second-look surgery (SLS) could transform a relatively low resolution cytopathology-based technique into a precision medicine tool of extreme sensitivity and specificity. The simultaneous goals would be to identify potentially drug targetable mutations at the start of treatment and then response to that treatment.

Method

We identified 10 patients with advanced-stage, high-grade serous OvCa who had previously undergone traditional SLS. Targeted next-generation panel sequencing (NGS) interrogating 56 cancer-relevant genes was used for ultra-deep sequencing primary and recurrent tumor specimens, blood, ascites fluid and peritoneal washes. All NGS-identified mutations were validated using an orthogonal technology, digital droplet PCR (ddPCR) or Sanger sequencing.

Results

26 tumor-specific mutations were identified including TP53 mutations in all patients. All five patients who originally had positive cytopathology from SLS were also positive by “molecular” SLS. Notably, mutations present in primary tumor were identified in both SLS and even tumor recurrences 2 years after initial presentation. Three of the five SL patients with negative cytopathology were re-diagnosed as molecular positive. Importantly, these mutations were detected in tumor recurrences 3 years later.

Conclusion

For the first time, we establish through targeted ultra-deep DNA sequencing that tumor-specific mutations present in a patient's primary and recurrent tumors are detectable at the time of SLS. The clinical value of this enhanced molecular diagnostic approach will need to be defined in future studies.

OVARIAN SMALL CELL CARCINOMA : A CASE REPORT

E. MARTINEZ LAMELA¹, J. Molero Vilchez², S. Sancho García³, M.D.L.R. Oliver Pérez⁴, J. Montáns Araujo⁵,
Y. Expósito Lucena⁶

¹Nuestra Señora del Rosario Hospital/Infanta Leonor University Hospital, oncological gynecology, Madrid, Spain
²Ntra. Sra. del Rosario Hospital-Toco-Gyn Gynecologic Center, Oncological Gynecology, Madrid, Spain
³Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain
⁴Hospital Universitario Doce de Octubre, Oncogical Gynecology, Madrid, Spain
⁵Pathologic Center, Pathology, Madrid, Spain
⁶Toco-Gyn Gynecologic Center, Obstetrics and Gynecology, Madrid, Spain

Aims

Extra-pulmonar small-cell carcinoma has a very low incidence (0.1% - 0.4%) and it represents less than 1% of ovary cancers, with less than 25 cases described in the literature.

It affects young women (average age 24 years) and it generally appears as a big sized, bilateral solid mass with bleeding and cystic degeneration areas.

It's constituted by a small cells diffuse neoplastic proliferation with scanty cytoplasm, abundant follicle-like structures with eosinophil content, elevated mitotic activity and necrosis areas.

It's a very aggressive tumor even with it is diagnosed on early stages, with survival rate less than 2 years. There is no consensus over the optimal treatment.

Method

Results

A 37 years old woman admitted to emergency due to pain and abdominal distension. CT Findings: ascites, bilateral anexial solid cystic masses, solid lump in pouch of Douglas compatible with ovarian neoplasia with peritoneal implants. CA 125 (14470U/ml)

A left adnexectomy with positive BIO for invasive ovarian cancer is carried out before surgical laparoscopy and it is complemented with optimal primary cytoreduction surgery.

Pathological Anatomy: small cells carcinoma in both ovaries. Metastasic tumor in peritoneal implant, positive peritoneal lavage. 45 Isolated nodes are unaffected (21 para-aortic / 24 pelvics). Stage IIB (pT2b pN0 pM0)

After presenting case at tumor Committee Tumors, concomitant chemotherapy (etoposid-cisplastino) with associated radiotherapy is proposed.

Following 9 months after treatment was finalized, the patient remains disease-free.

Conclusion

Small-cells carcinoma is a rare tumor with high level of malignancy and there is low experience in its treatment.

ESGO7-0084

PROGNOSIS OF EPITHELIAL OVARIAN CANCER PATIENTS (EOC) WITH ABDOMINAL WALL METASTASIS (AWM)

T. Mehmood1
1Shaukat Khanum Memorial Cancer Hospital and Research Centre, Radiation Oncology, Lahore, Pakistan

Aims

Patients with the detection of AWM in EOC are categorised as FIGO IVB irrespective of other biologic factors. We evaluated the impact of AWM on patients’ overall survival (OS).

Method

This retrospective study includes 48 patients treated at our institution between 2005 and 2015 and categorized in group A (FIGO IIIC, n=18), group B (FIGO IV-only AWM, n=20), and group C (FIGO IV- metastases other than AWM, n=10). Clinicopathological parameters and survival data were extracted from our prospectively maintained tumor registry. Survival analyses were calculated using Kaplan-Meier method and Cox regression models.

Results

The median overall survival (OS) in group A, B, and C was 37, 58, and 25 months (p <0.001) respectively. Multivariate analysis revealed that in reference with FIGO IIIC OS in patients with FIGO IV-only AWM was not significantly inferior (HR 0.84, 95%CI 0.55-1.23, p=0.340), but was superior compared with FIGO IV-metastases other than AWM (HR 1.61, 95%CI 1.25-2.04, p<0.001). Further independent prognostic factors for OS were pT-stage, nodal status, performance status, and residual tumor, respectively.

Conclusion

Prognosis of patients with AWM as the only site of distant metastasis differs significantly from other stage IV-patients. Therefore, up-staging of patients with AWM to FIGO IVB seems not be justified with respect to prognosis. A revision/clarification of the FIGO classification system should be considered to avoid unnecessary stigmatisation as FIGO IVB and to better classify these patients in their respective prognostic group.

PALB2 MUTATIONS IN HIGH-RISK WOMEN WITH OVARIAN OR BREAST CANCER

K. Metcalfe¹, J. Lerner-Ellis², M. Akbari³, S. Narod⁴

¹University of Toronto, Faculty of Nursing, Toronto, Canada
²Mount Sinai Hospital, Genetics, Toronto, Canada
³Women's College Research Institute, Breast Cancer Research, Toronto, Canada

Aims

In the current study, we examined the frequency of PALB2 mutations in women with breast or ovarian cancer who met criteria for genetic testing for BRCA1 and BRCA2 and tested negative.

Method

DNA samples from women with ovarian or breast cancer, who met criteria for provincial BRCA1 and BRCA2 genetic testing and tested negative between the years of 2007 and 2014 were included in this study. All 13 coding exons of PALB2 plus 20 base pairs from the exon boundaries were amplified using Wafergen SmartChip technology. The amplified DNA were paired-end sequenced at 2x250 cycles using an Illumina MiSeq sequencer.

Results

2,225 women with breast cancer and 429 women with ovarian cancer were tested for PALB2 mutations. No PALB2 mutations were found in women with ovarian cancer. Seventeen deleterious PALB2 mutations were detected in women with breast cancer (0.8%). The frequency of PALB2 mutations was significantly higher in women with bilateral breast cancer (2.4%) compared to women with unilateral breast cancer (0.6%) (p=0.01). There was no significant difference in age at diagnosis between those with and without a PALB2 mutation (50.9 years vs 53.8 years; p=0.34).

Conclusion

Genetic testing for PALB2 should be considered for high-risk women with breast cancer, especially those who present with bilateral breast cancer. However, PALB2 does not appear to contribute to ovarian cancer which has implications for counselling women who are identified with a PALB2 mutation.
MALIGNANT OVARIAN GERM CELL TUMORS - A RETROSPECTIVE ANALYSIS AT A TERTIARY CENTRE FROM 2001 - 2016

M. Meusel¹, D. Klotz¹, U. Canzler¹, P. Wimberger¹
¹Universitätsklinikum Carl Gustav Carus Dresden, Klinik für Gynäkologie und Geburtshilfe, Dresden, Germany

Aims

Malignant ovarian germ cell tumors (MOGCTs) are rare, accounting for 2-3% of all ovarian malignancies. Typically, they arise in girls and younger women. Due to the rarity and the distinct tumorigenesis, MOGCTs represent a challenge in diagnosis and therapy.

Method

In this retrospective analysis, we included all patients with the diagnosis of a MOGCT in the period from 2001 to 2016 at the University Women's Clinic Dresden. We examined the following parameters: age, presenting symptoms, tumor staging and the operative and systemic therapies.

Results

9 patients aged between 19 and 35 years were treated during the study period (5 immature teratomas, 3 dysgerminomas, 1 yolk sac tumor). In 78% of cases the disease was diagnosed in FIGO stage IA. The most frequently presenting symptoms were abdominal pain and a palpable tumor in the lower abdomen. In 44% of cases a typical tumor marker constellation indicated the presence of a MOGCT. Staging was mainly performed by CT of the chest and abdomen. The patients were treated primarily by surgery (a minimum of: unilateral adnexectomy and peritoneal sampling). In the majority of cases, it was possible to perform fertility-sparing surgery. 33% of the patients received adjuvant systemic chemotherapy according to the BEP scheme. All patients were followed-up in our clinic. To date, all patients are disease-free.

Conclusion

The majority of MOGCTs are diagnosed at an early stage of the disease. Due to fertility-sparing surgery and the use of platinum-based systemic therapy, this study confirms that these highly chemotherapy-sensitive tumors have an excellent survival outcome.
SIMPLE RULES, NOT SO SIMPLE

E. Meys¹, I. Rutten¹, R. Kruitwagen¹, B. Slangen¹, S. Lambrechts¹, H. mertens²,³, E. Nolting⁴, D. Boskamp⁵, T. Van Gorp¹
¹Maastricht University Medical Centre MUMC+, Obstetrics and Gynaecology, Maastricht, The Netherlands
²Previously: Zuyderland Sittard, Obstetrics and Gynaecology, Sittard, The Netherlands
³Currently: Maastricht University Medical Centre MUMC+, Board of directors, Maastricht, The Netherlands
⁴St.Jans Gasthuis Weert, Obstetrics and Gynaecology, Weert, The Netherlands
⁵VieCuri Venlo, Obstetrics and Gynaecology, Venlo, The Netherlands

Aims

Analyse how well untrained examiners – without experience in the use of International Ovarian Tumor Analysis (IOTA) terminology or simple ultrasound-based rules (simple rules) - are able to apply IOTA terminology and simple rules. And to assess the level of agreement between non-experts and an expert.

Method

This prospective multicentre cohort study enrolled women with ovarian masses. Ultrasound was performed by non-expert examiners and an expert. Ultrasound features were recorded using IOTA nomenclature, and used for classifying the mass by simple rules. Interobserver agreement was evaluated with Fleiss’s kappa and percentage agreement between observers.

Results

Fifty consecutive women were included. We observed 46 discrepancies in the description of ovarian masses when non-experts utilized IOTA terminology. Tumour type was misclassified often (n=22), resulting in poor interobserver agreement between the non-experts and expert (kappa=0.39, 95%-CI 0.244-0.529, percentage of agreement =52.0%).

Misinterpretation of simple rules by non-experts was observed 57 times, resulting in an erroneous diagnosis in 15 patients (30%). The agreement for classifying the mass as benign, malignant or inconclusive by simple rules was only moderate between the non-experts and expert (kappa=0.50, 95%-CI 0.300-0.704, percentage of agreement =70.0%). The level of agreement for all 10 simple rules features varied greatly (kappa index range: -0.08–0.74, percentage of agreement 66-94%).

Conclusion

Although simple rules are useful to distinguish benign from malignant adnexal masses, they are not that simple for untrained examiners. Training with both IOTA terminology and simple rules is necessary before simple rules can be introduced into guidelines and daily clinical practice.

9European Institute of Oncology, Department of Gynecology, Milan, Italy
10CEU San Pablo University, Department of Applied Mathematics and Statistics, Madrid, Spain
11Imperial College London, Department of Gynaecology, London, United Kingdom

Aims

To determine oncological outcomes and incidence of lymph node(LN) metastases in women who underwent systematic pelvic and para-aortic lymphadenectomy for surgical staging of apparent stage I low-grade epithelial ovarian cancer(LGEOC).

Method

A retrospective study was performed at nine institutions across Europe and USA. Patients who underwent surgical staging for presumed stage I LGEOC between 2000 and 2016 were included. A minimum number of ≥10 pelvic and ≥10 para-aortic LN was required. Patients with preoperative radiologic or clinical evidence of extraovarian or LN-disease, and those with non-epithelial histology, were excluded.

Results

The overall incidence of LN metastases was 4.3% in the 163 evaluated patients. The incidence of LN involvement in serous, endometrioid and mucinous subtypes was 10.7%, 1.5% and 0%, respectively. Upstaging due to LN involvement alone occurred in only 2.4% of the patients. Eighty-nine (54.6%) patients received adjuvant chemotherapy due to FIGO stage ≥IC disease. The five-year progression-free and overall survival was 93.2% (95%CI:89.4-97.1%) and 94.5% (95%CI:90.9-98.0%), respectively. There was no significant difference in PFS or OS between LN-negative versus LN-positive patients. However, fewer patients received adjuvant chemotherapy in the LN-negative group. Multivariate analysis did not identify any independent prognostic factor of survival.

Conclusion

The risk of LN involvement in non-serous apparent stage I LGEOC appears low with a rate of <1% in this retrospective analysis, raising questions about the value of lymphadenectomy in those patients. Larger scale prospective studies are warranted to evaluate the oncologic safety of omitting systematic LN-staging in apparent stage I non-serous LGEOC.
Aims

Macrophage migration inhibitory factor (MIF), CD74 and Ki-67 emerge as important players in pathogenesis and angiogenesis of several types of malignant tumors. The purpose of this study was to evaluate the expression of MIF, CD74 and Ki-67 in ovarian borderline tumor and ovarian cancer and explore the potential roles they play in ovarian tumor.

Method

Macrophage migration inhibitory factor, CD74 and Ki-67 expression was assessed by immunohistochemistry in 102 cases with various degrees of ovarian tissues, including 10 normal ovarian tissue, 46 borderline tumor, 48 ovarian cancer. Correlation between immunostainings and clinicopathological parameters, as well as the follow-up data of patients, was analyzed statistically.

Results

Immunohistochemical analysis showed that CD74 expression was significantly higher in ovarian cancer(26/48) than borderline ovarian tumor(10/46) and normal samples(0/10) (P< 0.01). Ki-67 expression was higher in ovarian cancer (18/48) than borderline ovarian tumor(2/46) and normal samples(0/10). (P< 0.001). MIF expression was high in all three group (40/48 vs 38/46 vs 10/10). Correlation analysis revealed that high CD74 expression in tumor cells were associated with advanced clinical stage, and worse prognosis of patients.

Conclusion

Correlation analysis revealed that high CD74 expression in tumor cells were associated with advanced clinical stage of patients.
POORLY DIFFERENTIATED CARCINOID TUMOR METASTATIC TO OVARY WITH PERITONEAL DISSEMINATION-A CASE REPORT

M. Mitrovic1, A. Stefanovic2, K. Jeremic1, S. Buzadzic1, D. Uljarevic1

1Clinic of gynecology and obstetrics - Clinical center Serbia, Postoperative department, Belgrade, Serbia
2Clinic of gynecology and obstetrics - Clinical center Serbia, Surgery department, Belgrade, Serbia

Aims

Neuroendocrine tumors account for about 2% of all gynecological malignancies, but may be also metastatic from other sites. Despite new developments for treatment of advanced neuroendocrine tumors, there are still not established standard protocols for management of this rare malignant disease. Every case report or small series of patients could make a contribution in this field.

Method

We report a case of woman, who had presented to our hospital under diagnosis of pelvic tumor in the right adnexal lodge, suggesting ovarian malignancy. After two surgery procedures, pathohystology and immunohistochemistry findings confirmed metastatic ovarian tumor, originating from neuroendocrine colorectal cancer.

Results

A 36-year old woman, who underwent postpartal hysterectomy with conservation of right adnexa, was referred to our Clinic with pelvic mass adjacent to right adnexa, hydronephrosis on the right kidney and possible infiltration of the right ureter. She underwent first diagnostic and second extensive open surgery procedure. Final immunohistochemical report confirmed high-grade poorly differentiated carcinoid tumor stage IVb, in most cases originated from appendix. She received four cycles of chemotherapy specific for colorectal cancer. The subsequent evaluation revealed complete regression of lesions and she was doing well 6 months after treatment.

Conclusion

The most common neuroendocrine neoplasms are gastroenteropancreatic. Most of patients with high grade poorly differentiated neuroendocrine carcinoma have metastatic disease and may present with large ovarian Krukenberg tumor. High-grade neuroendocrine colorectal cancer is a very rare differential diagnosis for secondary ovarian malignancies. Surgery is therapeutic choice for localised disease, but extent disease requires multidisciplinary approach and further future research in treatment.

2Gujarat Cancer & Research Institute, Dept. of Gyn Oncology, Ahmedabad, India
3Gujarat Cancer & Research Institute, Dept of Gyn. Oncology, Ahmedabad, India
4Gujarat Cancer & Research Institute, Dept. of Gyn. Oncology, Ahmedabad, India

Aims

To evaluate the incidence of pelvic nodal metastasis in patients with primary malignant sex-cord stromal tumours (SCSTs) of the ovary and add to the limited data available on nodal metastasis in ovarian SCSTs.

Method

A retrospective 5-year single institution review of patients with primary malignant ovarian SCSTs at The Gujarat Cancer and Research Institute (GCRI) between 2009 and 2014 was done. Information was collected regarding patient and tumour characteristics from pathology and medical records.

Results

A total of 48 patients were reviewed, 36 (75%) had granulosa cell tumour followed by fibroma-thecoma group (14.6%). All the nodal tissues examined in these patients were negative. Stage I (85.4%) was most common at presentation.

Table: Tumor characteristics as per histologic type

PELVIC NODAL METASTASIS IN PRIMARY MALIGNANT SEX-CORD STROMAL TUMOURS OF THE OVARY: A SINGLE INSTITUTION EXPERIENCE

R. Modi\(^1\), M. Mankad\(^1\), P. Dave\(^1\), A. Desai\(^1\), S. Patel\(^1\)

\(^1\)Gujarat Cancer & Research Institute, Department of Gynaecological Oncology, Ahmedabad, India

Aims

To evaluate the incidence of pelvic nodal metastasis in patients with primary malignant sex-cord stromal tumours (SCSTs) of the ovary and add to the limited data available on nodal metastasis in ovarian SCSTs.

Method

A retrospective 5-year single institution review of patients with primary malignant ovarian SCSTs at The Gujarat Cancer and Research Institute (GCRI) between 2009 and 2014 was done. Information was collected regarding patient and tumour characteristics from pathology and medical records.

Results

A total of 48 patients were reviewed, 36 (75%) had granulosa cell tumour followed by fibroma-thecoma group (14.6%). All the nodal tissues examined in these patients were negative. Stage I (85.4%) was most common at presentation.

PREOPERATIVE HEMATOLOGIC MARKERS IN PROGNOSIS OF OVARIAN CANCER SURGICAL OUTCOME

M. Mohamadianamiri

1Iran medical university-Firoozgar hospital, OB/GYN, Tehran, Iran

Aims

The current study aimed at assessing the association between Neutrophil-Lymphocyte Ratio (NLR) and Platelet Lymphocyte Ratio (PLR) for the prognosis of the surgical outcome of Epithelial Ovarian Cancer (EOC).

Method

EOC patients’ medical records of surgical operations between January, 2005 and December, 2015 were reviewed and their data of clinicopathological Complete Blood Counts (CBCs) and surgical outcomes were collected. To predict the surgical outcomes, PLR and NLR optimal predictive values were determined and then compared with each other.

Results

A statistically significant relation was found between surgical outcomes and NLR and PLR (p<0.001 and p<0.001), for which a new cutoff point was gained (PLR: 192; NLR: 3). The sensitivity and specificity was 0.74 and 0.67, respectively for PLR and 0.74 and 0.58, respectively for NLR.

Conclusion

NLR and PLR seem to be useful methods for the prediction of surgical outcomes in patients with EOCs. Enhancements of NLR and PLR as prognostic factors proved to be beneficial for poor surgical outcomes. Moreover, PLR increase showed to further help in the prognosis of EOC suboptimal debulking.

NEUROENDOCRINE CARCINOMA OF THE OVOTESTIS: A CASE REPORT AND REVIEW OF LITERATURES

M. Mohamadianamiri

1Iran medical university-Firoozgar hospital, oncology gynecology, Tehran, Iran

Aims

Case:

Here we represent a 77-year-old woman with primary amenorrhea, infertility and 10cm solid mass in left adnex with 46 XY in karyotype with ovotestis neuroendocrine neoplasm in pathology report which was treated with a multi-modality manner including surgery and chemotherapy but she came back with pulmonary metastasis after 2 cycles of chemotherapy.

Method

For women who present with a stage 1 primary ovarian neuroendocrine tumor the prognosis is excellent with greater than 90% survival. Neuroendocrine tumor of the ovary represents 3 % of all neuroendocrine tumors. The prevalence of ovotestis is 1/20000 births. For women with more advanced disease, the prognosis is poor. Neuroendocrine carcinoma of the ovary is a rare and aggressive tumor commonly associated with other surface epithelial and germ cell neoplasms. The prevalence of ovotestis is 1/20000 births and gonadal malignancies are the most reported neoplasm affected the ovotestis.

Results

Here we report a case of ovotestis which is presented with neuroendocrine carcinoma and poor prognosis.

Conclusion

Neuroendocrine carcinoma of the ovary is a rare and aggressive tumor commonly associated with other surface epithelial and germ cell neoplasms. The prevalence of ovotestis is rare and gonadal malignancies are the most reported neoplasm affected the ovotestis.

METASTASIC PAPILLARY SEROUS AXILLARY LYMPH NODE FROM OVARIAN ORIGIN: A CASE REPORT
M. Mohamadianamiri1
1, Tehran, Iran

Aims

From among gynecologic cancers, Epithelial Ovarian Cancer (EOC) is the major cause of mortalities in the United States, accounting for 3.6% of all types of gynecologic cancers. A major reason for this poor treatment is that most EOC patients are frequently involved in an advanced stage of the disease.

Case Presentation: Here we report a present a 70-year-old patient with ovarian cancer in whom an isolated metastatic axillary lymph node was detected following cyto-reductive surgery and adjuvant chemotherapy.

Method

Here we report a present a 70-year-old patient with ovarian cancer in whom an isolated metastatic axillary lymph node was detected following cyto-reductive surgery and adjuvant chemotherapy.

Results

Axillary area as a site of metastasis from ovarian carcinomas is unusual, representing as 0.03–0.6% of all breast malignancies. The most common type of ovarian malignancy to metastasize to the breast is serous carcinoma.

Conclusion

Case Presentation: Here we report a present a 70-year-old patient with ovarian cancer in whom an isolated metastatic axillary lymph node was detected following cyto-reductive surgery and adjuvant chemotherapy.

Keywords: Axillary lymph node, Ovarian cancer, metastasis
FERTILITY OUTCOME IN PATIENTS WITH BORDERLINE OVARIAN TUMOR IN IRAN
A. Mousavi
Imam Khomeini Hospital - Tehran University of Medical Sciences, gynecology-oncology department, Tehran, Iran

Aims

Objective:
To assess outcome and fertility in patients treated conservatively for a low malignant potential (LMP) ovarian tumor.

Method

Design: Retrospective study.

Setting: Gynecologic oncology department of Emam Khomeini Hospital, Tehran University of Medical Sciences

In this cohort-retrospective study we evaluated reproductive outcomes in women with borderline ovarian tumors treated with fertility-sparing surgery in Imam Khomeini hospital from 2011 to 2017.

Results

There are totally 43 patients included in the study. 24 patients had strong desire to become pregnant, from these 14 women had a successful spontaneous pregnancy and two patients had pregnancy with IVF (58.3% pregnancy rate). According to the lab data 22 of 24 patients had proper ovary preservation (91.7%). In this study we did not find any statistically significant difference in fertility between different types of pathologies, stages of tumors and type of surgery (laparotomy versus laparoscopy), but in the patients with relapse fertility rate reduced. For each year increasing in the age of the patient, the probability of conception decreased by 24%.

Conclusion

According to the fact that the major population of BOT patients are under forty, nowadays fertility-sparing operation methods are considered as the primary choice. Also because of most of the recurrences are borderline lesions so for women who wish to preserve their child bearing potential and who are willing to undergo careful and prolonged follow-up examination, conservative method and fertility-sparing surgeries can be an option.

ESGO7-0544

IS SELECTIVE INTERVAL DEBULKING SURGERY REALLY A FAULT IN THE MANAGEMENT OF ADVANCED HIGH-GRADE SEROUS OVARIAN CARCINOMAS (HGSOC)?

D. Hudry¹, V. Garcia Pineda¹, Y. Borghesi¹, B. Gachon¹, L. Bresson¹, P. Quincy¹, F. Narducci¹, E. Leblanc¹
¹Department of Gynecologic Oncology- Centre Oscar Lambret, Lille, Lille, France

Aims

Survival assessment of a series of HGSOC patients in a tertiary cancer center.

Method

We retrospectively reviewed the data of 228 consecutive patients diagnosed with advanced stages (FIGO stages IIIIC and IV) HGSOC, managed between 2008 and 2013 in our center.

Primary debulking (PDS) or Interval debulking surgeries (IDS) after chemotherapy were performed after a decisional laparoscopy for biopsy and tumor load assessment using Sugarbaker’s peritoneal cancer index (PCI), with the intent to perform a macroscopically complete (CC0) and safe surgery. During follow up, secondary surgery might have been indicated and repeated in selected recurrent diseases.

Results

PDS was possible in 28.6% and 71.3% for IDS, but 43 patients could never be operated. Median PCI was 10 (3-24), 24 (3-39) and 30.3 (8-39) in PDS, IDS and no surgery group respectively. CC0 was obtained in 92.5% cases and in 90.2% for PDS and IDS group respectively. With 35 months median follow-up, OS and DFS were 94.2/32.9, 67.9/20.5 months in PDS and IDS respectively.

During follow-up, 74.1% of patients recurred (50.9% and 83.3% in PDS and IDS respectively). For those who could be (optimally) operated, 79.7% were alive 5 years after the diagnosis versus 42.7% if surgery was not possible (p<0.0001).

Conclusion

In optimally cyto-reduced advanced HGSOC, initial tumor load is a more important survival factor than the moment of surgery. A centralized surveillance seems necessary as secondary surgical efforts represent an important factor to increase OS in these patients.

IMPACT OF RIGHT UPPER QUADRANT CYToreDUCTive TECHNIQUES FOR ADVANCED OVARIAN CANCER ON POSTOPERATIVE HEPATIC FUNCTION AND LIVER FAILURE

S. Nasser1, K. Lathouras1, J. Campbell2, L. Jiao3, C. Fotopoulou1

1West London Gynaecological Cancer Centre- Imperial College NHS Trust, Department of Surgery and Cancer, London, United Kingdom
2Hammersmith Hospitals- Imperial College NHS Trust, Department of Anaesthesia, London, United Kingdom
3Hammersmith Hospitals- Imperial College NHS Trust, Department of Hepatobiliary and Pancreatic Surgery, London, United Kingdom

Aims

The study evaluates postoperative hepatic function and risk of liver failure in patients with advanced ovarian cancer who underwent extensive right upper-abdominal cytoreductive surgery in the primary, relapsed or interval setting.

Method

Medical records were retrospectively reviewed for all women with primary or relapsed ovarian cancer(OC) between 01/2016-12/2016

All patients who underwent liver and/or right diaphragmatic cytoreduction were included in the present study.

Postoperative liver enzyme function(LFTs), as evaluated by alanine transaminase(ALT), alkaline phosphatase(ALP) and bilirubin(Bil), was reviewed and correlated with postoperative complications.

Results

A total of 39 patients were identified. 28(72%) with primary OC had undergone upfront, 8 (21%) interval and 11 (28%) secondary/tertiary cytoreduction.

Thirty-one cases were high grade serous at FIGO IIIC(22/39). The surgical procedures were full-thickness diaphragmatic resection(n=26; 67%), right partial pleural resection(n=in 3;12%), cardiophrenic lymph-node resection(n=2;8%), liver capsule stripping with subcapsular tumor resection(n=22; 56%) and porta-hepatis tumor resection(2; 5%). All patients(39/39) had normal preoperative LFTs.

In 2(56%) patients LFTs increased immediately and peaked on the 1st postoperative day. Mean value of the highest ALT across all patients was 89(range: 6-244), ALP 56(24-210) and Bilirubin 13(4-27).

In 33(85%) cases elevated LFTs normalized by 5th postoperative day with no major changes in bilirubin. No immediate complications were directly linked to right upper-quadrant cytoreduction. Two patients developed pulmonary oedema and atrial flutter that resolved with conservative management.

Conclusion

Right upper-abdominal debulkign for OC is associated with a transient 50-100% increase(of upper normal limit) in liver-enzymes postoperatively, with little clinical implications. Due to the existing, albeit rare, risk of liver failure patients should be monitored carefully.
EVALUATION OF RISK FACTORS ASSOCIATED WITH RELAPSE AND RECURRENCE OF BORDERLINE OVARIAN TUMORS WITH NO INVASIVE IMPLANT

N. Tounsi¹, H. Bouzaïene¹, M. Chemlali¹, N. Abdelwahed¹, R. Doghri², H. Hantouse², H. Bouazize¹, M. Hechiche¹, J. Ben Hassouna¹, K. Rahel²

¹Salah Azaïez, Department of Surgery Carcinologique, Tunis, Tunisia
²Salah Azaïez, Department of Pathology, Tunis, Tunisia

Aims

Borderline ovarian tumors (BOTs) have a good prognosis; however a few BOTs patients experience the relapse of disease, either borderline or malignant. The aims of this study were to analyze the risk factors of relapse.

Method

This is a retrospective study of 31 patients with confirmed BOTs treated in the Salah Azaiez Oncologic institute between 2005 and 2015.

Results

31 cases were identified; median age was 43 years. Most of the patients 27 (87%) demonstrated stage IA.

8 patients had laparoscopic surgery and they were all treated conservatively. 23 patients, which had laparotomy only two cases, underwent conservative surgery. The overall risk of recurrence was occurred in 5 (16.13%). The relapse was occurred 120 months after the primary surgery.

Among 5 recurrent cases, one cancerous transformation and 4 borderline recurrences were detected. 3 recurrences of 8 laparoscopic surgery group and 2 recurrent cases of 23 laparotomic surgery groups were observed. Laparoscopic approach was not related to higher recurrence rate (P= 0.093). 3 recurrences of 10 conservative surgery group and 2 recurrent cases of 21 comprehensive surgery groups were observed. However, it did not show significant difference (P=0.175).

Mean age of disease-recurrence group was 42, 8 years whereas the one of non-recurrent group was 46, 5 years (P=0.65), age was not risk factor of disease recurrence.

Conclusion

Age, conservative treatment and laparoscopic technique does not seem as a risk factor for recurrence. However, it is necessary to perform more randomized controlled trials to confirm such an assumption.
CARCINOSARCOMA OF THE OVARY: ANALYSIS OF 18 CASES

N. Tounsi1, M. Chemlali1, B. Lamouri1, A. Hadiji1, H. Henchiri1, R. Doghri2, M. Hechiche1, J. Ben Hassouna1, K. Rahel1
1Salah Azaize, Department of Surgery, Tunis, Tunisia
2Salah Azaize, Department of Pathology, Tunis, Tunisia

Aims

Carcinosarcoma is a rare clinical entity, and account for less than 1% of all ovarian cancers. These tumors represent one of the most highly aggressive cancers of female genital tract with poor long-term prognosis. The aim of this study was to review our experience with ovarian carcinosarcoma, to analyze their clinical and histopathological features, to discuss about diagnostic and therapeutic difficulties.

Method

Retrospective chart review of 18 patients referred for ovarian carcinosarcoma was carried out from 1996 to 2015 in institute of Salah Azaiz.

Results

The median age at diagnosis was 59 years. All patients underwent initial surgical treatment. Stage distribution was as follows: 4 stage I, 1 stage II, 12 Stage III, and 1 stage IV. 16 patients underwent complete surgical staging. Optimal cytoreductive surgery with no residual tumor was performed in 6 patients. Three Patients demonstrated heterologeous histology.

14 patients underwent adjuvant chemotherapy, from these: 4 patients achieved a complete response, 4 a partial response, 6 had progressive disease. Two patients suffered from recurrence of disease.

A median follow-up was 20.7 months. Only 3 (16.66%) patients have 5-year overall survival.

Conclusion

Some reports indicate that complete cytoreduction, advanced age, grade, and the use of adjuvant chemotherapy are prognostic factors.

Further prospective trials are clearly warranted in a larger group of patients.

OVARIAN CARCINOSARCOMA WITH PERIRENAL METASTASIS: A CASE REPORT
S.F. Ngu\textsuperscript{1}, H. Bolton\textsuperscript{1}, A. Riddick\textsuperscript{2}, S. Freeman\textsuperscript{3}, R. Ahmed\textsuperscript{4}, M. Shafi\textsuperscript{1}
\textsuperscript{1}Cambridge University Hospital NHS Foundation Trust- Addenbrooke's Hospital, Department of Gynaecological Oncology, Cambridge, United Kingdom
\textsuperscript{2}Cambridge University Hospital NHS Foundation Trust- Addenbrooke's Hospital, Department of Urology, Cambridge, United Kingdom
\textsuperscript{3}Cambridge University Hospital NHS Foundation Trust- Addenbrooke's Hospital, Department of Radiology, Cambridge, United Kingdom
\textsuperscript{4}Cambridge University Hospital NHS Foundation Trust- Addenbrooke's Hospital, Department of Pathology, Cambridge, United Kingdom

Aims

Ovarian carcinosarcoma is a rare and aggressive biphasic tumour comprising of both carcinomatous malignant epithelial and sarcomatous mesenchymal elements. Patient usually presents with advanced stage disease which is associated with poor prognosis. The mainstay of treatment is cytoreductive surgery followed by platinum-based chemotherapy.

Method

We report a case of a patient with ovarian carcinosarcoma with metastasis to perirenal space, which is unusual for ovarian malignancy.

Results

A 76-year-old woman presented with abdominal bloating and examination found a large mass arising from the pelvis. CT scan showed 20cm complex right ovarian tumour with internal septations and solid mural nodules, small volume ascites, peritoneal disease within the pelvis and a 6.3cm enhancing mass at the upper pole of the right kidney. Her CA125 was 89 kU/l and serum creatinine 70 umol/l. Preoperative differential diagnosis included synchronous primary ovarian and renal malignancies or ovarian carcinoma with renal metastasis. She underwent primary debulking surgery with laparotomy, total abdominal hysterectomy, bilateral salpingo-oophorectomy, right nephrectomy, omentectomy and peritoneal stripping of nodular disease. Optimal debulking was achieved with <1cm residual disease. Histopathology showed right ovarian carcinosarcoma with heterologous elements and metastatic carcinosarcoma to right perirenal space (tumour arise in perinephric fat), pelvic peritoneum, omentum, bilateral parametrium and left ovary. Postoperatively, she made a good recovery and received adjuvant chemotherapy.

Conclusion

Ovarian cancer may rarely metastasise to perirenal space, especially in high grade tumours. Preoperative diagnosis to differentiate between synchronous cancers and metastasis may be difficult.
BEVACIZUMAB IN EPITHELIAL OVARIAN, FALLOPIAN TUBE AND PRIMARY PERITONEAL CANCER: A SINGLE CENTRE EXPERIENCE

S.F. Ngu1, K. Chan1, K.Y. Tse1, M. Chu1, H. Ngan1
1The University of Hong Kong, Department of Obstetrics & Gynaecology, Hong Kong, Hong Kong S.A.R.

Aims

To review the use of bevacizumab in epithelial ovarian, fallopian tube and primary peritoneal cancer at the Division of Gynaecological Oncology, Queen Mary Hospital, Hong Kong.

Method

Patients who received bevacizumab with chemotherapy between January 2011 and December 2015 were included. A retrospective chart review was performed. Main outcome measures were adverse events and progression-free survival.

Results

41 patients received bevacizumab: 24 for primary treatment and 17 for recurrent disease. Of 24 patients who received bevacizumab as primary treatment, the median age was 52 years, 13% had early-stage high-risk disease, 88% had FIGO stage III/IV disease, 46% had high-grade serous adenocarcinoma and 54% had residual disease after debulking surgery. Of 17 patients who received bevacizumab for recurrent disease, the median age was 52 years, 94% were having their first recurrence, 65% had platinum-sensitive disease and 41% had high-grade serous adenocarcinoma. Median follow-up was 28 months (range 4-76 months), at which point 26 patients had died. Grade 3 or higher hypertension and proteinuria occurred in 22% and 7% of patients, respectively. Bevacizumab was discontinued due to proteinuria in 10% of patients, while none discontinued bevacizumab because of hypertension. The median progression free survival was 18.1 months (95% CI 14.3-21.9) for primary treatment and 10.9 months (95% CI 8.1-13.7) for recurrent disease.

Conclusion

The most common adverse events were hypertension and proteinuria, but these rarely led to discontinuation of bevacizumab. The progression free survival was comparable to those reported in large randomised trials.

ESGO7-0411

COMPARISON OF DIAGNOSTIC PERFORMANCES OF HE4, RISK OF MALIGNANCY ALGORITHM AND MORPHOLOGY INDEX IN DISCRIMINATION OF OVARIAN ENDOMETRIOSIS FROM EPITHELIAL OVARIAN CANCER IN PREMENOPAUSAL WOMEN

T. Nikolova¹, R. Zivadinovic², N. Nikolova¹, V. Klisaroska³, N. Evtimovska⁴, M. Stanojevic⁵

¹University Clinic of Obstetrics and Gynecology- Skopje, Gynecological Oncology, Skopje, FYR Macedonia
²University Clinic of Obstetrics and Gynecology- Clinical Center Nis, Gynecological Oncology, Nis, Serbia
³University Clinic of Oncology and Radiotherapy, Gynecologic Oncology, Skopje, FYR Macedonia
⁴University Clinic of Oncology and Radiotherapy- Skopje, Biochemical Laboratory, Skopje, FYR Macedonia
⁵University Clinic of Obstetrics and Gynecology- Clinical Center- Nis, Gynecological Oncology, Nis, Serbia

Aims

Comparison of the diagnostic performance of HE4 with the Risk of Malignancy Index (RMI) and Morphology Index (MI) in differentiation of ovarian endometriosis from epithelial ovarian cancers (EOC) in premenopausal women.

Method

Prospective, comparative study was conducted at the University Clinic of Obstetrics and Gynecology in Skopje. 164 premenopausal women were consecutively recruited and analyzed in three study groups: ovarian endometriosis-ASRM stage III and IV (37 cases), “other benign pelvic masses” (57 cases), EOC (11 cases) and one control group (59 healthy women). Morphology Index was calculated as a sum of the scores for tumor’s structure and tumor’s volume according to the Ueland’s criteria. RMI was calculated according to the Jacobs’ criteria. After ultrasonography, all subjects were blood sampled for HE4 and CA125. Surgery and histology verification of the material was performed. Group classification done according to the histologic results. Cut-offs for HE4, RMI and MI as follows: ≥70pmol, ≥25 and ≥5, respectively.

Results

Sensitivity, specificity, positive and negative predictive values and accuracy for ovarian endometriosis vs. EOC, for each of the tested markers are given accordingly: HE4 (81.82%; 100%; 100%; 94.87%; 95.83%); RMI (90.91%; 35.14%; 29.41%; 92.86%; 47.92%) and MI (100%; 75.68%; 55%; 100%; 81.25%).

Conclusion

HE4 performs best in discrimination of ovarian endometriosis from EOC in premenopausal women, but ultrasonography through MI is most sensitive method, detecting all cancer cases. Both HE4 and MI should be done for optimal management in a patient with pelvic mass.

DESCRIBING INTRA-TUMOURAL HETEROGENEITY IN HIGH GRADE SEROUS OVARIAN CANCER

K. Nixon¹, P. Cunnea¹, R. Wulandari¹, E. Curry¹, C. Albert-Morera¹, N. Rama¹, D. Bowtell², H. Gabra¹, E. Stronach¹, C. Fotopoulou³

¹Imperial College London, Surgery and Cancer, London, United Kingdom
²Peter MacCallum Cancer Centre, Cancer Genomics and Genetics Program, Melbourne, Australia
³West London Gynaecological Cancer Centre- Imperial College NHS trust, Surgery and Cancer, London, United Kingdom

Aims

High Grade Serous Ovarian Cancer (HGSOC) remains the leading cause of death among gynaecologic malignancies despite advances in surgical techniques and novel targeted regimens. Disparity in response to treatment is partially due to the vast spatial and temporal intra-tumoural heterogeneity (ITH) observed, making the development of longer term effective therapeutic approaches challenging. We aim to characterise this ITH to understand the molecular mechanisms behind peritoneal dissemination and to define the link between heterogeneity and patient outcome.

Method

Tumour deposits from multiple anatomical sites were collected from advanced (FIGO III/IV) HGSOC patients during maximal effort upfront debulking at a single institution. Tumour cells were extracted, cultured short-term in-vitro, treated with cisplatin and apoptosis and cell viability measured. Patients are tracked for relapse and relapse samples collected where possible.

Results

Thirty-eight patients (mean age: 60 years; range 32-91) were anatomically mapped. Mean number of tumour deposits collected was 8 (range: 4-16) across the entire peritoneal cavity and paracardiac lymph nodes. Phenotypic apoptosis assays showed vast heterogeneity in platinum response across different tumour deposits and individual patients in 64% of patients sampled to date (>2 standard deviation (SD) score of in-vitro cisplatin sensitivity). Correlation with clinical response showed a trend of low heterogeneity (low SD score) with higher probability of future development of platinum-resistant relapse.

Conclusion

Data from phenotypic assays demonstrate a spatial and temporal functional tumour heterogeneity in advanced HGSOC. This functional data coupled with parallel proteomic and genomic analysis will provide a definitive description of ITH and clonally evolved chemo-resistance in HGSOC.
INCIDENTAL THORACIC FINDINGS ON ROUTINE COMPUTED TOMOGRAPHY IN EPITHELIAL OVARIAN CANCER

B. O’Leary¹, T. Treacy¹, T. Geoghegan², T. Walsh¹, B. Boyd¹, D. Brennan¹
¹Mater Misercordiae University Hospital, Gynaecological Oncology, Dublin 7, Ireland
²Mater Misercordiae University Hospital, Radiology, Dublin 7, Ireland

Aims

Epithelial ovarian carcinoma is the most common cause of death from gynecological malignancy in Europe and the United States. Typically disease is restricted to the peritoneal cavity at presentation. Distant metastases are more common than previously thought, with studies showing metastases in up to 38% of cases at some time over the natural history of the disease. Many centres image from the lung apices to the inguinal region, however recent European Society of Urogenital Radiology guidelines recommend reducing exposure to radiosensitive breast tissue by only imaging up to the lung bases. The aim of this retrospective study was to investigate the incidence of thoracic findings on CT imaging in patients with epithelial ovarian carcinoma.

Method

An assessment of 100 consecutive computed tomography scans of the thorax, abdomen, and pelvis for surveillance of epithelial ovarian carcinoma in a tertiary referral unit was performed.

Results

35 (35%) patients were found to have thoracic findings on CT. Pleural effusions developed in 14 (40%) of these patients. Small lung nodules (<1cm) were present in 13 (37%) patients. Mediastinal lymphadenopathy was seen in six (17%) patients. Two patients (6%) had thyroid nodules of unknown significance. Pleural effusions are the most common thoracic finding in ovarian cancer. Small lung nodules were present at a similar level to that of the general population.

Conclusion

The CT protocol proposed by the European Society of Urogenital Radiology is safe for monitoring patients with tissue-proven epithelial ovarian cancer. This reduction in scanning may alleviate patient anxiety, and offers a cost benefit to hospitals.

DOES OVARIAN CANCER HAVE A DIFFERENT BEHAVIOR IN THE ELDERLY?
S. Olbrecht1,2, T. Baert1,3, A. Laenen1, I. Vergote1,2,3, A. Coosemans1,3
1University Hospital Leuven, Department of Gynecology and Obstetrics, Leuven, Belgium
2KU Leuven, Department of Oncology- Laboratory of Gynecologic Oncology- ImmunOvar Research Group- KU Leuven- Leuven Cancer Institute, Leuven, Belgium
3KU Leuven, Department of Oncology- Laboratory of Tumor Immunology and Immunotherapy- ImmunOvar Research Group- KU Leuven- Leuven Cancer Institute, Leuven, Belgium

Aims

The mean age at diagnosis of ovarian cancer (OC) is 66.7 years (yrs). However, a substantial proportion is above 75. Since increasing evidence arises that the immune system behaves differently in elderly, considering age in treatment might be relevant. This study provides an overview of OC patients aged above 75 to map histopathology, survival and treatment tolerance.

Method

Women with OC, diagnosed between 2005 and 2015, were included into two groups (above 75yrs (+75yrs) or below 75yrs (-75yrs)). Groups were matched for stage, year of diagnosis and histopathology.

Results

We included 129 patients +75yrs and 88 patients -75yrs. In the +75yrs, 17.05% refused initial treatment. In 69.77% chemotherapy was indicated, of which 3 patients underwent surgery but refused chemotherapy. The difference in delay in chemotherapy administration was non-significant between groups. Thrombocytopenia was more common in +75yrs receiving Carboplatin-Paclitaxel (TC) (p=0.012). For anemia and neutropenia no significant differences were found. A trend was seen to more neutropenic fever in the -75yrs who received Carboplatin (p=0.08). Recurrence occurred in 73.56% +75yrs who underwent the state-of-the-art treatment from which 15 patients chose palliation in second line, compared to 68.12% -75yrs from which only 5 chose palliation. There was no statistical age related difference in progression free survival (PFS) when patients received optimal treatment. The overall survival after 12 months was better in the -75yrs (p=0.0132).

Conclusion

The toxicity profile of TC or Carboplatin in the elderly is comparable to toxicity in younger patients. When elderly patients are treated with the state-of-the-art treatment PFS is similar to -75yrs.

SURVIVAL COMPARISON IN PATIENTS WITH AND WITHOUT NORMAL-SIZED OVARY CARCINOMA SYNDROME: PROPENSITY-SCORE MATCHING STUDY

E.S. Paik1, K.A. Son1, J.H. Kim1, J.Y. Park1, H.J. Choi1, T.J. Kim1, J.W. Lee1, B.G. Kim1, D.S. Bae1, C.H. Choi1

1Samsung Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Normal-sized ovary carcinoma syndrome (NOCS) is an ovarian cancer with ovaries being of normal size, accompanied by diffuse metastatic disease of the peritoneal cavity. We aimed at comparing survival outcomes of EOC patients with and without NOCS by propensity score matched analysis.

Method

The clinical records of EOC patients treated at Samsung Medical Center between 2002 and 2015 were retrospectively reviewed. We investigated 429 EOC patients with serous type histology and FIGO stage III and IV who underwent primary debulking surgery and adjuvant chemotherapy, and we identified 49 patients with NOCS. A propensity score match was performed to compare 49 patients with NOCS to 147 patients without NOCS (ratio 1:3) according to age, FIGO stage, initial CA-125 level, and residual disease status after primary debulking surgery.

Results

Of the included 429 EOC patients, 304 patients (70.9%) experienced relapse and a further 194 patients (45.2%) died within a median follow-up period of 43 months. The matching was successful without significant differences between the two groups in all matched variables. After matching, there was no significant differences in progression-free survival (PFS) (median PFS, 18.9 vs. 20.9 months, p=0.243) but disadvantage of overall survival (OS) was shown in group with NOCS (median OS, 41.4 vs. 71.5 months, p=0.025). In multivariate analysis for OS, NOCS remained as significant factor.

Conclusion

The current study among matched patients indicates there is statistically significant difference in OS (but not in PFS) between EOC patient with and without NOCS.
OVARIAN CANCER

ESGO7-0420

CLINICAL OUTCOMES OF PATIENTS WITH CLEAR CELL AND ENDOMETRIOID OVARIAN CANCER ARISING IN ENDOMETRIOSIS

Samsung Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The aim of this investigation was to compare outcomes of patients with clear cell carcinoma (CCC) and endometrioid carcinoma (EC) of the ovary arising in endometriosis (ES) to CCC and EC not arising in ES.

Method

This study retrospectively enrolled 224 CCC and EC patients treated in Samsung Medical Center from 2001 to 2015 to identify cancer arising in endometriosis. Clinicopathologic variables, progression-free survival (PFS) and overall survival (OS) were recorded. Student’s t test and chi square test were used to analyze continuous and categorical data. The Kaplan–Meier method was used for survival analysis.

Results

Forty-five cases arising in ES were identified and then compared with 179 cases without ES. CCC and EC arising in ES tended to be presented with early age (mean 45.2 years vs. 49.2 years p=0.003), early stage (stage I and II, 92.7% vs. 62.3 %, p<0.001), lower CA125 level (mean 307.1 vs. 556.7, p=0.041), higher percentages of no gross residual disease after surgery (87.8% vs.56.8%, p=0.001), and higher percentages of negative lymph node metastasis (82.9% vs. 59.0%, p=0.008) compared with those without ES. Kaplan-Meier curves for PFS and OS seemed to show better outcome for group arising in ES (p=0.014 for PFS, and p=0.010 for OS). However, association with ES was not significant in multivariate analysis.

Conclusion

CCC and EC with tumors associated with endometriosis appear to be diagnosed at an earlier stage and confers trend of better survival outcome.
TOTAL PARIETAL PERITONECTOMY WITH POSTERIOR PELVIC RESECTION FOR ADVANCED OVARIAN CANCER MAY HIDE POSTOPERATIVE PERITONISM SYMPTOMS. A CASE REPORT

L. Parodi1, N. Bizzarri1, R. Paolucci1, A. Palmeri1, M. Maramai1, M. Valenzano Menada1, N. Morelli2, P.L. Venturini1, S. Costantini2

1San Martino Hospital, Obstetrics & Gynecology, Genova, Italy
2San Martino Hospital, General Surgery, Genova, Italy

Aims

Parietal peritoneum is innervated by pain nerve fibers. The aim of this report is to highlight possible alterations of abdominal symptoms after an extended debunking with a total parietal peritonectomy for treatment of advanced ovarian cancer.

Method

All clinical datas were collected from medical reports of our department.

Results

A 59 years old patient affected with advanced ovarian cancer with peritoneal carcinomatosis was admitted to our department. CT-scan demonstrated subdiaphragmatic involvements, omental cake, and presence of a big pelvic mass infiltrating the uterus and pelvic peritoneum.

Primary debulking surgery was decided due to the likelihood of complete cytoreduction.

The patient underwent a dissection of the parietal peritoneum from the subdiaphragmatic, paracoelic and pelvic areas, retrograde retroperitoneal hysterectomy with bilateral salpingo-oophorectomy, resection of rectosigmoid colon and cul-de-sac with primary anastomosis. End result: no macroscopic disease.

On the 14th post-operative day, patient had no abdominal symptoms and a completely normal clinical examination, faecal material was observed within the drain tube.

Explorative laparotomy was performed and fecaloid peritonitis was found due to anastomosis dehiscence.

The patient underwent an extended adhesiolysis and formation of an end colostomy.

Recovery after re-operation was uneventful and she is going to receive adjuvant chemotherapy regularly.

Conclusion

Total parietal peritonectomy in a context of an extended debunking for advanced ovarian cancer is a feasible procedure for removing peritoneal metastasis because contributes to optimal cytoreduction in order to improve prognosis but clinicians need to be aware during the postoperative recovery that abdominal symptoms that may be hidden by the absence of the parietal peritoneum.
COMPARISON OF SEROUS VERSUS MUCINOUS BORDERLINE OVARIAN TUMORS

H.J. Jung¹, J.Y. Park¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The staging and surgical method for borderline ovarian tumor (BOT) are controversial issue. In BOT compare to malignant ovarian tumors, it is difficult to determine the surgical method due to development of tumors at the earlier stage and in younger women. This study aims to compare the serous (sBOT) and mucinous borderline ovarian tumors (mBOT), with respect to clinic-pathologic factors, disease-free survival (DFS), and recurrence.

Method

This is a retrospective study conducted at Asan Medical Center, Seoul, Korea between 1990 and 2009 among patients diagnosed with borderline tumors histopathologically.

Results

Of the total 428 patients, patients with sBOT and mBOT were 138 and 290, the mean ages were 43.6-years and 39.8-years, and the largest tumor diameter were 10.0-cm and 17.1-cm respectively. Patients who underwent open surgery was 70.7%(sBOT) and 79.9%(mBOT). The rate of staging procedure was 42.9%(sBOT) and 25.3%(mBOT). In sBOT, the recurrent rate was lower in the staging procedure group compared with the non-staging group. While, there was no difference in the recurrent rate according to the staging procedure in mBOT. Furthermore, there was also no difference in DFS between sBOT and mBOT (p=0.003).

Conclusion

During surgery, sBOT was found to be more advanced than mBOT. Also, the recurrent rate was lower in the staging procedure group compared with the non-staging group in sBOT. Our study has shown that the staging procedure can be omitted in mBOT, however it should be considered carefully when stage is more than IA in sBOT. Also, more research is needed to confirm whether the staging procedure is meaningful.
THE SAFETY AND EFFICACY OF BLEOMYCIN, ETOPOSIDE AND CISPLATIN (BEP) CHEMOTHERAPY IN PATIENTS WITH MALIGNANT OVARIAN GERM CELL TUMOR

G.W. Lee¹, S.W. Lee¹, J.Y. Park¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The safety and efficacy of bleomycin, etoposide, and cisplatin (BEP) chemotherapy have rarely been evaluated in malignant ovarian germ cell tumor (MOGCT) because of its rarity. The aim of this study was to evaluate the safety and efficacy of BEP chemotherapy in MOGCT patients.

Method

This was a retrospective study including 150 patients with MOGCT who underwent surgery followed by adjuvant BEP chemotherapy at Asan Medical Center (Seoul, Korea). The safety of BEP chemotherapy was evaluated by Common Terminology Criteria for Adverse Events (CTCAE) v 4.03. Response rates and survival outcomes were analyzed.

Results

150 patients received 687 cycles of BEP chemotherapy after surgery. 112 patients had stage I/II (74.7%) disease while 38 patients had stage III/IV (25.3%) disease. Ninety-three (62.2%) patients had grade 3-4 hematologic toxicity and 16 patients (10.7%) had grade 3-4 non-hematologic toxicity. Twenty-five patients (16.7%) suffered from neutropenic fever. Dose reduction due to toxicity was required in 7 patients (4.7%), and schedule delay due to toxicity was required in 7 patients (4.7%). Bleomycin was deleted during chemotherapy due to toxicity in 22 patients (14.7%). Cisplatin was replaced with carboplatin during chemotherapy due to toxicity in five patients (3.3%). 141 patients (94.0%) achieved complete response; one patient showed a partial response, three patients had stable disease, and eight patients experienced progression of disease with BEP chemotherapy. 14 patients had recurrent disease, and four patients died of disease. Overall survival rate was 94.7%.

Conclusion

BEP chemotherapy was highly effective and showed acceptable toxicity profile for patients with MOGCT.

FOUR RISK OF MALIGNANCY INDICES IN EVALUATION BETWEEN BORDERLINE AND MALIGNANT PELVIC MASSES

J.W. Park¹, M. Han¹, Y.J. Cho¹
¹Dong-A University Hospital, Obstetrics & Gynecology, Busan, Republic of Korea

Aims

The purpose of this study was to evaluate the ability of the four malignancy risk indices for discrimination of a borderline mass from a malignant pelvic mass.

Method

This is a retrospective study of 339 women admitted to the Department of Obstetrics and Gynecology of Donga University College of Medicine, between January, 2000, and December, 2015, for surgical exploration of a pelvic mass (borderline = 115, malignant = 224). Sensitivity, specificity, positive (PPV) and negative predictive values (NPV), and diagnostic accuracy of four RMIs (RMI 1, RMI 2, RMI 3, and RMI 4) were obtained for diagnosis of a malignant pelvic mass.

Results

Results of receiver operating characteristic (ROC) analysis of RMI 1-4 showed values of the area under the curve of 0.792, 0.791, 0.785, and 0.785, respectively. The achievement of RMI 1, RMI 2, RMI 3, and RMI 4 at different cutoff levels are 235, 340, 235, and 630, respectively. The four RMIs showed no statistical difference (p > 0.05).

Conclusion

Four RMIs (RMI 1, RMI 2, RMI 3, and RMI 4) were found to be statistically significant diagnostic criteria, which can discriminate between borderline and malignant pelvic masses.
E. Pavlik

University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

The unique intricacies of ovarian cancer screening and the associated perspectives of each screening method are presented as ten considerations.

Method

The basis for these ten considerations are empirically based, arising from observations in the Kentucky Ovarian Screening Program that includes 46000+ participants in over 20 years of operation. These considerations are presented in depth along with illustrations of how they impact the outcomes of ovarian cancer screening.

Results

Included in the considerations presented are: (1) Deciding on the number of individuals to be screened with the intent of identifying incident cancers; (2) Anticipating screening group reductions due to death; (3) Deciding on the duration and frequency of screening; (4) Deciding on an appropriate follow-up period after screening; (5) Deciding on time to surgery when malignancy is suspected; (6) Deciding on how screen-detected ovarian cancers are treated and by whom; (7) Deciding on how to treat the data of enrolled participants; (8) Deciding on the most appropriate way to assign disease-specific death; (9) Deciding how to avoid biases caused by enrollments that attract participants with late-stage disease who are either symptomatic or disposed by factors that are genetic, environmental or social; and (10) Deciding whether the screening tool or a screening
Conclusion

The considerations presented provide explanations of effects that have an important bearing on interpreting ovarian screening outcomes.

OVARIAN CANCER INCIDENCE CORRECTED FOR OOPHORECTOMY
E. Pavlik1, L. Baldwin1
1University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

Current reported incidence rates for ovarian cancer may significantly underestimate the true rate because of the inclusion of women in the calculations who are not at risk for ovarian cancer due to prior benign salpingo-oophorectomy (SO). We have considered prior SO to influence risk estimates for ovarian cancer and here report the effect of SO on population risk.

Method

Kentucky Health Claims Data, International Classification of Disease 9 (ICD-9) codes, Current Procedure Terminology (CPT) codes, and Kentucky Behavioral Risk Factor Surveillance System (BRFSS) Data were used to identify women who have undergone SO in Kentucky, and these women were removed from the at-risk pool in order to re-assess incidence rates. All age-adjusted rates were calculated based on the standard 2000 US population. The protective effect of SO on the population was determined on an annual basis for ages 5–80+ using data from the years 2009–2013. Analyses were done using SAS Statistical software version 9.4. and for programs calculating the complete prevalence rates from the KHCD data. Statistical tests were two sided with a p-value ≤ 0.05 for statistical significance.

Results

The corrected age-adjusted rates of ovarian cancer that considered SO ranged from 33% to 67% higher than age-adjusted rates from the standard population. Correction of incidence rates for ovarian cancer by accounting for women with prior SO gives a better understanding of risk for this disease faced by women.

Conclusion

The calculated rates of ovarian cancer were substantially higher when SO was taken into consideration than those obtained from estimates for the standard population.

PAIN Persisting AFTER THE RESOLUTION OF OVARIAN ABNORMALITIES

E. Pavlik¹, R. Ore¹, E. Ueland⁴, B. Headley¹, M. Altman¹, H. Palalay¹, L. Haggenjos¹, L. baldwin¹, R. Miller¹, C. DeSimone¹, S. Johnson¹, T. Fredericks¹, F. Ueland¹, J. van Nagell⁶

¹University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To determine whether pain continues when ovarian abnormalities spontaneously resolve.

Method

Ovarian abnormalities were identified in a population of 44,475 individuals that had received 270,302 ovarian screens by transvaginal ultrasonography. Participants reported the presence or absence of abdominal pain using a detailed questionnaire (CLINICAL OBSTETRICS GYNECOLOGY 55,36–42, (2012). Chi square testing was used for all comparisons.

Results

8067 women with 20303 ovarian abnormalities completed questionnaires with 2737 reporting symptoms of abdominal pain. Ovarian abnormalities included: cysts (n=5033), cysts with septations (n=1931), cysts with solid areas (n=900) or solid ovarian structures (n=203). Abnormalities were followed through 31627 sonographic exams (average=3.9 exams). The majority of women (96.2%, 2634/2737) reported resolution of pain when the ovarian abnormality spontaneously resolved. There were no differences in frequency of pain with regard to type of ovarian abnormality (P=.28153, table). For those reporting pain versus no pain after resolution, there were differences observed in BMI (P=.056) and volume of the abnormality prior to resolution (P<.0001), but not patient age (P=.19730). After the ovarian abnormality was no longer visualized, women were less likely to report pain with BMI <25 or when the abnormality had been small (<20mL).

<td>30 (3.9%)</td>
<td>5 (1.7%)</td>
<td>3 (4.8%)</td>
</tr>
</tbody>
</table>

Conclusion

One third of women monitored by serial transvaginal sonography will have pain associated with their ovarian abnormality. When the abnormality is followed to resolution, associated abdominal pain will disappear in 96% of cases. The frequency of pain resolution does not appear to be related to the type of ovarian cyst, but may be associated with the volume of the ovarian abnormality.

ULTRASOUND SURVEILLANCE OF OVARIAN ABNORMALITIES CHARACTERIZED BY STABLE MORPHOLOGY OR MORPHOLOGIES CHANGING BETWEEN CYSTS, SEPTATED CYSTS, CYSTS WITH SOLID STRUCTURE OR SOLID STRUCTURES

E. Pavlik¹, S. Johnson¹, E. Ritter¹, B. Headley¹, M. Altman¹, H. Palalay¹, L. Haggenjos¹, E. Ueland¹, E. Harvey¹, R. Ore¹, T. Fredericks¹, L. Baldwin¹, C. DeSimone¹, R. Miller¹, F. Ueland², R. Kryscio¹, J. van Nagell¹
¹University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To determine time to resolution of ovarian abnormalities that demonstrated either stable or changing morphologies.

Method

44,475 individuals received 270,302 ovarian screens by transvaginal ultrasonography. Ovarian abnormalities that demonstrated changes in morphology and resolved (n=1117) were compared to ovarian abnormalities with stable morphology that resolved (n=1800). Significance was determined by Chi square and t-testing.

Results

1117 resolving ovarian abnormalities, characterized by changes in structure, were examined: (cysts=503, cysts with septation(s)=396, cysts with solid areas=180, solid abnormalities=38). Resolving abnormalities received a total of 5658 scans by transvaginal sonography for an averaged 5.1 scans, see table. Resolution times of abnormalities with changing morphology paralleled those with a stable morphology (shown in parenthesis). Half of the cysts & cysts with septations that changed morphology resolved in ~24 months while over 75% resolved in 4+ years and the remainder took more than 5 years. Half of the unstable cysts with solid areas resolved in 8 months. Half of the unstable solid structures resolved in 18 months. Resolution time increased by 10 months with cysts and cysts with septations that had changes in morphology compared to those with unchanging morphology.

</table>

* P<0.05; **not significantly different changing vs unchanging.

Conclusion

When the morphology of an ovarian abnormality is changing, time to resolution increases for cysts and cysts with septations. Half will resolve within 24 months regardless of complexity. Half of the remainder will resolve under a four year surveillance plan. The remainder will persist for more than 5 years before resolving and should be subject to continuing surveillance.
OVARIAN CANCER

ESGO7-0811

UTERINE LAVAGE: AN OFFICE PROCEDURE WITH A PROMISING POTENTIAL FOR DIAGNOSING EARLY-STAGE OVARIAN CANCER THROUGH LIQUID BIOPSY

T. Perri1, K. Levanor2, K. Bahar-Shany2, M. Beiner1, B. Brandt1, E. Friedman3, Y. Hants1, J. Korach1
1Sheba medical center, Gynecologic Oncology, Ramat Gan, Israel
2Sheba medical center, Oncology, Ramat Gan, Israel
3Sheba medical center, The Suzanne Levy-Gertner Oncogenetics Unit, Ramat Gan, Israel

Aims

To date, no screening strategy exists for early diagnosis of high-grade ovarian carcinomas (HGOC). In-line with the increasing evidence that HGOC originate from the fallopian tube, it is potentially possible to obtain tumor cells or tumor-associated biological molecules from a liquid-biopsy through uterine lavage. We aimed to develop the technique into a feasible test for early-HGOC detection in high-risk populations.

Method

Eligible patients were BRCA-mutation non-pregnant carriers, who have not undergone risk-reducing salpingo-oophorectomy. An intrauterine insemination-catheter (InsemiTM-Cath, 3.5Frq13cm, Cook Inc. USA) was inserted into the cervical canals during routine office-visit. No anesthetic or analgesic was administered and no cervical dilatation/manipulation was used. Ten mL saline were infused into the uterine cavity and immediately retrieved. The liquid was analyzed for proteins, DNA and RNA biomarkers. Proteomic-profiling of microvesicles to characterize early “cancer signature” in biopsies are being developed.

Results

To date, we performed the lavage procedure on 18 patients who provided informed consent, some repeatedly during two consecutive follow-up visits. Time consumption was 1-2 minutes. Most patients reported no-or-minimal discomfort or pain. One lavage procedure was stopped due to pain, and two patients reported mild spontaneously-resolving abdominal pain. In all cases, enough fluid (average 4-5ml) was retrieved for further analysis, enabling the characterization of 2500 different proteins in a sample and providing enough DNA and mRNA to allow PCR and next-generation sequencing.

Conclusion

Our uterine lavage technique is an easy, low-burden, minimal-complication office-procedure, providing a potential method for obtaining liquid-biopsy for early detection of HGOC.

ESGO7-0883

BEVACIZUMAB- CONTAINING FIRST LINE CHEMOTHERAPY MIGHT REDUCE PROGRESSION-FREE SURVIVAL AFTER RECURRENCE IN ADVANCED EPITHELIAL OVARIAN CANCER

T. Perri¹, Y. Bart¹, M. Beiner¹, B. Brandt¹, L. Helpman², G. Ben-Baruch¹, J. Korach¹
¹Sheba medical center, Gynecologic Oncology, Ramat Gan, Israel
²Meir Medical Center, Gynecologic Oncology, Kfar-Saba, Israel

Aims

Recently, the VEGF inhibitor Bevacizumab was added to the standard front-line therapy of high-grade epithelial ovarian carcinoma (HGEOC). Large randomized trials have shown Bevacizumab benefit, with both progression-free and overall survival. Yet, it was shown that tumor vessels can rapidly regrow after cessation of Bevacizumab, and tumor burden can then increase. We aimed to describe changes in progression free survival after recurrence (PFS2) in advanced stage HGEOC patients treated with and without Bevacizumab at first line.

Method

Included in this cohort study were all consecutive HGEOC patients who have had a debulking surgery between 2011-2015, with either stage 4 or stage IIIC with any residual disease. Sixty seven patients were treated with carboplatin-paclitaxel. Fourty-one patients who were diagnosed after 2013 were treated with carboplatin-paclitaxel-Bevacizumab as it was then approved in our country. Their clinical data was compared.

Results

The groups did not differ in either age at diagnosis, stage, rate of BRCA-mutation carriers or neoadjuvant chemotherapy use. Median follow up was 29 and 32 months in the patients treated with and without Bevacizumab respectively. Progression free survival (PFS) was longer in the Bevacizumab group (14.5 Vs. 10.5 months). Although response rate to second line was comparable, PFS2 in those who received Bevacizumab at first line was significantly shorter (5.9 vs.8.8 months).

Conclusion

According to our cohort, bevacizumab prolongs progression-free survival after first line in stages IIIC with residual disease and stage 4 HGEOC patients, yet it might interfere with PFS2.

IMPACT OF MAGE-A10 IMMUNOEXPRESSION ON EFFICACY OF FIRST-LINE PLATINUM-BASED CHEMOTHERAPY IN ADVANCED OVARIAN CANCER

B. Petric Mise, N. Lisica Sikic, S. Tomic, A. Juretic, G. Spagnoli, E. Vrdoljak

1Clinical Hospital Centre Split, Department of Oncology, Split, Croatia
2General Hospital Zadar, Department of Pathology, Zadar, Croatia
3Clinical Hospital Centre Split, Department of Pathology, Split, Croatia
4KBC Zagreb, Department of Oncology, Zagreb, Croatia
5Institute for Surgical Research and Hospital Management, Department of Biomedicine, Basel, Switzerland

Aims

In search for predictive biomarkers we have analyzed correlation between immunoexpression of MAGE-A10 (melanoma-associated antigen) and efficacy of first-line platinum-based chemotherapy in patients with advanced-stage high-grade serous ovarian carcinoma.

Method

The expression of MAGE-A10 was analyzed immunohistochemically in formalin-fixed, paraffin-embedded samples from 93 patients with advanced-stage high-grade serous ovarian cancer treated at our institutions between January 1996 and December 2013. The MAGE-A10 was related to response to platinum-based chemotherapy, platinum sensitivity, patients progression free survival (PFS) and overall survival (OS).

Results

Negative MAGE-A10 expression predict significantly better response to first line platinum-based chemotherapy ($p=0.005$) and platinum sensitivity ($p<0.001$). Moreover, positive MAGE-A10 expression predict significantly poorer PFS ($p<0.001$) and OS ($p<0.001$). The multivariate analysis for OS showed that negative MAGE-A10 expression is predictor to platinum sensitivity ($p=0.005$) and longer OS ($p<0.001$).

Conclusion

Negative MAGE-A10 expression seems to be a predictor of better response to first-line platinum-based chemotherapy, platinum sensitivity and favorable clinical outcome in patients with advanced-stage serous ovarian cancer. Larger retrospective and prospective confirmation of this finding is warranted.

SURGICAL CYTOREDUCTION OF THE UPPER ABDOMEN IN GYNAECOLOGICAL CANCER: AN EXPERIENCE OF ADDITIONAL SKILL ACQUISITION BY THE GYNAECOLOGY ONCOLOGY TEAM FROM COLLABORATION WITH HEPATOBIILIARY SURGEONS

S. Phadnis¹, C. Neuzillet², D. Verneré³, A. Jeyarajah⁴, H. Kocher⁵, E. Brockbank¹

¹BARTS HEALTH NHS TRUST, Gynaecological Oncology, LONDON, United Kingdom
²BARTS CANCER INSTITUTE, Liver and Pancreas Surgery, London, United Kingdom
³UNIVERSITY HOSPITAL OF BESANCON, Methodology and Quality of Life in Oncology, BESANCON, France

Aims

A recent survey in UK reported clinical equipoise with regards to ultraradical cytoreductive surgery and nationwide inequalities in available resources and surgical training. Upper-abdominal debulking procedures often require skills of, or learnt from hepatobiliary (HBP) surgeons. We compare surgical outcomes in two cohorts: GO and HPB operating together (combined) and the GO team operating without the direct input of the HPB team (independent).

Method

Consecutive patients who had upper abdominal procedure for cytoreduction for advanced stage ovarian cancer from 01/2010 till 11/2015 were retrospectively analysed; 47 patients were included in the combined cohort and 19 in the independent cohort. Primary endpoints were R0 resection rate and 30-day post-operative complications.

Results

Most patients (95%) had high grade serous ovarian carcinoma. Twenty four patients (36%) had primary debulking surgery. Median complexity procedure score was 7 (IQR: 6-8) and median of 3.5 organs (IQR: 3-5) were resected. R0 resection was achieved in 88%. Major complication rate was 18%, including one perioperative death. The median length of stay was 7 days (IQR: 6-11). The two cohorts displayed similar FIGO stage, Peritoneal Carcinomatosis Index, and complexity procedure score; liver resections were performed only in the combined surgery cohort. Comparative analysis of the two cohorts showed no significant differences in terms of R0 resection (85% v 95%; p=0.42) and complication rate (23% v 5.3%; p=0.15).

Conclusion

Following skill acquisition by collaboration with HBP surgeons, upper abdominal surgery can be performed safely by GO surgeons with acceptable perioperative morbidity and oncological outcome.
RECOMMENDATION FOR BENCHMARKING AND QUALITY STANDARDS IN OVARIAN CANCER.

Aims

Combined surgery and platinum-based chemotherapy is the internationally agreed standard therapy for advanced ovarian cancer (AOC). However, international cancer registry datasets demonstrate a significant proportion of patients do not receive both or either therapies. Our objective was to evaluate the effect of total patient cohort data (‘Denominator’) on median overall survival (OS) and determine how frequently this was reported in literature.

Method

We retrospectively reviewed OS outcomes for 593 patients diagnosed with AOC for 77 months at a regional cancer centre. Patients were stratified into five progressively overlapping categories based on treatment received: Primary debulking surgery (PDS), PDS or Interval debulking (IDS), all surgery and those considered for IDS, patients receiving any treatment and total patient cohort. A systematic search of literature was performed.

Results

Median OS progressively decreased from 54.5 months in patients receiving PDS, 38.7 months in the PDS+IDS group, 35.4 months in the PDS/IDS + patients considered for IDS, 33.3 months in patients receiving any treatment and 30.2 months in the total patient cohort. OS in the surgically treated group was statistically significantly different from the OS in the total patient cohort (Denominator)(p=0.000353). Denominator descriptors were identified in 11% of studies.

Conclusion

Denominator data is critical to understanding selection and OS in AOC. Published outcomes of selected cohorts should routinely incorporate outcomes for all women managed within the reporting Centre. This is essential for benchmarking and quality assurance in gynaecological cancer and should be an integral part of any publication on outcomes from AOC.

²Medical University of Vienna, Department for Gynecology and Gynecologic Oncology- Gynecologic Cancer Unit- Comprehensive Cancer Centre, Vienna, Austria

Aims

High grade serous ovarian cancer (HGSOC) is comprised of clinically and molecularly distinct subtypes, characterized by peritoneal tumor spread—miliary versus non-miliary—different origin—fallopian tube secretory versus ovarian epithelial cells—and different outcome. Patients with miliary spread of fallopian origin with unfavorable outcome would benefit most from new targeted therapies.

Method

We constructed a planar-scale free small world-co-association gene network from The Cancer Genome Atlas samples (using “Tool for Inferring Networks of GEnes” and R-package “Multiscale Clustering of Geometrical Network”). Sub-networks with corresponding hub-genes were identified and searched for significant associations to peritoneal tumor spread.

Results

A sub-network significantly up-regulated in miliary tumors was identified with Nectin 4 as hub-gene and positively validated for its survival impact via gene signature in six cohorts (Fig. 1). Ovarian cancer cell lines were also characterized according spread type, origin, and Nectin 4 gene expression, revealing each three HGSOC cell lines of either miliary characteristic and tubal origin with high versus non-miliary characteristic and ovarian origin with low (36-times) Nectin 4 expression, useful for in vitro and murine cancer model experiments.

Conclusion

An anti-Nectin 4 antibody with a linked antineoplastic drug (monomethyl auristatin), Enfortumab Vedotin, already used in trials, would render a perfect candidate for a targeted therapy for patients with metastatic HGSOC of the poor-prognosis miliary tumor spread type.
Aims

We analysed PARP immunohistochemistry results and clinical data of 65 advanced (stage III and IV) ovarian cancer cases to clarify prognostic relevance of PARP expression.

Method

PARP protein expression was determined by immunostaining using a Leica Bond MAX Immunostainer (Leica Microsystems, Wetzlar, Germany) with rabbit polyclonal anti-PARP antibody (ab6079330, Abcam, Cambridge, UK). Intensity and distribution of immunostaining was assessed by light microscopy (Leica DM2500 microscope, DFC 420 camera and Leica Application Suite V3 software; Leica) and evaluated with a four grade (0-3+) system. Mean progression-free survivals were generated for each groups of PARP expression.

Results

Thirty-five cases (53.8%) were chemotherapy naive and 27 of them (77%) showed no PARP expression. PARP expression among 30 cases following at least one prior line of chemotherapy was negative in 20 cases (67%). Mean PFS after first-line chemotherapy was 17.5 months. PFS of PARP 0, 1+, 2+ and 3+ cases were 18.4, 20.3, 7.8 and 7.4 months, respectively. Mean PFS after second-line chemotherapy was 11.8 months. Among PARP 0, 1+, 2+ and 3+ cases PFSs were 10.4, 12.8, 8.7 and 22.6 months, respectively. Restricting analysis to the population dichotomized by “any” or “no” PARP expression resulted in a significant difference in PFS achieved by first-line taxol-carboplatin chemotherapy (9.9 vs 19.2 months, respectively, p=0.0067). PFS achieved by the second-line chemotherapy also showed survival advantage for PARP negative cases (22.7 vs 13.8 months), however this difference was not statistically significant (p=0.4770).

Conclusion

PARP expression assessed by immunohistochemistry may predict platinum-sensitivity in ovarian cancer.
OVARIAN CANCER

11AstraZeneca, Medical Affairs, Cambridge, United Kingdom
12Hôpital Tenon and GINECO, Medical Oncology Service, Paris, France
13University of Leuven and BGOG, Gynaecological Oncology, Leuven, Belgium

Aims

Maintenance monotherapy with the PARPi olaparib (Lynparza™) significantly improves PFS in patients with platinum-sensitive relapsed ovarian cancer receiving olaparib either in capsule formulation (Ledermann et al NEJM 2012) or tablet formulation (Pujade-Lauraine et al SGO 2017). Patients with epithelial ovarian cancer (EOC) typically respond to multiple lines of platinum-based chemotherapy. OReO/ENGOT Ov-38 (NCT03106987; D0816C00014) will evaluate whether patients with EOC and platinum-sensitive disease who have previously received PARPi therapy can derive clinical benefit with olaparib maintenance retreatment.

Method

OReO/ENGOT Ov-38 is a randomized, double-blind, placebo-controlled study recruiting patients with non-mucinous EOC who have received maintenance PARPi treatment (Table 1) and had at least a partial response to their most recent platinum-based chemotherapy. Patients will be randomized 2:1 to olaparib (300 mg twice daily) or placebo (Figure 1). Primary endpoint is investigator-assessed PFS (RECIST v1.1). Secondary endpoints include TTP by GCIG criteria (time to the earliest of disease progression by RECIST or CA-125, or death); TDT; TSST; TSST; HRQoL using FACT-O; safety, including adverse events of special interest (potential risks of myelodysplastic syndrome/acute myeloid leukemia, other new primary malignancy, pneumonitis). Target for enrolment: ~416 patients.

AHIF, A HYPOXIA-INDUCED LONG NONCODING RNA, ENHANCES HYPOXIA EPITHELIAL OVARIAN CANCER PROLIFERATION BY INHIBITING APOPTOSIS

J. Qiu¹, H. Keqin¹
¹Obstetrics and Gynecology Hospital of Fudan University, Obstetrics and Gynecology, Shanghai, China

Aims

Hypoxia is a common characteristic of solid tumor, and is a key stress that triggers apoptosis in many cancer types, including epithelial ovarian cancer (EOC). Previous studies discovered a hypoxia-upregulated long non-coding RNA (lncRNA), named “a natural antisense transcript of hypoxia-inducible factor 1 (aHIF)” in some tumors. However, the contributions of aHIF to EOC remain unknown. In this study, we aimed to investigate the expression, function and underlying mechanisms of aHIF under hypoxia conditions in EOC progression.

Method

Expression of aHIF in EOC tissues and its correlation with clinicopathological factors were examined. A series of in vitro and in vivo assays were performed to determine the function and mechanism of aHIF in hypoxia-induced EOC progression.

Results

Clinically, aHIF was overexpressed in EOC tissues relative to normal controls, and the overexpression correlated with advanced International Federation of Gynecologists and Obstetricians stage and high histological grade. In vitro, aHIF was upregulated by hypoxia in EOC cells. Under hypoxia conditions, aHIF knockdown inhibited cell proliferation and accelerated apoptosis. In vivo, aHIF knockdown inhibited tumorigenesis of EOC cells. Mechanically, Dysregulation of mitochondrial apoptosis pathway-associated genes including Caspase-9, Caspase-7, Bax and Bcl-2 by aHIF may partially explain aHIF-induced EOC progression under hypoxia conditions.

Conclusion

Our data offers convincing evidence for the first time that aHIF could enhance EOC proliferation by inhibiting apoptosis through aHIF-mitochondrial apoptosis pathway under hypoxia conditions. These results can help to understand hypoxia-induced EOC progression from the perspective of lncRNA.
ELNCRNA1, A LONG NONCODING RNA TRANSCRIPTIONALLY INDUCED BY OESTROGEN, PROMOTES EPITHELIAL OVARIAN CANCER CELL PROLIFERATION

J. Qiu¹, H. Keqin¹
¹Obstetrics and Gynecology Hospital of Fudan University, Obstetrics and Gynecology, Shanghai, China

Aims

We previously identified a novel oestrogen (E2)-upregulated IncRNA, TC0101441, via microarray analysis. However, the detailed mechanism by which E2 upregulates TC0101441 and the role of TC0101441 in epithelial ovarian cancer (EOC) progression have not been elucidated. In the present study, we further analysed TC0101441, which we designated oestrogen-induced long non-coding RNA-1 (ElncRNA1), and investigate the function and underlying mechanisms of ElncRNA1 in E2-dependant EOC progression.

Method

A serial of assays were performed to determine the mechanism by which E2 upregulates ElncRNA1. ElncRNA1 expression in EOC tissues was examined. In vitro and in vivo functional assays were performed to elucidate the role of ElncRNA1 in E2-dependant EOC progression.

Results

E2 transcriptionally upregulates ElncRNA1 through the oestrogen receptor α (ERα)-oestrogen response element (ERE) pathway using RNA stability assays, bioinformatics-based searches for ERE binding sites, chromatin immunoprecipitation (ChIP) assays and dual luciferase reporter assays. Clinically, ElncRNA1 levels are significantly higher in EOC tissues than in normal ovarian surface epithelium. In vitro and in vivo loss-of-function assays revealed that ElncRNA1 promotes EOC cell proliferation. This pro-proliferation effect of ElncRNA1 was partially mediated by the regulation of Cyclin D1/CDK4/CDK6 pathway.

Conclusion

These findings provide the first evidence that E2 upregulates ElncRNA1 at the transcriptional level through the ERα-ERE pathway and that this novel E2-upregulated IncRNA has an oncogenic role in EOC growth. The placement of ElncRNA1 in the E2-ERα-ERE-Cyclin D1/CDK4/6 signalling pathway may provide greater insight into the effects of oestrogen on EOC progression from the perspective of IncRNA.
C-REACTIVE PROTEIN AS A PREOPERATIVE DIFFERENTIAL DIAGNOSTIC MARKER IN PATIENTS WITH ADNEXAL MASSES

E. Reiser¹, S. Aust¹, H. von Mersi¹, A. Reinthaller¹, S. Polterauer¹, C. Grimm¹
¹Department of Gynecology & Gynecologic Oncology, Medizinische Universität Wien, Vienna, Austria

Aims

Various serum tumor markers have been investigated as a preoperative differential diagnostic marker in women with adnexal masses. Serum C-reactive protein (CRP) is a widely used biomarker for inflammatory processes and was shown to be a valid prognostic biomarker in patients with epithelial ovarian cancer (EOC).

Method

CRP serum levels of 3234 patients with adnexal masses and subsequent surgery were investigated (patients with benign ovarian tumors: n= 2719; borderline tumor of the ovary [BTO]: n = 125; EOC: n = 390).

Results

Mean (standard deviation) serum CRP in patients with benign ovarian tumors, BTO, and EOC were 0.9 (2.5) mg/dL, 1.2 (2.5) mg/dL, and 3.7 (4.7) mg/dL, respectively (p < 0.001). Sensitivity and specificity for the combination of CRP and CA 125 was 80.1% and 90.8%, respectively. NPV (negative predictive value) and PPV (positive predictive value) was 92.2% and 76.9%, respectively. In univariate and multivariate analysis, CRP serum levels were independently associated with the diagnosis of BTO and EOC (HR 6.7 [5.2-8.5], p<0.001 and HR 2.2 [1.4-3.3], p < 0.001). The combination of CRP and CA-125 serum levels resulted in number needed to treat (NNT) of 1.5 (suspicious ultrasound and normal CRP and CA-125 serum levels compared to suspicious ultrasound and elevated CRP and CA-125 serum levels) to detect one additional case of EOC/BTO.

Conclusion

CRP serum levels independently predicted the presence of BTO and EOC in patients with adnexal masses. Particularly in combination with CA-125, CRP serum levels seem to be of additional value in the preoperative differential diagnosis of adnexal masses.
PERITONEAL CARCINOMATOSIS FROM OVARIAN CANCER: COMPARISON BETWEEN EARLY POST-OPERATIVE INTRAPERITONEAL CHEMOTHERAPY (EPIC) AND HYPERThERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC)

M.D. Rodríguez García¹, A. Couso González³, A. Zapico Goñi¹, R. García Berrio¹, V. García Pineda², M. Guzman Muñoz², J.M. Menéndez Fuster², M. Martín Angulo¹, A. Gutierrez Calvo¹

¹Hospital Universitario Príncipe de Asturias, Gynecology, Alcalá de Henares- Madrid, Spain
²Hospital Universitario Infanta Cristina, Gynecology, Parla- Madrid, Spain

Aims

Compare results between HIPEC and EPIC in our hospital.

Method

We analyzed 19 patients diagnosed with IIIC-IV ovarian cancer between 2012 and 2015.

Results

10 patients received EPIC (52.6%) with:

Day 1: Intravenous paclitaxel. Day 2: Cisplatin intraperitoneal. Day 8: Intraperitoneal paclitaxel. Every 21 days, 6 cycles or 4 cycles if they received neoadjuvant chemotherapy.

3 patients completed treatment (27.3%), 2 are still under treatment (18.2%) and 6 didn’t complete treatment (54.5%), 4 were non-tolerant (36.1%) and 2 were anaphylactic (18.2%). The cycles average were 3 ± 1.7 (1-6).

9 patients received HIPEC (42.1%), 1 (5.3%) after surgery, EPIC and relapse. 3 (33.3%) received cisplatino and adriamicina. 6 (66.7%) cisplatino and doxorribicina. 8 EPIC patients and 7 of HIPEC (77.8%) received neoadjuvant chemotherapy (72.7%). All patients underwent optimal surgery.

The rate of postoperative complications was higher in HIPEC group (44.4% (4/9) versus 36.4% (4/10)), for transfusion 77.8%(7/9) versus 54.5%(6/10)) and for hospital stay (8.56 ± 2.8 (2-12) versus 6.64 ± 4.6 (3-17)). 2 patients relapsed in EPIC group (18.1%) and 5 in HIPEC group (55.6%). 3 patients died in HIPEC group (33.3%).

Conclusion

We found higher rates of post-surgical complications and hospital stay in HIPEC group.

In EPIC group, 54.5% of the patients couldn’t complete treatment.

We found higher recurrence rate in HIPEC group (5.6% versus 18.2%) and mortality (33.3% versus 0%).

Despite the poor tolerance, EPIC presents a lower relapse and mortality rate. However it is necessary wait more time to evaluate the patients evolution because they present less follow-up time.
WHAT ARE THE EXPECTATIONS AND PREFERENCES OF PATIENTS WITH OVARIAN CANCER TO A MAINTENANCE THERAPY? A NOGGO/ENGOT-OV22 SURVEY (EXPRESSION IV) IN 2101 PATIENTS

1Charité, Department of Gynaecology, Berlin, Germany
2Charité, SPZ, Berlin, Germany
3NOGGO, Department of Gynaecology, Berlin, Germany
4VKF Koc University School of Medicine, Department of Obstetrics and Gynecology, Istanbul, Turkey
5Centre François Baclesse-CHU, Centre François Baclesse-CHU, Caen, France
6Paracelsus Medical University, Department of Obstetrics and Gynecology, Salzburg, Austria
7Ljubljana University Medical Centre Ljubljana, Clinic of Gynaecology and Obstetrics, Ljubljana, Slovenia
8University Hospital, Department of Obstetrics and Gynaecology, Leuven, Belgium
9Dr. Horst Schmidt Klinik, Department of Gynecology & Gynecologic Oncology, Wiesbaden, Germany
10Fondazione IRCCS - Istituto Nazionale Tumori, Fondazione IRCCS - Istituto Nazionale Tumori, Milan, Italy
11Tampere University Hospital, Department of Obstetrics and Gynecology, Tampere, Finland

Aims

The primary aim of the survey was to investigate the expectations of European patients about maintenance therapy.

Method

A 24-item questionnaire was provided to ovarian cancer patients via internet or paper-version in 9 European countries (Austria, Belgium, France, Germany, Italy, Romania, Slovenia, Finland and Turkey). Data was captured about demographics, tumor stage and therapy after first line and/or recurrent disease and particularly about preferences of administration and expectations concerning a maintenance therapy.

Results

2101 questionnaires were evaluated. 96% of the patients had a surgery and 93% received a chemotherapy. 38% of respondents had recurrent disease. 45% patients had already heard of and 29% received maintenance therapy. 85% of the patients heard about maintenance therapy from the doctor and 10% from other patients, 9% read about it on the internet. The four most disturbing side effects of maintenance therapy were polyneuropathy (37%), nausea (36%), loss of hair (34%) and vomiting (34%). The main objective of maintenance treatment was to increase the chances of cure (73%), followed by an improvement in the quality of life (47%) and the delay of tumor growth (37%). Many patients are willing to take a maintenance therapy until tumor progression (38%). 39% would prefer an oral administration. When we performed cross country sub-analysis we observed no significant differences of expectations to a maintenance therapy.

Conclusion

There is an urgent need for more information regarding side effects and treatment goals of maintenance therapy to avoid misunderstandings by patients. This information may increase patient’s compliance for maintenance therapy in ovarian cancer.
THE ROLE OF THE PERITONEAL CANCER INDEX IN SURGERY FOR ADVANCED OVARIAN CANCER

M. Rosendahl, H. Phillip, P. Sonia, A. Traut, B. Ataseven, S. Schneider, M. Sporkmann

1Rigshospitalet, Department of Gynecology and Obstetrics, København Ø, Denmark
2Kliniken Essen-Mitte, Department of Gynecology and Gynecology, Essen, Germany

Aims

The Peritoneal Cancer Index (PCI) is integrated in the ESGO Ovarian Cancer Operative Report as it describes peritoneal tumor distribution and is a predictor of residual tumor (RT).

We hypothesized that the qualitative anatomical distribution, and not the sum of PCI, predicts RT.

Method

Prospective data from 213 consecutive patients with epithelial ovarian cancer FIGO IIIB-IV undergoing upfront surgery with maximal cytoreductive effort from the Kliniken Essen-Mitte were analyzed with regards to pre-, peri-, and postoperative factors.

Results

Total PCI was significantly related to CA-125 and albumin levels, ascites, FIGO stage, surgical complexity score, duration of surgery, blood loss and number of transfusions and was predictive of RT (P<0.0001).

Complete resection rates according to PCI scores were: PCI 1-5:100%, PCI 6-10:85%, PCI 11-15:70%, PCI 16-20:42%, PCI 21-25:47%, PCI>25:47%. With a cut-off of 15, ROC curve analysis for RT provided an AUC of 0.75 with a sensitivity of 74% and a specificity of 67%.

There was RT in 82 patients (38%). The only limiting intraperitoneal areas were carcinosis in the liver hilus, on the small bowel or in the mesenteric root corresponding to PCI regions 2 and 9-12 respectively (N=68 (83%)).

Seven patients had only extra-abdominal, visceral or retroperitoneal metastases not evaluable with PCI. Conclusion

The anatomical locations and not the sum of PCI predict complete resection.

Evaluating the liver hilus and the small bowel gives adequate information of possible RT in most patients. Therefore, PCI seems of questionable clinical relevance in ovarian cancer surgery.
OVARIAN CANCER

ESGO7-0309

THE PERITONEAL CANCER INDEX (PCI): SELECTED REGIONS - AND NOT THE TOTAL PCI - ARE PREDICTIVE OF SURVIVAL IN ADVANCED OVARIAN CANCER
M. Rosendahl1, P. Harter2, C. Høgdall1
1Rigshospitalet, Department of Gynecology and Obstetrics, København Ø, Denmark
2Kliniken Essen-Mitte, Department of Gynecology and GyneOncology, Essen, Germany

Aims

The peritoneal cancer index (PCI) describes the peritoneal cancer spread in 13 peritoneal areas (0-12) and has been shown to correlate with complete resection (CR) rates in advanced epithelial ovarian cancer (AOC).

We hypothesized that only certain PCI-areas were predictors of complete resection.

In this study we critically evaluate the usefulness of the PCI as a predictor of complete resection (CR) and median overall survival (OS) (months) in AOC.

Method

Prospective preoperative, surgical and survival data from 878 consecutive cases of AOC was obtained from the Nationwide Danish Gynecological Cancer Database.

Results

CR rate was 57%. Patients with CR had significantly longer OS compared to patients without CR: 62.6 (95%Confidence Interval (CI): 53.7-71.5) vs. 23.9 (95%CI:19.1-28.6); p<0.0001.

Patients with PCI>median (13) had poorer OS compared to patients with PCI ≤ median: 26.7 (95%CI: 23.7-28.9) vs. 56.8 (95%CI: 49.5-64.2); p<0.0001.

In COX regression, TotalPCI (HR:1.028(95%CI:1.017-1.039)), Tumor Rest (HR:1.64(95%CI:1.29-2.08)), Performance Status (HR:1.31(95%CI:1.15-1.50)), Age (HR:1.02(95%CI:1.01-1.03)) and FIGO stage (HR:1.05(95%CI:1.02-1.09)) were significant cofactors for survival.

In 88% of the cases, the primary limiting factor for CR was carcinosis on the small bowel/mesenterium, stomach or hepatoduodenal ligament, corresponding to areas 2 and 9-12 in PCI (PCI 2+9-12).

ROC curve AUC for the total PCI was 81%. Selecting only PCI 2+9-12, AUC increased to 83%. In COX regression, PCI 2+9-12, had a higher HR than TotalPCI (HR:1.061(95%CI: 1.03-1.09).

Conclusion

Liver hilus and small bowel carcinosis are stronger predictors of CR and survival than the sum of the PCI. PCI therefore seems of limited value in the peri-operative evaluation of AOC.
QUALITY OF LIFE OF LONG-TERM SURVIVORS AFTER COMPLETE RESECTION FOR ADVANCED OVARIAN CANCER WITH MAXIMUM CYTOREDUCTIVE EFFORT: LYMPH NODE DEBULKING COMPROMISES QOL MOST
I.B. Runnebaum, J. Jimenez Cruz, M. Rengsberger, H. Diebold
1Jena University Hospital, Klinik u. Poliklinik für Frauenheilkunde u. Fortpflanzungsmedizin, Jena, Germany

Aims

Objective: Analysis of which procedure step in complete resection of advanced ovarian cancer compromises QOL after 10 years of survival.

Method

Methods: Review of patients at least 10 years after complete resection of advanced ovarian cancer with maximum cytoreductive effort in our department. Seventy patients returned validated questionaires. Maximum effort was defined as a debulking procedure including atypical liver resection, splenectomy, lymphadenectomy in the upper abdomen (proximal of left renal vein), bowel resection or diaphragm resection.

Results

Results: Statistically significant morbidity regarding QOL resulted from debulking lymphadenectomy with persistent lymphedema. Other procedures had not impact QOL persistently.

Conclusion

Conclusion: Overall quality of Life of long-term survivors after complete resection for advanced ovarian cancer with maximum cytoreductive effort was acceptable. Lymphadenectomy for debulking remains a factor contributing to persistent lymphedema compromising QOL.
Aims

Paragangliomas are extremely rare tumors. Incidence of paraganglioma is 2-8 per million. They are chromaffin cell tumors that develop from the neural crest cells in the autonomic nervous system, and their usual location is along the paraaortic chain. The absence of its symptoms, as paroxysmal hypertension, headache and palpitations, an extraadrenal paraganglioma may be incidentally discovered during unrelated surgery, at autopsy, or with abdominal CT for abdominal pain or abdominal mass. Paraganglioma and ovarian carcinoma very rarely occur together. In our case, paraaortic paraganglioma mimicking lymph node metastasis in an ovarian carcinoma patient.

Method

A 67 year-old, postmenopausal woman visited our hospital, with complaints of abdominal pain. Radiologic image analysis showed bilateral polycystic ovarian mass with solid components. She underwent total abdominal hysterectomy, bilateral salphingo-oopherectomy, omentectomy, pelvic and paraaortic lymphadenectomy. Paraortic lymph nodes were palpable. During the paraaortic lymph node dissection, blood pressure fluctuated intraoperatively. Immediately after the paraaortic lymphadenectomy, the blood pressure declined precipitously.

Results

The pathological diagnosis showed that bilateral ovarian tumors were high grade serous papillary carcinoma and histopathology revealed ovarian cancer metastasis to lymph nodes and paraganglioma in the paraaortic lymphadenectomy material. She was diagnosed as having ovarian carcinoma stage IIIA1i (FIGO) with coincident paraganglioma. Surgical excision remains the mainstay of treatment in paragangliomas. Our patient underwent six cycles carboplatin-paclitaxel chemotherapy for metastatic ovarian cancer but not for paraganglioma.

Conclusion

If blood pressure fluctuation is observed during dissection of the paraaortic lymph node, paraganglioma should be suspected and blood pressure must be carefully controlled.
OVARIAN CANCER

ESGO7-0576

APPENDICEAL MUCINOUS NEOPLASM MIMICKING OVARIAN CANCER : TWO CASE REPORTS

G. Sahin¹, C. Ugurluoglu², S. Akar¹, A. Gul¹, C. Celik¹, S.A. YILMAZ¹
¹SELCUK UNIVERSITY, gynecologic oncology, KONYA, Turkey
²SELCUK UNIVERSITY, Pathology, KONYA, Turkey

Aims

Appendiceal mucocele is an entity that is characterized by cystic dilatation in the lumen of the appendix, caused by the intraluminal accumulation of mucoid material. Its incidence is 0.2–0.7% ; it is more common in females. Because of a lack of specific sign or due to its sometime quiet presentation, Appendiceal mucocele must be considered in differential diagnosis of adnexial masses. We presented two cases operated as ovarian cancer but definitive diagnosis was appendiceal mucocele

Method

51–year-old and 63–year old postmenauposal women were admitted with abdominal pain. The gynecological exam, usg and MRI revealed a right adnexial mass both of them. They underwent exploratory laparotomy for ovarian cancer diagnosis. During exploration bilateral adnexa and uterus were observed to appear normal. In first case, there were intensively mucoid material in pelvis. Appendix was found to be enlarged and it was observed that perforated previously. We performed total abdominal hysterectomy and bilateral salpingo-oopherectomy, peritoneal washing and appendectomy. In second case, 50x40 mm appendix originate cystic mass was detected. We performed right hemycolectomy and ileotransversostomy.

Results

The pathological diagnosis showed that in first case, low grade appendiceal mucinous adenocarcinom spread to both ovary and in second case, low grade appendiceal mucinous neoplasm.

Conclusion

Appendiceal mucocele can be confused radiologically with an ovarian tumor, which may prove to be a diagnostic challenge. Definitive therapy is controversial, although requires surgery. Accurate preoperative diagnosis of the appendiceal mucocele is very important to prevent rupture during surgery, which can cause pseudomyxoma peritonei, in predicting malignant transformation.
LIMITED DEVELOPMENT OF PROLIFERATION ACTIVITY MONITORED BY KI-67 EXPRESSION IN REPEATEDLY RELAPSED MALIGNANT PERITONEAL MESOTHELIOMA.

Jikei Daisan Hospital, obstetrics and gynecology, Tokyo, Japan

Aims

Ki-67 could be the indicator for cellular proliferation activity as well as drug sensitivity. This study was conducted to extend the monitoring of chronological increase of Ki-67 expression in malignant peritoneal mesothelioma (MPM) reported recently (Int Canc Conf J 2017) to investigate the biological characteristics of this rare tumor.

Method

The case is a 29-year-old Japanese woman showed upper abdominal induration with adnexal tumor. On primary surgery, all tumors were resected completely. Histologically, the tumor was diagnosed as MPM, for which she received adjuvant chemotherapy containing platinum agent. After primary treatment, she experienced 3-times relapse every 2-5 years. Each time of her relapse, she received complete resection followed by platinum containing chemotherapy except for the last time. Clinically, chemotherapies were all evaluated as responded. The Ki-67 expression was examined in each tumor by calculating MIB-1 index in 500 cells in most strongly expressed area.

Results

MIB-1 indices were 4.2 ± 1.1 (mean ± SE), 11.8 ± 2.3, 37.3 ± 2.5, and 34.2 ± 2.5 in primary, 1st-, 2nd-, and 3rd-relapsed tumor respectively without any changes of mitotic index, demonstrating lineal increase of Ki-67 expression has reached plateau level over the surviving time of 10 years.

Conclusion

MPM demonstrated lineal increase of Ki-67 expression with the highest level of plateau, suggesting that MPM developed proliferation ability by each regrowth to its limited level along with continuing highest drug sensitivity in this tumor, resulting in long-term survival.
CLEAR CELL CARCINOMA OF THE OVARY
'salah azaiz, department of oncologic surgery, Tunis, Tunisia

Aims

Clear cell carcinomas of ovary are extremely rare tumors accounting for less than 5% of cases and have a very poor prognosis in terms of survival and response to chemotherapy. Case Reports: We document 3 cases of clear cell carcinoma treated by debulking surgery of ovarian mass and chemotherapy.

Method

A retrospective study was carried out in the Salah Azaiez Tunis Institute over a period of 15 years. The diagnosis of clear ovarian carcinoma was retained in 10 patients and confirmed histologically.

Results

The diagnosis of clear ovarian carcinoma was retained in 10 patients and confirmed histologically. The median age of patients was 61 years. 6 patients were menopausal. The most frequent symptoms for consultation was the increase in the size of the abdomen followed by pelvic or abdominal pain. Tumors were unilateral in 8 patients and bilateral in 2 patients. The median size of the tumor was 10 cm. All the patients were The CT scan was performed in all patients, the most characteristic image was a cystic-cystic image. All the patients underwent a debulking surgery of ovarian mass.

Conclusion

The management of ovarian cancers is difficult and requires great expertise and experience due to complications encountered while operating. Presence of an oncology department at our center helps us to a great deal in the chemotherapy management of such cases.
Aims

Malignant non-Hodgkin’s lymphoma (LMNH) of the ovary is a very rare tumor. It accounts for 1.5% of ovarian cancers and 0.5% of NHLs. Bilateral forms are frequent (41-71% of cases). Only a few cases of primary ovarian LMNH have been described in the literature.

The aim of this case is to study the treatment and prognosis of primary ovarian lymphoma.

Method

We retrospectively reviewed the clinical records of patients with primary ovarian lymphoma treated at Salah Azaiez institute, Tunis, Tunisia.

Results

A 28-year-old patient with no antecedent history of an ovarian cyst torsion. She underwent an emergency surgery. In peroperative operation, a bilateral ovarian solid mass was found without vegetation, it size was 10 cm on the right and 12 cm on the left. She had a left adnexectomy and a conservative treatment on the right. Histological examination was in favor of a CD20-positive and CD3-negative large cell LMNH B. The LMNH was ranked IE (Ann Arbor) with IPI at 0. The decision was to do 6 cycles of chemotherapy type CHOP21 (according to the Tunisian national protocol GELT 2013). The patient was in full response at the end of treatment. Overall survival was 2 years. She maintained primary infertility despite conservative treatment.

Conclusion

Primary non hodkin lymphoma of the ovary is a rare entity and it must be differentiated from other ovarian malignancies as its management and prognosis differs significantly from them. Early diagnosis with high index of suspicion is essential to avoid radical surgery. Treatment is mainly based on chemotherapy.

PRIMARY LYMPHOMAS OF THE FEMALE GENITAL TRACT

1salah azaiez, surgery, Tunis, Tunisia

Aims

The aim of this study is to establish the symptoms, treatment and prognosis of lymphoma of the female genital.

Method

We retrospectively reviewed the clinical records of three patients with primary lymphoma in female genital treated at Salah Azaiez institute, Tunis.

Results

Lymphoma of the cervix: A 32-year-old woman presented with menometrorrhagia. A computed tomography revealed the presence of diffuse, heterogeneous uterine cervical mass with no lymphatic node. A biopsy was conducted and the histopathological examination revealed large cell lymphoma. The patient received chemotherapy according to the CHOP protocol followed by a pelvic external radiotherapy.

Lymphoma of the vulva: A 32-year-old woman presented with a nontender mass in the upper part of the right labium maior. The gynecological examination revealed a solid mass of 4 cm, with irregular margins, in the right labium maior. An abdominal CT scan with contrast revealed a solid mass, without specific acquisition of contrast, within the right vulvar region with no lymphatic nodes. A biopsy of the mass and the histological examination showed a diffuse population of medium- to large-sized malignant lymphoid cells. The patient received chemotherapy.

Lymphoma of the vagina: A 64-year-old woman presented with a metrorrhagia, gynecological examination revealed a tumor involving most of the vaginal wall. A biopsy of this lesion confirmed NHL. Abdominal MRI detected a vaginal tumor. The patient underwent chemotherapy and radiotherapy.

Conclusion

Despite the absence of specific imaging patterns, there are radiologic appearances that must alert the radiologist about the possibility of primary lymphomas of the female genital tract.
NEUROENDOCRINE CARCINOMA OF THE OVARY
S. Sakhri¹, Z. Ines¹, B. Malek¹, B. Nedia², S. Meher¹, H. Monia¹, B.H. Jamel¹, R. Kahled¹
¹salah azaiez, surgery, Tunis, Tunisia
²salah azaiez, department of pathology, Tunis, Tunisia

Aims

Neuroendocrine is rare entity that is frequently associated with ovarian surface epithelial tumors, its a heterogened. Which have a common characteristic, expression of endocrine differentiation potential. The aim of this study is to established the characteristic, treatments and the prognosis of this disease.

Method

We retrospectively reviewed the clinical records of two patients with neuroendocrine ovarian treated at Salah Azaiez institute, Tunis, Tunisia.

Results

Case 1:

A 58-year old woman was referred because of pelvic pain and abdominal distension, clinical examination showed a left fixed supra-clavicular lymph masse. CT scan revealed a 5-cm multisepated mixed solid and cystic mass in the left ovary, and a retroperitoneal and iliac lymph node flow. The patiente underwent a biopsy of the supraclavicular lymph node that showed a metastasis from an neuroendocrine carcinoma of the ovary. She underwent total abdominal hysterectomy, bilateral salpingo-oophorectomy. The pathologic diagnosis of the mass was neuroendocrine carcinoma. She was treated with a combination chemotherapy.

Case 2:

A 40 year old woman was referred after being diagnosed with neuroendocrine carcinoma of the ovary at a private clinic. She had complained of pelvic pain and was found to have an ovarian mass. She underwent total abdominal hysterectomy with bilateral salpingo-oophorectomy at the private clinic. She was treated with 6 sessions of a combination chemotherapy. But then the patient was lot to view.

Conclusion

Neuroendocrine carcinoma of the ovary is rare, shows aggressive behaviors and poor responses to treatment. The survival rates are relatively low due to biological aggressiveness despite extensive surgery and chemotherapy.

OVARIAN TUMOR WITH BONE METASTASES

S. Sakhri1, Z. Ines1, B. Malek1, B. Nedia2, L. Boutheina1, H. Monia1, B.H. Jamel1, R. Kahled1
1salah azaiz, surgery, Tunis, Tunisia
2salah azaiz, department of pathologie, Tunis, Tunisia

Aims

To study the clinical characteristics of bone metastasis from ovarian cancer, and facilitate physicians to develop treatment strategies

Method

This retrospective study was carried out in the institut of Salah Azaiez, Tunisie 3 cases of bone metastasis from ovarian cancer treated between were reviewed.

Results

Three cases of bone metastasis were confirmed by biopsy. 1 in the acetabulum and the 2 others were in cervical vertebra. Lung metastasis occurred concomitantly in one case and lymphatic metastasis in 2 cases. 2 cases of bone metastasis were detected in stage III-IV, and in one case in stage II. Two patients had cytoreductive surgery the other patient, The other patient are treated only by chemotherapy.

Conclusion

Bone metastasis from ovarian cancer is rare, however, the increasing pathological stage of ovarian cancer may add to the risk of bone metastasis, especially in the cases with lung or lymphatic metastasis. The pelvis and vertebral bone are the most common location of bone metastasis, and comprehensive treatment may improve the survival time of patient

ESGO7-0869

CLINICAL, SURGICAL AND PATHOLOGICAL WORKUP OF RARE CANCER: A CASE OF ADULT GRANULOSA CELL TUMOUR

A. SALERNO1, A. PERRONE2

1Unità operativa di Anatomia Istologia Patologica e Citodiagnostica, Ospedale Maggiore AUSL-Bologna, Bologna, Italy
2Unità Operativa di Ostetricia e Ginecologia, Ospedale Maggiore AUSL-Bologna, Bologna, Italy

Aims

Granulosa cell tumour (GCT), rare in humans but common in dogs and cats, represents 2–5% of ovarian cancers. It is a malignant tumour with a long natural history and tends to recur late. Women with adult GCT (aGCT) diagnosed at FIGO stage I are expected to have a favorable outcome. Stage of disease, tumour size, tumour rupture, age at diagnosis, nuclear atypia, mitotic index, surgical method and residual disease after initial surgery are important prognostic factors.

Method

We report on a case of aGCT in a 44-years-old woman treated only by surgery.

Results

A 44-year-old woman was evaluated for menometrorrhagia and abdominal pain. Examinations revealed a large left adnexial mass. The patient underwent surgery and after an intraoperative diagnosis of adult granulosa cell tumour an abdominal hysterectomy, bilateral salpingo-oophorectomy and lymphadenectomy was performed. Grossly the mass was 14 cm in maximum diameter, yellowish, solid and cystic. Microscopically, it was composed of small, bland, cuboidal to polygonal cells with typical coffee bean nuclei, trabecular and solid pattern, with 7/10HPF mitoses. Immunohistochemistry positivity for alpha-inhibin, vimentin and calretinin, supported the diagnosis of aGCT, Stage IA. Uterus showed atypical endometrial hyperplasia: right adnexus, peritoneal fluid and lymph nodes were negative. A second opinion in a referral centre was advised.

Conclusion

Diagnosis and surgical management were confirmed and the patient received appropriate follow-up. In consideration of unpredictability, rarity and natural history, a long follow-up even in early-stage GCT is recommended. After 1 year the patient is in good health condition.
Aims

Primary fallopian tube cancer accounts for 0.3 to 1.0% of all gynaecologic cancers. It is difficult for any one centre to accrue a large number of cases for meaningful analysis.

The aim of this study is to investigate the clinico-pathological features and the treatments of this rare entity.

Method

We report two cases of primary fallopian tube carcinoma (PFTC).

Results

Case 1

A 57-year-old patient, presented to our clinic with a right inguinal adenopathy. A biopsy was performed. The specimen was interpreted as an adenocarcinoma with suspected gynaecologic origin. The CA-125 level was elevated (950 Unit/ml). She underwent a laparotomy. She had total hysterectomy, bilateral salpingo-oophorectomy, appendectomy, and omentectomy. The pathological diagnosis was primary serous carcinoma of the left fallopian tube. All other organs were free of tumour.

The patient received three consecutive courses of chemotherapy. Then she had inguinal, pelvic and para-aortic lymph node dissection followed by three more sessions of chemotherapy.

She has been disease-free for 18 months since surgery.

Case 2

A 60-year-old patient was sent to our institute with the histopathological diagnosis of primary serous carcinoma of the left fallopian tube. Indeed, the patient consulted a regional hospital for persisting metrorrhagia. An MRI was performed and showed a 4.5 cm left ovarian mass. The CA-125 was elevated (714 Unit/ml). She underwent a laparotomy and had bilateral salpingo-oophorectomy. Currently, the patient is scheduled for ovarian staging.

Conclusion

PFTC is often found either during or after the surgery. The optimal treatment is the excision of the reproductive organs with lymphadenectomy.
IDENTIFICATION OF HIGHLY DIFFERENTIALLY EXPRESSED GENES IN PRIMARY OVARIAN CANCER AND RELATED DISTANT METASTASIS USING RNA SEQUENCING

Aims

High grade serous ovarian cancer is the most common subtype of epithelial ovarian cancers (EOC) with poor prognosis. In most cases EOC is widely disseminated at the time of diagnosis. Our aim was to determine whether gene expression in distant metastasis of high grade serous EOC differ from that of primary tumors to gain better understanding of disease process.

Method

We analyzed the gene expression profile of ten primary high grade serous EOC tumors and related omental metastasis using RNA sequencing. The functions of differentially regulated genes were studied using Ingenuity Pathway Analysis and by comparing our results to TCGA data.

Results

We identified 100 differentially regulated genes between primary tumors and metastasis, majority of which were downregulated in the omental samples. Gene ontology analysis revealed that cellular functions related to embryonic development were increased within the metastasis. Many of the embryonic developmental genes were also highly expressed in TCGA ovarian cancer samples compared to any other cancer type. Interestingly, 17 of our 100 most differentially regulated genes were also found significantly altered in TCGA primary tumors that had led to metastasis formation. For survival analysis TCGA data was divided to poor and high survival according to our 100 differentially regulated genes. Our analysis identified 12 candidate genes that were significantly associated with poor survival that will be subject of future studies.

Conclusion

The gene expression of primary tumors and metastasis of high grade serous EOC exhibited significant differences. Many of the identified genes have functions in embryonic development.
RISK FACTORS FOR APPENDICEAL INVOLVEMENT IN WOMEN WITH EPITHELIAL OVARIAN CANCER

M.E. Sarı¹, E. Korkmaz², M. Oz¹, T. Gungor¹, M.M. Meydanlı²

¹Zekai Tahir Burak Women’s Health Training and Research Hospital- Faculty of Medicine- University of Health Sciences, Gynecologic Oncology, Ankara, Turkey

Aims

In this study we aimed to evaluate the risk factors for appendiceal involvement in women with epithelial ovarian cancer (EOC) who underwent appendectomy at the time of initial surgery.

Method

Patients with a final diagnosis of EOC who underwent appendectomy at the time of initial surgery were evaluated retrospectively. Risk factors related to the presence of appendiceal involvement were analyzed.

Results

A total of 210 patients underwent appendectomy during staging surgery. Appendiceal involvement was detected in 61 patients. No women with apparent clinical early-stage tumors had evidence of isolated metastatic disease to the appendix; therefore, no upstaging is detected due to solitary appendiceal involvement in this group of patients. For all patients univariate analysis of the appendiceal involvement revealed age, stage, grade, extragenital organ involvement (omentum, bowel, periton), positive cytology, and lymph node metastasis as significant factors (p<0.05). In multivariate analysis appendiceal involvement was significantly affected by age and omental involvement. Older age (>50 years) (odds ratio [OR] 2.8, 95% confidence interval [CI] 1.24-6.37; p=0.014) and presence of omental involvement (OR:3.2, 95% CI 1.22-8.59; p=0.018) seemed to be independent risk factors for appendiceal involvement in women with EOC.

Conclusion

Our findings indicate that routine appendectomy at the time of surgery for apparent early-stage EOC is not warranted. Nevertheless, the surgeon can take initiative whether to perform appendectomy as the morbidity rates due to this procedure is negligible. Older age (>50 years) and presence of omental involvement seem to increase the risk of appendiceal involvement by 2.8 and 3.2 times, respectively.

**ESGO7-0150**

**ASSESSMENT OF THE RISK OF RELAPSE OF NEOPLASM OVARI (ARRNO): A NEW APPLICATION FOR CLINICAL PRACTICE**

A. Savinova¹, I. Gataullin²

¹Regional Clinical Oncological Center of Tatarstan, Department N4, Kazan, Russia
²Kazan State Medical Academy, Department of Oncology-Radiology and Palliative Care, Kazan, Russia

**Aims**

The aim of the present study was to develop an algorithm of the assessment of the individual risk of ovarian cancer relapse after accomplishment of the first line therapy.

**Method**

A retrospective analysis of the data of 1103 patients (01.01.2010-01.01.2015) with ovarian cancer, who received primary cytoreductive surgery with combination of platinum-based chemotherapy in their first line of treatment was performed. The prognostic role of the following 12 parameters was studied: age, stage, tumour status (T), grade, hystotype, results of ultrasound and CT after first line chemotherapy, CA 125ₚᵢᵣₑ (before start of combined therapy) and CA 125ₚₒᵣₑ (after accomplishment of first line chemotherapy), HE 4ₚᵢᵣₑ (before start of combined therapy) and HE 4ₚₒᵣₑ (after accomplishment of the first line therapy), the level of cytoreduction (optimal, suboptimal and radical).

**Results**

After binary regression analysis we defined best data set: stage, hystotype, grade, pelvic ultrasound examination, CA 125ₚᵢᵣₑ and HE 4ₚₒᵣₑ. Based on the developed algorithm we designed an ARRNO score with AUC (area under the curve) was 0.761 (95%CI: 0.733-0.789). After ROC-analysis we defined as well 3 intervals, corresponding to the low (0-0.39), moderate (0.40-0.85) and high (0.86-1.0) risk of relapse. At the final step the ARRNO score was integrated into application for personal computers, which, in case of integration into internal network of hospitals, provides the possibility to assess the risk of relapse at the moment of accomplishment of the first line therapy.

**Conclusion**

ARRNO score provides oncologists with a new tool for the more sophisticated follow-up of patients with ovarian cancer.
LOW GRADE SEROUS OVARIAN CARCINOMA: AN EVALUATION OF PRACTICE PATTERNS
J. Siemon, M. Guillermo, D. Gershenson, B. Slomovitz, M. Schlumbrecht

1University of Miami Sylvester Comprehensive Cancer Center, Gynecologic Oncology, Miami, USA
2University of Texas MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston, USA

Aims

Low Grade Serous Carcinoma (LGSC) is a rare subtype of ovarian cancer with a typically indolent and chemoresistant course. Optimal treatment strategies are unknown. Our objective was to identify differences in practice patterns amongst physicians who treat LGSC.

Method

A de novo survey was distributed to members of the Society of Gynecologic Oncology. Questions about demographics, management of primary and recurrent disease, and use of consolidation were included. Statistical analyses was performed using Chi-square and logistic regression.

Results

There were 235 respondents. 48% had completed fellowship within the last 10 years, 83% recommended somatic testing during treatment, and 67% always send patients for genetic counseling. Treatment preferences for primary disease varied by debulking status. 47% of practitioners use hormone antagonism as consolidation after primary treatment. Physician experience with LGSC did not influence the decision to use consolidation (OR 1.09 [0.60-1.97], p=0.78). In contrast to patients with platinum resistant disease, secondary cytoreduction was preferred for patients with long disease-free intervals following primary treatment (p<0.001). Hormone antagonism was the preferred treatment for platinum resistant disease (52.3%), with 18% of physician utilizing targeted agents in the recurrent setting.

Conclusion

There is significant variation in the management of LGSC among practitioners. Further efforts to improve knowledge and disseminate information about the optimal management of this disease should be encouraged.
COMPARISON OF OVERALL SURVIVAL AND PROGNOSTIC FACTORS IN HIGH AND LOW GRADE OVARIAN SEROUS ADENOCARCINOMAS

T.H. Schnack¹, S. Mejer Sørensen¹, H. Claus¹
¹Rigshospitalet - University hospital Copenhagen, Gynecological Clinic, Copenhagen Ø, Denmark

Aims

Low grade serous tumors are characterized by young age at diagnosis a slow growth pattern and despite a high level of chemoresistance a better prognosis as compared to high grade serous adenocarcinoma. We aim to examine overall survival in early and advanced stage low and high grade ovarian serous adenocarcinomas.

Method

Methods: Population based prospectively collected data on ovarian low grade serous adenocarcinomas (n=327) and high grade serous adenocarcinomas (n=2488) was obtained from the Danish Gynecological Cancer Database. Univariate Kaplan Meier and multivariate Cox regression were used. Statistical test were 2-sided. P-values of <0.05 were considered statistically significant.

Results

Results: The overall survival was higher among low grade than in high grade ovarian adenocarcinomas in univariate (log rank < 0.0001) and multivariate cox analysis (HR 1.4 95% CI: 1.1-1.7). This association was strengthened in sub-analysis limited to stage Ib-Illa with no residual tumor (HR 2.2, 95% CI: 1.5-3.7), whereas no significant difference was observed in stage Ib-Illa with residual tumor or stage IIC-IV (HR 0.8 95% CI: 0.5-1.6 and HR 1.2 95% CI 0.9-1.6, respectively). The cox analyses were adjusted for age at diagnosis, residual tumor (yes vs. no), stage and performance status, which were significant prognostic factors in all analyses.

Conclusion

Low grade ovarian serous adenocarcinoma have a better overall survival when diagnosed in early stages with no residual tumor, whereas no survival benefit was observed in cases with residual tumor or advanced stage disease as compared to high grade serous adenocarcinomas in analyses adjusted for age, residual tumor, stage and performance score.

CYTOREDUCTIVE SURGERY AND HYPERTERM INTRAPERITONEAL CHEMOTHERAPY (HIPEC) USED IN TREATMENT OF OVARIAN, TUBAL AND PRIMARY PERITONEAL CANCER: A PILOT STUDY

M.S. Mikkelsen¹, L.H. Iversen², T. Christiansen¹, L.K. Petersen³, J. Blaakaer⁴
¹Aarhus University Hospital, Department of Gynaecology and Obstetrics, Aarhus, Denmark
²Aarhus University Hospital, Department of Surgery, Aarhus, Denmark
³Regional Hospital of Randers, Department of Gynaecology and Obstetrics, Randers, Denmark
⁴Odense University Hospital, Department of Gynaecology and Obstetrics, Odense, Denmark

Aims

Hypertherm intraperitoneal chemotherapy (HIPEC) consists of intra-operative perfusion of the abdominal cavity with a heated solution with a cytotoxic agent to prevent disease recurrence. Study aims were to evaluate feasibility, morbidity and mortality of cytoreductive surgery (CRS) combined with HIPEC in patients with ovarian, tubal and primary peritoneal cancer (OC).

Method

In a pilot study 15 patients were treated with CRS and HIPEC with carboplatin 800 mg/m² in 90 minutes. Inclusion criteria: Patients with primary OC FIGO stage III-IV subjected to up-front or interval CRS, age 18-75 years, ASA score I-II, and complete cytoreduction was achieved. In stage IV, only patients with resectable disease, and patients with complete remission of extra-abdominal metastasis after neoadjuvant chemotherapy were included. Study endpoints: 30-day mortality and adverse events 30 days postoperatively assessed using Common Terminology Criteria for Adverse Events (CTCAE). Severe and life-threatening (grade III/IV) complications are reported.

Results

Median age was 58 years (39-73 years). Eleven patients had up-front CRS and four patients had interval CRS. Median PCI was 11 (5-32).
No deaths were observed within 30 days. Reoperation (stoma revision) was necessary in one patient (6.7%) 27 days after surgery. Eight patients experienced at least one grade III complication within 30 days (53.3%), and the most frequent was fever/infection with unknown origin (20.0 %), transient neutropenia/thrombocytopenia (20.0%) and intraabdominal infection (13.3%). There were no grade IV complications.

Conclusion

CRS and HIPEC with carboplatin in selected patients with advanced stages of OC is feasible and with an acceptable rate of severe complications and no life-threatening complications in present small-scale study.

CLINICOPATHOLOGICAL IMPACT OF INTRINSIC CHEMORESISTANCE/CHEMOSENSITIVITY AND BIOMARKER PROFILES IN OVARIAN CANCER PATIENTS

I. Sedláková¹, J. Laco², K. Brigulová¹, M. Červinka³, J. Tošner⁴, V. Študent⁴, J. Špaček⁴

¹University Hospital Hradec Králové and Medical Faculty Charles University in Hradec Králové, Gynecology and Obstetrics, Hradec Králové, Czech Republic
²University Hospital, The Fingerland Department of Pathology, Hradec Králové, Czech Republic
³Charles University- Faculty of Medicine, Department of Medical Biology and Genetics, Hradec Králové, Czech Republic
⁴University Hospital Hradec Králové, Department of Gynecology and Obstetrics, Hradec Králové, Czech Republic

Aims

To find out the impact of in vitro intrinsic chemoresistance and biomarker profiles (Pgp, MRP1, estrogen and progesterone receptors) in epithelial ovarian cancer.

Method

Malignant ovarian tissues of 104 chemonaïve ovarian cancer patients were examined by the MTT – (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay for in vitro chemoresistance/chemosensitivity. Immunohistochemistry were employed to determine resistance proteins (Pgp, Multidrug Resistance-Associated Protein) and hormonal receptors expression.

Results

The incidence of in vitro chemoresistance were: cisplatin 9.6%, topotecan 11.6%, paclitaxel 41.4%, carboplatin 56.3%, gemcitabine 86.9%, etoposide 86.8%. Mucinous ovarian cancer was chemoresistant to carboplatin and paclitaxel in 50% and chemosensitive to topotecan in 100%. The highest incidence of Pgp (Med 100%; P=0.151) and MRP1 (Med 95.0%; P=0.013) expression and the lowest incidence of estrogen and progesterone receptors expression (P=0,001) was observed in mucinous tumors. Endometrioid ovarian cancer was chemoresistant to carboplatin in 50% and chemoresistant to cisplatin in 0%. The lowest incidence of Pgp (Med 62%; P=0.151) and MRP1 expression (Med 63.0%; P=0.013) and the highest incidence of estrogen and progesterone receptors expression (P=0.001) was observed in endometrioid tumors. We found 56% chemoresistance to carboplatin and 38% to paclitaxel in serous ovarian carcinoma and middle expression of resistance proteins and estrogen receptors in these tumors. Strong Pgp and MRP1 expression correlated with shorter progression free survival (P=0.051, P=0.046) and poor patient survival (P=0.018). Higher expression of steroid receptors correlated with longer overall survival.

Conclusion

Every histologic subtype can profit from different type of primary systemic treatment. These methods could contribute to individualization of primary treatment in ovarian cancer patients.

ESGO7-0898

DEVELOPMENT OF A TOOL FOR PREDICTION OF OVARIAN CANCER IN PATIENTS WITH ADNEXAL MASSES: VALUE OF PLASMA FIBRINOGEN

V. Seebacher¹, S. Aust¹, D. D’Andrea², C. Grimm¹, E. Reiser¹, D. Tiringer¹, H. Von Mersi¹, S. Polterauer¹, A. Reinthaller¹, H. Koelbl¹, S. Helmy-Bader¹

¹Medical University of Vienna, Department for Gynecology and Gynecologic Oncology, Vienna, Austria
²Medical University of Vienna, Department for Urology, Vienna, Austria

Aims

To develop a tool for individualized risk estimation of presence of cancer in women with adnexal masses, and to assess the added value of plasma fibrinogen.

Method

We performed a retrospective analysis of a prospectively maintained database of 906 patients with adnexal masses who underwent cystectomy or oophorectomy. Uni- and multivariate logistic regression analyses including pre-operative plasma fibrinogen levels and established predictors were performed. A nomogram was generated to predict the probability of ovarian cancer. Internal validation with split-sample analysis was performed. Decision curve analysis (DCA) was then used to evaluate the clinical net benefit of the prediction model.

Results

Ovarian cancer including borderline tumours was found in 241 (26.6%) patients. In multivariate analysis, elevated plasma fibrinogen, elevated CA-125, suspicion for malignancy on ultrasound, and postmenopausal status were associated with ovarian cancer and formed the basis for the nomogram. The overall predictive accuracy of the model, as measured by AUC, was 0.91 (95% CI 0.87 – 0.94). DCA revealed a net benefit for using this model for predicting ovarian cancer presence compared to a strategy of treat all or treat none.

Conclusion

We confirmed the value of plasma fibrinogen as a strong predictor for ovarian cancer in a large cohort of patients with adnexal masses. We developed a highly accurate multivariable model to help in the clinical decision-making regarding the presence of ovarian cancer. This model provided net benefit for a wide range of threshold probabilities. External validation is needed before a recommendation for its use in routine practice can be given.
Aims

The role of secondary cytoreductive surgery in platinum-sensitive recurrent ovarian cancer (PSROC) has not been defined by level-1 evidence.

Method

Pts with PSROC and 1st relapse if they presented with a positive AGO-score which selects approximately 50% of all PSROC pts. They were randomized to 2nd-line chemotherapy vs cytoreductive surgery followed by chemo. We report results of the predetermined interim analysis.

Results

409 pts were randomized 2010-2014. Platinum-free interval exceeded 12 mos in 75% and 76% pts in both arms. Complete resection was achieved in 72.5% of operated pts; 87% and 88% received a platinum-containing 2nd-line therapy. 60/180-d mortality rates were 0 and 0.5% in the surgery and 0.5 and 2.5% in the no-surgery arm. Re-laparatomies were performed in 7pts (3.5%). With the exception of myelosuppression no further significant differences were observed with respect to grade 3+ adverse events.

Median PFS was 14 mos without and 19.6 mos with surgery (HR: 0.66, 95%CI 0.52-0.83, p=0.001). Median time to start of first subsequent therapy (TFST) was 21 vs 13.9 mos in favor of the surgery arm (HR 0.61, 95%CI 0.48-0.77, p<0.001). Analysis of primary endpoint OS is hampered by unexpected good OS and therefore kept blinded due to immaturity.

Conclusion

Surgery in PSROC pts selected by a positive AGO-Score resulted in increase of PFS and TFST with very acceptable treatment burden. Until final OS data will definitively define the role of secondary cytoreductive surgery it should at least be considered as valuable option in pts with a positive AGO-Score.

THE MANAGEMENT OF PERITONEAL SURFACE MALIGNANCES AT THE AMERICAN UNIVERSITY OF BEIRUT MEDICAL CENTER: (AUBMC) INITIAL EXPERIENCE

F. Jamali- MD- FACS1, M. Seoud- MD- FACOG1, A. Shamseddine-MD2, M. Khalifeh- MD- FACS- FRCS3, A. El Housheimi-MD1, I. Jaafar-MS-RPH1

1American University of Beirut - Medical Center, OBGYN, Beirut, Lebanon
2American University of Beirut - Medical Center, Internal Medicine, Beirut, Lebanon
3American University of Beirut - Medical Center, Surgery, Beirut, Lebanon

Aims

Peritoneal carcinomatosis (PC) has been traditionally considered a terminal disease with median survivals reported in literature of 6-12 months. Cytoreductive surgery (CRS) & Hyperthermic intra-peritoneal chemo-therapy (HIPEC) have gradually gained acceptance as standard of care to manage selected PC cases.

Method

A program for multidisciplinary treatment of peritoneal surface malignancies of gastrointestinal or gynecological origin was initiated in January 2010 at AUBMC. We will present retrospective review of prospective collected database for Patients who were treated using multimodality therapy with combinations of systemic therapy, cytoreductive surgery (CRS), and HIPEC.

Results

Over the last 10 years, 36 patients were treated with CRS and HIPEC. There were 19 male and 17 female patients. Most common indication are Pseudomyxoma peritonei (42%) colorectal origin (25%), ovarian malignancies (14%), gastric cancer (6%) and Mesothelioma (6%). The Mean duration of surgery was 598 minutes. Mean Peritoneal Cancer Index was 25. Thirty-three (91%) patients had a complete cytoreduction. Perioperative major morbidity and mortality rates were 31% and 2.8% respectively whereas 14.2% where lost for follow-up. Mean hospital stay was 16 days. The median overall survival is at 40 months and progression free disease revealed a median of 18 months.

Conclusion

We report successful establishment of an active peritoneal surface malignancy multidisciplinary treatment program with excellent early results that are comparable to those published by reputable centers in literature. Careful patient selection, a multidisciplinary approach and proper surgical training and technique are essential for this successful program.

ADULT GRANULOSA CELL TUMOUR OF THE OVARY. A CLINICAL AND PATHOLOGICAL ANALYSIS OF 137 CASES.

M.B. Sert\textsuperscript{1}, J. Nesland\textsuperscript{2}, C. Trope\textsuperscript{1}
\textsuperscript{1}Oslo University Hospital, Gyn.Onc., Oslo, Norway
\textsuperscript{2}Oslo University Hospital, Department of Pathology, Oslo, Norway

Aims

The purpose of the present study was to identify the clinical and histopathologic prognostic factors and to determine the most appropriate mode of treatment for adult granulosa cell tumors of the ovary.

Method

We reviewed the hospital records retrospectively including surgical notes and clinico-pathologic results. The Histological slides were re-evaluated by JMN in order to confirm the diagnosis and histological features. We also examined the clinical factors such as stage, age, tumor size, menopausal status. In addition to that the pathologic factors such as microscopic patterns, mitotic activity, Call-Exner bodies presence, nuclear atypia were also examined again. Univariate and multivariate analysis were used to identify the prognostic factors. Survival rates were calculated using the Kaplan-Meier method.

Results

The patients’ median age was 55 years (range: 26 to 87). 80\% of the patients were postmenopausal. 89.5 \% cases represented Stage I tumors. Tumor size was reported median 8 cm (range: 1-50 cm.). Cyst rupture occurred in 8/21 cases (38\%) in the relapsed group and 20/116 cases (17.2\%) in the non-relapsed group. Totally 20\% cyst rupture was found in this series. 52\% of cases were treated with surgery alone while 48\% of cases received additional treatment. 12 cases received chemotherapy (9\%) and 54 cases received Radiotherapy (39\%).

Conclusion

Of the various clinical and pathologic features that were evaluated for prognostic significance, patients with early stage I and mitotic rate less then 3/10 HPF had an very good prognosis. Stage, Cyst Rupture and Atypia are main prognostic factors regarding to recurrence situation.

PROGNOSTIC IMPACT OF THE TIME INTERVAL FROM SURGERY TO CHEMOTHERAPY IN PATIENTS WITH ADVANCED OVARIAN CANCER

S.H. Shim¹, D.Y. Kim², S.W. Lee², J.Y. Park², S. Dae-Sik², J.H. Kim², Y.M. Kim², Y.T. Kim², J.H. Nam²

¹ School of Medicine - University of Konkuk, Obstetrics and Gynecology, Seoul, Republic of Korea
² Department of Obstetrics and Gynecology - University of Ulsan College of Medicine - Asan Medical Center - Seoul - Korea

Aims

To evaluate the effect of the "time to chemotherapy" (TTC) interval after debulking surgery on survival in patients with advanced ovarian cancer.

Method

We retrospectively studied data from 276 patients with International Federation of Gynecology and Obstetrics stage III or IV ovarian cancer who were consecutively treated between January 2006 and 2013. TTC was analysed and correlated with outcome.

Results

Median age at diagnosis was 54 years (range, 20–80 years), and 258 patients received postoperative platinum-based chemotherapy. The 25%, 50%, and 75% quartiles of intervals from surgery to start of chemotherapy were 18, 22, and 28 days, respectively. TTC [≤28 days versus >28 days; hazard ratio (HR) 1.578 (95% CI 1.057–2.355), P = 0.026], complete debulking with no gross residual disease [HR 0.419 (95% CI 0.274–0.640), P <0.05], and preoperative albumin level [HR 0.549 (95% CI 0.382–0.791, P=0.001] were significant prognostic factors for progression-free survival in multivariate analysis. While delayed TTC (>28 days) did not possess prognostic significance in patients without postoperative residual disease (n = 94), it significantly correlated with progression-free survival in patients with postoperative residual disease [n = 164, HR 1.893 (95% confidence interval 1.209–2.962), P = 0.005].

Conclusion

Our findings suggest that delayed initiation of chemotherapy might compromise progression-free survival in patients with advanced serous ovarian cancer, especially in case of gross residual disease. A prospective study randomizing patients to different time intervals could clarify the definitive relevance of the time between surgery and chemotherapy.

RETROSPECTIVE STUDY OF COMBINATION CHEMOTHERAPY WITH ETOPOSIDE AND IFOSFAMIDE IN PATIENTS WITH HEAVILY PRETREATED RECURRENT OR PERSISTENT EPITHELIAL OVARIAN CANCER

W. Shin1, B.G. Kim1, D.S. Bae1, E.S. Paik1, H. Choi1, C.H. Choi1, J.W. Lee1

1Samsung Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

This retrospective study is to evaluate the efficacy and toxicity of combination chemotherapy with etoposide and ifosfamide (ETI) in the management of pretreated recurrent or persistent epithelial ovarian cancer (EOC).

Method

Patients with recurrent or persistent EOC who had measurable disease and at least one chemotherapy regimen were to receive etoposide at a dose of 100 mg/m²/day intravenously (IV) on days 1 to 3 in combination with ifosfamide 1 g/m²/day IV on days 1 to 5, every 21 days.

Results

From Aug 2008 to Aug 2016, sixty-six patients were treated with ETI regimen. Most patients were heavily pretreated prior to ETI: Fifty-three (80.3%) patients had received 3 or more chemotherapy regimens. The response rate of ETI chemotherapy was 18.2% and median duration of response was 6.8 months (range, 0-30). Median survival of all patients was 5 months at a median follow up of 7.2 months. Platinum free interval more than 6 months prior to ETI has statistically significant correlation with overall survival (9.2 versus 5.6 months, P=0.0292) and RR (34.5% versus 5.4%, P<0.01).

Conclusion

The ETI combination regimen shows comparatively low toxicity and modest activity in heavily pretreated recurrent or persistent EOC patients with more than 6 months of platinum free interval after last platinum treatment.
NON-CONVULSIVE SEIZURE RELATED TO A CREMOPHOR EL™-FREE, POLYMERIC MICELLE FORMULATION OF PACLITAXEL: A CASE REPORT

Y.S. Shin

Korea University Ansan Hospital, Obstetrics and Gynecology, Kyung Gi Do, Republic of Korea

Aims

Paclitaxel is an effective drug to treat ovarian, breast, lung and other cancers. Peripheral neurotoxicity is one of its common side effects while central nervous system toxicity are rarely reported. We report a case of a non-convulsive seizure developed in a 72-year-old woman with ovarian carcinoma after administration of cremophor-free, polymeric micelle formulation of paclitaxel (Genexol-PM).

Method

A 72-year-old women presented our Department of Gynecology in December, 2015 due to pelvic mass. Abdominal CT revealed a 9.2cm sized huge heterogenous mass at superoposterior aspect of uterus. She underwent pelviscopic left salpingo-oophorectomy, with the histology confirming left carcinosarcoma (Malignant mullerian mixed tumor). Adjuvant chemotherapy was started 1 month after surgery with pacilitaxel and carboplatin, which were administered every 3 weeks. Conventional dose of Genexol-PM (a novel Cremophor EL (CrEL)-free polymeric micelle formulation of paclitaxel) of 260mg/m2 was given.

Results

One week after her fourth round of chemotherapy, she presented a transient episode of aphasia for 45 minutes. Electroencephalographic recording demonstrated epileptiform discharges. Antiepileptic drug was administered and no further abnormal activities were detected during her hospitalization with normalized EEG performed after 4 days. Additional systemic chemotherapy was discontinued, and the patient did not experience overt seizures during 3 months observation.

Conclusion

To our knowledge, this is the first reported case of seizure related to a CrEL-free formulation of paclitaxel. Although rare, patients and clinicians should be aware of the possibility of the patient having a non-convulsive seizure after infusion with this paclitaxel formulation.

PFKFB3 AND PLA2G3 KNOCKDOWN LEADS TO THE GENERATION OF LIPID LADEN GRANULAR OSMIOPHILIC DEPOSITS AND MULTILAMELLAR BODIES IN OVARIAN CANCER

V. Shridhar¹, D. Roy¹, S. Mondal¹, D. Jung¹, A. Khurana¹, S. Bhattacharya¹, R. Hoffmann¹, L. Jin¹, E. Kalogera², S. Dowdy², J. Bakkum-Gamez²
¹Mayo Clinic, Experimental Pathology, Rochester, USA
²Mayo Clinic, Obstetrics and Gynecology, Rochester, USA

Aims

The aims of the study is to determine the effect of glycolysis inhibitor PFK-158 in ovarian cancer (OC). Among different regulators of this pathway, 6-PhosphoFructo-2-Kinase/Fructose-2,6-Bisphosphatases 3 (PFKFB3) a glycolytic enzyme that generates fructose-2,6-bisphosphate (F2,6BP) is recognized as an important control point in glycolysis.

Method

Using molecular techniques, we show that the active form of PFKFB3 (p-PFKFB3Ser461) is overexpressed in chemo-resistant OC cell lines and resistant patient derived xenograft (PDX) models compared to chemo-sensitive cell lines. Treatment with PFK158 (PFKI), a specific inhibitor of PFKFB3 activity reduced glucose uptake, ATP and lactate production in addition to inhibiting colony forming ability in both carboplatin (Carb-Pt) and paclitaxel (PTX) resistant OC cell lines in vitro and significantly reduced tumor weight, ascites and metastasis compared to single drug treatments alone in vivo in the highly resistant HEYA8MDR xenografts

Results

We show for the first time that PFKI promotes cell death by targeting the crosstalk between glycolysis and lipogenesis-two pathways active in OC by inducing autophagy resulting in the depletion of lipid droplets (LDs) in chemoresistant cells. PFKI downregulated the expression of both p-PFKFB3 and PLA2G3, involved in the biogenesis of LDs in several OC cell lines. TEM analysis revealed that genetic downregulation of PFKFB3 and or PLA2G3 resulted in the generation of granular osmiophilic deposits (GROD) and cholesterol rich multilamellar bodies (MLBs) respectively in the lysosomes, recapitulating lysosomal storage disorder phenotypes.

Conclusion

The functional consequence of this phenotype and the clinical implication of these results in the treatment of OC are currently under investigation.

MYASTHENIA GRAVIS IN AN OVARIAN CANCER PATIENT: A POSSIBLE PARANEOPLASTIC MANIFESTATION CASE
M. Simonsen¹, M. Minamoto Miyabe¹, H. Toshio Ouik¹, A. Cezar Ribeiro Galvão¹, D. Leite¹, B. Alencar Rolim Murayama¹, F. Martins Laginha¹, M. Tosello Laloni¹, G. Paiva da Silva Lima², I. Correa Barboza¹, M. Penna Antonio¹, E. Falacci Matheus¹, M. Samora¹
¹Hospital 9 de Julho, Gynecologic Oncology, São Paulo, Brazil
²Biogen, Research, Boston, USA

Aims

Gynecologic cancer rarely courses with neurological paraneoplastic symptoms. We describe one case of myasthenia gravis as a possible paraneoplastic manifestation of ovarian cancer preceding the neoplasm symptoms.

Method

Case Report

Results

A 61 years old patient with no comorbidities presented bilateral ptosis. Electromyography was suggestive of neuromuscular junction blockade. Dosage of anti-acetylcholine receptor antibody was greater than 20 nmol/L and other anti-neuronal antibodies were negative. She had no thymic image alterations and the use of pyridostigmine resulted in no clinical benefit response. After 30 days, the patient is hospitalized due to abdominal distension, dysphagia and progressive dyspnea. Abdominal tomography showed massive ascites and peritoneal thickening with greater pelvic component; CA-125 was 9561.8 U/mL and biopsy diagnosed an ovarian serous papillary adenocarcinoma. She had respiratory worsening and orotracheal intubation mas necessary for 23 days. Plasmapheresis sessions and pulse therapy with methylprednisolone were implemented without clinical improvement. After the introduction of immunoglobulin and cyclophosphamide, ventilator parameters finally improved and CA-125 dropped to 899U/ml. According to tumor board decision, chemotherapy regimen was changed to carboplatin and paclitaxel. In the third cycle patient had no more myasthenic symptoms as well no medications were necessary for myasthenia. Cytoreduction surgery with R0 resection was performed and then 3 more cycles of chemotherapy. In the 6th month of follow-up she had complete resolution of the myasthenic condition, CA125 <35U/mL and normal abdomen images.

Conclusion

Until we know, this is probably the first reported case of possible causality between new diagnosis of ovarian neoplasm and myasthenia gravis as a paraneoplastic syndrome.

SEROUS BORDERLINE EPITHELIAL OVARIAN TUMOR IN ADOLESCENCE PERIOD AND LAPAROSCOPIC MANAGEMENT

T. Simsek

Akdeniz University Faculty of Medicine, Obstetrics and gynecology, Antalya, Turkey

Aims

In adolescence period ovarian germ cell tumor is the most frequent tumors of the ovary. Epithelial ovarian tumors consisting benign, borderline and malignant form are uncommon in adolescent period. Borderline epithelial ovarian tumors in adolescence age have been reported rarely and laparoscopic management in the period also is uncommon. In the case report, serous microinvasive borderline epithelial ovarian tumor managed by laparoscopy in adolescent patient is reported.

Method

Case report

Results

A 16 year-old girl was referred serous borderline ovarian tumor after laparoscopic cyst excision. After discussing intraperitoneal staging with the patient and family, they preferred to follow up. Before the laparoscopic excision she had right ovarian 75X60X60 mm cystic mass contained mural nodule. Ca 125 level was 56.8 IU(normal level up to 35). Four mounts later, 3 cm cystic mass was diagnosed with mural nodule and laparoscopic right salpingooopherectomy, intraperitoneal staging were performed. The pathology was reported as microinvasive serous carcinoma ovary and noninvasive peritoneal implants. The case was discussed with medical oncology for chemotherapy. It was decided to follow up without chemotherapy. Six months later, she had left ovarian cystic mas in 3cm diameter with solid nodule. Laparoscopic cystic mass excision was performed by laparoscopy. Cytology was normal and no intraperitoneal disease. Pathology was revealed serous borderline ovarian tumor. She is in her 3 years follow up period with no recurrence and normal Ca 125 level.

Conclusion

Although serous borderline ovarian tumor is uncommon in adolescence period, it can be managed by laparoscopy.

CONSERVATIVE MANAGEMENT OF OVARIAN YOULK SAC TUMOR
T. Simsek, H. Aydın, E. Pestereli
1Akdeniz University Faculty of Medicine, Obstetrics and gynecology, Antalya, Turkey
2Akdeniz University, Obstetrics and gynecology- Gynecologic cancer surgery, Antalya, Turkey
3Akdeniz University, Pathology, Antalya, Turkey

Aims

Malignant ovarian germ cell tumors arise primarily in young women between age of 10 and 30. Yolk sac tumors (YSTs) of the ovary, also known as endodermal sinus tumors, are highly malignant and consist of 1% of ovarian malignancy. Fertility sparing approach is crucial and the principal objective of surgical management in this ages. We report here fertility preserving management of the young patient with YST presented with ascites and serum high level of alpha-feto-protein (AFP).

Method

Case report.

Results

A 20 year-old girl, consulted for abdominal pain and distention. Pelvic MRI showed a abdominopelvic mass arising the right ovary with 25x20 cm in diameter associated with ascites. Preoperative tumor marker assays showed CA-125 antigen level of 497 IU/mL and AFP level of 7610 IU/mL. A midline incision was performed. The abdominal exploration confirmed large tumor of the right ovary associated with ascites. The contralateral ovary was normal. The conservative surgery including removal of the right adnexa with mass, surgical staging with peritoneal cytology, multiple peritoneal and omental biopsies, ipsilateral pelvic and para-aortic lymphadenectomy was performed. The final pathology showed YST of the ovary. Peritoneal cytology was positive for malignancy and all other samples were normal. The case had BEP chemotherapy protocol and follow up with no disease recurrence.

Conclusion

YST is a rare disease with high malignant potential but also highly sensitive to chemotherapy. It can be managed by conservative fertility sparing surgery and chemotherapy.

THE PROGNOSTIC IMPACT OF NANOG EXPRESSION IN OVARIAN SEROUS CARCINOMA

N. KENDA ŠUSTER¹, S. Smrkolj², I. VIRANT-KLUN², S. FRKOVİĆ GRAZIO³

¹University Medical Centre Ljubljana, Department of Obstetrics and Gynecology, Ljubljana, Slovenia
²University Medical Centre Ljubljana, Department of Obstetrics and Gynecology - Reproductive unit, Ljubljana, Slovenia
³University Medical Centre Ljubljana, Department of Obstetrics and Gynecology - Department of Pathology, Ljubljana, Slovenia

Aims

The ongoing research about cancer stem cells opened a new perspective on pathogenesis, diagnosis and treatment of ovarian cancer. The objective of this study was to assess the expression of cancer stem cell related marker NANOG (NANOG) in ovarian serous carcinoma and to evaluate its prognostic significance.

Method

The expression of NANOG was evaluated in ovarian tissues from 109 patients with ovarian serous carcinomas. NANOG expression was measured immunohistochemically in a tissue microarray. According to a sum of signal intensity and proportion we divided samples into four NANOG groups: negative, slightly positive, moderate positive and strongly positive. We analyzed the correlation between the clinical data and results from immunohistochemistry.

Results

The positive reaction of the NANOG was shown as yellow-brown particles located in the cytoplasm and sometimes in nucleus. In ovarian serous carcinoma 69.7% cases were NANOG positive. There was no difference in clinical manifestation, response to therapy or survival between the four NANOG groups. At several places especially in the vicinity of small putative stem cells we also observed changes on epithelial cells similar to epithelial-mesenchymal transition.

Conclusion

NANOG was significantly expression in ovarian serous carcinoma. In our study there was no correlation between the intensity of NANOG expression and prognosis of ovarian serous carcinoma. Presence of NANOG predominantly in cytoplasm might be explained by translocation of NANOG protein from nucleus to cytoplasm as cancer progresses. The epithelial-mesenchymal transition, a mechanism that might play an important role in the manifestation of ovarian cancer, should be further investigated.

MESOTHELIN AS A POSSIBLE BIOMARKER FOR ENDOMETRIOSIS.
M. Sobstyl¹, K. Frąszczak², I. Werte³, W. Bednarek², B. Barczyński², M. Mazurek-Kociubowska², R. Tarkowski², P. Ziober-Malinowska², M. Maciejczyk-Pencula³, K. Kulak², J. Kotarski²
¹Medical University, Department of Endocrinology and Gynecological Endocrinology, Lublin, Poland
²Medical University, 1st Chair and Department of Gynecological Oncology and Gynecology, Lublin, Poland

Aims

Endometriosis is a common gynecological disease. Endometriosis is a benign disease, but the risk of cancerous endometriosis transformation to ovarian carcinoma is 0.7 – 1.5%. The most frequent types of cancer developing from endometriosis are clear-cell and endometrioid carcinoma, less common are serous and mucinous cancers. Mesothelin is widely recognized as ovarian cancer marker. The aim of the study was to assess the concentration of mesothelin in peritoneal fluid in women with endometriosis.

Method

69 fluid samples were collected from peritoneal cavity of patients undergoing laparoscopy, with endometriosis respectively. Endometriosis was diagnosed histologically and surgically, and then described with the use of the revised ASRM stages. 26 fluid samples were collected from patients with endometrioid cancer. All cancer patients were diagnosed with advanced disease (FIGO, stage I-IV). Concentration of mesothelin in peritoneal fluid was measured with the use of ELISA.

Results

The mesothelin concentration was statistically significantly higher (p=0.002) in the group with endometriosis than in the group with the endometrioid cancer. There were no statistically significant differences in the mesothelin concentration in particular stages of endometriosis.

Conclusion

High concentration of mesothelin in peritoneal fluid among women with endometriosis may suggest that this factor plays a crucial role in detecting and differentiating endometriosis and ovarian cancer. It seems that mesothelin is a stronger biomarker for endometriosis than for endometrioid cancer in the peritoneal fluid. The role of mesothelin in the development of endometriosis is poorly understood. This might be a promising target for future therapies in endometriosis.

MOLECULAR PROFILING OF ENDOMETRIOSIS AND ENDOMETRIOSIS-ASSOCIATED OVARIAN CANCER (EAOC)

G.S. Sohn¹, Y.M. Park¹, H.J. Kwon¹, H.Y. Shin¹, E.J. Lee¹, W.K. Yang¹, H.B. Cho¹, D.B. Chay¹, J.H. Kim¹, J.K. Gong¹
¹Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Endometriosis appears to be associated with some specific histologic subtypes of epithelial ovarian cancer, especially clear cell and endometrioid adenocarcinoma. However the pathogenesis of ovarian cancer development from endometriosis is not well understood. The purpose of this study is to investigate the molecular association of endometriosis and endometriosis associated ovarian cancer (EAOC).

Method

RNA was extracted from 36 paraffin tissue blocks comprising of endometriosis (n=8), atypical endometriosis (n=6) and endometriosis associated ovarian cancer (n=22). Lesion of endometriosis or cancer from whole paraffin-embedded tissue sections were obtained by Laser capture microdissection and differentially expressed genes were analyzed using RNA sequencing technology.

Results

Comparison of gene expression among endometriosis, atypical endometriosis and EAOC revealed different expression patterns by heatmap. 2,923 genes in EAOC and 125 genes in atypical endometriosis were differently expressed compared to endometriosis. 364 genes were up regulated and 296 genes were down regulated in EOAC compared to atypical endometriosis. Comparison merge revealed 6 percent of differently expressed genes were commonly upregulated in all three categories. Pathway analysis revealed that nine genes involving cell proliferation were positively regulated.

Conclusion

This study revealed gene alteration involving endometriosis and endometriosis associated ovarian cancer. These findings may be an important resource for studying the pathogenesis of ovarian cancer developing from endometriosis.

ESTABLISHMENT AND CHARACTERIZATION OF IMMORTALIZED HUMAN OVARIAN SURFACE EPITHELIAL CELLS USING LENTIVIRAL SYSTEM.

G.S. Sohn¹, Y.M. Park¹, H.J. Kwon¹, H.Y. Shin¹, E.J. Lee¹, W.K. Yang¹, H.B. Cho¹, D.B. Chay¹, J.H. Kim¹, J.K. Gong¹
¹Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Immortalization is a key difference that distinguishes cancer cell from normal cell. In cell line studies, normal cells like human ovarian surface epithelial cells (HOSE) are difficult to culture and limited due to the senescence nature of normal cell. The aim of this study is to establish normal ovary epithelial cell lines for the counterpart to research ovarian cancer.

Method

Immortalized human ovarian surface epithelial cells (IHOSE) were established by transfecting HPV E6/E7 and SV40 T antigen to short cultured HOSE using the lentiviral system. Cells were grown in Dulbecco’s Modified Eagle Medium in the presence of 10% fetal bovine serum and were cultured in 5% CO2 balanced air at 37°C. Thereafter, IHOSE were extracted genomic DNA and total RNA for DNA fingerprinting and RNA sequencing.

Results

Five IHOSEs that were arrived ten passages were established using the lentiviral system. Five IHOSEs were confirmed newly establishment using STR profiling. RNA sequencing was performed to identify IHOSEs characteristics, and gene expression changes were compared with HOSEs and ovarian cancer cell lines. IHOSEs have confirmed that the genes related to the cell cycle and DNA repair signal has changed more than HOSEs.

Conclusion

Newly established IHOSEs can be important research resources for the counterpart against molecular alternation of ovarian cancer.

THE ROLE OF APPENDECTOMY IN MUCINOUS BORDERLINE OVARIAN TUMORS
T. Song¹, M.K. Kim²
¹KangBuk Samsung Hospital - Sungkyunkwan University School of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Samsung Changwon Hospital- Sungkyunkwan University School of Medicine- Changwon- Republic of Korea, Department of Obstetrics & Gynecology, Changwon, Republic of Korea

Aims

To determine the frequency of appendiceal involvement in patients undergoing surgery for mucinous borderline ovarian tumors (mBOTs), and to evaluate the associated morbidity, and the recurrence risk and survival after appendectomy.

Method

The hospital databases were searched for women who underwent adnexal surgery at the Department of Obstetrics and Gynecology of four Korean academic hospitals, and whose final or frozen diagnosis was mBOTs. A literature search was performed, using electronic database (MEDLINE and EMBASE), to assess the available evidence on performing an appendectomy in patients with mBOTs.

Results

Of the 473 included patients with mBOTs, 201 (42.5%) underwent appendectomy, 247 (52.2%) did not undergo appendectomy at the time of initial surgery, and 25 (5.3%) had previously undergone appendectomy. Among the 201 patients who underwent appendectomy, primary and metastatic appendiceal mucinous neoplasms were occurred in 1 patient each (0.5%), who showed a macroscopically abnormal appendix. Appendectomy itself was not associated with operative complications ($P = 0.082$), recurrence risk ($P = 0.964$), or survival ($P = 0.219$). Consistent with our findings, a comprehensive search of the literature revealed that the frequency of appendiceal involvement in mBOTs was less than 1% in either primary or metastatic appendiceal neoplasms.

Conclusion

If the appendix is grossly normal, an appendectomy seems unnecessary in patients with mBOTs.
THE CLINICAL SIGNIFICANCE OF ELEVATED PREOPERATIVE CA125 OR CA19-9 IN BORDERLINE OVARIAN TUMORS

T. Song¹, M. Kim²
¹KangBuk Samsung Hospital - Sungkyunkwan University School of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Samsung Changwon Hospital- Sungkyunkwan University School of Medicine- Changwon- Republic of Korea, Department of Obstetrics & Gynecology, Changwon, Republic of Korea

Aims

To investigate whether elevated CA125 (≥35 U/mL) and CA19-9 (≥37 U/mL) suggest advanced-stage disease (defined as stage II or higher) or poor prognosis in patients with borderline ovarian tumors (BOTs).

Method

We retrospectively identified 591 patients with BOTs. Multivariate logistic regressions and Cox proportional hazard regressions were used to determine the clinicopathologic factors associated with the presence of advanced-stage disease and the prognostic factors associated with recurrence free-survival.

Results

CA125 was elevated more often in serous than in mucinous tumors (50.6% vs. 35.5%; P=0.003), whereas CA19-9 was elevated more often in mucinous than serous tumors (33.6% vs. 15.3%; P=0.001). An elevated CA125 level was independently associated with the presence of advanced-stage disease in serous (P=0.005) and in mucinous BOTs (P=0.015). However, preoperative elevation of CA19-9, unlike CA-125, was not associated with advanced-stage disease. Elevated preoperative CA125 level (P=0.037) was an independent prognostic factor for recurrence-free survival in patients with serous BOTs. However, neither CA125 nor CA19-9 had prognostic significance in mucinous BOTs.

Conclusion

Elevated preoperative CA125, unlike CA19-9, is a diagnostic and prognostic biomarker associated with the presence of advanced-stage disease and risk of relapse in patients with serous BOTs.

⁶Kuopio University Hospital- University of Eastern Finland- Institute of Clinical Medicine- A.I.Virtanen Institute for Molecular Sciences, Department of Gynecology- School of Medicine- Gynaecology- Department of Biotechnology and Molecular Medicine, Kuopio, Finland

Aims

The aim of the study was to explore the expression of VEGF, VEGF-C and VEGF-D as well as VEGF receptors 1, 2 and 3 in patients epithelial ovarian neoplasms and to compare expression also to related distant omental metastasis. In addition, we studied how expression of those angiogenic factors predict survival of patients with epithelial ovarian cancer.

Method

We enrolled 165 patients with ovarian epithelial tumor divided into benign (n=36), borderline (n=18), malignant (n=95) tumors and distant metastasis (n=16). The expressions of angiogenesis factors were measured with immunohistochemistry (n=165) and qRT-PCR (n=57).

Results

When expression of angiogenic factors in primary serous ovarian cancer was compared to related omental metastasis VEGF expression was higher in omental metastasis than in primary tumors (p= 0.022). Low expression of VEGF in primary serous tumors was associated with poor prognosis in univariate survival analysis (p=0.007). In qRT-PCR analyses the relative expression of VEGFR-2 and VEGFR-3 mRNA was significantly lower in primary ovarian cancer than in benign tumors (p=0.001, p=0.013, respectively). Other angiogenic factors were not constantly changed between samples in qRT-PCR.

Conclusion

There were significant differences in expression of VEGF receptors and their ligands between benign and malignant ovarian tumors and distant metastasis. It seems that VEGF protein expression is higher in distant metastasis than in primary lesions in ovarian cancer.

LYMPH NODE METASTASIS IN CLINICALLY STAGE I EPITHELIAL OVARIAN CARCINOMA

M. Sousa1, C. Andrade2, M. Vieira3, R. Reis3, G. Cintra3

1Barretos Cancer Hospital, Gynecology Oncology, Barretos, Brazil
2Barretos Cancer Hospital, Gynecology Oncology, Barretos, Brazil
3Barretos Cancer Hospital, Gynecology Oncology, Barretos, Brazil

Aims

Systemic pelvic and paraaortic lymphadenectomy in apparent stage I epithelial ovarian carcinoma (EOC) remains controversial. The study sought to determine the lymph node involvement in patients with ovarian cancer apparently confined to the ovaries.

Method

An analytical retrospective study was conducted with 21 patients with clinically stage I EOC, based on image exams and/or pathologic results of previous non oncologic surgery. These patients underwent to complete surgery staging with systematic pelvic and paraaortic lymphadenectomy at a Brazil Cancer Hospital from 2011 to 2016. Data were analyzed by applying frequencies of lymph node involvement. Student’s t-test or Wilcoxon-Mann-Whitney test were used to quantitative variables.

Results

The analyzed histological types were endometrioid, papillary serous, mucinous and clear-cells. Lymph node metastasis was found in four patients (19%). None of the four cases with mucinous histology had nodal dissemination. Two women presenting papillary serous tumors (28.6%), one present endometrioid (12.5%) and another clear cell carcinoma (50%). There was no difference in the number of resected pelvic and paraaortic lymph nodes among patients with and without nodal involvement [(14 ±7 vs. 19.3 ±9.8, p= 0.3245) and (10.2±6.4 vs. 14.7 ±10, p=0.41), respectively]. The lymph nodes metastatic sites were limited to pelvic. Serum CA125 levels showed no significant difference between patients with positive and negative lymph nodes (p=0.96).

Conclusion

The study implies that nodal involvement in stage I EOC may not be identified either by imaging studies or CA125 levels. Systematic pelvic and paraaortic lymphadenectomy might be required for accurate staging to endometrioid, serous and clear-cells ovarian cancer.

THE PROGNOSTIC ROLE OF PREOPERATIVE HYponatremia IN PATIENTS WITH ADVANCED EPITHELIAL OVARIAN CANCER (EOC)

M. Sporkmann¹, P. Harter², F. Heitz³, B. Ataseven¹, S. Schneider¹, S. Prader¹, A. Kahl¹, A. Traut¹, A. du Bois¹
¹Kliniken Essen Mitte, Gyn + Gyn. Oncology, Essen, Germany

Aims

To determine the impact of preoperative hyponatremia with regard to pre-, intra- and postoperative characteristics in patients with advanced primary epithelial ovarian cancer (EOC).

Method

All consecutive patients with EOC (FIGO stage III-IV) between 01/2011 and 12/2015 were prospectively included in the analysis. All data were collected in a prospectively maintained database. Hyponatremia was defined as serum sodium (Na) <135 mmol/l. Statistical analysis were mean and standard deviation or median (range) compared by the student’s t-test.

Results

In total, 390 patients (normal Na: n=363 (93.1%) and hyponatremia: n=27 (6.9%)) were analyzed. Patients with hyponatremia had significantly lower serum albumin (39 g/l vs. 42 g/l), higher age-adjusted charlson comorbidity score >2 (58.1% vs. 92.6%), and more often ascites >500ml (38.6% vs. 70.4%), respectively. Furthermore, complete resection rate was significantly lower in patients with hyponatremia (65.0% vs. 29.6%, p=0.001). We found no differences in postoperative characteristics like length of stay on intensive care unit, hospital stay, or the complications according to the Clavien-Dindo classification and 30-days mortality. But there was a significant difference in 60- (4.4% vs. 14.8%) and 90-days mortality (5% vs. 14.8%), p=0.018 and p=0.032 respectively.

Conclusion

Preoperative hyponatremia is associated with more ascites, lower rates of complete resection and higher 60- and 90-day mortality. The serum sodium might be useful for risk stratification in patients with advanced EOC.
THE PROGNOSTIC ROLE OF AB0 BLOODGROUP AND RHEUS FACTOR IN PATIENTS WITH ADVANCED EPITHELIAL OVARIAN CANCER (EOC)

M. Sporkmann¹, F. Heitz¹, P. Harter¹, S. Schneider¹, S. Prader¹, B. Ataseven¹, A. Hengsbach¹, A. Traut¹, A. du Bois¹

¹Kliniken Essen Mitte, Gyn + Gyn. Oncology, Essen, Germany

Objectives
Recently published data on patients with gastric cancer or with ovarian cancer showed an impact of the AB0 blood groups (BG) on the outcome. The aim of this study was to evaluate the prognostic value of AB0 BG and Rhesus factor (Rf) in patients with advanced primary epithelial ovarian cancer (EOC).

Methods
All consecutive patients with EOC (FIGO stage III-IV) treated between 01/2011 and 02/2017 were included in the analysis. All data were collected in a prospectively maintained database. Each BG was compared to each other, as well as a combined analysis with Rf.

Results
In total, 557 patients (BG A: n=267; BG 0: n=192; BG B: n=66; BG AB: n=32) were analyzed. The distribution of Rf positive patients in all groups showed no significant difference. There were no differences between patients’ characteristics nor between intra- or postoperative parameters, like FIGO-stage, residual disease or need of blood transfusion, between all BGs. Patients with BG AB had significantly less high-grade serous histology compared to non-BG AB (68.8% vs. 85.9%). Overall survival (OS) was not different between distinct AB0 BG. Progression free survival (PFS) in BG AB was significantly better compared to BG B (32 months vs. 20 months; p=0.026), compared to BG A it did not reach significance (32 months vs. 21 months; p=0.056). Analysis of Rf negative patients (n=77 (13.8%)) and Rf positive patients (n=480 (86.2%)) showed a significant difference in PFS (33 months vs. 22 months) but not in OS (58 months vs. 54 months), p=0.016 and p=0.577 respectively.

Conclusions
With regard to PFS, BG AB had a prognostic impact in patients with EOC compared to BG B. Rf positive patients had an impaired PFS compared to patients with Rf negative.
A SYSTEMATIC REVIEW ON COST-EFFECTIVENESS OF EARLY DETECTION AND PREVENTION STRATEGIES FOR OVARIAN CANCER

G. Sroczynski¹, A. Gogollari¹, F. Kühne¹, N. Pashayan², M. Widschwendter³, U. Siebert¹,⁴,⁵,⁶

¹UMIT - University for Health Sciences, Medical Informatics and Technology - Insti, Institute of Public Health - Medical Decision Making and Health Technology Assessment, Department of Public Health, Health Services Research and Health Technology Assessment, Hall in Tirol, Austria

⁵Harvard T.H. Chan School of Public Health, Center for Health Decision Science - Department of Health Policy and Management, Boston, USA
⁶Harvard Medical School, Institute for Technology Assessment and Department of Radiology, Boston, USA

Aims

We conducted a systematic review on cost-effectiveness studies evaluating early detection and prevention strategies for ovarian cancer in various populations.

Method

We systematically searched relevant databases (Medline/Embase/Cochrane Library/CRD/EconLit) for decision-analytic modelling studies assessing the cost-effectiveness of early detection and/or prevention strategies for ovarian cancer. We summarized study characteristics and results including quality-adjusted life-years (QALY), life-years gained (LYG), and incremental cost-effectiveness ratios (ICER; in cost/QALY or LYG) in standardized evidence tables. Economic results were converted to 2015 Euros using GDP-PPP and CPI.

Results

Twenty studies varying in terms of target population, discount rate, perspective and evaluated strategies were included. Ovarian cancer screening in women age 45+ yielded ICERS from 12,000 Euro/LYG in population with 5% prevalence of high-risk women to 68,000 Euro/LYG in average-risk women. A recent study reported 10,000 Euro/QALY for multimodal screening with a risk-adapted algorithm. Risk-reducing surgery in mutation carriers yielded ICERS from cost-saving to 4,000 Euro/LYG (2,000-16,000 Euro/QALY). In premenopausal women, risk-reducing interventions yielded ICERS ranging from 700 Euro/LYG in women with 10% lifetime cancer risk to 47,500 Euro/LYG in women with 2% lifetime risk (2,000-757,000 Euro/QALY). In postmenopausal women, respective ICERS were 2,000-47,000 Euro/LYG (2,000-757,000 Euro/QALY). Genetic testing in women at increased risk followed by risk-reducing interventions in mutation carriers yielded ICERS of 10,000-32,000 Euro/LYG (8,000-9,000 Euro/QALY).

Conclusion

Based on our findings, both screening and preventive surgery in women at increased or high risk for ovarian cancer can be considered effective and cost effective. Results were sensitive with regard to test accuracy, test costs, and the screening frequency.

ESGO7-0966

THE PREDICTIVE AND PROGNOSTIC VALUE OF THE PERITONEAL CANCER INDEX (PCI) IN PATIENTS WITH ADULT GRANULOSA CELL TUMORS OF THE OVARY

N. Stefanidou

Gynaecology, Berlin, Germany

Aims

Granulosa cell tumors are rare sex cord-stromal tumors of the ovary with malignant potential. Surgery is the cornerstone in their treatment. We evaluated the role of the in gastrointestinal cancers established Peritoneal Cancer Index, analysing surgical outcome and impact on progression survival. We compared PCI to our in our center validated documentation instrument (intraoperative mapping of ovarian cancer (IMO)), correlating it also to clinical features.

Method

The definition of PCI score was performed retrospectively, based on surgery report and histopathology. We compared the PFS (Kaplan Meier survival curves) between primary diagnosis and recurrence using the Log rank test. We tested the effect of PCI on clinical variables. To prove effect of PCI on PFS a Cox regression analysis was performed. A log rank testing was made in order to try out eventual cut offs that could have predictive significance on PFS. With Kaplan-Meier survival analysis we were able to detect which PCI areas were associated with prognosis.

Results

We examined 80 cases of adult granulosa tumors of the ovary, 26 primary and 54 recurrent tumors. Prognosis at primary diagnosis is significantly better than by recurrence. With a resectability of tumor by 95% in our cohort, we could not test PCI as a predictor for complete resection; PCI has not been shown predictive of PFS in our actual study. The median PCI differs significantly in cases with versus without tumor residual. PCI fields 1, 3 lead to poorer prognosis.

Conclusion

Eventually prognostic PCI cut off in cases with residual tumor remains to be examined.

HYPERTHERMIA AND CISPLATIN INCREASE HEAT SHOCK PROTEIN HEME OXYGENASE-1 EXPRESSION IN OVCAR-3 CELLS

S. Arturas¹, V. Cesna², J. Aldona³, M. Gedgaudaite¹, G. Barauskas², R.J. Nadisauskiene¹, Z. Dambrauskas³, S. Paskauskas¹, A. Gulbinas³

¹Lithuanian University of Health Sciences, Department of Obstetrics and Gynecology, Kaunas, Lithuania
²Lithuanian University of Health Sciences, Department of Surgery, Kaunas, Lithuania
³Lithuanian University of Health Sciences, Institute for Digestive Research, Kaunas, Lithuania

Aims

To evaluate the impact of different temperature and cisplatin combinations to the expression of heat shock protein heme-oxygenase-1 (HO-1) and the cells viability in OVCAR-3 cells.

Method

Imitating the typical clinical conditions of HIPEC, OVCAR-3 cells were exposed to different hyperthermia and cisplatin concentrations for one hour. Afterward the MTT viability test, flow cytometer analysis, isobologram analysis and quantitative reverse transcription polymerase chain reaction was performed and analysed.

Results

The rising temperature from 37°C to 42°C alone and in combination with half of the maximal inhibitory concentration of cisplatin (IC50) had insignificant effect on OVCAR-3 cells viability and apoptosis. The combination of hyperthermia up to 42°C and IC50 dose of cisplatin significantly increased the expression of heat shock protein HO-1 in OVCAR-3 cells. Cisplatin alone decreased cell viability in a linear pattern. The antagonistic effect of hyperthermia and cisplatin was revealed by the isobologram method.

Conclusion

Hyperthermia usable in clinical practise and cisplatin increase the expression of heat shock protein HO-1 in OVCAR-3 cells. Further research is essential regarding modulation of the HO-1 expression as a new therapeutic option to improve the results of HIPEC.
EVALUATION OF APPENDAGES’ TUMORS IN IOTA SYSTEM IN REFERENCE TO HISTOPATHOLOGICAL RESULTS

M. Szubert1, S. Malwina2, N. Anna2, M. Martyna2, L. Mokros2, J. Suzin1

1Medical University of Lodz, I Department of Gynecology and Obstetrics- Clinic for Operative and Oncological Gynecology, Lodz, Poland
2Medical University of Lodz, I Department of Gynecology and Obstetrics- Clinic for Operative and Oncological Gynecology- Students’ Scientific Society, Lodz, Poland
3Medical University of Lodz, Department of Clinical Pharmacology, Lodz, Poland

Aims

Ovarian cancer is one of the most common women cancers after menopause. The aim of the study was to evaluate how IOTA (International Ovarian Tumor Analysis) Simple Rules used in ultrasound examination modifies probability of occurrence malignant and benign ovarian tumor in tested population.

Method

The study group consisted of 426 patients with ovarian tumors operated in the years 2014-2015. Changes of appendages were rated according to IOTA Simple Rules. Results of this study were compared with the final histopathology reports. Statistical analysis was performed in STATISTICA 13 PL with Medical Pack.

Results

Malignant tumour patients (n=43) were statistically significantly older (mean age 61.0 ±11.6 vs 43.6±16.2, p<0.001), had higher BMI (mean 27.3±7.0 vs 25.2±5.2, p<0.05), more pregnancies (median 2 vs 1, p=0.001) and higher Ca125 level (median 251.5 vs 18.5, p<0.001) than patients with benign tumour (n=346). Also, they more often suffered from diabetes mellitus and arterial hypertension. For determining malignant tumour IOTA Rule 1 reached sensitivity of 83%, specificity 88%, positive predictive value (PPV) of 51% and negative PV 97%. IOTA Rules were better in prediction malignancy than Ca125 value alone (sensitivity of 71%, specificity 92%, positive predictive value (PV) of 56% and negative PV 96%).

Conclusion

In our study, performance of IOTA in predicting or ruling out malignant tumour was highly satisfying. IOTA Rules and Ca125 may be complementary and used to assess risk of malignant vs benign ovarian neoplasm, yet context of other clinical variables may also be important.

THE PROGNOSTIC AND PREDICTIVE VALUE OF SUBCLASSIFYING STAGE IV EPITHELIAL OVARIAN CANCER INTO IVA AND IVB BY THE REVISED 2014 FIGO STAGING SYSTEM

P. Tajik¹, R. van de Vrie², H. Zafarmand³, C. Coens⁴, M. Buist⁵, I. Vergote⁴, P. Bossuyt⁵, G. Kenter²

¹Academic Medical Center Amsterdam, Pathology, Amsterdam, The Netherlands
²Academic Medical Center Amsterdam, Obstetrics & Gynaecology, Amsterdam, The Netherlands
³EORTC Headquarter, Biostatistics, Brussels, Belgium
⁴University Hospitals- K.U. Leuven, Obstetrics & Gynaecology, Leuven, Belgium
⁵Academic Medical Center Amsterdam, Clinical Epidemiology & Biostatistics, Amsterdam, The Netherlands

Aims

The revised version of FIGO staging system (2014) for epithelial ovarian cancer (EOC) includes a number of changes, one of these is the division of stage IV in two subgroups. Data on the prognostic and predictive significance of this classification are scarce.

Method

We used data of the European Organization for Research and Treatment of Cancer (EORTC) 55971 trial in which 670 patients with previous stage IIIC or IV EOC were randomised to primary surgery or neoadjuvant chemotherapy (NACT). Information on previous FIGO staging and presence of pleural effusion with positive cytology were used to classify tumours as either stage IVA or IVB. Kaplan-Meier estimates, log-rank tests and Cox-proportional-hazards models were used for survival analyses.

Results

Among the 160 participants with previous stage IV disease, 103 (64%) were categorized as stage IVA and 57 (36%) as stage IVB tumours. Median overall survival was 24.1 months in FIGO stage IVA and 30.8 months in stage IVB patients (p=0.044). Stage IVB patients treated with NACT had a 9 months longer median overall survival compared to IVB patients undergoing primary surgery (p=0.025). Stage IVA patients had similar overall survival following either primary surgery or NACT (p=0.48). In the multivariable analysis, stage IVA/IVB was significantly associated with overall survival (HR=0.45, p=0.008) and a differential benefit from NACT, though not significantly so (HR interaction=2.08, p=0.066).

Conclusion

The reclassification of FIGO stage IV into stage IVA or IVB adds prognostic information. Compared to stage IVA patients, stage IVB patients have a better overall survival and may benefit more from neoadjuvant chemotherapy.

BRCA MUTATIONS IN ARAB ISRAELI MUSLIM POPULATION – A CASE REPORT
L. Cohen¹, M. Massalha¹, A. Tal¹, L. Levy¹, S. Romano¹,², Y. Ben David¹,²
¹Emek Medical center, Obstetrics and Gynecology, Afula, Israel
²Technion Rappaport Faculty, Medicine, Haifa, Israel

Aims

Muslims are the largest minority and consist of about 20% of the population in Israel. Although there is evidence for a reduction of breast cancer incidence in the Israeli Jewish population, there is an increase in the incidence of breast cancer, as well as lower ages of discovery and a more aggressive disease among Israeli Muslims. There are reports among other Muslim countries, consistent with higher prevalence, lower age of disease diagnosis and more aggressive disease, compared with breast cancer statistics of western countries. Germline mutations in BRCA1 and BRCA2 genes can be detected in high risk Breast/Ovarian Cancer Families.

Other genes associated with increased risks of breast / ovarian cancers include genes connected to syndromes such Fanconi anemia.

Fanconi anemia is connected to higher breast/ovarian cancer through the PALB2 Gene, Known also as FANCN Gene.

Mutations in BRCA2 (also known as FANCD1), and Mutations in BRCA1 (also known as FANCS), can cause Fanconi anemia subtypes.

Method

This is a case report

Results

We describe a case of 3 young Arab Israeli female cousins, in which one of them (33 Y/O) known to be Fanconi anemia Carrier, and has also been found to harbor BRCA1 Mutation. The 2 other cousins (ages 24 and 35), have been found to harbor Ovarian serous Carcinoma and Borderline Serous Carcinoma, Respectively.

Conclusion

Knowledge of these rare but important mutations can reveal some of the unknown reasons for the different, more aggressive statistics of ovarian and breast cancer among Muslim population in Israel and perhaps other Muslim populations worldwide.

IN VITRO CHEMOSENSITIVITY IN OVARIAN CARCINOMA – COMPARISON OF THREE LEADING ASSAYS

1Department of Gynecologic Oncology, Suleyman Demirel University School of Medicine, Isparta, Turkey
2Department of Gynecologic Oncology, Hacettepe University School of Medicine, Ankara, Turkey
3Department of Gynecologic Oncology, Zekai Tahir Burak Maternity and Teaching Hospital, Ankara, Turkey
4Onkosel Biotechnology, Hacettepe University Technopolis, Ankara, Turkey
5Department of Pathology, Hacettepe University School of Medicine, Ankara, Turkey

Aims

All the patients with ovarian carcinoma may not have equal response to the standard chemotherapeutic regimen although they have the same histologic type of tumor. An alternative approach to current therapy of ovarian carcinoma is individualization of the treatment by determination of sensitivity of tumoral tissue to chemotherapeutic agents before the initiation of chemotherapy. The study is designed to determine the efficacy of invitro chemosensitivity assays in ovarian carcinoma and to measure the correlation of three leading assays with each other.

Method

Fresh tumoral tissue samples of 26 newly diagnosed primary ovarian cancer patients were studied with MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide], ATP-TCA (Adenosine Triphosphate Tumor Chemosensitivity Assay) and DISC (Differential Staining Cytotoxicity) assays. Chemosensitivity of tumors were studied for paclitaxel, carboplatin, docetaxel, topotecan, gemcitabine and doxorubicin with each of the three assays. Subgroup analysis was done for stage, grade and histologic type.

Results

The invitro chemosensitivity results of MTT, ATP and DISC assays were found to be similar. The subgroups that invitro assays would be more useful are encountered for patients with advanced stage and serous histology ovarian carcinoma.

Conclusion

Invitro chemosensitivity can be determined in ovarian carcinoma with ATP, MTT or DISC assays before initiation of chemotherapy. These three assays correlate well with each other and they are especially useful for serous and advanced cancers. Large prospective studies comparing standard versus assay directed therapy with an end-point of overall survival are needed before routine clinical utilization of these assays.
ONCOLOGIC OUTCOMES AND REPRODUCTIVE SUCCESS AFTER FERTILITY SPARING MANAGEMENT IN WOMEN WITH MALIGNANT OVARIAN GERM CELL TUMORS

I. Anastasakis¹, N. Thomakos¹, M. Sotiropoulou², D. Haidopoulos¹, D. Vlachos¹, G. Vlachos¹, A. Rodolakis¹
¹University of Athens- “Alexandra” Hospital, 1st Department of Obstetrics & Gynecology, Athens, Greece
²University of Athens- “Alexandra” Hospital, Department of Histopathology, Athens, Greece

Aims

Malignant ovarian germ cell tumors (MOGCTs) represent a relatively rare malignancy that mostly affects young women with strong desire for fertility-preserving management. The aim of our study is to identify the oncologic and clinicopathologic characteristics of MOGCT, and report the prognostic factors and reproductive outcomes of patients treated with conservative surgery.

Method

Medical records from 42 women diagnosed and treated for MOGCTs between 1997 – 2015 in our hospital were analyzed retrospectively. Fisher's exact tests were used for the comparison of proportions and life table analysis for survival calculations.

Results

Mean age at diagnosis was 23.5 years. Thirty-one cases (74%) were stage I; 7 cases (17%) stage II; and 4 cases (9%) stage III. Immature teratoma represented the most common histological type (n = 18) followed by dysgerminomas, mixed tumors, and endodermal sinus tumors. Thirty-five patients underwent fertility-sparing surgery defined by unilateral oophorectomy, lymphadenectomy, and peritoneal biopsies. Adjuvant chemotherapy was administered in 29 patients with BEP (bleomycin, etoposide, and cisplatin). After a median follow-up period of 9.2 years, 4 patients (11.5%) had disease recurrence and 3 died. The overall survival rate was 94.1% for women in early stage (I/II) and 87.1% for women in advanced stages. During the follow-up period, 31% (11/35) of the women tried for a pregnancy, and 45% (5/11) of them resulted in normal deliveries.

Conclusion

Our data demonstrate that MOGCTs, if detected in early stages, have excellent survival outcomes with fertility-preserving surgery and chemotherapy. Patients maintain future reproductive potential and appear to achieve favorable reproductive outcomes.

ESGO7-0632

TOTAL PARENTERAL NUTRITION IN POSTOPERATIVE CARE OF OVARIAN CANCER PATIENTS REQUIRING BOWEL ANASTOMOSIS: AN IRISH GYNAECOLOGICAL ONCOLOGY EXPERIENCE

C. Thompson¹, A. Kalid², C. O'Regan², A. Higgins³, N. Gleeson¹

¹St James’s Hospital, Gynaecological Oncology, Dublin, Ireland
²Coombe Hospital, Obstetrics and Gynaecology, Dublin, Ireland
³St James’s Hospital, Nutrition Department, Dublin, Ireland

Aims

The use of Total Parenteral Nutrition (TPN) in ovarian cancer is controversial. Its application ranges from postoperative nutrition to the management of inoperable bowel obstruction. Enhanced recovery programmes suggest that TPN may be inadvisable postoperatively in cases of bowel anastomosis. However, bowel resection in the setting of ovarian cancer presents a special challenge. The extent of bowel wall and mesenteric metastases can be extreme, and systemic effects of the cancer can be profound. This is a review of our experience with TPN.

Method

Retrospective data collection from the electronic care records of all cases identified from January 2016 to December 2016. In terms of outcome, the duration of TPN, time interval to restoration of bowel function, incidence of anastomotic leaks, central line infections and length of hospital stay were recorded. A Dietician prescribed all parenteral feeding regimens after a full nutritional assessment.

Results

Twenty-four patients with a diagnosis of ovarian cancer required at least one bowel resection during surgery; 18 during first cytoreductive surgery, and 6 for bowel obstruction with progressive or recurrent disease. The average BMI for the group was 27kg/m². Median duration of TPN was 8 days (range 5-20). There were no bowel anastomotic leaks. There was one (4.1%) central line infection.

Conclusion

Postoperative TPN demonstrated potential benefits in association with a low complication rate. Further research is required to determine the optimal postoperative nutritional regimen in ovarian cancer. In the interim we recommend an individualized approach.
A CASE OF MALIGNANT STRUMA OVARI CONFINED TO THE OVARY WITH SYNCHRONOUS PAPILLARY THYROID CARCINOMA DETECTED FOLLOWING THYROIDECTOMY

C. Thompson, C. O'Riain, F. Abu Saadeh

1St James’s Hospital, Gynaecological Oncology, Dublin, Ireland
2St James’s Hospital, Histopathology Department, Dublin, Ireland

Aims

Struma ovarii is a mature teratoma, composed predominantly (over 50%) or entirely of thyroid tissue. Around 5% are malignant and most of papillary type. Although metastases are rare, detection of synchronous papillary thyroid carcinoma is present in around 9% of cases. This presentation of a case report will also review current evidence for treatment of this rare condition.

Method

Following presentation of case report a literature review was performed. Keywords applied to searches with PUBMED and MEDLINE.

Results

Case:
Forty-two year old with incidental finding of adenexal cyst. MRI showed complex 5cm multi-septated left adenexal mass. CA 125 was 17. Patient requested fertility sparing surgery. Laparoscopic procedure with cyst intact. Histology confirmed papillary thyroid carcinoma within struma ovarii. Progressed to total thyroidectomy and radioablation. Histology confirmed 5mm capsulated lesion defined as thyroid papillary carcinoma. Commenced clinical follow up with thyroglobulin.

Review:
In patients not desiring future fertility, surgical staging for ovarian cancer is advocated including total hysterectomy, bilateral salpingo-oophorectomy, lymph node sampling, total thyroidectomy, and radioablation. Debate continues regarding conservative management in cases of malignancy. Following thyroidectomy and radioablation, serum thyroglobulin levels can be followed as a marker for recurrence in cases of fertility-sparing surgery. The recurrence rate in patients who undergo surgery without subsequent radioablation has been cited as high as 50%.

Conclusion

Malignant struma ovarii remains rare. Therefore optimal management has not been clearly defined in the literature. Cases of synchronous thyroid carcinoma are becoming more frequently detected. Pelvic surgery for the ovarian lesion, total thyroidectomy and radioablation are therefore strongly advocated.

ESGO7-0471

INTERVAL BETWEEN CYTOREDUCTIVE SURGERY AND ADJUVANT CHEMOTHERAPY IS ASSOCIATED WITH OVERALL SURVIVAL IN PATIENTS WITH ADVANCED OVARIAN CANCER

M. Timmermans¹,²,³, M.A. van der Aa¹, K.K. Van de Vijver⁴, R.F.P.M. Kruitwagen²,³, G.S. Sonke⁵

¹Netherlands Comprehensive Cancer Organisation IKNL, Department of Research, Utrecht, The Netherlands
²GROW, School for Oncology and Developmental Biology, Maastricht, The Netherlands
³Maastricht University Medical Centre, Department of Obstetrics and Gynaecology, Maastricht, The Netherlands
⁴The Netherlands Cancer Institute, Divisions of Diagnostic Oncology and Moleculare Pathology, Amsterdam, The Netherlands
⁵The Netherlands Cancer Institute, Department of Medical Oncology, Amsterdam, The Netherlands

Aims

Optimal treatment for advanced epithelial ovarian cancer consists of cytoreductive surgery and (neo)adjuvant platinum based chemotherapy. The aim of this study was to evaluate whether the time to adjuvant chemotherapy (TTC) was associated with overall survival (OS).

Method

We selected all patients diagnosed with epithelial ovarian cancer (FIGO IIb-IV) between 2008 and 2015 from the Netherlands Cancer Registry. Logistic regression was used to identify factors associated with a longer TTC and multivariable Cox regression to evaluate the independent effect of treatment interval on OS. Patients receiving primary debulking surgery (PDS) and patients receiving interval debulking surgery (IDS) were analysed separately.

Results

4,143 patients were included, 1,693 underwent PDS and 2,450 IDS. Median TTC was 29 (interquartile range (IQR) 23-37) days. Perioperative complications (p<0.001), prolonged hospitalisation (p<0.001), and extended surgery (p<0.001) were independently associated with a longer TTC for both PDS and IDS. Patients who exceeded the 75% quartile of the TTC interval experienced worse survival when undergoing PDS (>37 days compared to 23-37 days; hazard rate (HR) 1.20, 95%CI 1.01-1.43) or IDS (HR 1.27(1.10-1.46)).

Conclusion

Our study provides evidence that delayed initiation of adjuvant chemotherapy is an independent prognostic factor for worse overall survival after both PDS and IDS, also when adjusting for residual disease and perioperative complications. Consequently we advice to start adjuvant chemotherapy within five to six weeks after debulking surgery.

ASSOCIATIONS BETWEEN MOLECULAR SUBTYPES AND POSTOPERATIVE COMPLICATIONS AFTER PRIMARY CYTOREDUCTIVE SURGERY FOR ADVANCED STAGE HIGH-GRADE SEROUS OVARIAN CANCER

D. Torres1, A. Kumar1, J. Bakkum-Gamez1, C. Langstraat1, E. Goode2, W. Cliby1, C. Wang1
1Mayo Clinic, Gynecologic Surgery, Rochester, MN, USA
2Mayo Clinic, Health Sciences Research, Rochester, MN, USA

Aims

Individualized treatment approaches to maximize oncologic outcomes and minimize perioperative morbidity in high-grade serous ovarian cancer (HGSOC) are lacking. Given the relationship between TCGA (The Cancer Genome Atlas) molecular subtypes, survival outcomes, residual disease (RD), and intraperitoneal disease spread, we seek to evaluate the association of molecular subtype with 30-day postoperative complications and 90-day mortality after primary cytoreductive surgery (PCS) in advanced stage HGSOC.

Method

TCGA subtypes were derived from Agilent 4x44k tumor mRNA expression profiles of 279 women with HGSOC undergoing PCS from 1994-2009. RD status was categorized as 0, 0.1-0.5, 0.6-1.0, or > 1cm. Surgical complexity (SC) scores were calculated as high, intermediate, or low. Complications were graded according to the modified Accordion classification 0-4 scale. Fisher’s exact test was used to assess categorical associations.

Results

TCGA molecular subtype distribution is listed in Table 1. MES was more likely to have preoperative albumin levels ≤ 3.5g/dL (33%, P<0.05). Despite higher rates of RD > 1cm (19%, N=14), lower rates of RD0 (12%, N=9) and similar SC scores (P=0.27), grade 3-4 complications were twice as likely in MES (29%, P=0.06) vs. any other subtype. No difference in 90-day mortality was noted (P=0.65).

</table>

Table 1. TCGA molecular subtypes by demographics and perioperative characteristics.

Conclusion

MES subtype of HGSOC is more likely to have grade 3-4 morbidity after PCS and lower preoperative albumin levels. Given the fine balance between RD and morbidity and mortality after PCS, preoperative molecular subtyping may assist in tailoring individualized treatment of HGSOC.
Aims

Mutations in cancer susceptibility genes BRCA1/2 are considered to be associated with better survival possibly due to a better response to platinum-based chemotherapy and PARP inhibitors. We wondered whether the expression of BRCA1/2 measured at the transcriptome level could also be indicative for platinum response and thus predict clinical outcome in ovarian cancer.

Method

We analyzed BRCA1 and 2 mRNA expression in 201 fresh-frozen ovarian cancer samples and in 12 healthy fallopian tubes using quantitative real-time PCR. BRCA mutations detection was performed by next generation sequencing. Associations between BRCA expression and clinicopathological parameters were evaluated using Mann-Whitney-U and Kruskal-Wallis tests. OS and PFS were estimated using Kaplan-Meier plots and multivariate Cox-Regression. Optimal cut-off points were defined using Youden index.

Results

We found higher BRCA1 and 2 expression in ovarian cancer tissues in comparison with control tissues (p=0.011; p<0.001, respectively). BRCA1 expression was higher in older patients (p=0.036) and in advanced FIGO stages (p=0.036). Higher BRCA2 expression was found in cases with residual tumor after primary debulking (p=0.032) and in high-grade tumors (p<0.001). Univariate survival analysis showed high BRCA2 expression to be associated with poor PFS (p=0.002) and both high BRCA1 and 2 expression levels associated with poor OS (p=0.012, p=0.001; respectively). Multivariable survival analysis confirmed poor PFS in patients with high BRCA2 expression (p=0.028) and poor OS in patients with high BRCA1 expression (p=0.033).

Conclusion

Higher expression of BRCA1 and 2 predicts poor survival in patients with ovarian cancer possibly due to improved homologous DNA damage repair, which may lead to reduced platinum sensitivity.
EFFECT OF LYMPHADENECTOMY ON SURVIVAL IN ADVANCED OVARIAN CANCER DURING PRIMARY DEBULKING SURGERY: A SINGLE CENTER EXPERIENCE

D. Tsolakidis¹, A. Papanikolaou¹, S. Pitis¹, V. Theodoulidis¹, D. Zouzoulas¹, E. Timotheadou², T. Theodoridis¹, B. Tarlatzis¹

¹Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloníki, Greece
²Papageorgiou Hospital, Pathological Oncology University Clinic, Thessaloníki, Greece

Aims

Systematic lymphadenectomy is strongly recommended in patients with ovarian cancer. The purpose of this study was to evaluate its diagnostic, prognostic and therapeutic value.

Method

We performed a retrospective analysis in the medical records of 160 patients with advanced ovarian cancer, who underwent primary debulking surgery between January 2004 and December 2016. Cytoreductive outcomes and survival rates were evaluated.

Results

Lymphadenectomy during primary debulking surgery was performed in 65 (40.6%) patients (LN group) and it was omitted in 95 (59.4%) patients (no-LN group). Median number of pelvic and para-aortic lymph nodes dissected was 21 (positive rate: 46.5%) and 16 (positive rate: 67.4%), respectively. Lymphocyst formation was present at 12 (18.5%) patients. Complete debulking rates were statistically significant higher in LN group than in non-LN group (78.5% vs. 35.8%). Median surgery duration and median surgery blood loss were also statistically significant higher in LN group than in no-LN group (240min vs. 230min / 700cc vs. 500cc), but there was no statistical significant difference in post-recovery time. On the other hand, median hospitalization was statistically significant higher in the no-LN group than in the LN group (10 days vs. 9 days). Median disease-free and overall survival were statistical significant higher in LN group than in no-LN group (LN: 38 months, no-LN: 19 months / LN: 70 months, no-LN: 35 months).

Conclusion

Systematic lymphadenectomy during primary debulking surgery in advance ovarian improves the rate of complete debulking, disease-free and overall survival.

BOWEL RESECTION IN ADVANCED OVARIAN CANCER: A SINGLE CENTER EXPERIENCE
D. Tsolakidis¹, A. Papanikolaou¹, S. Pitis¹, D. Zouzoulas¹, P. Lymeriadis¹, L. Zepiridis¹, G. Grimbizis¹, B. Tarlatzis²
¹Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

Bowel resection is often required in advanced ovarian cancer patients with high tumor dissemination in order to achieve complete cytoreduction. The purpose of this study was to evaluate the benefit of these patients from radical surgery.

Method

We conducted a retrospective review of medical records of 66 patients with ovarian cancer, who underwent bowel resection between January 2004 and December 2016. Complications, cytoreductive and oncological outcomes were reported.

Results

44 (66.7%) patients underwent bowel resection during primary, 13 (19.7%) during interval and 9 (13.6%) during secondary debulking surgery. Intestinal surgeries included: 41 patients underwent rectosigmoid resection, 7 had colectomy and 5 had colectomy plus rectosigmoid resection. From the rest patients 7 underwent small bowel resections and 6 multiple enterectomies. Complete and optimal (<1cm) debulking was achieved in 34 (51.5%) and 20 (30.3%), respectively. Median hospitalization was 11 days. Median perioperative blood loss was 700cc and postoperative blood transfusion was mandatory in 39 patients. Median resuscitation time was 4 hours and 22 (33.3%) patients required ICU admission after surgery. Postoperative complications such as pelvic abscess formation were observed in two patients and fistula in one of them. Median disease-free and overall survival was 22 and 41 months, respectively. Perioperative mortality was 4.5%.

Conclusion

Bowel resection is the most frequent additional procedure in order to achieve complete or optimal cytoreduction in advanced ovarian cancer. It has acceptable perioperative morbidity, mortality and increased survival rates.

DIAPHRAGMATIC SURGERY IN DEBULKING SURGERY FOR ADVANCED OVARIAN CANCER: A SINGLE CENTER 12 YEARS EXPERIENCE

D. Tsolakidis1, A. Papanikolaou1, D. Zouzoulas1, S. Pitis1, D. Aivazi1, T. Theodoridis1, A. Vatopoulou1, B. Tarlatzis1

1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

The aim of this study is to describe the role of diaphragmatic surgery during primary and interval cytoreduction in advanced ovarian cancer.

Method

We conducted a retrospective review of medical records of 62 patients with advanced ovarian cancer, who underwent diaphragmatic surgery during primary and interval debulking surgery between January 2004 and December 2016. Disease free survival, overall survival, cytoreductive outcome, intra and postoperative complications related to diaphragmatic surgery were analyzed.

Results

5 (8%) patients had FIGO stage IIIB, 39 (63%) stage IIIC and 18 (29%) stage IV. 46 (74%) underwent primary and 16 (26%) interval debulking surgery. In 22 patients the diaphragmatic peritoneum was stripped, in 11 patients was resected with the adjacent infiltrated part of diaphragmatic muscle and the adjacent pleura, in 17 patients was coagulated and in 12 a combination of these techniques was applied. Median disease-free survival and overall survival were 20 and 52 months, respectively. No residual disease or less than 1cm was achieved in 28 (45.2%) and 29 (46.8%) patients, respectively. The most frequent complication related to diaphragmatic surgery was pleural effusions in 38 (61.3%) patients. Chest tube placement was necessary in 13 (21%) and thoracocentesis in 5 (8%) patients. The median time of chest tube stay was 7 days.

Conclusion

Diaphragmatic surgery is an integral part of upper abdominal cytoreductive procedures during primary and interval debulking with an acceptable and manageable morbidity rate.

MANAGEMENT AND ONCOLOGICAL OUTCOMES OF OVARIAN CANCER: A SINGLE CENTER 12 YEARS EXPERIENCE
A. Papanikolaou1, D. Tsolakidis1, S. Pitis1, D. Zouzoulas1, E. Timotheadou2, V. Tzevelekis1, G. Pados1, D. Vavilis1, B. Tarlatzis1
1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece
2Papageorgiou Hospital, Pathological Oncology Clinic, Thessaloniki, Greece

Aims

Ovarian cancer is always a challenge for the gynecologic oncologist. The aim of this study is to present our experience and in the surgical treatment of patients with ovarian cancer.

Method

We conducted a retrospective review of medical records of 334 patients with ovarian cancer, who underwent 346 debulking surgeries (primary, interval and secondary) between January 2004 and December 2016. Cytoreductive and oncological outcomes were reported.

Results

The median age of the patients was 57 years old. 244 (70.5%) underwent primary, 77 (22.3%) interval and 25 (7.2%) secondary debulking surgery. 91 (26.3%) patients had early ovarian cancer and 255 (73.7%) advanced: 16 (4.6%) had FIGO stage IIIA, 31 (9%) stage IIIB, 155 (44.8%) stage IIIC and 53 (15.3%) stage IV. In patients with advanced ovarian cancer, complete and optimal (<1cm) debulking was achieved in 151 (59.2%) and 54 (21.2%), respectively. Pelvic and para-aortic lymphadenectomy was offered to 120 (34.7%) patients. Ultraradical surgical procedures include: bowel resections in 66 (19.1%) patients, splenectomy in 14 (4%) and diaphragmatic surgery in 66 (19.1%). Median disease-free and overall survival for early ovarian cancer was both >133 months. Median disease-free and overall survival for stage III was 17 and 66 months and for stage IV was 11 and 38 months, respectively. Perioperative mortality was 2.6%.

Conclusion

The use of ultraradical procedures in cytoreductive surgery for ovarian cancer is crucial to achieve optimal cytoreduction and improved survival rates.

SPLENECTOMY IN ADVANCED OVARIAN CANCER: A RETROSPECTIVE ANALYSIS IN A TERTIARY GREEK HOSPITAL
D. Tsolakidis1, A. Papanikolaou1, D. Zouzoulas1, S. Pitis1, M. Topalidou2, V. Theodoulidis1, T. Mikos1, E. Bill1, B. Tarlatzis1
1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece
2Papageorgiou Hospital, Radiotherapy Department, Thessaloniki, Greece

Aims

Splenectomy is occasionally required in advanced ovarian cancer patients with upper abdominal disease in order to achieve complete cytoreduction. We present our experience in splenectomy during ovarian cytoreduction.

Method

We retrospectively reviewed the indications, the complications and the oncological outcomes in ovarian cancer patients who underwent splenectomy during cytoreductive surgery in our unit from January 2004 to December 2016.

Results

14 (5.6%) out of 249 patients with advanced ovarian cancer underwent splenectomy during cytoreduction: 3 patients underwent primary, 9 interval and 2 secondary cytoreductive surgery. Splenectomy was performed due to hilar (4 cases), capsular (8 cases), parenchymal involvement (1 case) and 1 case due to spleen intraoperative trauma. Diaphragmatic stripping or coagulation was necessary in 9 (64%) patients, small and large bowel resection was required in 6 (43%) patients and one peripheral pancreatectomy was performed because of pancreatic tail infiltration. Complete and optimal cytoreduction achieved in 8 (57%) and 5 (36%) patients, respectively. Postoperative complications such as pleural effusions were observed in 9 (64%) cases, pelvic abscess formation in two patients and pancreatic leakage/fistula in one of them, who died 10 months after surgery due to rapid disease progression. No case of postoperative severe pneumonia or thrombosis was recorded. Median disease-free survival was 25 and overall survival was 70 months, respectively.

Conclusion

Splenectomy is sometimes necessary in order to achieve complete cytoreduction in advanced ovarian cancer with acceptable perioperative morbidity and increased survival rates.

PREDICTORS OF EXTENDED INTENSIVE CARE UNIT UTILIZATION AFTER SURGERY FOR ADVANCED OVARIAN CANCER

D. Tsolakidis¹, A. Papanikolaou¹, V. Theodoulidis¹, D. Zouzoulas¹, I. Theodoulidis¹, O. Anastasopoulou¹, B. Tarlatzis¹

¹Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

The objectives of this study were to identify variables associated with prolonged, over 48-hour admission to the ICU.

Method

A retrospective analysis of patients admitted to the ICU after surgery for advanced ovarian cancer between 01/2004 and 12/2016 was conducted. Patients admitted to ICU were separated into two groups, depending on the length of stay (48 hours or more). Perioperative variables were compared across the two groups by logistic regression analysis.

Results

255 patients with advanced ovarian cancer underwent primary, interval and secondary debulking. Forty of them (15.6%) were admitted to the ICU. One died after 48 hours of stay and two were readmitted to ICU after 2 and 3 days respectively. Twenty-four of them (60%) required less than 48 hours in ICU. Age, operation time, intraoperative iatrogenic complications, bowel resection, ASA score were significant different between two groups, predicting prolonged stay in the ICU.

Conclusion

Certain criteria can predict if a patient with advanced ovarian cancer may require extensive ICU stay. These data facilitate an appropriate preoperative counseling and enable gynecologic oncologist to identify those patients with ovarian cancer that will benefit most from postoperative ICU admission, helping to improve resources management in favor of patients.

PSOAS MUSCLE AREA IS NOT REPRESENTATIVE OF TOTAL SKELETAL MUSCLE AREA IN THE ASSESSMENT OF SARCOPEANIA IN OVARIAN CANCER

J. Ubachs¹, I. Rutten¹, R. Kruitwagen¹, T. van Gorp¹, R. Beets-Tar², S. Olde Damink³

¹MUMC+, Obstetrics and Gynaecology, Maastricht, The Netherlands
²Netherlands cancer institute, Radiology, Amsterdam, The Netherlands
³MUMC+, Surgery, Maastricht, The Netherlands

Aims

Computed tomography measurements of total skeletal muscle area can detect changes and predict overall survival (OS) in patients with advanced ovarian cancer. This study investigates whether assessment of psoas muscle area reflects total muscle area and can be used to assess sarcopenia in ovarian cancer patients.

Method

Ovarian cancer patients (n=150) treated with induction chemotherapy and interval debulking were enrolled retrospectively in this longitudinal study. Muscle was measured cross-sectionally with computed tomography in three ways: (1) software quantification of total skeletal muscle area (SMA), (2) software quantification of psoas muscle area (PA), and (3) manual measurement of length and width of the psoas muscle to derive the psoas surface area (PLW). Pearson correlation between the different methods was studied. Patients were divided into two groups based on the extent of change in muscle area and agreement was measured with kappa coefficients. Cox-regression was used to test predictors for OS.

Results

Correlation between SMA and both psoas muscle area measurements was poor (r=0.52 and 0.39 for PA and PLW, respectively). After categorising patients into muscle loss or gain, kappa agreement was also poor for all comparisons (all κ < 0.40). In regression analysis, SMA loss was predictive of poor OS (hazard ratio 1.698 (95%CI 1.038-2.778), P=0.035). No relationship with OS was seen for PA or PLW loss.

Conclusion

Change in psoas muscle area is not representative of total muscle area change and should not be used to substitute total skeletal muscle to predict survival in patients with ovarian cancer.
DOES PERITONEAL CARCINOMATOSIS DISTRIBUTION IMPACT SURVIVAL IN ADVANCED EPITHELIAL OVARIAN CANCER: RETROSPECTIVE STUDY OF 102 CASES

J. Uzan-slama¹, C. Ngô¹, A.S. Bats¹, L. Rossi¹, M. Gosset¹, F. Lécuru¹
¹Hopital Européen Georges Pompidou, Gynecologic Surgery, Paris, France

Aims

Background: No residual disease is the major prognostic factor for advanced epithelial ovarian cancer (AEOC). Nonetheless, the prognostic impact of initial tumor load is still a matter of debate, suggesting that some peritoneal carcinomatosis localizations could have a bad prognosis on survival.

Objective: To assess the impact of peritoneal carcinomatosis distribution on progression free survival (PFS) in AEOC patients without residual disease after cytoreductive surgery.

Method

Retrospective monocentric cohort study, from October 2001 to July 2014. Inclusion criteria were high-grade AEOC patients without residual disease after primary debulking surgery (PDS) or after interval debulking surgery (IDS) following neoadjuvant chemotherapy (NACT). Peritoneal carcinomatosis was assessed with operative reports according qualitative and quantitative criteria. Primary endpoint was PFS. Secondary endpoints included PFS in the two sub groups “PDS” and “IDS”.

Results

One hundred and two patients were included. Median PFS was 26.6 months and median OS was 39.9 months. Any peritoneal carcinomatosis localization was associated with PFS in the total group or in the “PDS” sub group. In the “IDS” sub group, histological residual disease and peritoneal carcinomatosis located in an area originated from the anterior intestine were associated with decreased PFS.

Conclusion

Initial tumor load has not been found associated with PFS in general population. These results could be due to a lack of power of our study. Larger-scale studies are needed to assess whether initial tumor load has a prognostic impact even if absence of residual disease is achieved during cytoreductive surgery.

PREDICTION OF RESIDUAL DISEASE AFTER INTERVAL CYTOREDUCTIVE SURGERY FOR EPITHELIAL OVARIAN CANCER

R. van de Vrie1, T. Korse2, M. Karslen3, W. van Driel1, G. Kenter4, C. Lok1

1Netherlands Cancer Institute - Antoni van Leeuwenhoek, Department of Gynecologic Oncology, Amsterdam, The Netherlands
2Netherlands Cancer Institute - Antoni van Leeuwenhoek, Department of Clinical Chemistry, Amsterdam, The Netherlands
3University Hospital of Copenhagen, Department of Gynecologic Oncolog, Copenhagen, Denmark
4Center of Gynaecologic Oncology Amsterdam, Department of Gynecologic Oncology, Amsterdam, The Netherlands

Aims

A poor prognostic feature of advanced epithelial ovarian cancer (EOC) is the presence of residual disease after a maximum effort of cytoreductive surgery. Surgery is of limited benefit when the diameter of remaining tumor lesions is >1 cm. Residual disease is difficult to predict before surgery and an accurate prediction model is needed. The Cancer Ovarii Non-invasive Assessment of Treatment Strategy (CONATS) index, based on serum biomarker HE4, age and WHO performance status, has an accuracy of 85% to predict residual disease in patients undergoing primary cytoreductive surgery (PCS). This model has been tested only in patients undergoing PCS, we evaluated this model in patients undergoing interval cytoreductive surgery (ICS).

Method

Serum was available for 146 patients with advanced EOC who underwent ICS between 2010 and 2016. HE4 was measured with electrochemiluminescence in pre-operative samples. CONATS was used to predict residual disease. Areas under the curve (AUC) was calculated for residual disease > 1 cm.

Results

We included 146 patients with EOC (96 with stage IIIC and 50 with stage IV disease). Following surgery, 71 patients (49%) had no residual disease, 75 patients (51%) had residual disease, of whom 20 had >1 cm disease. The AUC of >1 cm residual disease was 0.79 (95%Ci 0.67-0.91).

Conclusion

The CONATS model predicts surgical outcome of ICS and is useful in counseling patients whether or not a beneficial cytoreduction can be performed. This could be especially helpful in counseling elderly patients or patients with extensive comorbidity in whom surgery has a high risk for complications.
EVALUATION OF ULTRASOUND MODELS IN THE DIAGNOSIS OF ADNEXAL MASSES; A COST-EFFECTIVENESS ANALYSIS

E. Meys1, L. Jeelof1, B. Ramaekers2, C. Dirksen2, L. Kooremans1, B. Slangen1, R. Kruitwagen1, T. Van Gorp1

1Maastricht University Medical Center+ MUMC+, Obstetrics and Gynaecology, Maastricht, The Netherlands
2Maastricht University Medical Center+ MUMC+, Clinical Epidemiology and Medical Technology Assessment KEMTA, Maastricht, The Netherlands
3Maastricht University Medical Center+ MUMC+, Pathology, Maastricht, The Netherlands

Aims

To determine the cost-effectiveness of recently introduced ultrasound models in the diagnosis of adnexal masses compared to the Risk of Malignancy Index (RMI):

- Subjective assessment (SA);
- Simple rules added by subjective assessment (SR+SA);
- Simple rules with inconclusive results diagnosed as malignant (SR+Mal);
- Logistic regression model 2 (LR2); and
- Assessment of Different NEoplasias in the adneXa model (ADNEX).

Method

Potential cost-effectiveness was explored using an economic model, which was limited to short term costs. The comparative sensitivity, specificity and costs of the diagnostic strategies including surgical management and recovery, were explicitly incorporated in the model. The analysis took a hospital perspective including all costs from detection of the mass up to recovery following surgery. Incremental cost-effectiveness was expressed as the costs per correct diagnosis (i.e. either true positive/negative test results).

Results

Although effectiveness was highest for SA, cost of SR+SA were lowest (figure 1). The outcome of the cost-effectiveness analyses was most influenced by specificity. The probability of being the most cost-effective was the highest for the strategy of SR+SA for a wide range of willingness-to-pay thresholds (≤€39,817). RMI had low cost-effectiveness probabilities (<1%).

Conclusion

Although SA is the best diagnostic strategy in terms of diagnostic accuracy, SR+SA is the preferred method from a cost-effectiveness perspective.

POSTOPERATIVE COMPLICATIONS WITH OR WITHOUT THE PREOPERATIVE USE OF BEVACIZUMAB BEFORE INTERVAL DEBULKING FOR STAGE IV OVARIAN CANCER: A CASE-CONTROL STUDY

A. Van Lierde1, R. Salihi1, A. Vanderstichele1, E. Van Nieuwenhuysen1, H. Sileny1, N. Concin1, I. Vergote1

1Leuven cancer institute - University Hospital Leuven,
Department of gynecology and obstetrics - Division of gynecologic oncology, Leuven, Belgium

Aims

We aimed to examine the effect of Bevacizumab (BEV) on postoperative complications when applied together with iv paclitaxel and carboplatin (TC) prior to interval debulking surgery (IDS) in stage IV epithelial ovarian cancer (EOC) patients.

Method

This is a retrospective monocentric study in stage IV EOC patients undergoing IDS between 2010 and 2016 (45 preoperative BEV, 63 NO BEV). BEV was administered in all preoperative courses and IDS was planned 4-6 weeks following the last TC+BEV. Case-controls were selected on the basis of age and whether intestinal resection was needed, resulting in 45 cases and 45 controls. We used the comprehensive complication index (CCI) to determine the overall morbidity during 30 days after the surgery.

Results

All patients had stage IV EOC and an ASA score of 2 or 3 when IDS. Most patients underwent a complete resection (BEV N=43, NO BEV N=44). The median age at time of the IDS with and without BEV was 68 (range 59-73) and 64 (range 36-78) years, respectively.

The mean CCI for BEV and NO Bev was 24,2 and 19,5, respectively (not significant – NS). In the group undergoing bowel resection the CCI for BEV (N=7) and NO BEV (N=7) was 27,3 and 25,9, respectively (NS). Major complications observed were intestinal perforation (BEV N=2, NO BEV N=1) and wound dehiscence (BEV N=4, NO BEV N=2).

Conclusion

BEV prior to IDS tended to increase the complications rate at IDS. This difference was however not significant, even not in patients undergoing bowel surgery.

OPPORTUNISTIC TUBECTOMY IS SAFE IN WOMEN UNDERGOING HYSTERECTOMY FOR BENIGN GYNECOLOGICAL CONDITIONS; RESULTS FROM THE HYSTUB-TRIAL

L. van Lieshout1, B. Pijlman2, C. Vos3, M. de Groot4, S. Houtrman5, S. Coppus6, M. Harmsen6, I. van den Put1, J. Piek1

1Catharina Hospital Eindhoven, Obstetrics and Gynaecology, Eindhoven, The Netherlands
2Jeroen Bosch Hospital, Obstetrics and Gynaecology, ’s Hertogenbosch, The Netherlands
3Elisabeth-Tweesteden Hospital, Obstetrics and Gynaecology, Tilburg, The Netherlands
4Elisabeth-Tweesteden Hospital, Clinical Chemistry and Haematology, Tilburg, The Netherlands
5Catharina Hospital Eindhoven, Education and Research, Eindhoven, The Netherlands
6Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands

Aims

The Fallopian tube is most likely the organ of origin of high grade serous “ovarian” carcinomas. Therefore, opportunistic removal of this organ might lead to a lower incidence. Since this procedure has an opportunistic nature, it should not have adverse effects. To determine whether opportunistic tubectomy in premenopausal women undergoing hysterectomy for benign indications is both hormonally and surgically safe, we conducted this trial. The primary outcome was change in serum Anti-Müllerian Hormone (AMH) concentrations measured preoperative, and 6 months postoperative. Secondary outcomes were surgical parameters such as operative time, blood loss and complication rate.

Method

This multicentre randomised controlled trial was conducted in four hospitals in the Netherlands. A total of 104 premenopausal women, aged 30 to 55 years, were randomly assigned either hysterectomy with opportunistic bilateral tubectomy (N=52) or standard care hysterectomy with preservation of the Fallopian tubes (N=52).

Results

There were no significant differences between the two groups in baseline characteristics and preoperative AMH concentrations (2.21 pmol/L in the intervention group versus 1.24 pmol/L in the control group, P=0.19). Most importantly, postoperative AMH concentrations (2.11 pmol/L in the intervention group versus 1.43 pmol/L in the control group, P=0.35) did not differ significantly. Furthermore, addition of tubectomy to hysterectomy did not lead to poorer surgical outcomes.

Conclusion

Opportunistic bilateral tubectomy in addition to hysterectomy does not lead to a greater decline in ovarian function or poorer surgical outcomes when compared to hysterectomy alone. Therefore, tubectomy is a safe procedure in premenopausal women undergoing hysterectomy for benign indications.

ESGO7-1133

ANNUAL ACTIVITY OF CYTOREDUCTIONS FOR ADVANCED OVARIAN CANCER IN FUNDACION JIMENEZ DIAZ HOSPITAL

D. Vázquez Vicente¹, B. Fernández del Bas¹, J. García Villayzan¹, J. Utrilla-Layna¹, J. Plaza Arranz¹, M. Albi González¹

¹IIS- Fundacion Jiménez Díaz, GINECOLOGY, Madrid, Spain

Aims

To Know the number of patients operated in the FUNDACIÓN JIMÉNEZ DÍAZ HOSPITAL in the last year

To Know primary cytoreduction rate and interval surgery

To Know complete, optimum and suboptimal cytoreduction rate

To Know number of secondary reductions

To know incidence of complications and mortality rate

To know the mean of extirpated nodes

To verify if our service fulfills criteria of quality of advanced ovary cancer of the ESGO

Method

A retrospective review was conducted from September 2015 to August 2016

There were 33 surgeries for advanced ovarian cancer in our hospital

27 Cytoreductions in Ovarian Cancer of New Diagnosis

6 secondary cytoreductions by relapse

Results

Of the 27 cases of new diagnosis:

- 24 (88%) cases of primary cytoreduction
- 3 (12%) of interval surgeries
- 93% complete cytoreduction
- 7% optimal cytoreduction

- Mean of extirpated (pelvic and para-aortic) nodes: 41
- 66% of the patients a bowel resection was performed
- Mortality 0%
- Surgical complications 6%

Conclusion

Our hospital fulfill the criteria of quality indicators for advanced ovarian cancer proposed by ESGO
Aims

Tumor Treating Fields (TTFields), an non-invasive, regional treatment is approved for recurrent and newly diagnosed glioblastoma by the FDA. TTFields deliver intermediate-frequency alternating electric fields to the tumor by disrupting the mitotic spindle formation. INNOVATE is the first trial testing TTFields (200kHz) in ovarian cancer.

Method

Thirty-one recurrent platinum-resistant ovarian cancer patients were treated with TTFields plus weekly paclitaxel. Patients had unresectable tumors, ECOG performance 0-1, and measurable disease per RECIST. The primary endpoint was incidence and severity of treatment-emergent adverse events. Secondary endpoints included progression free and overall survival and radiological response rate.

Results

The median age was 60 (45-77 years), 77% had serous histology, 52% had ECOG score of 0. All patients were platinum-resistant. Ten (32%) patients had serious adverse events (SAEs) during the study, unrelated to TTFields: 31% related to gastrointestinal disorders (ileus, jaundice and ascites) and 31% to respiratory events (dyspnea, pleural effusion and pulmonary embolism). One tumor-related SAE led to permanent discontinuation of the device. Most patients reported mild-moderate TTFields-related skin irritation; only two patients (6.4%) had severe-grade events. Of evaluable tumors, 25% had partial response and 46.4% had stable disease — a clinical benefit of 71.4%. Six patients (19.4%) had a CA125 response: decrease of 50% or more in serum levels. The median OS was not reached.

Conclusion

Data show that TTFields plus weekly paclitaxel are tolerable and safe in heavily pre-treated platinum-resistant ovarian cancer patients. Further testing of TTFields with chemotherapy in ovarian cancer is warranted.

PERIOPERATIVE POSITIONING MANAGEMENT IN GYNECOLOGIC CANCER SURGERY: A NATIONAL NOGGO-AGO INTERGROUP SURVEY

1Park-Klinik Weissensee, Department of Gynecology, Berlin, Germany
2Kliniken Essen-Mitte, Department of Gynecology, Essen, Germany
3Charite-Universitätsmedizin Berlin, Department of Gynecological Oncology, Berlin, Germany
4University Hospital Munich-Großhadern, AGO and Department of Gynecology, Munich, Germany
5University Medical Center Hamburg-Eppendorf, AGO and Department of Gynecology, Hamburg, Germany
6Euregio-Klinik, Department of Gynecology and Obstetrics, Nordhorn, Germany
7Donau-Isar-Klinikum, Department of Gynecology and Obstetrics, Deggendorf, Germany
8Charite-Universitätsmedizin Berlin, Department of Gynecology, Berlin, Germany
9Charite-Universitätsmedizin Berlin- Campus Virchow Klinikum, AGO and Department of Gynecology, Berlin, Germany

Aims

Approximately 4% of all medical complications are perioperative positioning injuries. Aims of the survey were the analysis of perioperative positioning management in gynaecologic-oncological surgery, the process- and structure-reliability and the implementation of current guidelines into daily clinical practice.

Method

We sent an anonymous multiple-choice questionnaire to all gynecological departments in Germany. Sixty questions were divided into five different parts: 1) descriptive information about the department, 2) focus on the pre- and postoperative management, 4) on the quality management, and 5) information regarding the positioning management in the operation room based on two fictional case examples in gynecologic oncology procedures.

Results

184 of 633 departments participated in the survey (June-September 2016). 48.8% of all participating departments declared complications related to intraoperative positioning, independent from department size. Knowledge of the current guideline on positioning did not impact the incidence of complications. Positioning of the patient was mentioned in the team-time-out procedure in 66.1% of the participating departments. No difference was found between high-volume and low-volume gynecologic oncologic operative departments with regard to the use of supportive tools such as anti-thrombotic leg pumps. 92.7% included information of positioning injuries into the written informed consent. Knowledge of the guideline or a previous legal dispute did not influence the willingness to inform about possible positioning-related complications.

Conclusion

The awareness of perioperative positioning management in gynecologic cancer surgery is high throughout all departments in Germany. Almost half of all 184 participating departments report positioning-related complications in the previous 12 months, stressing the importance of this often underrated topic.
TUMOR TREATING FIELDS (TTFields) COMBINED WITH PACLITAXEL ENHANCES TREATMENT EFFICACY IN VITRO AND IN A MURINE MODEL OF OVARIAN CANCER

Novocure, Research and Development, Haifa, Israel
Novocure, Founder, Haifa, Israel

Aims

Long-term survival rates for advanced ovarian cancer have not changed over the past four decades justifying the development of new, effective treatment modalities. Tumor Treating Fields (TTFields), an approved anticancer modality, utilizes low-intensity, intermediate frequency, alternating electric fields to inhibit tumor growth. We evaluated the efficacy of combining TTFields with paclitaxel against ovarian cancer cells in vitro and in vivo.

Method

TTFields were applied for 72 hours to human ovarian cells (A2780, OVCAR-3, Caov-3) using the invitro system (Novocure). In vivo effect of the combined treatment was tested in mice orthotopically implanted with MOSE-LFL cells. TTFields delivery to the human abdomen was examined using finite element mesh simulations (Sim4life software).

Results

TTFields-treated ovarian cancer cell lines showed significant reduction in cell counts versus untreated cells. The effect was frequency and intensity dependent with a maximal effect observed at 200 kHz. Further reduction in the viable cells counts was achieved when TTFields were combined with paclitaxel. Combined treatment showed significant reduction in tumor luminescence and tumor weight versus untreated mice. Electric fields simulations demonstrated that the intensities inside and in the vicinity of the ovaries of a realistic human computational phantom are about 1 and 2 V/cm pk-pk, respectively, which is within the range of intensities required for TTFields effect.

Conclusion

TTFields plus paclitaxel enhances treatment efficacy in vitro and in vivo. TTFields was effectively delivered through a large nonuniform volume encompassing both ovaries and potential metastatic sites. Results support combination of TTFields with paclitaxel in ongoing clinical trial (INNOVATE) in recurrent ovarian-carcinoma.
A COMPUTATIONAL MODEL FOR STUDYING THE DELIVERY OF TUMOR TREATING FIELDS FOR THE TREATMENT OF OVARIAN CANCER

U. Weinberg\textsuperscript{7}, Z. Bomzon\textsuperscript{2}, N. Urman\textsuperscript{3}, A. Naveh\textsuperscript{4}, H.S. Hershkovich\textsuperscript{5}, O. Yesharim\textsuperscript{6}, E. Kirson\textsuperscript{8}

\textsuperscript{3}Novocure, Scientific Affairs, Haifa, Israel
\textsuperscript{4}Novocure, Scientific Affairs, Haifa, Israel
\textsuperscript{5}Novocure, Scientific Affairs, Haifa, Israel
\textsuperscript{6}Novocure, Scientific Affairs, Haifa, Israel
\textsuperscript{7}Novocure, Clinical Development, Root, Switzerland
\textsuperscript{8}Novocure, Research and Development, Haifa, Israel

Aims

Tumor Treating Fields (TTFields) are alternating electric fields in the intermediate frequency (100-300 kHz) known to inhibit the growth of solid tumors. A phase II clinical trial (INNOVATE) tested the feasibility and safety of TTFields for the treatment of advanced ovarian cancer. Optimizing the delivery of TTFields requires an understanding of how TTFields distribute within the body. Since measuring the electric fields in human subjects is technically difficult, numerical simulations are an excellent tool for performing such studies. Here we report on a simulation-based study examining the distribution of TTFields when treating ovarian cancer.

Method

To simulate delivery of TTFields to the abdomen, we used a realistic computerized model of a human female (ELLA 3.0 from ZMT-Zurich). Two pairs of transducer arrays were placed on the skin of the model: one pair of arrays was placed on the lower abdomen and back, while the second pair of arrays was placed laterally. To deliver TTFields, electric currents of 4A peak to peak at frequency of 200 KHz were delivered to the arrays.

Results

The simulations showed that the electric field was confined to the lower abdomen and pelvis, which is the volume located between the transducer arrays. The field was heterogeneous with intensity exceeding 1 V/cm in significant portions of the treated volume.

Conclusion

Our results suggest that TTFields can be delivered effectively to the ovaries and surrounding tissues. This work forms the basis for developing optimal strategies for delivering TTFields when treating ovarian cancer.

PATHOLOGIC DISTRIBUTION OF DISEASE DURING INTERVAL DEBULKING VERSUS PRIMARY TUMOR REDUCTION IN PRIMARY PERITONEAL, OVARIAN, OR FALLOPIAN TUBE CARCINOMA

R. Previs\(^1\), C. Bailey\(^2\), B. Fellman\(^2\), T. Zaid\(^1\), M. Huang\(^1\), A. Brown\(^1\), E. Ahmed\(^1\), B. Nyla\(^1\), R. Broaddus\(^2\), D. Bodurka\(^1\), A. Sood\(^1\), S. Westin\(^1\)

\(^1\)The University of Texas MD Anderson Cancer Center, Department of Gynecologic Oncology & Reproductive Medicine, Houston, USA
\(^2\)The University of Texas MD Anderson Cancer Center, Department of Biostatistics, Houston, USA
\(^3\)The University of Texas MD Anderson Cancer Center, Department of Pathology, Houston, USA

Aims

The surgical approach for primary tumor reductive surgery (PTRS) for primary peritoneal, ovarian or fallopian tube carcinoma has been used to extrapolate the technique for interval debulking after neoadjuvant chemotherapy (NACT). Few studies have evaluated whether procedures such as hysterectomy contribute to comparable removal of macroscopic disease after NACT. Our study compared pathologic distribution of disease after NACT versus PTRS.

Method

Patients who underwent NACT or PTRS were identified from 1995-2016. Involvement of organs at surgery was categorized as either macroscopic, microscopic, or no tumor. Statistical analyses included Mann-Whitney and chi-squared or Fisher’s exact tests.

Results

Of the 1000 patients identified, 374 (37.7%) received NACT and 618 (62.3%) underwent PTRS. Uterine involvement was significantly different in the NACT group compared to PTRS; the majority of uterine specimens from the NACT group were free of disease (macroscopic 30 % vs 49%, no tumor 52% v. 39 %, \(p <0.001\)). There was no difference in the amount of residual tumor in cervical specimens in the NACT group compared to PTRS (macroscopic 7.2% v. 6.6%, no tumor 90% v. 91.4%). Macroscopic large bowel involvement was 63.6% in NACT versus 84.7% in the PTRS versus (\(p < 0.001\)). There were statistically significant differences in the pathologic characteristics of disease in the ovaries/tubes, omentum, and bowel.

Conclusion

Pathologic disease distribution after NACT is significantly different than at PTRS. NACT appears to reduce macroscopic disease in surgical specimens. Hysterectomy including removal of the cervix may not be mandatory after NACT to achieve no gross residual disease.

AUDIT OF PATIENT PROFILE AND SEQUENCING OF THERAPY IN OVARIAN CANCER AT A TERTIARY HOSPITAL IN SOUTH AFRICA (2010-2014)

E. Wethmar¹, G. Dreyer²

¹University of Pretoria, Obstetrics and Gynaecology, Pretoria, South Africa
²University of Pretoria, Obstetrics and Gynaecology, Pretoria, South Africa

Aims

Ovarian cancer has the highest mortality rate of all female genital tract cancers. The first step in addressing the mortality rate of a disease is investigating the current trends in patient profile, disease profile and treatment profile. There is no data available describing these parameters in our setting. The aim of this study therefore was to describe the aforementioned in our setting.

Method

This retrospective clinical audit was conducted at the Steve Biko Academic Hospital in Pretoria, South Africa. The data was collected by reviewing the files of patients presenting with primary ovarian cancer in the time period 1 January 2010 – 31 December 2014. 140 patients were included. The data was electronically captured and all analysis was conducted in SPSS V 23.

Results

The mean age of diagnosis is 59 years. The intended primary treatment for 101 patients was surgery, for 24 patients was chemotherapy and 15 patients were palliated. 60.4% of the patients had a complete debulking surgery. 6 out the 24 patients referred for primary chemotherapy were evaluated for chemotherapy and 3 patients received the treatment. Of the 101 subjects that had an intended primary plan for surgery, 62 had adjuvant chemotherapy scheduled, and 22 patients received chemotherapy.

Conclusion

The findings of this study emphasize the need for a standard treatment protocol and improvement in the referral system between the Gynaecological Oncology Department and Medical Oncology Department in our unit.
SIGNIFICANCE OF PD-1 AND PD-L1 EXPRESSION IN OVARIAN CANCER BIOLOGY

1Medical University Innsbruck, Department of Obstetrics and Gynecology, Innsbruck, Austria
2Medical University Innsbruck, Division of Human Genetics, Innsbruck, Austria
3Medical University Innsbruck, Institute of Pathology, Innsbruck, Austria
4Academic Teaching Hospital of the Medical University Graz, Department of Pathology, Innsbruck, Austria

Aims

Induction of checkpoint molecules such as programmed cell death protein (PD-1) and its ligand PD-L1 is an essential step in tumor immune escape which may be regulated by interferon gamma (IFNγ, encoded by IFNG). Therapeutically, antibodies against PD-1 or PD-L1 restore T-cell immunogenicity and suppress tumor progression. Here, we investigate the role of intratumoral PD-1 and PD-L1 mRNA expression in ovarian cancer (OC) and explore its relation to IFNγ.

Method

We analyzed the mRNA expression of PD-1, PD-L1 and IFNγ determined by quantitative real-time PCR in tissue of 171 patients with low grade serous (LGSOC; n=11), high grade serous (HGSOC; n=107), endometrioid (n=43) and clear cell (n=10) OC and compared it to each 14 normal ovaries and fallopian tubes.

Results

We observed an induction of the PD-1 pathway in OC tissue compared to healthy controls. Further, a significant correlation between PD-1, PD-L1 and IFNγ expression was detected. PD-1 and PD-L1 mRNA expressions increased with tumor grade. However, only high PD-L1 mRNA expression was inversely associated with age. Notably, we further found that TP53 mutated tumors exhibited high PD-L1 levels and BRCA1/2 mutations were associated with both high PD-1 and PD-L1 levels. In the cohort of FIGO stage III/IV HGSOC, which represents the major subgroup, high PD-1 and high PD-L1 was associated with an adverse progression-free and overall survival, respectively.

Conclusion

Our study suggests that the PD-1 pathway is controlled by IFNγ in OC and is especially involved in immune biology of poorly differentiated, BRCA1/2 or TP53 mutated cancers.

ERCC1-EXPRESSING CIRCULATING TUMOR CELLS AS A POTENTIAL DIAGNOSTIC TOOL FOR MONITORING PLATINUM-BASED CHEMOTHERAPY AND FOR PREDICTING OUTCOME OF OVARIAN CANCER

P. Wimberger¹, I. Chebouti², J.D. Kuhlmann³, P. Buderath⁴, S. Weber⁴, Y. Bokeloh⁵, S. Hauch³, R. Kimmig², S. Kasimir-Bauer²

¹Carl-Gustav-Carus University Dresden- TU Dresden, Gynecology and Obstetrics, Dresden, Germany
²University Hospital of Essen, Gynecology and Obstetrics, Essen, Germany
³Carl-Gustav-Carus- University Dresden- TU Dresden, Gynecology and Obstetrics, Dresden, Germany
⁴Acomed Statistik, Acomed Statistik, Leipzig, Germany
⁵Qiagen, Qiagen, Hilden, Germany

Aims

We recently showed that the presence of ERCC1+CTCs (defined as positive for at least one of the AdnaTest markers and ERCC1-positivity), is an independent predictive biomarker for primary platinum-resistance and poor prognosis of ovarian cancer. The aim of our study was to determine, whether the additional assessment of ERCC1-transcripts increases the overall CTC-detection rate. Moreover, we analyzed clinical relevance of ERCC1+CTCs after adjuvant chemotherapy.

Method

65 paired blood samples of primary ovarian cancer patients at primary diagnosis and after adjuvant chemotherapy were studied for CTCs with the AdnaTest OvarianCancer (QIAGEN, Germany). We analyzed the tumor-associated transcripts EpCAM, Muc-1 and CA-125. ERCC1-transcripts were investigated in a separate approach by singleplex RT-PCR.

Results

Besides Adnatest+CTCs, the additional assessment of ERCC1 allows the detection of CTCs, which are negative for AdnaTest markers and exclusively positive for ERCC1-transcripts (Adnatest+ERCC1+CTCs). This results in an increased overall CTC-detection rate from 23% to 40% before surgery and from 20% to 38% after chemotherapy. However, CTCs with combined positivity for at least one Adnatest marker and ERCC1-positivity (ERCC1+CTCs) showed the most relevant prognostic information and correlated with platinum-resistance (p=0.01) and reduced PFS (p=0.029) and OS (p=0.0008). Moreover, the persistence of ERCC1+CTCs after adjuvant chemotherapy indicated poor prognosis (PFS: p=0.005; OS: p=0.006).

Conclusion

The combined detection of Adnatest+ERCC1+CTCs and Adnatest+ERCC1+CTCs increases the overall detection rate of CTCs in ovarian cancer patients. Specifically, we suggest that ERCC1+CTCs could be used as blood-based biomarker for monitoring platinum-based chemotherapy and for identifying ovarian cancer patients with poor prognosis.

7Roche Pharma AG, Biostatistics and Epidemiology, Grenzach-Wyhlen, Germany
8Roche Pharma AG, Medical Affairs, Grenzach-Wyhlen, Germany
9St. Vincentius-Kliniken, Department of Gynecology, Karlsruhe, Germany

Aims

Phase III trials demonstrated the efficacy and safety of front-line bevacizumab-containing therapy for ovarian cancer. Previous interim analyses of the single-arm OTILIA study (NCT01697488) evaluating front-line bevacizumab-containing therapy in German clinical practice showed a 21.7-month median progression-free survival (PFS) and similar outcomes irrespective of age. Post hoc analyses explored factors potentially predicting premature treatment discontinuation and PFS.

Method

Patients with newly diagnosed FIGO stage IIIB–IV ovarian cancer received the EU-approved bevacizumab-containing regimen. Co-primary endpoints were safety and PFS. A logistic regression model including age, diabetes mellitus, cardiovascular comorbidities, ascites, ECOG performance status and FIGO stage assessed factors associated with treatment discontinuation for reasons other than disease progression, death or documentation completion. Potential prognostic factors for PFS were explored using Cox regression analysis.

Results

By 31/01/2017, 433 of 808 patients had discontinued therapy. The most common reasons for treatment discontinuation were disease progression (12%), end of documentation (10%), treatment-related toxicity (8%) and non-toxicity-related patient request (6%). Factors suggesting increased risk of treatment discontinuation were age ≥70 versus <70 years (odds ratio 1.67 [95% CI 1.18–2.38]; p=0.004) and diabetes mellitus (odds ratio 1.79 [95% CI 1.06–3.03]; p=0.030). Cox regression analysis suggested worse PFS in patients with post-operative residual tumour ≥1cm or ascites >500mL; age and comorbidities were not associated with PFS.

Conclusion

In post hoc analyses, premature bevacizumab discontinuation seemed more likely in older or diabetic patients. However, neither age nor comorbidities was associated with worse PFS. Patient education and counselling are essential to ensure maximal duration of effective therapy.
AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE STUDY OF TRABECTEDIN PLUS PEGYLATED LIPOSOMAL DOXORUBICIN (PLD) IN PATIENTS WITH PLATINUM-SENSITIVE RECURRENT OVARIAN CANCER (PSROC)

³Lahn-Dill-Kliniken GmbH- Gynäkologie und Geburtshilfe, Onkologie, Wetzlar, Germany
⁴Agaplesion Diakonieklinikum Rotenburg GmbH- Frauenklinik - Gynäkologie und gynäkologische Onkologie- Geburtshilfe und Perinatologie, Onkologie, Rotenburg, Germany
⁵Städtisches Krankenhaus Kiel GmbH, Medical oncology, Kiel, Germany
⁶Klinikum der Friedrich-Schiller-Universität Jena - Klinik für Frauenheilkunde, Onkologie, Jena, Germany
⁷Charité Universitätsmedizin Berlin, Medical oncology, Berlin, Germany

Aims

The prospective, non-interventional phase IV OVA-YOND study evaluated trabectedin+PLD in real-life clinical practice to assess the toxicity and efficacy of the combination.

Method

Data from patients with PSROC treated with PLD 30 mg/m² followed by trabectedin 1.1 mg/m² 3-h i.v. infusion every three weeks have been collected.

Results

From 02/2013-12/2016, 77 enrolled patients from 31 sites across Germany and treated with ≥1 cycle of trabectedin+PLD were evaluated. All patients had PSROC with a median platinum-free interval of 12 months (range: 6-86 months). Median age of patients was 66 years (range: 40-78) and 80.5% had ECOG performance status 0/1. Median number of trabectedin+PLD cycles received per patient was 6 up to a maximum of 21 cycles. Median treatment duration was 4.24 months, mostly on an outpatient basis (≥66.7). Five patients (6.5%) had a complete response and 19 patients (24.7%) achieved a partial response for an ORR of 31.2% with a median duration of 6.25 months. Additionally, 16 patients (20.8%) had a disease stabilization for a disease control rate of 51.9%. With 64 PFS events recorded, median PFS was 6.3 months (CI95%: 5.1-7.3), whereas median OS was 16.4 months (CI95%: 11.3-19.3). Most common grade 3/4 trabectedin-related adverse events (TRAЕ) were leukopenia (18.2% of patients), neutropenia (15.6%), thrombocytopenia (9.1%), ALT (7.8%)/AST (6.5%) increase, and nausea/vomiting (5.2% each). No grade 5 or unexpected TRAE occurred.

Conclusion

Trabectedin+PLD confer clinically meaningful benefit to patients with PSROC, being either comparable or better to those observed in selected populations from clinical trials or other real-life studies, with a manageable safety profile.

5St'Johns Center Lublin Oncology, II Department of Gynecology, Lublin, Poland
6Medical Faculty of University of Rzeszów, Centre for Innovative Research in Medical and Natural Sciences, Rzeszów, Poland

Aims

Objective

Human invariant natural killer T (iNKT) cells are a newly discovered lymphocyte subpopulation with a restricted T-cell receptor Vα24Jα18. They play a crucial role in immunoregulation and antitumor activities. Our study focused on the assessment of iNKT cells in peripheral blood and tissue of benign and borderline ovarian tumors (BOTs) and in advanced-stage ovarian cancer.

Method

The study group consisted of 25 women with benign ovarian tumors, 11 patients with BOTs, and 24 women with primary advanced-stage (FIGO stages III or IV) ovarian cancers (OC). The control group was composed of 20 patients without ovarian pathology. The percentages of iNKT lymphocytes in peripheral blood and tissue specimens were assessed with a flow cytometry.

Results

A significant difference in the percentage of iNKT+/CD3+ of CD3+ lymphocytes, iNKT+/CD3+/CD161+ among CD3+ and iNKT+/CD3+/CD161+ among CD3+/iNKT+ between control group and patients with ovarian tumors in the peripheral blood and tumor tissue was found (Figure1,2). Significant correlations were noted between the percentage of lymphocytes iNKT+/CD3+/CD161+ of CD3+/iNKT cells in blood and those present in tumor tissue of both benign and malignant tumors. In the OC group, neither percentage of iNKT cells in blood (P=0.07), nor intratumor NKT-cell infiltration (P=0.5) were independent prognostic factors (Figure3).

Conclusion

An increased percentage of iNKT cells was observed in benign ovarian tumors compared to OCs. In ovarian cancer, a higher percentage of iNKT cells was present in tumor tissue that patient’s blood. Finally, the percentage of iNKT cells in blood or tumor tissue infiltration was not a significant prognostic factor for advanced-stage OCs patients.
SURGICAL MANAGEMENT OF OVARIAN CANCER AT THE UNIVERSITY HOSPITAL OF WALES: UTILISATION OF SURGICAL SERVICES IN ADVANCED OVARIAN CANCER

A. Wong¹, R. Jones¹, E. Rzyska¹, A. Sharma¹, R. Howells¹, K. Lim¹, F. Drews¹
¹University Hospital of Wales, Obstetrics and Gynaecology, Cardiff, United Kingdom

Aims

This project aimed to review how often colorectal procedures were performed by gynaecological oncologists and identify the frequency and extent other surgical specialties were involved in the management of advanced ovarian cancer (FIGO II-IV).

Method

A retrospective analysis reviewing all operations on stage II-IV ovarian cancers documented at University Hospital of Wales, Cardiff. All stage 1 disease and ovarian metastasis of other primaries were excluded.

Results

A total of 106 cases were identified from September 2014 to September 2016. 33 cases (31%) required assistance from other specialties; colorectal (49%), hepatobiliary (24%), urology (12%), vascular (9%) and general surgeons (6%).

The primary procedures included total abdominal hysterectomy and bilateral salpingo-oopherectomy (73%), unilateral/bilateral salpingo-oopherectomy (17%). While 9% had either explorative laparotomy, adhesiolysis or hernia repair.

16 cases required a colorectal procedure, the most common being Hartmann’s procedures and resection of transverse colon with primary anastomosis. The data showed a 67% primary anastomosis rate. 73% of cases requiring colorectal intervention did not have residual disease.

28 cases had additional non-gynaecological surgical procedures by gynaecological oncologists, for example repair of serosal bowel injuries (22%), appendectomy (9%), Hartmann’s procedure (9%) and ureteric stenting (12%). 57% of these cases did not have residual disease.

Conclusion

Our data demonstrates approximately a third of patients required surgical support from the colorectal team. A system to identify patients preoperatively who are likely to need external support would be useful and help improve patient outcomes in the future.

ARID1A MUTATION WITH LOSS OF PROTEIN EXPRESSION OF BAF250A MAY ACT AS AN EARLY EVENT IN THE TRANSFORMATION OF ENDOMETRIOSIS INTO OVARIAN CANCER

C.H. Wu¹, H. Lin¹, Y.C. Ou¹, C.C. Haung²

¹Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Chang Gung Memorial Hospital, Pathology, Kaohsiung, Taiwan R.O.C.

Aims

Ovarian clear cell carcinoma (CCC) and endometrioid adenocarcinoma (EMC), regarded as endometriosis-associated ovarian cancer, are the second most frequent types of epithelial ovarian cancer (EOC) accounting for 35~40% of EOC in Asia. Mutation of ARID1A (the AT-rich interactive domain 1A (SWI-like) gene) resulting in inactivation of its encoding nuclear protein, BAF250a, has been frequently identified in these tumors. The timing of loss of ARID1A protein expression during the development of endometriosis-related ovarian cancer would be investigated in this study.

Method

We retrospectively collected the cases diagnosed as CCC or EMC from 2001 to 2012 and further analyzed the expression of protein BAF250a from tumor blocks containing benign endometriosis, CCC or EMC by immunohistochemical study.

Results

During 2001 and 2012, 94 CCC and 136 EMC were collected and loss of ARID1A expression was found in 47 (50.6%) cases in CCC and 26 (18.9%) cases in EMC, respectively. 22 (23.4%) of CCC and 14 (10.3%) of EMC were disclosed having concurrent endometriosis in tumor side, and 82% (17 of 22) in CCC and 100% (5 of 5) in EMC of atypical endometriosis, adjacent to those ARID1A-deficient carcinoma were also found to be ARID1A deficient, comparing to none of the endometriotic epithelium not adjacent to the tumor (distant endometriosis foci).

Conclusion

In our study, it indicated that loss of expression of ARID1A might already present in a portion of atypical endometriosis, which possibly has undergone genetic alteration, indicating a risk of malignant transformation from benign endometriosis to CCC and EMC.

3All India Institute of Medical Sciences, Department of Ocular Pathology- Dr. R. P. Centre for Ophthalmic Sciences, New Delhi, India
4All India Institute of Medical Sciences, Department of Pathology, New Delhi, India
5All India Institute of Medical Sciences, Department of Obstetrics and Gynecology, New Delhi, India
6All India Institute of Medical Sciences, Department of Radiotherapy, New Delhi, India

Aims

Our objective was to identify a panel of salivary protein signatures which may have potential for detection of ovarian cancer. Further it can contribute to development of self tests since it can be collected easily.

Method

Differentially expressed Salivary proteins between ovarian cancer patients and matched healthy control subjects were identified by Fluorescence-based differential in-gel electrophoresis (DIGE) coupled with mass spectrometry. The expression levels of three differential proteins A, B and C were confirmed and validated by using western blot and ELISA respectively. Then, the selected salivary signatures were shown to be positive by immunohistochemistry in an independent cohort of ovarian tissue. Further these salivary signatures were also confirmed by gene expression profiling of tumors by microarray analysis followed by validation using qRT-PCR.

Results

Forty four differentially expressed proteins having significant differential expression (p < 0.05) were identified. Out of 44 identified proteins between normal healthy controls and ovarian cancer patients, 25 proteins were found to be up-regulated and 19 proteins were down-regulated. A, B and C were significantly increased in saliva of ovarian cancer patients, with the highest levels in invasive disease. Microarray and q-RT-PCR analysis also confirmed that A, B and C expression was significantly upregulated in ovarian cancer tissue.

Conclusion

This study provides the proof of concept of salivary biomarkers for the non-invasive detection of ovarian cancer. This ‘dual-omic’ strategy based identified tumour secreted proteins whose saliva concentrations are increased significantly could serve as a promising biomarker for identifying individuals with poor prognostic potential.

THE USEFULNESS OF COPY NUMBER AMPLIFICATION OF FGF3/FGF4 FOR PREDICTING THE EFFICACY OF TARGETED THERAPEUTIC AGENTS FOR OVARIAN CANCER

W. Yamagami1, F. Kataoka1, T. Hirano1, K. Sakai1, T. Makabe1, T. Ninomiya1, H. Nomura1, A. Hirasawa1, E. Tominaga1, H. Tsuda2, K. Nishio3, D. Aoki1

1Keio University School of Medicine, Obstetrics and gynecology, Tokyo, Japan
2Mizuho Women’s Clinic, Obstetrics and Gynecology, Tokyo, Japan
3Kindai University School of Medicine, Genome Biology, Osaka, Japan

Aims

The response rate of targeted therapeutic agents for recurrent ovarian cancer is lower than that of cytotoxic chemotherapy; the development of a companion diagnosis that predicts the response is necessary. The prediction of the effect of targeted therapeutic agents for hepatocellular carcinoma (HCC) using a copy number assay for FGF3 and FGF4 has been reported. Therefore, we aimed to develop the method for predicting the response of targeted molecular treatment in ovarian cancer.

Method

In this study, we analysed 14 ovarian cancer cell lines and 123 patients who were pathologically diagnosed with serous, endometrioid or clear cell adenocarcinoma of the ovary. A copy number assay of FGF3 and FGF4 was performed using DNA extracted from the tumour cells or the cancerous lesions scratched from paraffin-embedded sections. A cytotoxicity assay for ovarian cancer cell lines was performed to investigate the IC50 of the targeted therapeutic agents.

Results

The copy number amplification (>4) of FGF3 or FGF4 was found in 14% of serous carcinoma, 6% clear cell carcinoma, and 24% endometrioid carcinoma cases; however, no patients exhibited an extremely high copy number as observed with HCC. There were no significant differences in the clinicopathological factors and prognosis between the cases with amplified and normal copy numbers. The IC50 was extremely low in one cell line in which the FGF3/FGF4 copy number was substantially increased.

Conclusion

The copy number amplification of FGF3/FGF4 may be a useful predictive marker of sorafenib sensitivity in ovarian cancer.
THERAPEUTIC SIGNIFICANCE OF FULL LYMHPHADENECTOMY IN EARLY-STAGE OVARIAN CLEAR CELL CARCINOMA

H. Yamazaki, Y. Todo, H. Kato

HOKKAIDO CANCER CENTER, Gynecology, Sapporo, Japan

Aims

The aim of this study was to evaluate a therapeutic significance of full lymphadenectomy in early-stage ovarian clear cell carcinoma (OCCC).

Method

We retrospectively reviewed records of 127 consecutive OCCC patients with pT1/pT2 and M0 disease between January 1995 and December 2015. Survival outcome was compared with or without para-aortic lymph node dissection (PAND). Statistical analysis for selec were analyzed with Cox proportional hazard models.

Results

Of the 127 patients, 36 (28%) patients did not undergo lymphadenectomy and 12 (10%) patients underwent pelvic lymph node dissection (PLND) alone. Seventy-nine (62%) patients underwent PLND and PAND. Of the 91 patients with lymphadenectomy, ten (11%) had lymph node metastasis. There was no significant difference in age and distribution of positive peritoneal cytology, pT status, capsule rupture, peritoneal involvement, and combined chemotherapy between the PAND- group and the PAND+ group. Cox regression multivariate analysis confirmed that older age (HR, 2.5; 95% CI, 1.2–5.3), lymph node metastasis (HR, 5.4; 95% CI, 1.7–17.2), and positive peritoneal cytology (HR, 5.1; 95% CI, 2.0–13.2) were significantly and independently related to poor overall survival (OS), but implementation of both PLND and PAND (HR, 0.4; 95% CI, 0.2–0.9) were significantly and independently related to improved OS.

Conclusion

Although few in number, there are some patients with early-stage OCCC who can benefit from full lymphadenectomy. Its therapeutic role should be continuously investigated in OCCC patients at potential risk of lymph node metastasis.
ESTABLISHMENT AND CHARACTERIZATION OF A HUMAN OVARIAN CLEAR CELL CARCINOMA CELL LINE (FDOV1) DERIVED FROM A CHINESE PATIENT

W. Jiang¹, S. Ye¹, L. Xiang¹, W. Yang², T. He¹, X. Pei¹, H. Yang¹
¹Fudan University Shanghai Cancer Center, Department of Gynecologic Oncology, Shanghai, China
²Fudan University Shanghai Cancer Center, Department of Pathology, Shanghai, China

Aims

Ovarian clear cell carcinoma (OCCC) is a distinct histologic subtype with grave survival. The underlying molecular mechanism is not fully elucidated. Cell lines are useful experimental tools for research. We describe the establishment and characterization of a new OCCC cell line from a Chinese patient.

Method

FDOV1 was derived from an ovarian tumor from a 67-year-old woman. The morphology, growth pattern and karyotype were analyzed. Xenografts were established and characterized by histology and immunohistochemistry. Subsequently, whole-exome sequencing (WES) on both FDOV1 and patient’s formalin-fixed paraffin-embedded tissue block was performed to investigate the molecular profile.

Results

FDOV1 has been subcultured for more than 50 generations. Monolayer cultured cells are polygonal in shape, showing a transparent cytoplasm full of vacuoles (Fig 1.A). The number of chromosomes ranges from 45 to 90 (Fig 1.B). FDOV1 cells produces CA-125, but not CA-199. The cells could be transplanted (Fig 1.C) and produced tumors mimicking the donor tumor morphologically and immunohistochemically (Fig 1.D). WES showed both FDOV1 and tissue block harbored PIK3CA H1047R
mutation and ARID1A frameshift mutations (p.L2106fs, p.N201fs).

Conclusion

Only 13 patient-derived OCCC cell lines have been reported in the literature. FDOV1 is the very first one from a Mainland Chinese patient and has co-existing PIK3CA and ARID1A mutations, which would probably be a good model for exploring the molecular mechanism of OCCC.

ALTERATION OF THE TUMOR MICROENVIRONMENT BY NOTCH SIGNALING ENHANCES THE MUTUAL ASSOCIATION WITH EPITHELIAL OVARIAN CANCER AND MESOTHELIAL CALLS

M. Yoshihara, H. Kajiyama, M. Sugiyama, F. Kikkawa

1Nagoya University, Obstetrics and Gynecology, Nagoya, Japan

Aims

Peritoneal mesothelial cells (PMCs) are the primary components of the tumor microenvironment for epithelial ovarian cancer (EOC) cells. The Notch signaling-mediated alteration of the tumor microenvironment can play a crucial role in tumor progression; however, the exact role of Notch signaling between EOC and PMCs remains uncertain. The aim of this study was to assess changes of PMCs in the association with EOC, focusing on Notch pathways.

Method

We examined the effects of TGF-β1 treated PMCs on EOC progression via Notch signaling inhibition and analyzing how PMCs promote EOC cells attachment and proliferation, and induced chemoresistance.

Results

Level of TGF-β1 is higher in malignant ovarian tumor compared with benign ones. With TGF-β1 stimulation, expression of Notch 3 and Jagged 2 were increased in PMCs in immune-blotting analysis. We also confirmed elevation of HES1, a target gene of Notch signaling in TGF-β1 stimulated PMCs. We investigated the effects of TGF-β1 treated PMCs on EOC, using FACS systems, and revealed that EOC cells co-cultured with TGF-β1 stimulated PMCs showed higher chemoresistance than with control PMCs. In the EOC cells with TGF-β1 stimulated PMCs, Jagged 1, Notch3, and HES1 were elevated compared with control.

Conclusion

PMCs stimulated with TGF-β1 induced heterogeneity of EOC cells via Notch signals. Our results suggested that alteration of the tumor microenvironment by Notch signaling were effectively enhanced in the mutual association with chemoresistant EOC and PMCs.

NFKB SIGNALING PATHWAY AS A THERAPEUTIC TARGET IN CHEMORESISTANT OVARIAN CANCER

H. Yousefi\textsuperscript{1}, M. Momeny\textsuperscript{1}, A. Poursheykhani\textsuperscript{1}, S.H.A. Ghaffari\textsuperscript{1}, H. Eyvani\textsuperscript{1}, G. Zarrinrad\textsuperscript{1}, F. Barghi\textsuperscript{1}, Z. Sabourinejad\textsuperscript{1}, F. Esmaili\textsuperscript{1}

\textsuperscript{1}Tehran University of Medical Sciences, Medical Genetics, Tehran, Iran

Aims

Despite advances in surgical debulking and chemotherapy regimens, epithelial ovarian cancer (EOC) has exhibited marginal improvement in survival. Although the majority of patients with EOC achieve a clinical remission after induction therapy, over 80% relapse due to resistance to chemotherapies. In this regard, it is of paramount importance to devise novel therapeutics aimed at quelling the signaling pathways responsible for chemotherapeutic resistance in EOC. NFKB signaling pathway plays important roles in different hallmarks of cancer including chemoresistance, tumor growth and dissemination in human malignancies. In the EOC cells, enhanced phosphorylation and activation of NFKB correlates with tumor cell survival, proliferative and invasive capacities of these cells. Altogether, these seminal studies suggest that NFKB is an attractive preventive and therapeutic target in EOC.

Method

This study aimed to evaluate the effects of NFKB inhibitor Bay11-7082 on proliferative and invasive characteristics of EOC chemoresistance cell lines OVCAR3, SKOV3 and A2780CP through suppression of NFKB signaling. To achieve this, the effects of treatment of Bay11-7082 on proliferation, gene expression, clonogenicity and apoptosis were explored in vitro.

Results

NFKB inhibitor suppressed proliferation, migration and clonogenicity abilities of OVCAR3, A2780CP and SKOV3 cells via inhibition of activation of NFKB. NFKB inhibition resulted in a significant induction of apoptosis. Furthermore, Bay11-7082 treatment reduced invasive potentials of the EOC cells through quelling the NFKB pathway and suppression of anoikis resistance.

Conclusion

Altogether, these results suggest that NFKB inhibitors are potential anti-cancer drugs to overcome chemoresistance and inhibit proliferative and invasive characteristics of the EOC cells that exhibit platinum based chemoresistance.
IS IT REQUIRED TO PERFORM PARA-AORTIC LYMPH NODE DISSECTION IN EARLY STAGE OF OVARIAN CANCER

Z. Yousefi¹, M. Dehghani², E. Dehghani³

¹Ghaem Educational Hospital - Mashhad University of Medical Sciences MUMS, Obstetrics and Gynecology, Mashhad, Iran
²Ghaem Hospital, Cardiology, Mashhad, Iran
³Ghaem Hospital, Medical Student, Mashhad, Iran

Aims

To evaluate the effect of Para aortic Lymph node dissection in early stage of patients with ovarian cancer

Method

This descriptive cross-sectional cohort study was performed in Ghaem Hospital, 2012-2014. All patients with clinical early stage of ovarian cancer candidate to surgical treatment were selected. They underwent surgical staging surgery with concurrent systematic pelvic and para-aortic lymphadenectomy. After identification of left and right iliac artery, all lymph nodes have been properly exposed and dissected as a part of a staging laparotomy. The dissection was continued up to the nodal tissues surrounding the aorta, and inferior vena cava, until inferior mesenteric artery lymphadenectomy level.

Results

Among a total of 57 ovarian cancer patients, 27 of them apparent stage I disease cases were selected. Surgical staging surgery with concurrent systematic pelvic and para-aortic lymphadenectomy was carried for all of them. Positive para-aortic lymph node was found only in one case. The average number removed para-aortic lymph nodes in the pelvis was 9 and in para-aortic was 7, respectively. 20 minutes increase in total length of operation time was observed due to para-aortic lymphadenectomy. The increase in intra abdominal hemorrhage rate was estimated 60 cc.

Conclusion

Lymph node dissection will produce a significant benefit in accurate and complete surgical staging. Staging surgery in addition to systematic pelvic and para aortic lymphadenectomy in early stage ovarian cancer is preferred in gynecologic oncology centers.

BRCA1 AND BRCA2 MUTATIONS IN OVARIAN CANCER PATIENTS FROM CHINA: ETHNIC-SPECIFIC MUTATIONS IN BRCA1 ASSOCIATED WITH AN INCREASED RISK OF OVARIAN CANCER

R. Zang¹, T. Shi¹, P. Wang¹, C. Xie², S. Yin³, C. Wei³, D. Shi³, W. Tang¹, R. Jiang¹, X. Cheng¹, Q. Wei¹, Q. Wang⁵
¹Zhongshan Hospital- Fudan University, Obstetrics and Gynecology, Shanghai, China
²Shanghai Topgen Bio-Pharm Co.- Ltd, -, Shanghai, China
³Shanghai Topgen Bio-Pharm Co.- Ltd, --, Shanghai, China
⁴Duke University Medical Center, Duke Cancer Institute, Durham, USA
⁵Plateforme de génomique des cancers, Centre Léon Bérard- Laboratoire de la génétique constitutionnelle HCL-CLB, Lyon, France

Aims

BRCA1/2 are cancer predisposition genes involved in hereditary breast and ovarian cancer (HBOC). Mutation carriers display an increased sensitivity to inhibitors of poly (ADP-ribose) polymerase (PARP). Despite a number of small-size hospital-based studies being previously reported, there is not yet precise data of BRCA1/2 mutations among Chinese epithelial ovarian cancer (EOC) pts.

Method

We performed a multicenter cohort study including 916 unselected consecutive EOC pts from eastern China, to screen for BRCA1/2 mutations using the next-generation sequencing approach.

Results

153 EOC pts were found to carry pathogenic germline mutations in BRCA1/2, accounting for an overall mutation incidence of 16.7% with the predominance in BRCA1 (13.1%) compared with BRCA2 (3.9%). We identified 32 novel pathogenic mutations, among which the c.283_286delCTTG and the c.4573C>T of BRCA1 were both found in two unrelated patients. More importantly, the most common mutation, c.5470_5477del8 was most likely to be Chinese population-related without an apparent founder origin. This hot-spot mutation was presumably associated with an increased risk of EOC. Taken together, germline BRCA1/2 mutations were common in Chinese EOC pts with distinct mutational spectrum compared to Western populations.

Conclusion

Our study contributes to the current understanding of BRCA1/2 mutation prevalence worldwide. We recommend BRCA1/2 genetic testing to all Chinese women diagnosed with EOC in order to identify HBOC families, to provide genetic counselling and clinical management for at-risk relatives. Mutation carriers may also benefit from PARP-targeted therapies.
Aims

High-grade serous ovarian cancer (HGSOC) has a high mortality rate because patients are generally detected in an advanced stage and show resistant relapses. Primary cell lines of relapsed patients were established and tested for a possible synergy of the HSP90 inhibitor ganetespib with paclitaxel and platinum drugs. HSP90 stabilizes mutated oncogenes and inhibits their proteasome degradation.

Method

Primary ovarian cell lines were established from ascitic fluid or pleural effusions (GANNET53: Ganetespib in Metastatic, p53-mutant, Platinum-resistant Ovarian Cancer) and chemosensitivity tested in MTT assays. Soluble carbonic anhydrase IX (sCAIX) was measured by ELISA.

Results

Primary ovarian cells grow adherent or as spheroids with prolonged doubling times and showed low sensitivity to ganetespib alone. Combination of ganetespib with paclitaxel proved to be antagonistic employing primary and established ovarian cancer cell lines whereas the combination of this HSP90 inhibitor with platinum drugs (cisplatin, carboplatin, oxoplatin) yielded synergistic effects. Furthermore, the primary cell lines of resistant patients revealed sensitivity to platinum drugs in vitro. Ascitic fluid is partially hypoxic and showed high levels of sCAIX which is associated with tumor aggressiveness and a poor prognosis. Expression of sCAIX was found to be sensitive to inhibition with ganetespib.

Conclusion

Cell lines established from recurrences of resistant ovarian cancer patients were resistant to paclitaxel but sensitive to platinum drugs. The cytotoxicity of platinum drugs could be enhanced in combination with ganetespib. Drug resistance seems to be associated with low proliferation, formation of spheroids and hypoxic conditions with expression of sCAIX and increased tumor aggressiveness.

PROGNOSTIC VALUE OF PROGRAMMED DEATH LIGAND 1 EXPRESSION IN OVARIAN CLEAR CELL CARCINOMA

J. Zhu¹
¹Fudan University Shanghai Cancer Center, Gynecologic Oncology, Shanghai, China

Aims

This study aimed to evaluate the expression of programmed death ligand-1 and its correlation with clinicopathologic features in ovarian clear cell carcinoma (OCCC).

Method

The PD-L1 expression was measured by tissue-microarray-based immuno-histochemistry from 123 patients diagnosed with OCCC. The associations of clinicopathologic features with PFS and OS were analyzed by Kaplan-Meier method and multivariate analysis was further performed by Cox regression model.

Results

Overall, high PD-L1 expression was observed in 44.7% (55/123) of OCCC patients, and was strongly associated with advanced stages (p = 0.026), positive ascitic fluid (p = 0.016), platinum-resistant disease (p = 0.045) and recurrence (p = 0.038). Moreover, patients with high PD-L1 expression were associated with poorer OS (Hazard ratio [HR], 2.877; p = 0.001) and PFS (HR, 1.843; p = 0.021) than those with low PD-L1 expression. In subgroup analysis, PD-L1high patients experienced a poorer PFS (HR, 1.926; p = 0.044) and OS (HR, 2.492; p = 0.021) than PD-L1low cases among advanced stages (III-IV), but this difference was not observed in stage I-II patients. Meanwhile, PD-L1high was associated with poorer prognosis than PD-L1low in platinum-resistant patients (OS, HR: 2.253, p = 0.037; PFS, HR: 1.448, p = 0.233). Multivariate analysis revealed that PD-L1high and advanced stages (III-IV) were adverse independent prognosticators for both PFS (HR_{PD-L1}, 2.0, p_{PD-L1} = 0.038; HR_{stage}, 10.2, p_{stage} < 0.001) and OS (HR_{PD-L1}, 3.0, p_{PD-L1} = 0.011; HR_{stage}, 14.3, p_{stage} < 0.001).

Conclusion

High PD-L1 expression might be a risk factor for PFS and OS in patients with OCCC. Immunotherapy targeting PD-L1 pathway could be used in OCCC.
VEGFR RECEPTORS, AS MOLECULAR MARKERS OF ANGIOGENESIS AND LYMPHANGIOGENESIS IN OVARIAN CANCER.
P. Ziober-Malinowska¹, M. Mazurek-Kociubowska¹, R. Tarkowski¹, M. Sobstyl¹, K. Kulak¹, W. Bednarek¹
¹Medical University of Lublin, 1st Chair and Department of Oncological Gynaecology, Lublin, Poland

Aims

Vascular endothelial growth factor VEGF is one of the cytokines responsible for multi-step process angiogenesis in tumors. Aim: To evaluate the expression of VEGF receptor immunohistochemistry in ovarian cancer in relation to the histological tumor grade, disease stage FIGO, the level of CA125 in the blood serum of patients, the female sex hormone concentration and histopathological.

Method

The study was performed on a group of 61 patients with ovarian carcinoma. Immunohistochemistry expression of VEGF receptors correlate with the histological tumor grade, disease stage FIGO, the level of CA125 in the blood serum of patients, the female sex hormone concentration and histopathological.

Results

63.93% of patients detected the expression of VEGFR3, especially in tumors with an average degree of histological differentiation. VEGF1 expression was more common in endometrial cancer, ovarian cancer, compared to serum. Statistical significance was proved expression of VEGF2 in patients with ovarian and CA125 values within normal limits.

Conclusion

The receptors VEGFR can be found in the future, used in the diagnosis and treatment of patients with ovarian cancer, can be considered as molecular markers of lymphocytes and angiogenesis. Their increased expression does not affect the clinical stage of the disease FIGO, and increased expression correlates with more frequent VEGF3 lymphatic metastases.

GENE EXPRESSION OF SERINE/THREONINE PROTEIN KINASES AS A PROGNOSTIC FACTOR FOR PATIENTS DIAGNOSED WITH OVARIAN CANCER.

P. Ziobier-Malinowska¹, R. Tarkowski¹, K. Kulak¹, K. Frąszczak¹, A. Kulak¹, B. Barczyński¹, M. Kociubowska¹, A. Wiśniewska¹, M. Sobstyl¹, J. Kotarski¹

¹Medical University of Lublin, Ist Chair and Department of Oncological Gynaecology, Lublin, Poland

Aims

Due to increase in ovarian cancer incidence observed over the last decades this disease have been intensively investigated on molecular levels to explore its origins and identify proteins which could serve as its markers. A serine/threonine protein kinase is a group of enzymes, that phosphorylate the OH group of serine or threonine. Aim of the study was to asses the correlation of serine/threonine kinase 25, serine/threonine protein kinase and serine/threonine kinase 4 genes expression with the survival rates of patients treated for ovarian cancer.

Method

48 women treated for ovarian cancer were included in the study. Genes expression was estimated using BD Atlas™ Human Cancer 1.2 Array-PT3547-3E (BD Biosciences Clontech, USA). Genes expression were assessed by comparing the normal tissue and tumor tissue, then there were estimated in relations to histopathological type and grade of the tumor, to stage of the disease and response to primary chemotherapy. Patients underwent a 36 month observation period.

Results

23 patients (47.9%) died in the observation period despite treatment due to ovarian cancer spread. ROC curves for serine/threonine kinase 25 (cut off 0.034), serine/threonine protein kinase (cut off 0.044) and serine/threonine kinase 4 (cut off 0.078) genes expression showed significant positive correlation with the survival presented a significant positive correlation between this genes expression and patient survival.

Conclusion

Evaluation of the expression of investigated/examined serine/threonine kinases genes can be a valuable factor for treatment and survival of women with ovarian cancer.

PALLIATIVE PELVIC EXENTERATION – A SINGLE INSTITUTION EXPERIENCE AND OUTCOMES IN CERVICAL AND VAGINAL CANCER

Ö. Akbayır1, S.C. Ulukent2, E. Canaz2, E.S. Özyürek3, B. Erdem1, B. Özköse4, O. Aşçıoğlu5, Y. Özgün6, A. Akça7

1S.B. University Kanuni Sultan Süleyman Education and Research Hospital, Gynecologic Oncology, Istanbul, Turkey
2S.B. University Kanuni Sultan Süleyman Education and Research Hospital, General Surgery, Istanbul, Turkey
3S.B. University Bağcılar Education and Research Hospital, Gynecology and Obstetric, İstanbul, Turkey
4S.B. University Kanuni Sultan Süleyman Education and Research Hospital, Gynecology and Obstetric, istanbul, Turkey

Aims

Pelvic exenteration (PE) can be performed both with curative or palliative intent in locally advanced, recurrent or persistent cervical and vaginal cancer. We aimed to report our experience in palliative pelvic exenteration (pPE) regarding to its surgical technique, complications, early surgical and oncological outcomes.

Method

Between July 2013 and June 2016, seven pPE cases (6 for cervical and 1 for vaginal cancer) selected from a series of 36 PEs performed for gynecological malignancies were reviewed.

Results

All of these exenterations were total pPEs. Four suprarelevator and 3 infrarelevator PEs (1 of these cases performed with an additional modified vulvectomy) were performed. The principal indication for these pPEs were impaired quality of life due to rectovaginal or vesicovaginal fistulae, bleeding and fetid odour originating from infected necrotic tumour. None of these patients had intraoperative major complications or mortality. Urinary infection and subileus were the main complications. We had one postoperative mortality associated with pulmonary aspiration. Four patients with cervical cancer died of disease at postoperative follow-up. The mean postoperative survival was 7 months. All of the patients expressed relief of their tumour-related symptoms postoperatively.
Conclusion

Locally advanced incurable cervical and vaginal cancers have very poor quality of life due to neighboring organ fistulae. pPE provides these patients a good quality of life by treating physical discomfort, emotional distress with reasonable morbidity, despite a lack of survival benefit.
PALLIATIVE CARE

ESGO7-0472

IS THERE TIMELY INTERVENTION OF PALLIATIVE CARE IN GYNAECOLOGICAL CANCER PATIENTS AT THE END OF LIFE?

N. Rahim1, S. Kaushik2

1Brighton and Sussex University Hospitals NHS Trust, Brighton and Sussex Medical School, Brighton, United Kingdom
2Brighton and Sussex University Hospitals NHS Trust, Gynaecology, Brighton, United Kingdom

Aims

Palliative care is a crucial element of care plans for gynaecological cancer patients. It maximises comfort and quality of life and addresses patient wishes to ensure a dignified death. This retrospective study aims to examine aspects of end of life care of gynaecological cancer patients who died during 2015 within the Brighton and Sussex University Hospitals Trust.

Method

31 women were suitable for inclusion in the study. Variables under study included last hospital admission and last active treatment before death, MDT discussions, palliative care input, DNAR form completion and discussions regarding preferred place of death.

Results

Within the last week of life, 23% (7/31) of women had their final admission and 8% (2/31) had active treatment. 32% (10/31) were last discussed at an MDT meeting more than 4 months before death. 81% (25/31) of the women had palliative care input with 39% (9/31) having an initial assessment during the week approaching death. 74% (23/31) had a signed DNAR form and 68% (21/31) had their preferred location of death documented, however only 29% (6/31) achieved this.

Conclusion

A number of components of end of life care need addressing to improve care for gynaecological cancer patients within the trust, specifically provision of palliative care, DNAR form completion and discussions regarding location of death. Implementation of advanced care plans for all women would ensure that these areas are adequately addressed in order to allow patients the most dignified death possible.
THE RELATIONSHIP BETWEEN SYMPTOM BURDEN, BODY IMAGE AND QUALITY OF LIFE IN ASIAN GYNAECOLOGICAL CANCER PATIENTS

K. Tewani1, Y. Lim2, I. Teo3

1K K Women’s and Children’s Hospital - Singapore, Palliative Consultant in Department of Gynecological Oncology, Singapore, Singapore
2K K Women’s and Children’s Hospital - Singapore, Department of Gynecological Oncology, Singapore, Singapore
3Lien Centre, Clinical Psychologist, Singapore, Singapore

Aims

This study examines symptom burden and body image disturbance in patients with gynaecological cancers, and the extent they are related to quality of life.

Method

A cross-sectional study in which patients diagnosed with gynaecological malignancies were recruited from a tertiary hospital in Singapore (n = 104). They were assessed using self-report assessments of symptom burden, quality of life (using the Functional Assessment of Cancer Therapy-General form), and body image dissatisfaction (using the Body Image Scale). Clinical factors were abstracted from patient medical records.

Results

Approximately 1 out of 4 patients reported feeling less physically attractive and dissatisfied with their body. Symptom burden alone predicted physical well-being, \( p < .001 \) and functional well-being, \( p < .001 \).

Body image dissatisfaction significantly predicted emotional well-being, \( p = .01 \) and symptom burden no longer predicted emotional well-being once body image dissatisfaction was entered into the model.

Patients with cervical cancer reported significantly higher body image dissatisfaction, \( p = .01 \), and younger age was found to be a significant risk factor for clinically-relevant score of body image distress, \( p = .02 \).

Conclusion

Symptom burden and body image dissatisfaction were associated to patient’s quality of life. Body image dissatisfaction explained the relationship between symptom burden and emotional well-being, and may be a potential target for intervention. Particular attention should be paid to patients who are younger and diagnosed with cervical cancer as they are more susceptible to body image disturbance.

CARDIOVASCULAR RISK AFTER RISK-REDUCING SALPINGO-OOPHORECTOMY IN BRCA1/2 MUTATION CARRIERS: CARSOBRA STUDY

M. Arts-de Jong1, M. Bots2, L. Van Westerop1, L. Massuger1, M. Hopman3, N. Hoogerbrugge4, J. De Hullu1, A. Maas5

1Radboud university medical center, Obstetrics & Gynaecology, Nijmegen, The Netherlands
2University Medical Center Utrecht, Julius Center of Health Sciences and Primary Care, Utrecht, The Netherlands
3Radboud university medical center, Physiology, Nijmegen, The Netherlands
4Radboud university medical center, Human Genetics, Nijmegen, The Netherlands
5Radboud university medical center, Cardiology, Nijmegen, The Netherlands

Aims

Early menopause leads to an increased cardiovascular risk. Cardiovascular risk assessment based on traditional risk factors often underestimates the actual risk in middle-aged women. Measures of atherosclerosis such as carotid intima-media thickness (CIMT) and pulse wave velocity (PWV) could help to predict future cardiovascular events in this group. BRCA1/2 mutation carriers are generally exposed to an earlier menopause due to an risk-reducing salpingo-oophorectomy (RRSO) around the age of 40 to reduce their elevated ovarian cancer risk. Until now, cardiovascular risk in BRCA1/2 mutation carriers after RRSO is not yet studied. The aim was to investigate if time since RRSO in BRCA1/2 mutation carriers is related to advanced signs of subclinical atherosclerosis measured by CIMT and PWV.

Method

We performed a cohort study in 165 BRCA1/2 mutation carriers (aged 40 to 63 years) who underwent RRSO at age ≤ 45 years and at least five years previously. Main study endpoints were CIMT and PWV, and traditional cardiovascular risk factors were collected by questionnaires and single cardiovascular screening visit.

Results

The mean CIMT was 0.69 mm (SD 0.087), and the PWV was 6.40 m/s (SD 1.42). After adjustment for systolic blood pressure, insulin resistance, total cholesterol and body mass index, no association was found between age-adjusted CIMT and time since RRSO. Age-adjusted PWV and time since RRSO were also not associated, after adjusting for systolic blood pressure, total cholesterol and waist hip ratio.

Conclusion

Time since RRSO is not related to CIMT and PWV in BRCA1/2 mutation carriers. However, a longer follow-up period is needed.

REVIEW THE RESULTS OF HUMAN PAPILOMAVIRUS DNA TEST, CYTOLOGY SCREENING AND COLPOSCOPY EXAMINATION IN YOUNG WOMEN

S. Babloyan1, G. Beglaryan2, E. Gharibyan3, A. Pogosyan3

1Yerevan State Medical University- EREBOUNI MEDICAL CENTER, OBGYN N1, Yerevan, Armenia
2Yerevan State Medical University, OBGYN N1, Yerevan, Armenia
3EREBOUNI Medical Center, OBGYN, Yerevan, Armenia

Aims

The aim of this study is detect the value of human papillomavirus (HPV) testing, cytological results and colposcopy findings in young women.

Method

Totally 650 women aged 19 to 45 underwent to primary screening with cytology and HPV DNA test in 2015. In 219 women HPV DNA test was positive. The rates of HPV-positive and abnormal cytology were compared and colposcopy examination was performed in those who has a positive results. During next years, all women with positive HPV results were followed up (n =219).

Results

In 24/219 (11%) women with HPV positive testing no cytological or colposcopy abnormality were found. In 127 (58%) cases CIN1 and in 43 (19%) cases CIN2/3 was found in cytological examination of women with HPV positive test. In 19 women with only negative cytology examination CIN 1 was confirmed and in 6 women CIN 2/3 was confirmed in punch biopsy material that was taken during colposcopy examination. From 219 HPV positive women 170 (78%)were in age 19-30 years old and 49 (22%) women older than 30 years old. HPV-positive rates were significantly higher in young women from 19- 30 years old (n= 170) compared with women older then 30 years old (95% CI). The rate of CIN2/3 (n=49) progression was also higher in young women from 19 to 30 years old (n=39), than in women over 30 years old (n=10).

Conclusion

According to results cytological screening is appropriate and recommended. HPV testing is a useful for predicting of CIN, however, can also have a false-positive results.
ASSESSING THE RISK OCCULT CANCERS AND 30-DAY MORBIDITY IN BRCANESS WOMEN UNDERGOING RISK-REDUCING SURGERY: A PREDICTIVE MODEL AND NOMOGRAM

1National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To investigate the incidence and predictive factors of 30-day surgery-related morbidity and occult precancerous and cancerous conditions in patients undergoing risk-reducing surgery

Method

This is a prospective cohort study evaluating BRCAness (BRCA 1 and 2 mutation carriers and BRCAx) women undergoing minimally invasive risk-reduction surgery. A nomogram has been created in order to assess the risk of diagnosis of occult precancerous and cancerous malignancies at the time of surgery

Results

Overall, 85 BRCAness women had risk-reducing surgery: 30 (35%) and 55 (75%) women had hysterectomy plus bilateral salpingo-oophorectomy (BSO) and BSO alone, respectively. Overall, 6 (7%) patients were diagnosed with undiagnosed cancers: three early stage ovarian / fallopian tube cancer, two advanced stage ovarian cancer (stage IIIA and IIIB) and one serous endometrial carcinoma. Additionally, 3 (3.6%) patients had incidental diagnosis of serous tubal intraepithelial carcinoma (STIC). A nomogram of predicting factors for the risk of having occult malignancies was built (Figure). Regarding 30-day morbidity, we observed 4 postoperative complications that were managed conservatively, including fever (n=3) and postoperative ileus (n=1). No severe (grade 3 or more) complication occurred among patients having risk-reduction surgery. Only presence of occult cancer correlated with an increased risk of developing postoperative complications (p=0.02); basically, due to the adjunctive staging procedures needed.

Conclusion

Minimally invasive risk-reducing surgery is a safe and effective strategy to manage BRCA mutation carriers. Patients should have to be counseled about the high prevalence of undiagnosed cancers observed at the time of surgery.
PREVENTION OF GYNAECOLOGIC CANCER

POTENTIAL CLINICAL IMPACT OF THE INTRODUCTION OF THE NONAVALENT HUMAN PAPILLOMAVIRUS VACCINATION: AN ANALYSIS OF 13,665 PATIENTS OVER A 18-YEAR STUDY PERIOD

G. Bogani¹, A. Ditto¹, F. Martinelli¹, M. Signorelli¹, V. Chiappa¹, D. Lorusso¹, R. Francesco¹

¹National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To test the theoretical utility of the incorporation of quadrivalent and nonavalent vaccination against HPV into a clinical setting.

Method

Data of consecutive patients undergoing sampling for HPV DNA testing from 1998 to 2015 were retrospectively searched in order to identify changes in HPV prevalence during three study periods (T1, 1998-2003; T2, 2004-2009; and T3, 2010-2015).

Results

We enrolled 13,665 patients: 1361, 5130, 7174 patients, in T1, T2 and T3, respectively. Potentially, the quadrivalent vaccine protected against HPV infection in 71.5%, 46.5% and 26.5% of patients tested in T1, T2 and T3, respectively (p-for-trend<.001). While, the nonavalent vaccine protected against HPV infection in 92.5%, 72.3% and 58.1% of patients tested in T1, T2 and T3, respectively (p-for-trend<.001). The proportion of patients with genital dysplasia grade 2+, not related to HPV types covered by quadrivalent vaccine (13% in T1, 21% in T2 and 34% in T3) and nonavalent vaccine (3% in T1, 12% in T2 and 19% in T3) increased over the time (p-for-trend<.001). For all study period the nonavalent vaccine was superior that quadrivalent vaccine in protect against HPV infection (p<.001). The figure displays the prevalence of dysplasia related to HPV 16-18 and to high-risk HPV infection other than 16-18.
Conclusion

Nonavalent vaccine would improve protection against HPV infections and HPV-related genital dysplasia. Moreover, we can speculate that cross protection of nonavalent vaccine will be related to a highest coverage against other HPV types.
Aims

The tubal origin of high-grade serous ovarian cancer (HGSC) represents an opportunity to reduce the risk of ovarian cancer. The Royal College of Obstetrics and Gynaecology advises that ‘women who have completed their families should be carefully considered for prophylactic removal of the fallopian tubes …at the time of gynaecological or other intra-peritoneal surgery’. We aimed to evaluate current knowledge and attitudes of relevant healthcare professionals to the concept of the tubal origin of HGSC, and opportunistic salpingectomy.

Method

We carried out surveys of professionals who may be involved in women undergoing gynaecological or abdominal surgery, including primary health care providers, obstetricians, gynaecologists and general surgeons who carried out pelvic surgery.

Results

19 of 21 primary care practitioners, and 12 of 15 surgeons were totally unaware of the tubal origin of HGSC. Obstetricians & Gynaecologists were better informed (17 of 26 were well informed). There was a lack of confidence in discussing or offering opportunistic salpingectomy across all specialties for a variety of reasons. The majority of professionals surveyed volunteered that written information for healthcare professionals and patients would be helpful, along with teaching sessions or direct surgical training from a specialist.

Conclusion

There is limited knowledge around the tubal origin of HGSC amongst healthcare professionals who may be in a position to counsel or offer opportunistic surgery. Strategies to educate and alter attitudes of healthcare professionals may be required before we see a paradigm shift in offering the choice of this potentially life-saving opportunity to women.
THE HPV VACCINE CRISIS!

M. Cheung¹, E. Cosgrave¹, Z. Fonseca-Kelly¹, E. McSharry², O. Smith³, C. Windrim⁴, S. O’Brien⁴, D. Brennan⁵

¹Mater Misericordiae University Hospital, Gynaecology, Dublin, Ireland
²Coombe Women and Infants University Hospital, Gynaecology, Dublin, Ireland
³Rotunda Hospital, Gynaecology, Dublin, Ireland
⁴National Maternity Hospital, Gynaecology, Dublin, Ireland
⁵Mater Misericordiae University Hospital, UCD School of Medicine- Catherine McAuley Research Centre, Dublin, Ireland

Aims

A National Vaccination Program was commenced in Ireland in 2011, offering Gardasil® to 12-13 year old girls. Claims have emerged suggesting an associated between the vaccine and chronic fatigue syndrome receiving extensive mainstream and social media coverage resulting in a significant decrease in vaccination rates. We sought to assess the opinions of midwifery, nursing and allied health professionals towards the HPV vaccine and how recent media coverage has impacted this.

Method

A 12-question paper survey was compiled, assessing basic demographic information, vaccination status and the perceived impact of the media coverage on their opinion of the HPV vaccine.

Results

Of 204 participants, 95.6% support routine childhood vaccination. Only 28.4% of participants with eligible children consented to HPV vaccine, compared to 63.4% of those without children. 85% of participants were aware of the HPV vaccine media coverage, which made 22% more likely consent for the HPV vaccine 33% less likely and 41% stated it would make no difference. Media coverage influenced participants recommending HPV vaccination, 23% were more likely, 26% less likely and 45% stated it made no difference.

Conclusion

Social and mainstream media coverage is affecting opinions and decisions to vaccinate, even within the midwifery, nursing and allied health professions. Participants stated they felt media coverage was the only source of information about the vaccine and adverse effects, highlighting a need for better education of health care professionals, if we are to tackle the negative and inappropriate media coverage and improve HPV vaccine uptake rates.
HUMAN PAPILLOMAVIRUS VACCINE UPTAKE IN SOUTH KOREA

J.Y. Choi¹, M. Kim², B.S. Kwon³, S.J. Jeong⁴, D.H. Suh², K. Kim², Y.B. Kim², J.H. No²

¹Chungbuk National University Hospital, Obstetrics and Gynecology, Cheongju-si, Republic of Korea
²Seoul National University Bundang Hospital, Obstetrics and Gynecology, Seongnam si, Republic of Korea
³Pusan National University School of Medicine and Biomedical Research Institute- Pusan National University Hospital, Obstetrics and Gynecology, Busan, Republic of Korea
⁴Korea University, Statics, Seoul, Republic of Korea

Aims

This study aimed to assess the human papillomavirus (HPV) vaccine uptake rate in South Korean women and to identify factors affecting vaccination rate before initiation of the national HPV vaccination program.

Method

A nationwide online survey of 2,000 9–59-year-old women collected information on their HPV vaccination status and associated correlates such as age, residential region, education, and socioeconomic status. The regional and age distribution of subjects was based on the South Korean census data.

Results

The overall HPV vaccine uptake rate was 23.1%, and the highest rate of vaccination was observed in women aged 20–29 years (38.6%), followed by those aged 30–39 years (36.9%), 9–19 years (16.9%), 40–49 years (14.2%), and 50–59 years (12.5%). Women from the metropolitan cities showed a higher vaccination rate than those from rural areas (26.2% vs 20.5%, P=0.003). A multivariate regression analysis showed that HPV vaccine uptake was independently associated with age, residential region, educational level, regular influenza vaccination, clinic visit within the last 6 months, and a high family income. The main barriers to HPV vaccination were the cost of vaccination (24.3%), and concerns regarding vaccine safety (23.1%).

Conclusion

HPV vaccine uptake was low among the South Korean women, especially among women aged 9–19 years and women living in rural areas. The national HPV vaccination program will improve vaccine uptake rate by overcoming barriers to vaccination.
PREVENTION OF GYNAECOLOGIC CANCER

URINARY HIGH-RISK HUMAN PAPILLOMAVIRUS DETECTION OFFERS AN ALTERNATIVE STRATEGY FOR CERVICAL SCREENING

A. Sargent1, S. Fletcher2, K. Bray2, H. Kitchener2, E. Crosbie2

1Central Manchester University Hospitals NHS Foundation Trust, Virology Department, Manchester, United Kingdom
2University of Manchester, Gynaecological Oncology Research Group, Manchester, United Kingdom

Aims

HPV testing in cervical screening offers the potential for self-sampling, to improve uptake amongst non-attenders. High-risk (HR) HPV detection in urine shows promise, but few studies have examined its sensitivity for CIN2+ detection compared with standard cervical samples. This pilot study was designed a) to optimise conditions for HPV testing from urine, b) to determine the concordance of HPV testing in matched urine/vaginal/cervical samples, c) to compare the sensitivity of HR-HPV testing from urine in the detection of underlying CIN2+, and d) to gauge women’s acceptability of urine self-sampling.

Method

Triplets of self-collected urine and vaginal plus practitioner-obtained cervical samples were collected from women attending the colposcopy clinic in St Mary’s Hospital in Manchester. Colposcopist impression was recorded and cervical biopsies taken if clinically indicated. HR-HPV was tested for by the Abbott RealTime (ART) and Roche Cobas (RC) 4800 assays. Neat and preservative-fixed urine were compared. The acceptability of self-testing was evaluated by questionnaire.

Results

Triple matched samples were suitable for analysis in 79 and 66 women using the ART and RC assays respectively. a) Preservative-fixed, but not neat urine, b) showed strong analytical concordance: 61/66(94%) and 65/79(82%) for RC and ART respectively. c) Sensitivity for urine samples relative to cervical samples in the detection of underlying CIN2+ was 15/15(100%) and 15/16(94%) for RC and ART respectively. d) Women considered urine based testing broadly acceptable.

Conclusion

Urinary HR-HPV detection offers an alternative strategy for cervical screening. Larger studies to determine its clinical utility are warranted.
Low, Medium and High – Risk HPV Type Distribution in Cervical Carcinoma in Situ

J. Celiesiute, A. Vitkauskaite, J. Vijoletas, S. Paskauskas, K. Jariene, A. Cizauskas, M. Gedgaudaite, A. Gaurilcikas, D. Vaiktiene

1Lithuanian University of Health Sciences, Obstetrics and gynaecology, Kaunas, Lithuania
2Lithuanian University of Health Sciences, Laboratory Medicine, Kaunas, Lithuania
3Lithuanian University of Health Sciences, Pathology, Kaunas, Lithuania

Aims

To detect low, medium and high-risk human papilloma virus (HPV) types in histological samples of cervical cone biopsies for carcinoma in situ (CIS) in order to evaluate different HPV types and other risk factors influence on development of cervical CIS.

Method

100 formalin fixed and paraffin – embed histological samples of cervical CIS after cone biopsy were investigated for low, medium and high-risk HPV types, using specific set for HPV-DNA extraction from tissue and amplification using polymerase chain reaction (PCR). We evaluated 15 high-risk (16, 18, 31, 33, 35, 39, 45,51, 52, 56, 58, 59, 68, 73, 82), 3 possibly-carcinogenic (26, 53, 66) and 6 low-risk (6, 11, 42, 43, 44) HPV types. The influence of other factors on developing CIS was evaluated using an original questionnaire.

Results

Nine different HPV types were detected in 77% of samples. In 85.7% of samples – only one HPV type was detected, in 14.3% - two HPV types. HPV 16 was detected statistically more frequently in all samples (p=0.002) and this trend was seen in all age groups. The biggest HPV types variety was seen in 30 – 49 years old patients group. No significant differences between different HPV types combinations were found. The non-smokers were statistically older at the time of the cervical cone biopsy (p<0.05).

Conclusion

From all the HPV types detected in our study the HPV 16 had strongest influence on development of cervical carcinoma in situ.
PREVENTION OF GYNAECOLOGIC CANCER

ESGO7-0820

LONG-TERM EFFICACY AND IMMUNOGENICITY OF THE 9-VALENT HUMAN PAPILLOMAVIRUS VACCINE: FINAL ANALYSES OF A DOUBLE-BLIND, RANDOMIZED CLINICAL STUDY

E. Joura1

1Medical University of Vienna, Department of Gynecology- Comprehensive Cancer Center, Vienna, Austria

Aims

The 9-valent human papillomavirus (9vHPV) vaccine targets the four HPV types (HPV6/11/16/18) covered by the quadrivalent HPV (qHPV) vaccine, with the addition of the five oncogenic types most commonly associated with cervical cancer after HPV16/18 (HPV31/33/45/52/58). Analyses of 9vHPV vaccine efficacy and immunogenicity were conducted in a clinical trial (V503-001; NCT00543543) in young women aged 16-26 years.

Method

Participants (N=14,215) were randomized to receive a three-dose series of 9vHPV or qHPV (control) vaccine. Cervical and external genital swabs for HPV-DNA testing and cervical cytological samples for Papanicolaou staining were collected regularly. Tissue samples from biopsy or cervical definitive therapy (loop electrosurgical excision procedure, conization) were tested for HPV DNA. Serum antibody responses to the nine vaccine HPV types were assessed.

Results

Prophylactic efficacy against HPV31/33/45/52/58-related outcomes was 100% (95% CI: 39.4, 100) for cervical intraepithelial neoplasia Grade 3 (CIN 3); 97.7% (93.3, 99.4) for cervical, vulvar, and vaginal disease; 96.0% (94.6, 97.1) for 6-month persistent infection; 92.9% (90.2, 95.1) for Pap test abnormalities; and 90.2% (75.0, 96.8) for cervical definitive therapy. Efficacy was high against each HPV type and in subgroups defined by age, race, and geographic region. Incidences of HPV6/11/16/18-related infection, cytological abnormalities, disease, and definitive therapy were similar in both vaccine groups. Antibodies to vaccine HPV types persisted through 5 years following vaccination.

Conclusion

The 9vHPV vaccine prevents HPV31/33/45/52/58-related infection and disease and provides similar protection against HPV6/11/16/18 as the qHPV vaccine. Vaccine efficacy was sustained for up to 6 years.
PREVENTION OF GYNAECOLOGIC CANCER

ESGO7-1178

DEATH AFTER HPV VACCINATION: ANALYSIS OF VAERS DATA

T. Bese¹, I. Kahramanoglu¹, H. Turan¹, F. Demirkiran¹, M. Arvas¹
¹Istanbul University Cerrahpasa School of Medicine, Obstetrics and Gynecology, ISTANBUL, Turkey

Aims

The aim of this study is to analyse the death cases after HPV vaccination.

Method

Vaccine Adverse Events Reporting System (VAERS) Database was assessed from 2006 to 2016 for all death cases following any kind of HPV vaccination. The possible causes of deaths were discussed.

Results

Between 2006-2016 records, we reached to 175 death cases. Table 1 and 2 shows the details. Median age was 17.3 years (11-42 years). More than one fifth of deaths occurred after first dose, 17.6% after second dose, 15.4% after third dose. Time interval between vaccination and death were widely different. Nine of them occurred in the first 24 hours after vaccination, 5 of them were died more than one year after vaccination. Possible causes of death such as sudden collapse, seizure and anaphylaxis were reported in 8.5% (15) of patients and only one of them occurred just after second dose of HPV vaccine. Most of the records were submitted by non-physicians.
Conclusion

Safety of VAERS data about HPV vaccination is a controversial issue. Only one of 175 death cases seems to be associated with vaccination. Encouragement of girls and boys and their families about HPV vaccination should be recommended.

PRELIMINARY REPORT OF HEREDITARY ENDOMETRIAL CANCER IN KOREA

M.K. Kim¹, M.C. Lim², J.W. Kim³, M.C. Choi⁴

¹Samsung Changwon Hospital, Obstetrics and Gynecology, Changwon-Si, Republic of Korea
²National Cancer Center, Cancer Healthcare Research Branch-Center for Uterine Cancer-and Center for Clinical Trials-Research Institute and Hospital and Department of Cancer Control and Population Health-Graduate School of Cancer Science and Policy, Goyang, Republic of Korea
³Seoul National University College of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
⁴CHA Bundang Medical Center-CHA University, Comprehensive Gynecologic Cancer Center-Department of Obstetrics and Gynecology, Seongnam-si, Republic of Korea

Aims

To investigate practice patterns for patients with hereditary endometrial cancer (HEC) as parts of Lynch syndrome among Korean clinicians.

Method

Members of the Korean Society of Gynecologic Oncology conducted with a self-administered questionnaire about knowledge and clinical management of HEC

Results

Of the 54 participants, about half physicians (22, 47.1%) responded to draw a pedigree in woman with endometrial cancer. Immunohistochemistry and microsatellite instability tests as a screening test of HEC are done about 37%(17/54) and 7%(4/54) in woman with endometrial cancer. Physicians preferring universal gene test are only 7%(6/54). Most physicians (38/54) do not have experience in any gene test for women with endometrial cancer. Among physicians preferring selective screening Amsterdam criteria is major (22/54, 43%) and the combination of other screening tools including Amsterdam, immunohistochemistry and microsatellite instability are second most common (11/54, 21.6%). Over half affected patients are always recommended for cascade testing (29/54, 56.9%) and risk screening education (28/54, 55.0%) for sequential Lynch related other cancer

Conclusion

Genetic risk assessment and patient counseling about HEC has not been settled in clinical practice. Continuous education for physician and development of the guideline for HEC are needed
USING MICRODATELLITE INSTABILITY TEST TO ASSESS LYNCH SYNDROME RISK AMONG OVARY CANCER PATIENT IN KOREA

M.K. Kim¹, H.J. Choi²
¹Samsung Changwon Hospital, Obstetrics and Gynecology, Changwon-Si, Republic of Korea
²Samsung Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

BRCA mutation is the most common hereditary cancer syndrome about ovary. But mismatch repair genes related Lynch syndrome is also associated with it. There is not much study about risk evaluation about this among Korean population. We investigate this.

Method

Retrospective study was done to select ovary cancer patients who was counseled and tested about Lynch syndrome in Department of Obstetrics and gynecology, Samsung Changwon Hospital by single surgeon. Clinical information was extracted from the medical record including age, family and personal history of cancer, immunohistochemistry (IHC) of MLH1/MSH2, microsatellite instability test (MSI).

Results

Twenty six patients was found, mean age was 54(16~75) and fifty percent was serous type (13/26). There were 2 patients with Lynch syndrome related cancer family history (stomach and ovary) among their 1st degree relatives. Only one patient has abnormal MLH1 IHC. There were three unstable MSI patients (BAT26, D2S123, D5S5346, and NR21).

Conclusion

We found three abnormal MSI patients among this population. Cost effective algorithm using multiple genetic testing to find Lynch syndrome associated ovary cancer patients should be developed through large population study.
SENSITIVITY AND SPECIFICITY OF THE FROZEN SECTION IN RELATION TO THE FINAL HISTOLOGICAL IN OVARIAN TUMORS

E. Klonos*

*Aristotle University of Thessaloniki, Thessaloniki, Greece

Aims

The aim of the present retrospective study is to evaluate the diagnostic accuracy of frozen section in relation to the final histological results of women with suspicious ovarian tumors.

Method

Patients with ovarian tumors, who were operated at the oncology unit of the 1st Department of Obstetrics and Gynecology. The sensitivity and specificity of the frozen section were determined in relation to the final histological result, for the classification of the ovarian tumors as benign, borderline and malignant. Moreover, the final histological results of the tumors are presented, the rate of incidence of ovarian malignancy in relation to the patient’s age as well as the frequency of relapse.

Results

In a total of 130 patients who underwent surgical treatment due to suspicious ovarian tumors, 104 presented a histological diagnosis of ovarian Cancer, 9 characterized as borderline and 14 were negative for malignancy. The sensitivity and specificity of frozen section for patients with benign tumors amounted to 77.8% and 95.8 % respectively, while ovarian malignancy the percentage reaches 96.8% and 95.8%. Regarding borderline tumors the sensitivity and specificity of the frozen section reached 57.1% and 89.1% respectively.

Conclusion

The use of frozen section offers very good diagnostic accuracy in distinguishing women with malignant and benign ovarian tumors, in contrast to borderline tumors frozen section results in more diagnostic discrepancies, in relation to the final histological diagnosis is a more sensitive examination regarding benign and malignant damage, in contrast to the borderline tumors where, based on the sensitivity percentage, it constitutes a particularly precarious exam.
LLETZ CONE BIOPSY FOR CERVICAL INTRAEPITHELIAL NEOPLASIA. ANALYSIS OF SENSITIVITY AND SPECIFICITY OF COLPOSCOPY AND CYTOLOGY

E. Klonos

Aristotle University of Thessaloniki,
First Department of Obstetrics & Gynaecology "Papageorgiou" General Hospital of Thessaloniki, Thessaloniki, Greece

Aims

The aim of this retrospective study is to evaluate the results of cytology and colposcopy in relation to the final histological diagnosis of women undergoing Large Loop Excision of the Transformation Zone cone biopsy.

Method

Patients with abnormal cytology results, at least ASCUS (Atypical Squamous Cells of Undetermined Significance), who were examined at the Oncology Unit of the First Department of Obstetrics and Gynaecology were included in the study. The sensitivity and specificity of the cytology results and colposcopy were determined for the diagnosis of low grade (LGSIL) and high grade (HGSIL) intraepithelial neoplasia of the cervix in relation to the final histological results.

Results

From the total of 129 patients who underwent colposcopy due to abnormal cytology test results, 63 underwent LLETZ cone biopsy. In 12 (19%) of the 63 patients LGSIL was diagnosed, in 41 (65%) patients HGSIL, in 2 (3%) cases invasive cancer, and in 3 (5%) cases chronic cervicitis, while in 5 (8%) cases no residual disease was found in the cone. The sensitivity and specificity of the cytology for LGSIL lesions were 40% and 75%, and of the colposcopy 90% and 77%, respectively. Regarding HGSIL lesions, the sensitivity and specificity of the cytology results were 41% and 80%, and colposcopy 78% and 80% respectively. The sensitivity of colposcopy was significantly better (p = 0.0002).

Conclusion

Colposcopy is more sensitive than cytology to accurate diagnose cervical dysplasia. LLETZ cervical cone biopsy is a successful treatment method of cervical intraepithelial neoplasia.
APPLICATION OF LEARNING SKILL “TEACHING ON THE RUN” TO POST-GRADUATE FIRST-YEAR RESIDENTS FOR IMPROVEMENT IN THE QUALITY OF PAPANICOLAOU SMEAR

S.C. Liu¹, H.J. Chiang¹, Y.C. Ou¹, H. Lin¹, F.T. Kung¹, M.L. Liu², K.C. Lan¹
¹Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Chang Gung Memorial Hospital, Cancer Center, Kaohsiung, Taiwan R.O.C.

Aims

Papanicolaou smear (Pap smear) with cervical cytology could reduce incidence and mortality rate of cervical cancer. However, poor quality of Pap smear decreases screening efficacy. The aim of our study was to evaluate whether “Teaching On The Run (TOTR)” training program could help junior residents to improve skill and quality of Pap smear.

Method

Since May through December 2015, a total of 40 post-graduate first-year (PGY1) residents were randomly divided into two groups. The with-TOTR group (n=22) received the protocol-driven TOTR training program composed of plan learning, learn, appraise/assess, feedback and outcome evaluation. The without-TOTR group (n=18) received traditional big-class teaching instead. The rate of unidentifiable Pap smear and causes of unsatisfactory Pap smear were analyzed between the two groups.

Results

The results showed that TOTR training program significantly reduced the rate of unsatisfactory Pap smear quality from 34.1% to 24.1% (p<0.0001). In addition, the rate of unidentifiable Pap smear was significantly lower in the with-TOTR than without-TOTR group (2.16% vs. 5.81%, p=0.018), and was similar to that performed by gynecologists (2.16% vs. 2.34%, p=0.425). Furthermore, we identified the most two significantly improved items through TOTR training were less scarce cells (12.8% to 8.2%) and overlapping cells or contained blood (5.8% to 3.6%) (both p-values <0.005).

Conclusion

TOTR training program effectively helps PGY1 residents to improve their skills on accuracy and quality of Pap smear within a short-term training period.
INCREASED RISK OF CANCERS AMONG BRCA1 CARRIERS WITH LOW BLOOD SELENIUM LEVELS

J. Lubinski¹, W. Marciniak¹, R. Derkacz¹, P. Baszuk¹, M. Muszyńska¹, M. Kuświk¹, T. Huzarski², J. Gronwald², S.A. Narod³, A. Jakubowska¹

¹Read-Gene SA, - Dobra, Poland
²Pomeranian Medical University in Szczecin, Department of Genetics and Pathology, Szczecin, Poland
³Women’s College Research Institute, - Toronto, Canada

Aims

Prospective evaluation of relationship between selenium and cancer among women with BRCA1 constitutional mutations.

Method

We performed a nested case-control study of baseline blood selenium levels and cancer risk using data and biological samples from 4276 BRCA1 carriers that were participants in a biobanking initiative between 2010 and 2017. Cases included women with any incident breast/ovarian cancer (n=48) and controls (n=92) were women with no cancer at baseline or follow up. Blood from cases was collected at least 6 months before cancer diagnosis. Cases and controls were matched for year of birth, adnexectomy status and smoking. Blood selenium was quantified using mass spectroscopy.

Results

Women with blood selenium level <110 µg/l had a higher than 3-fold increased risk of cancer (logistic regression OR 3.12; CI – 1.17-9.89; p – 0.033).

Conclusion

The optimum level of blood selenium in BRCA1 carriers living in Poland can not be lower than 110 µg/l.

Supported by grant of the National Centre for Research and Development (NCBiR) no INNOMED/I/16/NCBR/2014.
PREVENTION OF GYNAECOLOGIC CANCER

ESGO7-0462

WOMEN’S ATTITUDES TO AUSTRALIAN CERVICAL SCREENING PROGRAM CHANGES AS EXPRESSED IN AN ONLINE PETITION

H.M. Obermair¹, R.H. Dodd¹, C. Bonner¹, J. Jansen¹, S. Carter¹, K. McCaffrey¹

¹University of Sydney, School of Public Health, Sydney, Australia

Aims

The Australian Cervical Cancer Screening Program, which has halved the incidence and mortality of cervical cancers in Australia since 1991, will change in 2017 from currently two-yearly Pap smears from age 18 to 69 to five-yearly HPV DNA testing from ages 25 to 74. An opposing petition on the website “Change.org” received 70,000 signatures and 20,000 comments. This study aimed to identify reasons for opposition to the revised cervical cancer screening program, expressed in the open-ended comments.

Method

Of 19,633 comments posted between 16th February and 19th March 2017, a random 2000 comments were analysed by two researchers.

Results

33% of statements highlighted that commenters placed high value on women’s health. 17% were concerned about the five-yearly screening interval. Women with a personal experience of cervical cancer or pre-cancerous lesions expressed opposition to the changes (15%). Support for disease prevention/early detection (14%), belief that the changes were a cost-cutting measure (14%), and a belief that men should not make decisions about women’s health (8%) were other central themes. Concern about increased age of first invitation was voiced in 9% of comments, and concern about HPV testing itself was expressed in only 3% of comments.

Conclusion

Many women expressed concerns that the screening program changes may adversely impact women’s health, indicating a need for health education in this area. The primary concern of commenters specific to the program was potentially missing cases of cervical cancer due to later age of first invitation and increased screening interval, with a perception this was a cost-cutting measure.
PREVENTION OF GYNAECOLOGIC CANCER

ESGO7-1154

VULVAR HIGH-GRADE SQUAMOUS INTRAEPITHELIAL LESION INVOLVING THE CLITORIS

M. Preti\(^1\), L. Bucchi\(^2\), S. Privitera\(^1\), E. Corvetto\(^1\), E. Palmese\(^1\), N. Gallio\(^1\), L. Micheletti\(^1\), C. Benedetto\(^1\)

\(^1\)A.O. Citta’ Della Salute E Della Scienza- P.O. S.ANNA, Obstetrics and Gynecology, Torino, Italy
\(^2\)Romagna Cancer Registry, Romagna Cancer Institute, Meldola, Italy

Aims

Despite a marked incidence increase, vulvar high-grade squamous intraepithelial lesion (VHSIL) involving the clitoris remains a rare and ill-defined condition. This study was aimed at evaluating the patient characteristics associated with clitoral vs. non-clitoral VHSIL and the clinical correlates of the disease.

Method

The study population included 216 consecutive eligible patients seen at an Italian tertiary-level centre for gynecologic oncology between 1981-2014. Patients’ records were reviewed by trained personnel. Statistical analysis was based on the \(\chi^2\) test, the Mann-Whitney test, and backward stepwise multiple logistic regression.

Results

Clitoral VHSIL was detected in 41 (19%) patients (median age, 50 years; range, 19-88). In univariate analysis, HIV infection, associated cervical intraepithelial neoplasia and vaginal intraepithelial neoplasia, and multifocality were significantly (p<0.05) associated with clitoral VHSIL. In multivariate analysis, multifocality retained a strong effect (OR, 17.5; 95% CI, 6.9-44.7; p=0.000). In turn, clitoral VHSIL was a weak risk factor for patient loss to follow-up in univariate (24.4% vs. 13.1%; p=0.072) and multivariate analysis (OR, 2.13; 95% CI, 0.92-4.92). In multivariate analysis, the risk of invasive carcinoma detection in excisional histological specimens was greater for patients in the highest tertile of age (p=0.008), for patients with a lesion \(\geq 20\) mm in size (p=0.013) and with clitoral involvement (p<0.001).

Conclusion

This study is a contribution to bridge the gap of knowledge on the determinants and clinical correlates of clitoral involvement in VHSIL. There is initial evidence that this condition is more likely among multifocal lesions and conveys an increased risk of unrecognized invasive carcinoma detection and loss to follow-up.
PREVENTION OF GYNAECOLOGIC CANCER

RISK FACTORS ASSOCIATED WITH ENDOMETRIAL CANCER: AN UMBRELLA REVIEW
O. Raglan1,2, I. Kalliala1,2, G. Markozannes3, M. Gunter4, J. Nautiyal1, H. Gabra1,2, E. Paraskavaidis5, P. Martin-Hirsch6,7
1Institute of Reproductive and Developmental Biology, Surgery and Cancer- Imperial College London, London, United Kingdom
2Queen Charlotte's and Chelsea Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom
3Department of Hygiene and Epidemiology, University of Ioannina School of Medicine, Ioannina, Greece
4Section of Nutrition and Metabolism, International Agency for Research on Cancer IARC, Lyon, France
5Department of Obstetrics and Gynaecology, University of Ioannina, Ioannina, Greece
6Department Gynaecologic Oncology, Lancashire Teaching Hospitals, Preston, United Kingdom
7Department of Biophysics, University of Lancaster, Lancaster, United Kingdom

Aims

Endometrial cancer is the most common gynaecological cancer among European women. Many modifiable risk factors have been associated with endometrial cancer, although the associations may be affected by inherent bias. We evaluated the strength and validity of the available evidence on modifiable risk factors for endometrial cancer (EC).

Method

We conducted an umbrella review of meta-analyses investigating modifiable risk factors for endometrial cancer. The primary analysis focused on cohort studies, with evidence graded as strong, highly suggestive, suggestive or weak based on random effects summary estimate, largest study per meta-analysis, number of cases, between-study heterogeneity, 95% prediction intervals, small study effects, excess significance bias and sensitivity analysis with credibility ceilings.

Results

We identified 144 meta-analyses investigating associations between 9 categories of risk factors for endometrial cancer (93 cohort studies). Only three (7%) risk factors demonstrated strong evidence without hint of bias for association with EC: rise in body mass index in premenopausal women and increase in waist-to-hip ratio (increased risk), and multiparous women (reduced risk of EC).

Conclusion

Of the many identified risk factors for endometrial cancer, only three were found to have strong association without hint of bias. Other claimed associations may also be valid, but further evidence is required. Our findings re-emphasise the importance of targeting the increasing number of obese and overweight women at high risk of endometrial cancer with weight-loss strategies. Future research efforts should explore the effect of obesity on metabolic dysregulation and metabolic pathways which, when altered, may promote endometrial cancer.
THE DIAGNOSTIC DILEMMA OF A PATIENT WITH OVARIAN MASS LESION: IS IT PRIMARY TUMOR OR METASTASIS FROM GASTRIC CANCER?

Aims

Ovaries are the most common site of metastasis of extragenital cancers although their metastasis to the female genital tractus are very rare. Breast, colon-rectum and gastric cancers are known to be the most important primary cancers having metastasis to the ovaries. It is crucial to define the appropriate surgery timing of ovarian masses which have co-existence with extragenital cancers to avoid disproportionate anxiety of patients.

Method

We presented a case with operated gastric cancer and newly detected papillary ovarian mass.

Results

A 55 year-old, gravida 2 parity 2, woman with no other medical history except operation for gastric adenocarcinoma and underwent chemoradiotherapy was admitted to our gynecology clinic for routine control. In gynecologic examination, left lower quadrant abdominal pain was present and ultrasonography revealed 31x27 mm, multi-loculated papillary mass in left ovary. Tumor markers were completely negative and there was no pathological finding in other laboratory parameters. Magnetic resonance imaging reported total of 43x22 mm multicystic mass. Laparotomy was performed and consulted for frozen section. The intraoperative consultation result was benign. Histopathological result was serous papillary cystadenoma for left ovary with no other pathological finding in hysterectomy and salpingo-oophorectomy specimens. Postoperative period was uneventful. Patient was discharged at postoperative 3rd day.

Conclusion

The differential diagnosis between benign/malign primary and metastatic tumor may be difficult with clinical presentation, serum biomarkers and imaging findings. Therefore, diagnosis process may create disproportionate anxiety for both gynecologist and patient. We suggest that it is very important to shorten the time between diagnosis and surgery to avoid such a great anxiety.
Aims

To bring down health burden of gynec cancers in India, through massive awareness, early detection/screening hunt.

Method

World’s first, “Learned Bodies Endorsed” National Day of Gynec Cancer on 11th March in International Women’s week. 10,000+ oncological personnel communicated.

Last 10 years recommendations:

1. Targeted Radio, TV media blitz on women, youth, health and science magazines.
3. Role of moral education and celibacy, dissuading Indian youth from free ethical and non-ethical sexual relations.
5. Spouse awareness of breast lump, post coital bleeding.
7. Opportunistic screening in medical colleges.
8. Infrastructure for gynec cancer detection.
9. Popularisation of HPV vaccination.
10. Declaration of cancer a notifiable disease.

Results

National Day of Gynec Cancer observance by oncology community helped increase in media programs and opportunistic screening in medical institutions for a breast and gynec cancer. Govt schemes for school sanitary pad program. Popularisation of HPV vaccine limited due to cost factor. Failure on declaring cancer as a notifiable disease and inclusion of health education in school syllabus.

Conclusion

Long way to go in activating the oncological and gynec community to participate in creative awareness and opportunistic screening, population based screening at its best.
PREVENTION OF GYNAECOLOGIC CANCER

ESGO7-0246

COST-EFFECTIVENESS OF ENDOMETRIAL CANCER EARLY DETECTION AND/OR PREVENTION - A SYSTEMATIC REVIEW

G. Sroczynski, A. Gogollari, A. Conrads-Frank, M. Widschwendter, N. Pashayan, U. Siebert

1 UMIT - University for Health Sciences - Medical Informatics and Technology, Institute of Public Health- Medical Decision Making and Health Technology Assessment- Department of Public Health- Health Services Research and Health Technology Assessment, Hall in Tirol, Austria
2 UCL - University College London, Department of Women’s Cancer, London, United Kingdom
3 UCL - University College London, Faculty of Population Health Sciences, London, United Kingdom
4 ONCOTYROL - Center for Personalized Cancer Medicine, Division of Health Technology Assessment and Bioinformatics, Innsbruck, Austria
5 Harvard Medical School, Institute for Technology Assessment and Department of Radiology, Boston, USA
6 Harvard T.H. Chan School of Public Health, Center for Health Decision Science- Department of Health Policy and Management, Boston, USA

Aims

To systematically review current evidence on long-term effectiveness and cost-effectiveness of endometrial cancer early detection and prevention strategies in asymptomatic women.

Method

We performed a systematic literature search for decision-analytic modeling studies assessing early detection and/or prevention strategies for endometrial cancer. We included studies evaluating the cost-effectiveness, reporting incremental cost-effectiveness ratios (ICER) in cost per life-years gained (LYG) or per quality-adjusted life years (QALY). We summarized relevant information and results in standardized evidence tables. Economic results were converted to 2015 Euros using GDP-PPP and CPI.

Results

Five studies evaluating early detection and prevention strategies in asymptomatic women with different cancer risk profiles were included. Annual serum screening with a biomarker panel including prolactin in women at increased risk (obese, Tamoxifen usage) dominated annual transvaginal ultrasound and biopsy with ICERs of 19,000-39,000 Euro/LYG. The ICER for screening increased to 58,000 Euro/LYG in the female general population. Another study in obese women revealed ICERs above 82,000 Euro/LYG for prevention with contraceptives or annual screening with biopsy. In women with a family history of endometrial cancer, genetic testing for Lynch syndrome followed by prevention strategies yielded ICERs below 40,000 Euro/QALY for women age 25-40 years with risks of carrying mutations above 5%. In asymptomatic women with Lynch syndrome, prophylactic surgery at age 40 years achieved ICERs below 11,000 Euro/QALY.

Conclusion

Based on the results, in asymptomatic women at increased risk for cancer, annual biomarker screening, genetic testing with preventive strategies for mutation carrier as well as preventive surgery in mutation carrier can be considered cost effective.
PREVENTION OF Gynaecologic Cancer

Histological Findings After Prophylactic Risk-Reducing Salpingo-oophorectomy in BRCA Patients. Experience in Our Center

B. Valenzuela-Mendez1, E. Duran-Arboles1, A. Tarrats-Oliva1, E. Carballas-Valencia1, S. Martinez-Román1

1HOSPITAL UNIVERSITARI GERMANS TRIAS I PUJOL, Obstetrics and Gynecology department, BADALONA- BARCELONA, Spain

Aims

The objective of this study is the retrospective evaluation of the findings in the histological examination of the surgical pieces obtained after risk-reducing bilateral salpingo-oophorectomy (rrBSO) in patients affected by mutations in the BRCA genes carried out by the Gynecology Service of the Hospital Universitari Germans Trias i Pujol (Barcelona) between 2010 and 2017.

Method

We included 55 patients affected by BRCA1 or 2 mutation in which a rrBSO by laparoscopy was performed. Epidemiological data, age of the intervention, family history of cancer, prior personal history of breast neoplasia, prophylactic mastectomy as well as the findings in the histological study of the surgical specimen were collected.

Results

55 patients, 27 affected by BRCA1, 27 by BRCA2 and 1 by both. The mean age at rrBSO was 49.77 ± 9.30. 27 patients (49.1%) had a personal history of breast cancer. The mean age of rrBSO in those with a prior history of breast cancer was 50.50 ± 11.60 whereas in those diagnosed from opportunistic genetic studies were 46.50 ± 6.96. As for the histological findings, 74.5% did not show histological alterations, 1.81% showed müllerian inclusions, 9% tubaric hiperplasia, 3.6% serous intraepithelial tubal carcinoma (STIC) and 10.9% endometriosis.

Conclusion

BRCA1- and BRCA2-associated hereditary breast and ovarian cancer syndrome (HBOC) is characterized by an increased risk for breast and ovarian cancer. The finding of STICs, among other potential precursor lesions, supports its relation with the pathogenesis of high grade pelvic serous carcinomas justifying the role of rrBSO in the prevention of ovarian cancer in these patients.

SELF-COMPASSION AND CLIMACTERIC SYMPTOMS IN OOPHORECTOMIZED BRCA1/2 MUTATION CARRIERS

M. Arts-de Jong1, L. Van Westerop1, N. Hoogerbrugge2, L. Massuger1, A. Maas3, M. Van Beek4, J. de Hullu1

1Radboud university medical center, Obstetrics & Gynaecology, Nijmegen, The Netherlands
2Radboud university medical center, Human Genetics, Nijmegen, The Netherlands
3Radboud university medical center, Cardiology, Nijmegen, The Netherlands
4Radboud university medical center, Psychiatry, Nijmegen, The Netherlands

Aims

To reduce ovarian cancer risk, BRCA1/2 mutation carriers are advised to undergo risk-reducing salpingo-oophorectomy (RRSO) around the age of 40, which may induce severe climacteric symptoms. Dealing with these symptoms may be difficult and success is related to several coping strategies. Successful coping depends in part on self-compassion. This describes a positive and caring way of relating toward the self when facing difficult experiences; it is a skill that can be taught. The aim of this study was to explore the association between climacteric symptoms and self-compassion in late postmenopausal BRCA1/2 mutation carriers.

Method

This cross-sectional study using questionnaire data examined climacteric symptoms, self-compassion, physical fitness in 165 BRCA1/2 mutation carriers who underwent an RRSO ≤ 45 years, at least 5 years ago.

Results

Late postmenopausal BRCA1/2 mutation carriers reported low levels of climacteric symptoms and being highly self-compassionate. Higher self-compassion was associated with less climacteric symptoms. Furthermore, anti-depressant use was associated with more climacteric symptoms, whereas physical fitness with less symptoms.

Conclusion

Being self-compassionate and physically fit, and not using anti-depressants was associated with less climacteric symptoms in oophorectomized BRCA1/2 mutation carriers. Future research is needed to investigate the effect of self-compassion training on climacteric symptoms after RRSO in BRCA1/2 mutation carriers.

PELVIC LYMPHOCELE INCREASE AFTER LYMPH DRAINAGE FOR LYMPHEDEMA TREATMENT: CASE REPORT AND LITERATURE REVIEW

J. Baiocchi\textsuperscript{1}, L. Kopittke\textsuperscript{2}, L. Campanholi\textsuperscript{1}, G. Pinto\textsuperscript{3}, G. Baiocchi\textsuperscript{4}

\textsuperscript{1}Oncofisio, Physical Therapy, Sao Paulo, Brazil

\textsuperscript{2}Oncofisio, Physical Therapy, Brazil

\textsuperscript{3}IBCC, Sao Paulo, Brazil

\textsuperscript{4}AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil

Aims

Pelvic lymphocele prevalence varies from 0% to 58.5% and symptomatic lymphoceles are reported from 5% to 6% of the cases. Lymphedema is treated by the Complex Decongestive Therapy or Complex Decongestive Physiotherapy, which consists of manual lymph drainage, pneumatic pressotherapy, skin care, exercises and use of compression bandages and garments. We report a case of lymphocele increase after lymphedema treatment.

Method

Report the outcome of 59 years old female, diagnosed with endometrial high grade adenocarcinoma (Stage IIIA – FIGO), submitted to complete surgical treatment on December 19th, 2015, which included the resection of 64 pelvic and retroperitoneal lymph nodes, followed by adjuvant chemotherapy. Previously she already has undergone a melanoma resection at her left thigh with inguinal lymphadenectomy.

Results

She presented with stage II lymphedema at the left lower limb and supra pubic. Lymphocintilography observed dermic reflux at her left foot and preserved lymph drainage at right lower limb. Lymphedema was treated with manual lymph drainage, pneumatic pressotherapy and use of compression garment (20/30mmHg). On January 22\textsuperscript{nd}, 2016 she had a computed CT that revealed the existence of a lymphocele with 300 milliliters, asymptomatic. The patient kept her lymphedema treatment, twice a week. In April, 2016 she had a new CT that evidenced the growth of the lymphocele to 500 milliliters, still asymptomatic. In June 22\textsuperscript{nd}, 2016, we noted a sudden decrease of the lymphocele to 17 milliliters, suggesting spontaneous drainage to the abdominal cavity.

Conclusion

Complex decongestive physiotherapy for the lymphedema treatment can be related to the increase of pelvic lymphocele.

A RETROSPECTIVE ANALYSIS OF COMPLICATIONS OF SURGICAL MANAGEMENT OF ENDOMETRIAL CANCER

I. Ben Safta 1, O. Jaidane 1, H. Mansouri 1, S. Gadria 1, J. Ben Hassouna 1, K. Rahal 1

1Institut Salah azeiz of oncology, surgical oncology, TUNIS, Tunisia

Aims

to evaluate the surgical morbidity and mortality of lymphadectomy in the surgical management of endometrial cancer.

Method

A total of 249 patients with proven histologically endometrial cancer were treated in the Tunisian departement of surgical oncology of salah Azaiez between 2000 and 2015 were retrospectively reviewed.

Results

of the total of 249 patients who underwent surgery, 136 (54.6%) had hysterectomy with bilateral oophorectomie, and 73 patients (29.3%) had Piver II procedure with pelvic lymphadenectomy, simple hysterectomy with pelvic lymph node prelevement was performed in 37 patients (14.8%) and only tow patients underwent pelvic exenteration. Complete pelvic lymphadenectomy was performed in 165 (66.2%) and 56 patients (22.4%) underwent only pelvic lymph node prelevemnet. From all, 11 patients (4.4%) had complete Para-aortic lymphadenectomy and 15 patients underwent only resection of pathologic para-aortic lymph node. The mean operation time of hystectomy with open surgery was 138.2 mn and increase to 182.2 mn in case of additionnal lymphadenectomy procedure. Per operative blood transfusion was necessary in 25 cases (10%). The rate of vascular complication was 2.4% (6cases), tow patients had urinary woods (0.8%). Early specific post operative complications occurred in 9 patients (3.6%) with 3 cases of hemorrhage (1.21%) and 4 cases of peritonitis (1.6%). The rate of post operative mortality was 2% (5 patients). Late post operative complication was dominated by pelvic lymphocyst (4%) and acute bowl obstruction (2%).

Conclusion

The morbidity of the surgical management of endometrial cancer is increased by the lymphadenectomy and the radiotherapy.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

PREDICTION MODEL FOR 30-DAY MORBIDITY AFTER GYNECOLOGICAL MALIGNANCY SURGERY

S.H. Chae¹, S.H. Shim¹, S.J. Lee¹, J.H. Suh¹, S.N. Kim¹, S.B. Kang¹, J. Kim²
¹Konkuk University Medical Center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Konkuk University Medical Center, Research Coordinating Center, Seoul, Republic of Korea

Aims

The potential risk of postoperative morbidity is important for gynecologic cancer patients because it leads to delays in adjunctive therapy and additional costs. We aimed to develop a preoperative nomogram to predict 30-day morbidity after gynecological cancer surgery.

Method

Between 2005 and 2015, 533 consecutive patients with elective gynecological cancer surgery in our center were reviewed. Of those patients, 373 and 160 patients were assigned to the model development or validation cohort, respectively. To investigate independent predictors of 30-day morbidity, a multivariate Cox regression model with backward stepwise elimination was utilized. A nomogram based on this Cox model was developed and externally validated. Its performance was assessed using the concordance index and a calibration curve.

Results

Ninety-seven (18.2%) patients had at least one postoperative complication within 30 days after surgery. After bootstrap resampling, the final model indicated age, operating time, and serum albumin level as statistically significant predictors of postoperative morbidity. The bootstrap-corrected concordance index of the nomogram incorporating these three predictors was 0.656 (95% CI, 0.608–0.723). In the validation cohort, the nomogram showed fair discrimination [concordance index: 0.674 (95% CI = 0.619–0.732)] and good calibration (P = 0.614; Hosmer-Lemeshow test).

Conclusion

The 30-day morbidity after gynecologic cancer surgery could be predicted according to age, operation time, and serum albumin level. After further validation using an independent dataset, the constructed nomogram could be valuable for predicting operative risk in individual patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAEOCOLOGIC CANCER

ESGO7-0910

LONG-TERM OUTCOMES AFTER CONSERVATIVE AND RADICAL TREATMENT OF BORDERLINE OVARIAN TUMOURS

V. Sirvydyte1, M. Gedgaudaite2, A. Gaurilcikas2

1Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania
2Lithuanian University of Health Sciences, Obstetrics and Gynaecology, Kaunas, Lithuania

Aims

1. To evaluate the remote outcomes of patients with borderline ovarian tumours (BOTs) after radical (RS) and conservative (CS) surgery: survival and recurrence rates and their dependence on surgery type, patients’ age, FIGO stage, histological tumour type, preoperative CA 125 levels.
2. To assess the pregnancy rate after conservative surgery.
3. To evaluate the Quality of life (QOL) after CS and RS.

Method

Retrospective data analysis of 56 patients treated for BOT in Oncogynaecology Department of LUHS Hospital. According to the surgery type, patients were divided into CS and RS groups. For QOL evaluation, the validated EORTC–QLQ30–OV28 questionnaire was used. The results were compared between CS and RS groups.

Results

The 5-year survival rate was 97.6% and recurrence rate – 17.9% (10 patients). BOTs significantly more often recurred after CS (80% vs. 20% respectively), and among younger patients (36.9 vs. 46.4 years). 21 patients had CS, 6 (28.57%) of them tried to get pregnant. The pregnancy rate was 66.7% (4 patients). QOL evaluation showed that patients after CS had less symptoms (30.3 vs. 26.0 points), however, the difference is not significant. Nevertheless, sexual function was evaluated significantly better in the RS group (73.0 vs. 53.3, p<0.05).

Conclusion

The 5-year survival rate was 97.6%. Recurrence rate was 17.9%, more often after fertility sparing surgery and among younger patients. Pregnancy rate was 66.7% among patients who tried to conceive after CS. Despite the fact that overall QOL was similar between two groups, sexual function was evaluated better among RS patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0528

RISK PREDICTION OF SEVERE POSTOPERATIVE COMPLICATIONS IN PATIENTS UNDERGOING GYNECOLOGIC CANCER SURGERY: RESULTS OF A PROSPECTIVE STUDY IN 237 PATIENTS

G. Inci1, J. Rasch1, H. Woopen1, R. Richter1, Z. Muallem1, R. Chekerov1, J. Sehouli1
1Charité - Universitätsmedizin Berlin, Gynecologic Oncology, Berlin, Germany

Aims

Physicians need to risk-stratify their patients preoperatively to adjust the radicality of surgery. Aim of this study is to evaluate predictive clinical characteristics such as polypharmacy and Charlson-Comorbidity Index (CCI) for postoperative complications in patients undergoing gynecologic cancer surgery.

Method

This is a prospective cohort study with patients undergoing gynecologic cancer surgery at a tertiary hospital from October 2015 through January 2017. Surgical complications were graded using Clavien-Dindo. Using logistic regression, we identified predictive clinical characteristics for complications.

Results

Out of the 237 enrolled patients 41(17.3%) experienced a grade≥3b complication and 9 (3.8%) patients died. Charlson Comorbidity index (CCI)>2 (p<0.015, OR 2.33, 95% CI 1.18–4.61), polypharmacy (p<0.001, OR 3.40, 95% CI 1.63–7.10), ASA (p<0.001, OR 2.96, 95% CI 1.65–5.38), BMI>25kg/m² (p<0.001, OR 4.25, 95% CI 1.86–9.69), albumin<3.5 g/dl (p<0.009, OR 3.22, 95% CI 1.33–7.79) and potassium < 3.6 mmol/L (p=0.007, OR 5.11, 95% CI 1.55–16.81) were predictive for complications grade≥3b. A multivariable model included duration of surgery (p=0.012, OR 1.26, 95% CI 1.05–1.52), ASA (p=0.01, OR 2.60, 95% CI 1.20–5.38), albumin<3.5 g/dl (p=0.028, OR 3.37, 95% CI 1.14–10.00), BMI >25kg/m² (p=0.009, OR 3.81, 95% CI 1.40–10.35) and potassium < 3.6 mmol/L (p=0.02, OR 3.69, 95% CI 1.20–11.38) was predictive for complications. Age (p=0.49, OR 0.89, 95% CI 0.95–1.02), CCI >2 (p=0.88, OR 1.06, 95% CI 0.42–2.69) and polypharmacy (p=0.65, OR 1.26, 95% CI 0.41–3.98) showed no association for complications.

Conclusion

ASA, BMI, albumin and potassium are associated with severe postoperative complications. Subsequent studies should confirm this results to identify better frail cancer patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

DEVELOPMENT AND PRE-TESTING OF THE EORTC QUALITY OF LIFE QUESTIONNAIRE FOR VULVA CANCER PATIENTS – THE SIGNIFICANCE OF PATIENT INVOLVEMENT

P. Jensen1, L. Froeding2, E. Greimel3, A. Lanceley4, A. Nordin5, A. Oberguggenberger6, I. Vistad7

1Odense University Hospital, Department of Gynecology, Odense, Denmark
2Copenhagen University Hospital, Gynecology, Copenhagen, Denmark
3Medical University of Graz, Obstetrics and Gynecology, Graz, Austria
4UCL, Dept. of Women’s Cancer, London, United Kingdom
5East Kent Hospital, Gynecology, Kent, United Kingdom
6Department of Psychology, University of Innsbruck, Innsbruck, Austria
7Soelandet Hospital, Gynecology, Arendal, Norway

Aims

Objective: Patients with vulva cancer (VC) and health care professionals representing Northern, Central, and Southern Europe participated in the development of an EORTC Quality of Life (QoL) Group VC specific questionnaire. The objective of phase 3 is to pre-test the provisional questionnaire to identify and solve potential conceptual and operational problems to ensure broad cross-cultural adaptation.

Method

Methods: The provisional questionnaire underwent rigorous forward-backward translation and was then administered to VC patients representative across age, stage, treatment modality, and country. A structured interview was conducted after questionnaire completion to assess the patient’s perspective on clarity and acceptability. Response questionnaire- and debriefing interview data were collected and audited by a multinational collaborative module team. Standardized decision rules for deletion, addition, and changing of the wording were applied.

Results

Results: A well-balanced sample of 77 patients from nine European countries was included. Most items, 32/36 (89%) satisfied decision rules and showed a high compliance, >95% for 31/36 (86%) items. Three items displayed serious patient concern. Weighting the patients’ comments, final pre-testing resulted in the deletion of five items, re-phrasing of three items while five items on sexuality, 4 on urological problems and 2 on proctitis were made conditional. Preliminary explorative psychometric analyses suggested a structure of 9 multi-items scales and one single item

Conclusion

Conclusion: The EORTC QoL group has developed and pre-tested a VC specific questionnaire. Debriefing interviews supplemented the quantitative test results and appeared to add highly significant information leading to substantial and relevant changes for final field testing in phase 4.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0523

IMPACT OF HORMONE REPLACEMENT THERAPY ON PATIENTS WITH OVARIAN OR CERVICAL CANCER

S. Jiang

1Shandong Cancer Hospital and Institute, Department of Gynecologic Oncology, Jinan, China

Aims

To investigate the influence of HRT on patients with ovarian or cervical cancer.

Method

158 patients with ovarian/cervical cancer were involved and divided into HRT and NHRT groups. 65 patients (31 with ovarian cancer, 34 with cervical cancer) underwent HRT treatment while 93 (44 with ovarian cancer, 49 with cervical cancer) did not undergo HRT after surgery/radiotherapy. PR, ER and its subtypes were detected in cancer tissues by immunohistochemical staining assay. And the serum concentration of calcitonin and TGF were detected by radio-immunity and ELISA. The data were analyzed by Kaplan-Meier survival curve and Cox's proportional hazard model. Quality of life was measured by EORTC-C30 and other scale made by ourselves.

Results

There was no statistical significance between HRT and NHRT groups in survival interval. Cox model showed that HRT is not an independent factor for prognosis. There were no statistical significance between positive expression group of ER, ERα,ERβ, PR and negative expression group of them for survival interval. The serum concentration of TGF had no statistical significance between HRT and NHRT groups whether pre, post surgery, or half to one year after surgery. The serum calcitonin concentration of NHRT group is higher than HRT group. For HRT group, there's no statistical significance for serum calcitonin concentration pre and post surgery. HRT could improve quality of life.

Conclusion

HRT has no detrimental effects on patients. HRT maybe stabilize calcitonin concentration in serum and improve quality of life. TGF concentration and ER, ERα,ERβ, PR expression have no association with prognosis.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

USE OF CARDIO-PULMONARY EXERCISE TESTING IN DECISION MAKING PRIOR TO MAJOR GYNAECOLOGICAL ONCOLOGY SURGERY

P. Jones¹, K. Janoowala², F. Drews¹, E. Rzyska², R. Howells¹, K. Lim¹, A. Sharma¹
¹University hospital of Wales, Gynaecological Oncology, Cardiff, United Kingdom
²University hospital of Wales, Obstetrics & Gynaecology, Cardiff, United Kingdom

Aims

Cardiopulmonary exercise testing (CPET) provides a patient-specific, non-invasive assessment of combined cardio-pulmonary and circulatory function, quantifying the functional ability to respond to the increased metabolic demands of surgery. An anaerobic threshold (AT) ≥11mg/ml/min determined by CPET has been proposed to indicate cardio-respiratory fitness for major surgery.

In our centre, CPET is used in high risk patients and those being considered for ultra-radical surgery. The aim of our study was to look at the role of CPET and its influence on decision for surgery.

Method

We conducted a retrospective case notes review of patients referred to CPET prior to gynae-oncology surgery from 01/01/2015-31/12/2016.

Results

24 women were referred for CPET during the review period (age range 36-84 years, median 73 years). Of the 24 women referred, 16 underwent CPEX; 2 women reached an AT of ≥11, both underwent surgery; 9 women reached their AT <11mg/ml/min (5 underwent surgery, 1 declined surgery, 3 were deemed not fit for surgery); 5 women did not reach an AT (1 underwent surgery, 3 declined surgery & 1 was deemed not fit for surgery).

3 women had ≤ grade 3 complications following surgery. There were 4 patient deaths in the follow-up period, all in the no surgery group, 1 of which was confirmed as disease related.

Conclusion

This study suggests CPEX is useful to clinicians & patients for pre-operative planning & quantifying risk. In this small sample the previously accepted AT of ≥11mg/ml/min appears to be an appropriate threshold to prompt discussion of the increased risk with the patient.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-1314

EVALUATION OF THE SEXUAL FUNCTION IN YOUNG WOMEN AFTER SURGERY FOR BREAST CANCER

O. Kaabia\textsuperscript{1}, S. Hidar\textsuperscript{1}, M. Bibi\textsuperscript{1}, H. Khairi\textsuperscript{1}
\textsuperscript{1}CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia

Aims

The objective of our work was to evaluate the sexual function, the body image and the marital agreement in women in remission for at least one year, after breast surgery for breast cancer and aged under 40 years at the diagnosis and followed at the department gynecology and obstetrics at Farhat Hached University Hospital in Sousse Tunisia.

Method

We carried out a cross-sectional study involving 105 patients. The feminine sexuality function was explored the Female Sexual Function Index (FSFI). We considered the marital agreement in the couple that was assessed by the Marital Adjustment Test (MAR), anxiety and depression that were assessed by the Hospital Anxiety and Depression Scale (HAD-S), and finally the body image that was evaluated by Body-Esteem Scale for Adolescents and Adults (BESAA).

Results

Sexuality assessment returned an average FSFI score of $22.7 \pm 13.3$ (range 3.6-69) and 64% of the patients had a FSFI score of less than 26.55, probably a sexual dysfunction.

Conclusion

If we consider that this impairment of sexual function can be related to breast cancer, the rate found in our study is close to that reported in the literature.

EVALUATION OF THE SEXUAL FUNCTION AFTER SURGERY FOR BREAST MENOPAUSAL WOMEN

O. Kaabia¹, S. Hidar¹, M. Bibi¹, H. Khairi¹
¹CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia

Aims

The objective of our work was to evaluate the sexual function, the body image and the marital agreement in women in remission for at least one year, after breast surgery for breast cancer and already menopausal at the diagnosis and followed at the department gynecology and obstetrics at Farhat Hached University Hospital in Sousse Tunisia.

Method

We carried out a cross-sectional study involving 100 patients. The feminine sexuality function was explored the Female Sexual Function Index (FSFI). We considered the marital agreement in the couple that was assessed by the Marital Adjustment Test (MAR), anxiety and depression that were assessed by the Hospital Anxiety and Depression Scale (HAD-S), and finally the body image that was evaluated by Body-Esteem Scale for Adolescents and Adults (BESAA).

Results

Sexuality assessment returned an average FSFI score of 21.1 ± 13.2 (range 2-52) and 78% of the patients had a FSFI score of less than 26.55, probably a sexual dysfunction.

Conclusion

If we consider that this impairment of sexual function can be related to both breast cancer and menopause, the high rate found in our study is close to that reported in the literature.

EVALUATION OF THE SEXUAL FUNCTION AFTER SIMPLE HYSTERECTOMY FOR STAGE I ENDOMETRIAL CANCER IN MENOPAUSAL WOMEN

O. Kaabia 1, S. Hidar 1, F. Hacheni 1, M. Bibi 1, H. Khairi 1

1CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia

Aims

The objective of our work was to evaluate the sexual function, the body image and the marital agreement in women in remission for at least one year, after simple hysterectomy for stage 1 endometrial cancer in already menopausal women at the time of diagnosis and followed at the department gynecology and obstetrics at Farhat Hached University Hospital in Sousse Tunisia.

Method

We carried out a cross-sectional study involving 52 patients. The feminine sexuality function was explored the Female Sexual Function Index (FSFI). We considered the marital agreement in the couple that was assessed by the Marital Adjustment Test (MAR), anxiety and depression that were assessed by the Hospital Anxiety and Depression Scale (HAD-S), and finally the body image that was evaluated by Body-Esteem Scale for Adolescents and Adults (BESAA).

Results

Sexuality assessment returned an average FSFI score of 18.1 ± 9.7 (range 2-45) and 81% of the patients had a FSFI score of less than 26.55, probably a sexual dysfunction. This rate was the same either hysterectomy was performed after laparoscopy or after laparotomy.

Conclusion

This impairment of sexual function can be related to the endometrial cancer, to menopause and to the impairment of the body image due to the hysterectomy.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0434

EFFECT OF RED GINSENG ON GENOTOXICITY AND HEALTH-RELATED QUALITY OF LIFE AFTER ADJUVANT CHEMOTHERAPY IN PATIENTS WITH OVARIAN CANCER: A RANDOMIZED, DOUBLE BLIND, PLACEBO-CONTROLLED TRIAL

K. Se Il1, H.S. Kim1, L. Maria1, K. Jae Weon1
1Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

We evaluated the effect of red ginseng on toxicity, health-related quality of life (HRQL) and survival after adjuvant chemotherapy in patients with epithelial ovarian cancer (EOC).

Method

A total of 30 patients with EOC were randomly assigned to placebo (n=15) and red ginseng groups (n=15) after cytoreductive surgery and adjuvant chemotherapy. All patients took placebo or red ginseng (3,000 mg/day) for three months. Then, we compared toxicity using laboratory markers, adverse events and genotoxicity between the two groups at week 0 (before consumption) and week 12 (after consumption). For genotoxicity, we evaluated binucleated cells (BN) index and micronuclei (MN) yield. Moreover, HRQL was investigated using questionnaire of the EORTC QLQ-C30, BFI, BPI, HADS and MOS-SS.

Results

Red ginseng reduced MN yield in comparison with placebo despite no difference of BN index. Although red ginseng increased serum levels of alanine aminotransferase and aspartate aminotransferase significantly, they were within the normal value. Moreover, there were no differences in adverse events between placebo and red ginseng groups. In terms of HRQL, red ginseng was associated with improved emotional functioning and decreased symptoms of fatigue, nausea and vomiting, and dyspnea, reduced anxiety and interference affecting life and improved daytime somnolence. However, there was no effect of red ginseng on prognosis of EOC.

Conclusion

Red ginseng may be safe and effective to reduce genotoxicity and improve HRQL despite no benefit of survival in patients with EOC who received chemotherapy.

ESGO7-0180

POSTOPERATIVE RECOVERY AFTER ABDOMINAL SURGERY FOR GYNECOLOGIC MALIGNANCY WITH INTRATHECAL MORPHINE OR EPIDURAL ANALGESIA. A RANDOMIZED TRIAL

P. Kjölhede¹, O. Bergdahl², N.B. Wodlin¹, L. Nilsson³

¹Department of Obstetrics and Gynecology, Department of Clinical and Experimental Medicine, Linköping, Sweden
²Department of Obstetrics and Gynecology, Department of Obstetrics and Gynecology, Norrköping, Sweden
³Department of Anaesthesiology and Intensive Care, Department of Medical and Health Sciences, Linköping, Sweden

Aims

To determine whether the use of regional analgesia with intrathecal morphine (ITM) in an enhanced recovery program (ERAS) gives a shorter duration of hospital stay with a similar health-related quality of life (QoL) to epidural analgesia (EDA) in women after laparotomy for proven or assumed gynecological malignant tumors.

Method

An open-label, randomized, controlled single center study. Eighty women undergoing midline laparotomy for proven or assumed gynecological malignant tumors were included. ERAS with standardized perioperative routines including a standardized general anesthesia was used. The allocated treatment (ITM or EDA) was applied immediately preoperatively. The ITM group received morphine, clonidine and bupivacaine intrathecally; the EDA group an epidural infusion of bupivacaine, adrenalin and fentanyl.

Results

The length of hospital stay did not differ between the groups (median 3.3 vs. 4.3 days) but the time to meet the standardized discharge criteria was significantly shorter for the ITM group (3.0 vs. 4.0 days). Significantly, more women allocated to ITM were discharged on day 3, 62.5% vs. 30%. The ITM group used significantly less opioids whereas no differences were observed in pain assessment or QoL. No serious adverse events were attributed to the ITM or EDA.

Conclusion

Compared with EDA, ITM reduces the duration of hospital stay and the opioid consumption postoperatively with an equally good pain alleviation and QoL. ITM is even effective as EDA for postoperative analgesia in gynecological cancer surgery and is easier to administer.

CONSERVATIVE TREATMENT OF POSTOPERATIVE CHYLOUS ASCITES IN GYNECOLOGIC CANCER SURGERIES.

Y.S. Kwon¹, H.J. Roh¹, S.H. Lee¹, J.Y. Kwack¹
¹Ulsan University Hospital, Obstetrics and Gynecology, Ulsan, Republic of Korea

Aims

This study aimed to evaluate the efficacy of conservative treatment with the formula for postoperative chylous ascites in patients with gynecologic surgeries.

Method

We retrospectively analyzed 107 patients who underwent pelvic and/or para-aortic lymphadenectomy for gynecologic malignancies at Ulsan University Hospital from March 2011 to February 2013.

Results

The 107 cases consisted of 41 cervical cancers, 24 endometrial cancers, 34 ovarian cancers, and eight other cancers. Among the 107 cases, 81 patients underwent pelvic and para-aortic lymphadenectomy, 23 patients underwent pelvic lymphadenectomy without para-aortic lymphadenectomy, and three patients underwent only para-aortic lymphadenectomy. Postoperative chylous ascites occurred in 13/81 of patients who received pelvic and para-aortic lymphadenectomy, in 2/3 patients who received only para-aortic lymphadenectomy, and none of the patients who received only pelvic lymphadenectomy.

The average age of the patients was 55.8 yr. The mean time interval between the operation and the appearance of chylous ascites was 2.8 days (range, 2–5 days). All cases of postoperative chylous ascites were treated with the conservative treatment with our department formula. The cure rate of chylous ascites with the conservative therapy was 100%. None of the cases had recurrent chylous ascites during follow-up.

Conclusion

In gynecologic surgeries, para-aortic lymphadenectomy induced postoperative chylous ascites could be treated in high cure rate by the formula of effective conservative strategy.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0397

QUALITY OF LIFE AFTER ENDOMETRIAL CANCER SURGERY WITH AND WITHOUT LYMPHADENECTOMY: A SINGLE INSTITUTION RETROSPECTIVE COHORT STUDY

E. Lajtman¹, M. Mlynček¹, M. Matejka¹, T. Kapusta¹
¹Faculty Hospital Nitra and Constantine the Philosopher University in Nitra, Department of obstetrics and gynecology, Nitra, Slovak Republic

Aims

To compare the quality of life of endometrial cancer patients treated with surgery with and without lymphadenectomy.

Method

Quality of life of the endometrial cancer (FIGO stages I and II) patients treated with surgery between 2012 and 2016 was analyzed. The patients were divided into two groups: Group A consisted of 102 patients who had hysterectomy and bilateral salpingo-oophorectomy without lymphadenectomy (HBSO); Group B consisted of 53 patients who had hysterectomy and bilateral salpingo-oophorectomy with lymphadenectomy (HBSO+LYA). The EORTC Quality of Life Questionnaire Endometrial Cancer Module (QLQ-EN24) and Quality of Life Questionnaire Cancer Module (QLQ-C30) were administered to the selected patients. The data were analyzed using the manual of the EORTC Group.

Results

According to QLQ-C30 fatigue showed statistically significant difference between Group A and Group B (3.033 ± 8.05 vs. 16.99 ± 22.35, p=0.045). As to the symptom scales according to QLQ-EN24 lymphedema showed a statistically significant difference between two groups with a score of 11.74 ± 16.63 in Group A and 21.94 ± 23.63 in Group B (p=0.0279).

Conclusion

Our study showed that fatigue and lymphedema decrease the quality of life in the patients with endometrial cancer treated with lymphadenectomy. Systematic pelvic and paraaortic lymphadenectomy should be accomplished only in the high risk endometrial cancer group to select the adjuvant treatment after surgery.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0178

EFFECT OF POSTMENOPAUSAL HORMONE THERAPY ON CERVICAL ADENOCARCINOMA PATIENTS’ SURVIVAL

S. Lee¹, K. Lee¹, Y. Cho¹, K. Cho¹

¹Gachon University Gil Medical Center, Obstetrics and Gynecology, Incheon, Republic of Korea

Aims

Gynecologic oncologists are uncertain about the safety of postmenopausal hormone therapy (HT) in cervical adenocarcinoma (AC) patients. This study evaluated the possible adverse effects of HT on cervical AC patients’ survival.

Method

The medical records of 70 cervical AC patients with FIGO stage IA – IB were reviewed. Bilateral salpingo-oophorectomy was performed for all patients. Survival outcomes between HT users (n = 38) and non-users (n = 32) were compared. Tibolone was given to 18 patients and estradiol was given to 20 patients.

Results

Comparison of users with non-users revealed no significant differences in several clinicopathologic variables. Neither progression free survival (PFS; \( P = 0.34 \)) nor overall survival (OS; \( P = 0.22 \)) differed significantly between users and non-users. Neither the risk of progression (HR, 1.71; 95% CI, 0.46 – 6.37; \( P = 0.43 \)) nor the risk of death (HR, 1.59; 95% CI, 0.06 – 45.66; \( P = 0.79 \)) in users were significantly higher than non-users. Clinicopathologic factors did not differ significantly between tibolone users and estradiol users. Neither PFS (\( P = 0.72 \)) nor OS (\( P = 0.30 \)) differed significantly between tibolone users and estradiol users.

Conclusion

HT had no adverse effect on cervical AC patients’ survival and can be given safely to cervical AC patients. Survival did not differ significantly according to HT regimen. This findings may be helpful in improving quality of life in cervical AC patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0993

SEXUAL FUNCTION AFTER GYNECOLOGIC CANCER.
A. Lubrano¹, V. Benito¹, O. Arencibia¹, M. Esparza¹, N. Medina¹, S. Carballo¹, A. Falcon¹
¹Hospital universitario materno infantil de Canarias, Department of Obstetrics and Gynecology, Las Palmas de Gran Canaria, Spain

Aims

The aim of this study is to evaluate the sexual function in that patient who have suffered from a gynaecological malignancy at early stages. Moreover the questionnaire in spanish of the sexual function of the women (FSM) will be evaluated.

Method

An observational cross-sectional study was designed, in which healthy women and women with a history of gynaecological pathology at least five years before were studied. FSM questionnaire was used. This questionnaire is validated in Spanish.

Results

The sample under study was 100 women, 27 healthy women and 73 women with gynaecological malignancies. 23 of that women had suffered from a uterus cancer, 23 from a cervix cancer and 27 from ovary cancer. The average age of healthy women was 41.2 and the average age of oncological patients was 50.9. Just 56.2% of oncological patients had sexual activity in the last four weeks, compared with 81.5% of healthy women who had been sexually active in the past four weeks. From the oncological group, 20 received adjuvant therapy in addition to surgical treatment.

Conclusion

49.3% of oncological patients experienced a negative change in their sex lives after treatment. Patients who had received adjuvant therapy had worse sexual function than patients undergoing just surgery and healthy women (p = 0.001). Adjuvant therapy produces a strong negative impact on the personal assessment of the sexual life of patients.

ESGO7-0580

PREVENTION OF EMPTY PELVIC SYNDROME FOLLOWING PELVIC EXENTERATION WITH A MAMMARY IMPLANT IN THE PELVIC CAVITY: CASE REPORT.

G. Mancebo1, J.M. Sole-Sedeno1, E. Miralpeix1, K. Vellvé1, M. Pera-Román2, L. Cecchini3, R. Carreras1, A. Payà1
1Hospital del Mar, Obstetrics and Gynecology, Barcelona, Spain
2Hospital del Mar, General Surgery Dept, Barcelona, Spain
3Hospital del Mar, Urology Dept, Barcelona, Spain

Aims

Pelvic exenteration (PE) refers to en-bloc resection of multiple endopelvic and exopelvic organs. In Gynaecologic Oncology it’s most used to treat recurrent tumours of the lower and middle female genital to achieve locorregional control with clear margins.

After the pelvis exenteration, a large defect will remain at the level of the pelvic diaphragm that increases the risk of acute and chronic complications included under the term of Empty Pelvic Syndrome (EPS). EPS can be avoided by isolating small bowel loops from the pelvic defect.

Method

We present a case of a 52-year-old patient submitted to a total PE for locally recurrent cervical cancer treated by chemorradiation 2 years before. After other sites of relapse were excluded a Total PE was performed with a middle and posterior extralevator abdominoperineal excision. A bioabsorbable mesh was used to pelvic floor reconstruction. To isolate the intestinal loops from the pelvic defect, we placed a mammary prosthesis after filling the pelvis with fluid to calculate the volume to hold. No omental flap was interposed between the prosthesis and the small bowel.

Results

After initial postop, a pelvic effusion appeared requiring pelvi-perineal drainage and antibiotic treatment for 2 weeks. A superficial perineal wound dehiscence was treated conservatively. No other complications such as occlusion or fistulas related to a EPS appeared. No other morbidity related to the prosthetic implants was observed.

Conclusion

After PE, the use of mammary implants to avoid EPS is feasible, safe and effective to isolate small intestine from the pelvic cavity.

PROSPECTIVE CLINICAL COHORT STUDY FOR EFFICACY ASSESSMENT OF TOPICAL TREATMENT WITH OLIVOLEINA ON POST-SURGICAL SCARS IN PATIENTS UNDERGOING RADIOTHERAPY FOR GYNEACOLOGIC CANCERS

J. Molero Vilchez1,2, E. Martinez Lamela1,2, S. Sancho Garcia1, B. Castro Rodriguez2, J.L. Prieto Alonso6

1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, MADRID, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Ramon y Cajal University Hospital, Radiation Oncology, Madrid, Spain
5Carris Skin Laboratory, Pharmacy, Madrid, Spain
6Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain

Aims

Evaluate the effectiveness of the topical treatment with olivoleina on the post-surgical quality of healing in patients treated with radiotherapy for gynecologic cancers.

Method

Prospective Cohort study (case/control) (Canadian Task Force classification IIa) in 100 patients operated for gynecologic cancers. The study was carried out by Gynecological Oncologic Unit from January 2014 to July 2016. A comparative analysis of the healing response to topical treatment with olivoleina was carried out in patients who received radiotherapy, with a monitoring at 3, 6 and 12 months. The features of the scars were assessed according to the Vancouver Scale, Manchester Scale and Posas Scale.

Results

52 patients took part in the radiotherapy group, divided into: Group 1 - 36 cases (69.2%) with topical treatment and 16 control cases. Group 2 - 48 patients who didn’t receive radiotherapy, divided into 30 cases (62.5%) with olivoleina topical treatment and 18 control cases. The quality of the healing in patients treated with radiotherapy for gynecological cancers and after that, treated with olivoleina was significantly better (p<0.01). The tolerance was good –very good in 96.9% of the cases. The dermatological effects studied, were good-very good in 95.2% of the cases in relation with the wound hydration, in 73% in relation with the restoring of the skin barrier and in 76,5% in the anti-inflammatory action.

Conclusion

The topical application of olivoleina can be introduced within the therapeutic options of abnormal healing prevention in patients who have received radiotherapy.

INFLUENCE OF SURGICAL AND HISTOPATHOLOGICALS FACTORS ON THE HEALING AND THE THERAPEUTIC RESPONSE TO THE TOPICAL TREATMENT WITH OLIVOLEINA IN A COHORTS STUDY

J. Molero Vilchez1,2, E. Martínez Lamela1,2, S. Sancho García4, B. Castro Rodríguez2, J.L. Prieto Alonso6
1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, MADRID, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Ramon y Cajal University Hospital, Radiation Oncology, Madrid, Spain
5Carris Skin Laboratory, Pharmacy, Madrid, Spain
6Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain

Aims

Study of the influence of surgical and histopathologicals risks factors on the abnormal healing in patients operated of gynecological cancers and the response to the topical treatment with olivoleina.

Method

Prospective cohorts study in 100 patients, randomised and comparative, between January 2014 and July 2016. Groups of patients were defined whether the studied risk factor was present or not. In a randomly way, olivoleina was prescribed in 66 patients. The monitoring was carried in 3, 6 and 12 months. The scars were assessed according to the Vancouver, Manchester and Posas Scales.

Results

64 patients received lymphadenectomy. The average of surgical time was 188.06 minutes, of blood loss was 761.90 cc and of monitoring was 10.13 months. When the lymphadenectomy was made, the patients used to have difficulty to the healing in a significant way from the beginning until 6 months later (p<0.01). The subgroup of patients with treatment showed an improvement from the 6th month (p<0.05) and from the 12 months (p<0.01). The high average blood loss during the surgical intervention and the surgical time hindered in the initial healing and 3 months later (p<0.01). The treatment proved a significant improvement in the final result (p<0.01). Dermatologic effects and the tolerance perceived were good-very good in 95.2% and 96.9% of the cases respectively.

Conclusion

The quality of the healing after the topical treatment with olivoleina was significantly better in the patients who received lymphadenectomy. It can be recommended to patients after they have undergone gynecological cancer surgery.

ESGO7-0674

THE EFFECT OF Hysterectomy ON PELVIC FLOOR SYMPTOMS
A. Obermaier1, P. Higgs2, P. Forder3, R. Asher4, M. Janda5, V. Gebski4
1Queensland Centre for Gynaecological Cancer, Royal Brisbane and Women’s Hospital, Brisbane, Australia
2The Sunshine Coast Private Hospital- Sunshine Coast University Hospital, Gynaecology, Sunshine Coast, Australia
3University of Newcastle, Faculty of Health and Medicine, Newcastle, Australia
4University of Sydney, NHMRC Clinical Trials Centre, Sydney, Australia
5Queensland University of Technology, Institute of Health and Biomedical Innovation, Brisbane, Australia

Aims

Pelvic floor functioning is a major concern for women requiring a hysterectomy for endometrial cancer and for benign conditions. This study reports the effect of hysterectomy on pelvic floor symptoms preformed using an open abdominal (TAH) or total laparoscopic approach (TLH).

Method

381 women who participated in the Laparoscopic Approach to Cancer of the Endometrium (LACE) trial and required surgery for stage 1 endometrial cancer, were asked to complete the Pelvic Floor Distress Inventory (PFDI-20) before surgery, 6-months post-surgery, and yearly thereafter until 54 months follow-up. The mean change in scores in the TAH and TLH groups were compared using student t-test.

Results

At baseline, women were on average 63 years (SD 10 years), and 88% were overweight or obese. The mean PFDI-20 score was 13.5 (13.8) at baseline, indicating a low level of pelvic floor concerns among the women. Six months after surgery, women in both treatment groups reported better pelvic floor quality of life compared to baseline. Women who received a TAH reported a score of 11.01 (12.71), and women who received TLH 8.95 (11.77). The mean change in PFDI-20 score from baseline to 6-months post-surgery was not significantly different between TAH and TLH groups (0.06 (95% CI -3.18, 3.31); p=0.97).

Conclusion

Prevalence of pelvic floor symptoms in this trial was comparatively low. Surgical treatment of stage 1 endometrial cancer led to improvements in pelvic floor quality of life six months after surgery regardless of whether the surgery was performed via TAH or TLH.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0682

THE ASSOCIATION OF LYPHEDEMA TRAJECTORIES WITH SYMPTOMS AND SYMPTOM SEVERITY FOLLOWING GYNAECOLOGICAL CANCER TREATMENT IN QUEENSLAND: A PROSPECTIVE COHORT STUDY

1Queensland Centre for Gynaecological Cancer, Royal Brisbane and Women’s Hospital, Brisbane, Australia
2Royal Brisbane and Women’s Hospital, Queensland Centre for Gynaecological Cancer, Brisbane, Australia
3Queensland University of Technology, Institute for Health and Biomedical Innovation, Brisbane, Australia
4University of Queensland, School of Chemistry and Molecular Biosciences, Brisbane, Australia
5Royal Brisbane and Women’s Hospital, Physiotherapy Department, Brisbane, Australia

Aims

To describe the trajectory of leg swelling and leg symptoms from before, to 24 months after, gynaecological cancer surgery, the association of leg swelling with symptoms and the severity of those symptoms.

Method

Women (n = 408) diagnosed with gynecological cancer (235 uterine, 114 ovarian, 69 cervical, vulvar, or vaginal cancer; respectively) were enrolled in the prospective longitudinal Lymphoedema Evaluation in Gynecological cancer Study (LEGS). Eligibility included: 18 years and older, treated in one of six Queensland hospitals, and diagnosed from June 1, 2008 to February 28, 2011.

Results

Data from 281 women with complete data contributed to the trajectory analyses. Up to 19% of patients reported leg swelling at baseline before surgery. The swelling trajectory of women after surgery was diverse, including 38% of women who continued to have no swelling over the next two years, 32% of women who had low and decreasing trajectory of swelling, and women who had either low (14%) or high (15%) swelling at baseline whose swelling increased further. Women who reported swelling had 4 times increased odds of reporting 12 other symptoms including pain, numbness and weakness. Women in the increasing swelling trajectories had more severe other leg symptoms.

Conclusion

This study adds to previously available leg swelling prevalence estimates by showing that distinct trajectories exist after gynaecological cancer surgery. It furthermore found that persistent or increased swelling is associated with greater odds of also having up to 12 other leg symptoms, most prominently pain, numbness or weakness.

⁹Sorlandet Hospital, Department of Obstetrics and Gynaecology, Sorlandet, Norway
¹⁰Copenhagen University Hospital Rigshospitalet, Department of Gynecology and Obstetrics, Copenhagen, Denmark
¹¹Odense University Hospital, Department of Gynecology and Obstetrics, Odense, Denmark

Aims

Vulva cancer (VC) treatment causes severe morbidity that may negatively impact the patient’s Quality of Life (QoL). The aim of the present review was to evaluate available patient reported outcome measures (PROMs) to assess disease and treatment related effects in VC patients.

Method

A systematic literature search was performed to identify studies using PROMs in the assessment of disease and treatment related effects in VC patients. The systematic review was conducted in accordance with the PRISMA statement. This review comprises part of phase one in the development of a European Organisation for Research and Treatment of Cancer QoL questionnaire for VC patients.

Results

No randomized controlled trials were identified. Eleven of 2299 articles were selected including 535 women with VC. The selected studies exhibited great heterogeneity. Twenty one different instruments were used to assess QoL in VC patients. Most of the questionnaires were generic. Different issues (sexuality, lymphedema, body image, urinary and bowel function, vulva specific symptoms) were reported as potentially important but results were not systematically collected. One VC specific questionnaire was identified but did not allow assessment and reporting on scale level.

Conclusion

The present review identified several QOL domains of potential relevance for VC patients but a lack of a robust and sensitive PROM to validly assess effects of disease and treatment. Most studies relied on self-constructed non-validated questions. Our study confirms a need to develop a VC specific questionnaire that allows broad cross-cultural adaptation for use in clinical trials.

³Bakırköy Dr. Sadi Konuk Education and Research Hospital, Department of Gynecologic Oncology, Istanbul, Turkey
⁴Izmir Tepecik Education and Training Hospital, Department of Gynecologic Oncology, Izmir, Turkey

Aims

To evaluate the effect of an intraoperative hemostatic cellulose agent (BLOODCARE powder®) on reducing the incidence of postoperative chylous ascites (PCA) after complete pelvic and para-aortic lymphadenectomy (PPALN) in patients with gynecological cancers.

Method

This case control study reviewed 150 patients (75 patients each in the control and case groups) with gynecological cancer who underwent retroperitoneal PPALN. In the case group, BLOODCARE powder® was applied via the left renal vein and bilateral obturator fossa. In the control group, no sealant agent was used after the procedure, such as fibrin glue or a hemostatic cellulose agent.

Results

The demographic and surgical characteristics of the patients in both groups were similar (Table 1). Chylous ascites occurred in nine (6%) cases. The incidence of PCA was lower in the case group [1 (1.3 %) vs. 8 (10.7%); P = 0.03]. Logistic regression analysis indicated that using BLOODCARE powder® during the...
surgery independently protected against the development of PCA (Table 2).

### Table 2. Logistic regression analysis of risk factors for chylous ascites after gynecological malignancy surgery.

ESGO7-0861

QUALITY OF LIFE ASSESSMENT IN OVARIAN CANCER PATIENTS RECEIVING CHEMOTHERAPY: A PILOT STUDY
A.V. Silva1, L. Bei1, C. Faria2, M. Silva2, L. Antunes3, A. Petiz2, D. Pereira1, J. Savva-Bordalo1
1Instituto Português de Oncologia do Porto, Medical Oncology, Porto, Portugal
2Instituto Português de Oncologia do Porto, Gynecology, Porto, Portugal
3Instituto Português de Oncologia do Porto, Epidemiology, Porto, Portugal

Aims

Assessment of Quality of Life (QoL) of patients with ovarian cancer admitted in our institution undergoing chemotherapy. Identification of areas and variables associated with worse results in view of possible future intervention.

Method

A prospective longitudinal observational study was performed for 12 months. After obtaining an informed consent, patients completed EORTC QLQ-C30 and ovarian cancer-specific QLQ-OV28 questionnaires at diagnosis, after 3 and 6 cycles of treatment. Association between QoL scores and clinical variables was assessed using Mann-Whitney or Kruskal-Wallis tests, as applicable.

Results

Twenty-one patients were recruited, 62% (n=13) had ECOG PS 0. Median age was 55 years old (range 27-73). During the study only one patient died and 102 questionnaires were completed. The mean global QoL score was 49.6 ± 20.15 at diagnosis, 51.11± 23.75 after 3 cycles and 62.5 ± 26.7 after 6 cycles of therapy. At baseline, scales with worst results were emotional functioning (within functional scales), constipation, fatigue, appetite loss (within symptom scales) and attitude to disease/treatment. Except for the last one, all of them have had an improvement at third evaluation. There was an impairment of mean score in cognitive functioning, body image, sexuality, hair loss and neuropathy. Age above 50 years old and post-menopausal status at diagnosis were associated with worst QoL (p< 0.05).

Conclusion

This prospective study reinforce the importance of quality of life assessment in ovarian cancer patients ongoing chemotherapy, as a potential tool for therapeutic and management decisions, in order to benefit of our patients care.

PROGNOSIS OF DONOR PATIENTS ACCORDING TO THE CHARACTERISTICS OF PATIENTS DERIVED XENOGRAFT (PDX) TUMOR IN GYNECOLOGICAL CANCER.

G.S. Sohn¹, Y.M. Park¹, H.J. Kwon¹, H.Y. Shin¹, E.J. Lee¹, W.K. Yang¹, H.B. Cho¹, D.B. Chay¹, J.H. Kim¹, J.K. Gong¹
¹Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Patients derived xenograft (PDX) reflects molecular and cellular characteristics of the donor tumor and is an important model in the study of cancer biology. PDX models also have been developed to apply more personalized strategy against cancer, such as evaluation of drug efficacy and biomarker validation. The purpose of this study is to evaluate the prognosis of donor patients according to the characteristics of PDX tumor in gynecological cancer.

Method

Cancer tissues from gynecological cancer patients were fragmentized to 3 mm pieces and transplanted into athymic nude mice. The volume of each PDX tumor were measured using a digital caliper for up to 1 year and 4 months after transplantation. The largest PDX tumor in each patient's cases were selected. Donor patient's prognosis were evaluated by survival rate calculated using survival significance methods, applied with the previously reported cut-off value.

Results

Engraftment results showed that implantation succeeded PDX tumor cases had a tendency of poor prognosis than failed cases in 5 year disease free survival. As for the growth of PDX tumors, fast growing cases showed a tendency of poor prognosis in 5 year disease free survival and showed a significant poor prognosis in 5 year overall survival than slow growing PDX tumors.

Conclusion

This study reveals concordance of aggressive cancer biology, with fast growing in PDX tumors and poor prognosis of the donor patient. These findings may be an important resource for studying cancer biology and supporting PDX model for developing personalized strategy against cancer.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

SEXUAL FUNCTIONING AND QUALITY OF LIFE AFTER VULVAR RECONSTRUCTION WITH THE LOTUS PETAL FLAP

N.C. te Grootenhuis¹, J. Hellinga², P.M. Werker², A.G. van der Zee¹, M.H. Oonk¹, M.W. Stenekes²

¹University Medical Center Groningen, Obstetrics and Gynaecology, Groningen, The Netherlands
²University Medical Center Groningen, Plastic Surgery, Groningen, The Netherlands

Aims

Resection of (pre) malignant lesions in the vulvoperineal area may result in large defects that cannot be closed primarily. In these cases reconstruction is needed. In the vulvoperineal area the lotus petal flap technique is widely used. The aim of this study was to evaluate both sexual functioning and quality of life of patients who underwent reconstructive surgery with a lotus petal flap in the vulvoperineal area, since no data are available on this topic.

Method

A cross-sectional study was performed on all patients undergoing a reconstruction with a lotus petal flap from 2005-2016 in the University Medical Center Groningen. The Female Sexual Function Index (FSFI), European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-C30 (EORTC QLQ-C30) and Body Image Scale (BIS) were used.

Results

Twenty-six (68%) patients responded to the questionnaires. The mean age was 65.5 years (SD 16.3) and median follow-up time was 38.5 months (range 15.8-141.4). Quality of life scores were slightly decreased compared to healthy females aged 60-69 years. The total median FSFI score was 13.4 out of 36.0 (SD 8.2) and 53% reported to be sexually active. The mean score on the BIS was 9.6 out of 30.0 (SD 7.3).

Conclusion

Quality of life after vulvoperineal reconstructive surgery with a lotus petal flap is slightly decreased compared to healthy females and vulvar cancer patients. Sexual functioning and body image are decreased after reconstruction of a vulvoperineal defect with a lotus petal flap. Our results should be used for pre-operative counseling and follow-up of these patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0551

QUALITY-OF-LIFE OF OVARIAN CANCER PATIENTS WITH PROLONGED USE OF CHEMOTHERAPY - A PROSPECTIVE COMPARATIVE QUANTITATIVE AND QUALITATIVE STUDY

K.Y. Tse¹, T.N. Wei¹, T.T.T.C. Kwan¹, M.M.Y. Chu¹, S.F. Ngu¹, K.K.L. Chan¹, H.Y.S. Ngan¹

¹Queen Mary Hospital- the University of Hong Kong, Obstetrics and Gynaecology, Pokfulam, Hong Kong S.A.R.

Aims

To assess the quality-of-life, perception and expectation of patients who received multiple courses of chemotherapy (Group A), and to compare with those who had complete response after adjuvant chemotherapy (Group B).

Method

Patients were recruited in a 1:1 ratio in July 2010 to October 2011. A mixed (quantitative and qualitative) approach, using questionnaires and interview, was used.

Results

The EORTC-QLQ-C-30 Questionnaire showed lower level of physical (72.16±4.40 Vs 84.89±2.56, p=0.019), role (71.57±7.93 Vs 93.33±3.17, p=0.019) and social functioning (59.8±7.01 Vs 88.89±3.87, p=0.001), and more nausea and vomiting (17.65±6.92 Vs 1.11±1.11, p=0.031) and appetite loss (25.49±7.3, Vs 2.22±2.22, p=0.007), in Group A than Group B. The only difference in the EORTC-QLQ-OV28 was more hair loss in Group A than Group B (50.98±7.49 Vs 10.71±5.13, p<0.001). The Hospital Anxiety and Depression Scale showed more Group A patients were depressed than Group B (60.0% Vs 0%, p=0.001). In the interview, most Group B patients received chemotherapy because of their family, and were satisfied with it because there was no recurrence. However, in Group A, most expected a cure initially and so were disappointed when there were further recurrence or progressive diseases. Most were not willing to continue chemotherapy because of poor physical health or financial reason, but did so because of family members or symptoms. After prolonged use, a few still expected chemotherapy would prolong their survival.

Conclusion

Prolonged chemotherapy was tolerable but it was necessary to have a proper counseling on its palliative intent to avoid unrealistic expectation and hence depression.

QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-1237

BIG DATA ARE NEEDED IN RESEARCH ON RARE TUMOURS
M. van Gent¹, M. Kagie², J.B.M.Z. Trimbos³, C. de Kroon³
¹Center for Gynecologic Oncology Amsterdam, Antoni van Leeuwenhoek, Amsterdam, The Netherlands
²Haaglanden Medical Center, Gynaecology, The Hague, The Netherlands
³Leiden University Medical Center, Gynaecology- K6-P, Leiden, The Netherlands

Aims

Before the ESMO-ESGO-ESTRO guideline on conservative treatment in endometrial cancer (EC) was published in 2015, a similar nationwide Dutch protocol served as a guide for clinicians treating patients with low-grade EC with the wish to preserve fertility. The protocol was introduced to uniform treatment of respective women in order to obtain firm knowledge about response, recurrence and efficacy of treatment after recurrence. We evaluated adherence to the protocol and consequences of adherence.

Method

Within 10 years, 33 patients were enrolled in a registry and oncological and obstetrical outcomes were analysed. A strict treatment advise (medroxyprogesterone 200mg/day) and follow-up regime (3-monthly biopsies, at least 3 months of consolidation therapy, maximum length of therapy 9 months) was provided. Re-treatment after recurrence was allowed using the same protocol. The accuracy with which the protocol was followed was evaluated.

Results

Nineteen out of 33 patients were completely treated according to protocol. Deviation[Cd1] of the protocol was mostly the result of a request from the patient e.g. persistent desire to conceive whilst not responding to therapy within the set time frame. There was a strong improvement in adherence to the protocol over time.

Conclusion

In rare tumours, like EC in women under 40, deviations from protocols like this, will make it hard to draw conclusions and impossible to improve safety of tailored treatment. In our opinion only 'big data', provided by intensifying international collaboration, creating a large database with prospective data,is highly needed and will enhance shared decision making, which is mandatory, especially in rare tumours.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0077

PATIENTS’ AND GENERAL PRACTITIONERS’ VIEWS OF FOLLOW-UP AFTER TREATMENT OF GYNECOLOGICAL CANCER

I. Vistad1, H. Fidjeland1, M. Brekke2
1Sørlandet hospital Kristiansand, Gynecology, Kristiansand, Norway
2Institute of Health and Society, Department of General Practice, Oslo, Norway

Aims

Greater involvement by general practitioners (GPs) in cancer follow-up has been suggested. We aimed to explore gynecological cancer survivors’ attitudes toward follow-up by GPs and whether time in the surveillance program influences their opinions. We also aimed to assess GPs views of increased responsibility for gynecological cancer survivors.

Method

A questionnaire on expectations and attitudes to follow-up after gynecological cancer treatment was distributed to women after end of treatment (new) and >1 year in the surveillance program (experienced). Further, a questionnaire was mailed to GPs regarding their attitudes toward follow-up of gynecological cancer.

Results

239 patients (100 new, 139 experienced) and 317 GPs responded. 36% of new patients were willing to be followed-up by their GP compared to 17% of experienced patients, p=0.02. 42% of the GPs were willing to assume exclusive responsibility within three years after treatment. A patient-specific letter from the specialist and expedited routes of re-referral were important conditions to help them provide follow-up care. Both survivors and GPs thought that detection of recurrence was the most important reason for follow-up. 90% of GPs believed that they were better suited than hospital specialists at providing psychosocial support, but the survivors preferred to talk to the gynecologist about psychological and physical late effects after cancer treatment.

Conclusion

Our results suggest that patients change their attitude of who should be responsible for follow-up after they have started in the surveillance program. Before alternative follow-up regimens are implemented, patients’ and GPs’ attitudes to follow-up should be taken into account.
Aims

Because of the lack of quantitative data on sexual function after ovarian cancer, both for survivors and their partners, it is difficult to counsel patients on expected effects. We hypothesized that ovarian cancer may cause sexual problems, not only for survivors, but also for partners. The purpose of this study is to compare sexual function after ovarian cancer for survivors and partners with normdata in age-matched controls.

Method

After an average of six years after their primary treatment, patients with ovarian cancer (n=275) and their partners (n=137) conducted surveys for HR-QoL and sexual function with the EORTC-QLQC30 and OV-28. Normdata for age-matched controls were gathered through the PROFILES-registry. Scores on the questionnaires were linearly transformed. Differences between the groups were compared and correlations were calculated.

Results

Sexual function showed a non-normal distribution. Median level of sexual function of survivors was 83 (minimum 17 – maximum 100). Hundred (36%) of 275 survivors had undisturbed sexual function. For partners, the median level of sexual function was 43 (0-100) with only 2 persons reported undisturbed function and 21 with a score of 0. Normdata showed a median sexual function for female age-matched controls 17 (0-100) and for male age-matched controls 50 (0-100). Sexual function between survivors and partners correlated strongly (Spearman’s rho .617, p<0.01).

Conclusion

An effect on sexual function for survivors of ovarian cancer is present in the majority of cases. However when compared to age-matched controls, the effect seems limited. Further exploration of sexual function in ovarian cancer survivors is warranted.
PORT-SITE METASTASES AFTER LAPAROSCOPIC SURGERY FOR GYNAECOLOGICAL MALIGNANCIES IN A SOUTHEAST ASIAN POPULATION: A CASE SERIES

J. Wang1, Y.K. Lim1

1KK Women's and Children's Hospital, Department of Gynaecological Oncology, Singapore, Singapore

Aims

Port-site metastases (PSMs) are known but uncommon complications of laparoscopic surgery for gynaecological malignancies. Minimally invasive surgeries are commonly used in the management of gynaecological malignancies all over the world. Our series showed that even low risk, early stage disease may be complicated by PSMs. Therefore, surgeons should take necessary precautions to prevent these rare recurrences.

Method

We present a series of 4 cases with PSMs after laparoscopic surgery for gynaecological malignancies diagnosed between 1999 and 2014.

Results

The incidence of PSMs was 0.7% in patients treated with laparoscopic surgery in this period. One patient had immature teratoma, one had epithelial ovarian cancer and the remaining 2 had endometrial cancer. 3 of the patients had laparoscopic pelvic lymphadenectomy done. The median time to occurrence of PSM was 15 months (range 4-30 months). Two of these patients had ascites but all washings performed were negative for metastatic cells. All four cases had no lymph node or lymphovascular space involvement. The median time of survival from diagnosis of PSM was 58 months (range 29-119 months). All patients underwent resection of PSM, of which two were given megace and only one was given additional chemotherapy and radiotherapy. One patient died 29 months after diagnosis of PSM due to recurrence of peritoneal and hepatic metastases post-resection.

Conclusion

Due to the increasing use of laparoscopic surgery in the management of gynaecological malignancy, an evaluation of the clinical factors involved in PSMs is important. Surgeons need to be aware that PSMs can occur in low grade, early stage disease.

IMPACT ON SURVIVAL OF INTEGRATIVE SYSTEMIC AND LOCAL METABOLOMICS IN HIGH-GRADE SEROUS OVARIAN CANCER

S. Aust¹, A. Bachmayr-Heyda¹, K. Auer², S. Meier³, K. Schmetterer³, S. Dekan¹, C. Gerner², D. Pils⁴

¹Medical University of Vienna, Department for Gynecology and Gynecologic Oncology- Gynecologic Cancer Unit- Comprehensive Cancer Centre, Vienna, Austria
²University of Vienna, Dept. of Analytical Chemistry- University of Vienna, Vienna, Austria
³Medical University of Vienna, Clinical Institute of Laboratory Sciences, Vienna, Austria
⁴Medical University of Vienna, Center for Medical Statistics- Informatics- and Intelligent Systems & Dept. of Surgery, Vienna, Austria

Aims

Little is known about how and wherefrom cancer cells get fuel, building blocks, and reducing equivalents for their increased cell growth and division.

Method

Targeted metabolomics of preoperative and follow-up sera, ascites, and tumor tissues, RNA sequencing of isolated tumor cells, local and systemic chemokine, and local immune cell infiltration data from up to 65 high-grade serous ovarian cancer patients and 62 healthy controls were correlated to overall survival and integrated in a Systems Medicine manner.

Results

43 mainly (poly)unsaturated glycerophospholipids and 4 essential amino acids (citrulline) were significantly reduced in patients with short survival. The glycerophospholipid fingerprint is identical to the fingerprint from isolated (very)low-density lipoproteins (vLDL), indicating that the source of glycerophospholipids consumed by tumors is (v)LDL. A glycerophospholipid-score (HR0.46; \( P=0.007 \)) and a 100-gene signature (HR0.65; \( P=0.004 \)) confirmed the independent impact on survival in training (\( n=65 \)) and validation (\( n=165 \)) cohorts. High concentrations of LDLs and glycerophospholipids were independent predictors for favorable survival. Patients with low glycerophospholipids presented with less adaptive immune cell tumor infiltration, less oxygenic respiration and increased triglyceride biosynthesis in tumor cells, and lower histone expressions, correlating with higher numbers of expressed genes and more transcriptional noise - a putative neo-pluripotent tumor cell phenotype.

Conclusion

Low serum phospholipids and essential amino acids are correlated with worse outcome in ovarian cancer, accompanied by a specific tumor cell phenotype (figure.1).

WHY SHOULD WE INCREASE RESEARCHES IN PHOTODYNAMIC THERAPY OF PERITONEAL METASTASES OF EPITHELIAL OVARIAN CANCER?

H. Azaïs1,2, N. Delhem3, L. Colombeau4, C. Frochot4, G. Anne2,3,5, O. Moralès3, S. Mordon2, P. Collinet2,5

1Hôpital de la Pitié-Salpêtrière, Department of gynecologic and breast surgery, PARIS, France
2INSERM, U1189-ONCO THAI - Image Assisted Laser Therapy for Oncology, Lille, France
3CNRS- Institut de biologie de Lille, UMR 8161, Lille, France
4LRGP- Lorraine-University, UMR-CNRS 7274, Nancy, France
5University hospital of Lille, Department of gynecologic surgery, Lille, France

Aims

Epithelial ovarian cancer (EOC) management is underlined by the high rate of peritoneal recurrence that may be related to microscopic peritoneal metastases ignored by conventional cytoreductive surgery. Intraperitoneal photodynamic therapy (PDT) could improve microscopic cytoreduction. In addition, immune response seems to be enhanced after PDT.

Method

We use a folic acid coupled photosensitizer that specifically target EOC cells (through folate receptors). Preclinical studies have been performed in vitro on murine and human (SKOV3 / OVCAR3) cell lines of EOC and in vivo with a preclinical model of peritoneal carcinomatosis (Fisher F344 rat / NuTu-19 cell line). They aimed to precise the ability of photosensitizer to target specifically tumor tissue, to emit specific fluorescence, and to obtain cell death. We also studied human immune response after PDT.

Results

Tissue quantification of a folic acid conjugate showed its specific incorporation within tumor (tumor-to-normal tissue ratio: 9.6). Specificity for EOC metastases is better than previously reported with other photosensitizers. We could detect fluorescence in vitro and in vivo in peritoneal metastases. PDT induces cells death in human EOC cell lines in vitro (100% mortality 24h after PDT). PDT activates the mitochondrial metabolism and the proliferation of human peripheral blood mononuclear cells.

Conclusion

Our project is a multidisciplinary approach that aims to enable intraperitoneal PDT of peritoneal metastases of EOC and to provide original solutions from photosensitizer synthesis to innovative illumination set up. In addition to direct cytotoxicity, PDT could stimulate a delayed immune response and could act as immunotherapy promoting a potential "abscopal" effect.

MYELOID DERIVED SUPPRESSOR CELLS (MDSC) DETERMINE OUTCOME IN OVARIAN CANCER.
T. Baert1,2, A. Van Hoylandt1,2, P. Busschaert6, I. Vergote1,2,3, A. Coosemans1,2
1UZ Leuven, Department of Gynaecology and Obstetrics- Leuven Cancer Institute, Leuven, Belgium
2KU Leuven, Department of Oncology- Laboratory of Tumor Immunology and Immunotherapy- ImmunOvar Research Group, Leuven, Belgium
3KU Leuven, Department of Oncology- Laboratory of Gynecologic Oncology, Leuven, Belgium

Aims

Immunotherapy trials in ovarian cancer have so far yielded poor results, possibly due to severe immunosuppression. Macrophages are abundant in ovarian cancer (OC) and a predominance of M2 macrophages is correlated with poor survival. Clodronate Liposomes (CL) are a commonly used drug, which effectively depletes macrophages.

Method

Tumorbearing ID8-fLuc-C57BL/6 and ID8-fLuc-Rag1tm1Mom mice were treated with weekly CL. Immune-monitoring on ascites was performed by fluorescent activated cell sorting (FACS). Furthermore peripheral blood mononuclear cells were collected prospectively in 39 patients at diagnosis of OC.

Results

Mice treated with CL died significantly faster compared to immunocompetent mice (p=0.004), whereas the survival was not altered in mice lacking T- and B-cells (Rag1tm1Mom). After treatment with CL, macrophages were nearly absent. There were no significant changes in T- and B-cell populations. After treatment with CL, monocytic myeloid derived suppressor cells (mMDSC) (CD11b+Ly6CHi) increased significantly (p=0.004), whereas granulocytic MDSC (CD11b+Ly6C-Ly6GHi) decreased. In patient samples, we observed a decrease in progression free survival in patients with a high number of mMDSC (CD11b+HLA-DR-CD14+) (17.5 vs 20 months).

Conclusion

In OC mice the absence of adaptive immune system did not influence survival. Depletion of macrophages by CL significantly reduced survival in tumorbearing mice. This could be explained by a significant rise in mMDSC in mice. The increase was also observed in patients with OC. Our research demonstrates for the first time a prominent role for mMDSC as the driver of immunosuppression in OC, which is a new concept in the field of OC.

ESGO7-0753

SEARCHING FOR SYNERGY BETWEEN STANDARD CHEMOTHERAPY AND IMMUNOTHERAPY IN AN OVARIAN CANCER MOUSE MODEL

T. Baert1,2, H. Ruts2, A. Van Hoylandt1,2, G. Thirion1,2, I. Vergote1,2,3, A. Coosemans1,2
1UZ Leuven, Department of Gynaecology and Obstetrics- Leuven Cancer Institute, Leuven, Belgium
2KU Leuven, Department of Oncology- Laboratory of Tumor Immunology and Immunotherapy- ImmunOvar Research Group, Leuven, Belgium
3KU Leuven, Department of Oncology- Laboratory of Gynecologic Oncology, Leuven, Belgium

Aims

Up till now, results from trials with checkpoint inhibitors in ovarian cancer (OC) have yielded response rates ranging from 10-15%, possibly due to severe (innate) immunosuppression. The combination of standard chemotherapy with immunotherapy could overcome this immunosuppressive hurdle. To forge synergistic combinations we need more information on the immunological effects of chemotherapy for OC.

Method

Tumor-bearing ID8-fLuc-C57BL/6 mice received a single dose of Carboplatin (100 mg/kg), Gemcitabine (500mg/kg), Pegylated Liposomal Doxorubicin (PLD) (6 mg/kg), Paclitaxel (10 mg/kg) or the combination of Carboplatin (100 mg/kg) and Paclitaxel (TC) (10 mg/kg) or Gemcitabine (CG) (2 mg/kg). Immune-monitoring on tumor was performed by fluorescent activated cell sorting (FACS).

Results

Differences (Δ) in immune cell infiltration (%) between chemotherapy-treated mice and untreated controls are displayed in the table.

gMDSC: granulocytic Myeloid-derived suppressor cells - mMDSC: monocytic Myeloid-derived suppressor cells

Conclusion

We demonstrated that the use of Carboplatin reduced M2 macrophages. CG did not reduce M2 due to an increase in total macrophages, but reduced mMDSC. M2 and mMDSC are major players of innate immunosuppression. Further research is needed to investigate the synergistic effect of chemotherapy in combination with immunotherapy.
CLINICAL RELEVANCE OF CIRCULATING TUMOR CELLS IN OVARIAN, FALLOPIAN TUBE AND PERITONEAL CANCER

M. Banys-Paluchowski1, H. Neubauer2, N. Krawczyk2, A. Kaczerowsky Flores de Sousa1, P. Paluchowski2, F. Meier-Stiegen2, A. Abdel-Kawi4, T. Fehm2, G. Gebauer1

1Marienkrankenhaus Hamburg, Obstetrics and Gynecology, Hamburg, Germany
2University Duesseldorf, Gynecology, Duesseldorf, Germany
3Regioklinik Pinneberg, Gynecology, Pinneberg, Germany
4Assiut University, Faculty of Medicine, Assiut, Egypt

Aims

Presence of circulating tumor cells (CTCs) is associated with impaired clinical outcome in a variety of cancers. Limited data are available on the significance of CTCs in gynaecological malignancies. Aims of the present study were to evaluate the dynamics of CTCs in patients with ovarian, fallopian tube and peritoneal cancer during chemotherapy and to assess the clinical relevance of these changes.

Method

50 patients with ovarian (n=40), fallopian tube (n=5) and peritoneal (n=5) cancer were included. All patients received chemotherapy in the first-line setting (n=25) or tumor recurrence (n=25). CTC analysis was performed prior to chemotherapy, after three and six cycles and analysed using CellSearch.

Results

26 patients had at least one CTC/7.5ml blood at baseline. Positivity rate was 18% in patients with first-line setting and 35% in those with tumor recurrence (p=0.216). Presence of CTCs was not correlated with other prognostic factors, such as the FIGO stage, nodal status, or grading. CTC positivity declined to 5% after three cycles of cytotoxic therapy and no patient was CTC positive after 6 cycles of chemotherapy. 15 patients died during follow-up. Patients with CTCs at baseline had significantly shorter overall survival compared with CTC negative patients (p=0.014; median OS 3.1 vs. 13.4months). In the subgroup of patients with primary cancer, CTC positivity was significantly associated with OS in univariate analysis (p=0.046).

Conclusion

Hematogenous dissemination is a common phenomenon in ovarian, fallopian tube and peritoneal cancer. Patients with CTCs at time of diagnosis are more likely to die than those who are CTC-negative at baseline.
ESTROGEN RECEPTOR BETA AS A PREDICTIVE MARKER IN OVARIAN CANCER PATIENTS TREATED WITH PLATINUM AND TAXANE-BASED CHEMOTHERAPY

T. Bogush¹, A. Basharina¹, E. Dudko¹, N. Vikhlanceva¹, I. Vorobjeva¹, E. Bogush², A. Tjulandin³, M. Davydov⁴, S. Tjulandin³
¹N.N. Blokhin Russian Cancer Research Center, Laboratory of medicinal chemistry, Moscow, Russia
²N.N. Blokhin Russian Cancer Research Center, Surgical department of tumor diagnostics, Moscow, Russia
³N.N. Blokhin Russian Cancer Research Center, Department of Clinical Pharmacology and Chemotherapy, Moscow, Russia
⁴N.N. Blokhin Russian Cancer Research Center, Surgical department thoracic, Moscow, Russia

Aims

Predictive markers for platinum and taxane-based chemotherapy of ovarian cancer are widely discussed. A number of earlier studies investigated the relationship between of estrogen receptor beta (ERbeta) expression and progression-free survival (PFS) of ovarian cancer patients, but the findings are controversial. The present study aimed at investigating the predictive significance of ERbeta expression in a cohort of platinum and taxane treated ovarian cancer patients.

Method

ERbeta expression was estimated quantitatively using immunofluorescence method by flow cytometry in 35 serous ovarian cancer surgical specimens. All patients received the I line of chemotherapy with platinum+taxane. Antibodies: primary anti-ERbeta (ab14C8) and secondary (DyLight650, ab98729). Two levels of ERbeta expression around the median index were defined: high – ≥40% of cells expressing the marker and low – <40%. Kaplan-Meier statistics and log-rank tests were used.

Results

ERbeta were revealed in all the specimens investigated and median value of the expression level was 41.5%. Significant differences (p=0.002) were shown between the patients with low and high level of ERbeta expression: median PFS was 8 vs 25.5 months, number of relapses during 40 months of observation – 15 vs 6 in the groups respectively.

Conclusion

A direct correlation between ERbeta level and both PFS and number of relapses during 40 months after the I line of platinum+taxane chemotherapy indicates of a positive prognostic value of a quantitative index of ERbeta expression in prediction of platinum+taxane chemotherapy efficacy in ovarian cancer patients. Supported by RFBR grants (15-04-06991-a, 16-34-01049-mol-a) and President of RF grant MK-7709.2016.7.
A randomized multicenter controlled study showed a significant benefit of front line carboplatin paclitaxel oregovomab -an anti-CA125 mAb- (CIT) relative to carboplatin/paclitaxel (SOC) in optimally debulked ovarian cancer (Ferrandina G, ASCO Proceedings 2017). The present study evaluated peripheral blood for immune correlates.

Method

97 FIGO 3/4 ovarian cancer patients (CA125 >50U) were randomized to 6-cycles SOC with or without addition of oregovomab 2mg IV at cycle 1, 3, and 5 and cycle 5+12 weeks. Peripheral blood mononuclear cells were evaluated at baseline, cycle 5, and cycle 5+13 weeks. Patients were followed for disease progression and survival. Immune cell populations and CA125-specific IFN-γ producing CD8+ T cells (sensitized using autologous dendritic cells loaded with oregovomab/CA-125 immune complexes) were evaluated by flow cytometry.

Results

CIT (N=47) prolonged relapse free survival (RFS) relative to SOC (N=50) (median RFS= N.E. [21.3, N.E. ] vs 15.4 m [10.9,19.3] p=0.0009 log rank). Early survival data is consistent with RFS. Safety/toxicity was similar in both arms. CIT increased percentage and absolute cell count of CA125-specific IFN-γ producing CD8+ T cells (p=0.01 and p=0.02, respectively) at cycle 5. The neutrophil-monocyte/lymphocyte ratio (NMLR) cutoff 3.612 at baseline predicted outcome in the CIT population with HR 9.75 (p<0.001).

Conclusion

Peripheral blood analyses of patients on SOC and CIT indicate that appearance of treatment-emergent CA-125 specific IFN-γ producing CD8+ T cells is associated with treatment efficacy and that baseline NMLR is useful as a predictive marker for clinical response.

PRECLINICAL EVALUATION OF A NOVEL ALPHA-PARTICLE EMITTING THERAPEUTIC AGENT FOR SELECTIVE INTRAPERITONEAL THERAPY OF PERITONEAL METASTASES

T. Bønsdorff1, S. Westrøm1, Ø.S. Bruland2, R.H. Larsen3

1Oncoinvent AS, Oncoinvent, Oslo, Norway
2The Norwegian Radium Hospital- Oslo University Hospital, Institute of Clinical Medicine- Department of Oncology, Oslo, Norway
3Sciencons AS, Sciencons AS, Oslo, Norway

Aims

Intraperitoneal radionuclide therapy with β-emitting 32P-colloid has been previously used in treatment of ovarian cancer. It was then shown to be as effective as adjuvant cisplatin therapy for some groups of patients, but late bowel complications occurred more frequently, most likely caused by a combination of long half-life and several millimeters range of electrons from 32P. We have developed a composition of a microparticle and an α-emitting radionuclide, with a considerably shorter range in tissues, specifically designed for local treatment of peritoneal carcinomatosis. Biocompatible microparticles, with no antigen-targeting, act as carriers for the α-emitter 224Ra. This novel α-radiation therapy has a range in tissue of less than 100 µm and is designed to confine the zone of radiation exposure to the intraperitoneal cavity including peritoneal surfaces and liquid volumes. The therapeutic efficacy and safety of the 224Ra-microparticles in murine models are presented.

Method

Radium-224 loaded onto calcium carbonate microparticles was evaluated in immunodeficient athymic nude mice inoculated with human ovarian cancer cells in the peritoneal cavity. Different activities of 224Ra-microparticles were administered intraperitoneally. Tumor growth, survival and tolerance of the treatment were assessed.

Results

Intraperitoneal treatment with 224Ra-microparticles resulted in considerable survival benefit. An advantageous discovery was that only a few kilobecquerels per mouse were needed to yield therapeutic effects. The treatment was well-tolerated up to doses of 1000 kBq/kg and no clinical signs of toxicity were observed.

Conclusion

Intraperitoneal α-therapy with 224Ra-microparticles demonstrated a significant potential for treatment of residual microscopic intraperitoneal disease with a very promising safety profile.

TARGETED PROTEOMICS IDENTIFIES PROTEOMIC SIGNATURES IN LIQUID-BIOPSIES OF THE ENDOMETRIUM TO DIAGNOSE ENDOMETRIAL CANCER AND ASSIST IN THE PREDICTION OF THE OPTIMAL SURGICAL TREATMENT

⁶University of Santiago de Compostela, Faculty of Mathematics, Santiago de Compostela, Spain
⁷International University of Catalonia, Basic Sciences Department, Barcelona, Spain

Aims

Endometrial cancer (EC) diagnosis relies on the observation of tumor cells in endometrial biopsies obtained by aspiration (i.e., uterine aspirates), but it is associated with 22% undiagnosed patients and up to 50% of incorrectly assigned EC histotype and grade. We aimed to identify biomarker signatures in the fluid uterine aspirates to overcome these limitations.

Method

The levels of 52 proteins were measured in the fluid fraction of uterine aspirates from two independent cohorts of patients of 38 and 116 patients by LC-PRM, the latest generation of targeted mass-spectrometry acquisition. A logistic regression model was used to assess the power of protein panels to differentiate between EC and non-EC patients and between EC histological subtypes. The robustness of the panels was assessed by the “leave-one-out” cross-validation procedure performed in the cohort of 116 patients and 38 patients.

Results

The levels of 28 proteins were significantly higher in EC patients (n=69) compared to controls (n=47). The combination of MMP9 and KPYM exhibited 94% sensitivity and 87% specificity for detecting EC cases. This panel perfectly complemented the standard diagnosis, achieving 100% of correct diagnosis in this dataset. Nine proteins were significantly increased in endometrioid EC (n=49) compared to serous EC (n=20). The combination of CTNB1, XPO2 and CAPG achieved 95% sensitivity and 96% specificity for the discrimination of these subtypes.

Conclusion

We developed uterine aspirate-based signatures to diagnose EC and classify tumors in the most prevalent histological subtypes. This will improve diagnosis and assist in the prediction of the optimal surgical treatment.
DIFFERENTIAL EXPRESSION OF MTOR COMPONENTS IN ENDOMETRIOSIS AND ENDOMETRIOID OVARIAN CANCER CELL LINE: EFFECTS OF RAPAMYCIN, RESVERATROL AND BEZ-235

1Royal Surrey County Hospital, Department of Gynaecology, Guildford, United Kingdom
2College of Health and Life Sciences- Brunel University London, Department of Biosciences, Uxbridge- UB8 3PH, United Kingdom
3Queen Charlotte’s and Chelsea Hospital, Department of Obstetrics and Gynaecology, London, United Kingdom
4University of Thessaloniki Medical School, Department of Medicine, Thessaloniki, Greece
5Medical University Vienna- Comprehensive Cancer Center & Ludwig Boltzmann Cluster Oncology-, Division of Oncology- Department of Medicine, Vienna, Austria

Aims

Endometriosis is a well-known risk factor for ovarian cancer with previous history of endometriosis being present in up to 28% of patients with ovarian cancer. The genetic changes that characterise endometriosis are poorly understood; however, the mechanistic target of rapamycin (mTOR) pathway has been implicated in a number of ways. For example, protein expression of both Akt and p70S6K is increased in both the ectopic endometrium and endometriotic lesions of patients with deep infiltrating endometriosis (DIE) in comparison to endometrium lining the uterus.

Method

In this study, we investigate the expression of key mTOR components and used endometrioid ovarian carcinoma (MDAH 2774) cell line as an in vitro model to study the effects of rapamycin, resveratrol and BEZ-235 (Dactolisib; a dual kinase inhibitor).

Results

mTOR and Raptor showed a significant increase in expression in endometriosis patients compared to non-affected controls. Rictor showed a significant increase in gene expression in patients aged 20-29 years, but not in patients aged 30-39 years. There was also a significant increase in Rictor expression in patients with disease grade points above 50 but not in those with a disease grade below 50 compared to non-affected controls. Treatment of MDAH 2774 cells with rapamycin and BEZ-235 (100nM) resulted in downregulation of mTOR protein expression at 48 hours of treatment, whereas resveratrol had no effect. None of the treatments resulted in translocation of mTOR from cytoplasm to the nucleus.

Conclusion

Collectively, these data provide evidence for the potential use of rapalogues and dual kinase inhibitors as treatment possibilities in endometriosis.
PROGNOSTIC SIGNIFICANCE OF UPREGULATED MICRORNA-944 EXPRESSION IN FFPE SAMPLE OF CERVICAL CANCER

D. Chung¹, Y. Wang¹, S.J. Oh¹, J.S. Park¹, J. Kim², S. Park², H. Lee², D. Chung¹

¹Yonsei University Wonju College of Medicine, Department of Obstetrics and Gynecology, Wonju, Republic of Korea
²Yonsei University College of Health Sciences, Department of Biomedical Laboratory Science, Wonju, Republic of Korea

Aims

MicroRNAs (miRNAs, miR-) regulate gene expression and modulate several cell pathways associated with tumor malignancy. Of the various miRNAs associated with cancers, miR-944 has been associated with cervical cancer tumorigenesis from the previous studies. The aim of this study was to investigate the clinical prognostic value of miR-944 expression in FFPE sample of cervical cancer.

Method

A total of 68 FFPE cervical cancer tissues were obtained and to check the validity of this biomarker, normal FFPE samples from 50 patients who underwent a hysterectomy for non cervical, benign gynecological diseases were included together. Using quantitative reverse transcriptase PCR (RT-qPCR) to measure mir-944 expression levels in both FFPE samples and simultaneously had electrical medical record assessment of enrolled cervical cancer patients to review their clinical prognostic factors.

Results

Expression levels of miR-944 in cervical cancer tissues were significantly higher than those in normal tissues (P < 0.0001). Increased expression of miR-944 was also markedly associated with tumor size (P = 0.049), FIGO stage (P = 0.027), and lymph node metastasis (P = 0.007). Furthermore, Kaplan Meier analysis suggested that cervical cancer patients with high miR-944 expression had shorter overall survival time than those with low miR-944 expression (P = 0.004). Multivariate Cox proportional hazards model analysis of miR-944 showed that high expression of miR-944 was independent prognostic factors for overall survival.

Conclusion

In conclusion, up-regulation of miR-944 is a meaningful biomarker that has association with poor clinical prognosis in cervical cancer patients.

SINGLE-STRAND-ANNEALING RATHER THAN NON-HOMOLOGOUS-END-JOINING PREDICT HEREDITARY OVARIAN CARCINOMA

M. Deniz1, L. Prof. Dr. Wiesmüller1, T. Dr. Romashova1, T. PD Dr. Friedl1, W. Prof. Dr. Janni1
1Universitätsklinikum Ulm, Frauenklinik, Ulm, Germany

Aims

Deficiency in DNA double-strand break repair especially in homologous recombination (HR) is associated with an increased risk for developing ovarian cancer. It is suggested that up to 25% of ovarian cancer patients have inherited mutations and up to 7% somatic mutations resulting in HR defects. HR deficiency opens new options for targeted therapies; the PARP inhibitor Olaparib is approved for BRCA-mutated ovarian cancers. Great efforts have been made to carve out prognostic markers and patient characteristics detecting cancer susceptibility and therapeutic responsiveness. In this work, we performed functional analyses in peripheral blood lymphocytes (PBLs) using a case-control design.

Method

We examined 38 women with defined familial history of breast and/or ovarian cancer, 40 women with primary ovarian cancer, and 35 healthy women without previous cancer or family history. Using a GFP-based test we analyzed error-prone DSB repair mechanisms which are known to compensate HR defects and to generate chromosomal instabilities.

Results

While non-homologous end-joining (NHEJ) did not discriminate between cases and controls, we found increases of single-strand annealing (SSA) in women with familial risk vs. controls (P=0.016) and patients with ovarian cancer vs. controls (P=0.002). Consistent with compromised HR we also detected increased sensitivities to carboplatin in PBLs from high risk individuals (P=0.019) as well as in patients with early-onset ovarian cancer (P=0.046) in comparison to cells from healthy controls.

Conclusion

These findings underscore the great potential of detecting distinct DSB repair activities in PBLs as method to estimate ovarian cancer susceptibility and associated treatment responses beyond the limitations of genotyping.

CLAUDIN 1 EXPRESSION AS A STRATIFICATION MARKER IN BORDERLINE TUMORS OF THE OVARY.
A. El-Balat1, I. Schmeil1, T. Karn1, U. Holtrich1, S. Becker1, K. Engels2
1Klinikum der Goethe-Universität, Gynecology, Frankfurt, Germany
2Pathologie Zentrum Neuss, Pathology, Neuss, Germany

Aims

To evaluate the integral transmembrane protein Claudin1 as marker for borderline ovarian tumors (BOTs).

Method

We analyzed a retrospective cohort of 114 BOTs with validated diagnosis by an independent pathologist. Immunohistochemical detection of Claudin1 was quantified as combined immunoreactive score blinded to clinical patient data. Analyses were performed for Claudin1 positive versus negative.

Results

We detected Claudin1 positivity in 26.3% of patients. There was no significant correlation between the different histological subtypes and Claudin1 detection. The expression levels of this protein were significantly reduced in patients with FIGO Stage I (p<0.045). This negativity was also correlated to micropapillary pattern as 82.1% of patients with negative Claudin1 had no micropapillary pattern. Claudin1 expression was highly associated with the presence of implants (p=0.003).

Conclusion

Our analysis links Claudin1 with micropapillary pattern. Positive expression is associated with the presence of implants, which is related to elevated risk of recurrence. Accordingly, Claudin1 is an interesting marker and worth further analyses of its prognostic value in BOTs.

ASCITES DERIVED TUMOR ASSOCIATED MACROPHAGE ALTERS CHEMOSENSITIVITY IN OVARIAN CANCER CELLS

S. Jeon¹, H. Jeon¹
¹Soonchunhyang university Cheonan hospital, OB & Gyn, Cheonan, Republic of Korea

Aims

Macrophages are the dominant myeloid cells found in tumor microenvironment. Tumor associated macrophage(TAM) has been proved to promote tumor growth, metastasis and chemoresistance. In this study we generated macrophage cell line from the ascites of ovarian cancer model of ID8 injected mouse, determined it’s phenotype and investigated carboplatin chemosensitivity on ovarian cancer cell line in the presence of Macrophage cell line by transwell assay

Method

To generate macrophage cell line we performed cell harvest, sorting, and immortalizing macrophage, and to determine phenotype of macrophage we perform flow cytometry, Quantitative real time polymerase chain reaction, immunofluorescence and LDL uptake assay. And to investigate carboplatin response of ovarian cancer cell cocultured with macrophages, we used transwell assay and cell viability assay

Results

TAMs from ascites of mouse ovarian cancer model had mixed phenotype with M1 and M2. In vitro transwell assay, ovarian cancer cells which were cocultured with TAMs had more chemoresistant than control group upon carboplatin treatment.

Conclusion

Our data suggest that soluble factors from ascites derived TAMs may alter carboplatin chemosensitivity in ovarian cancer cells. Blockade of these function of TAMs might increase the clinical effect of platinum-based chemotherapy
ANATOMICAL AND FUNCTIONAL ASSESSMENT OF THE PELVIC AUTONOMIC NERVES IN A FEMALE SWINE MODEL AND WOMEN

H.S. Kim¹, K. Se Ik¹, L. Maria¹, K. Jae Weon¹
¹Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To develop a female swine model for anatomical and functional assessment of the pelvic autonomic nerves, and then to validate the assessment in women.

Method

We used 11 female domestic swine, weighing 30 to 40 kg. Among them, we sacrificed three swine for the anatomical assessment, and eight swine for the functional assessment of the pelvic autonomic nerves. We developed a new stimulation & monitoring system for evaluating the function of the pelvic autonomic nerves of female swine. Moreover, the results from swine were compared with those of 11 women with cervical cancer during surgery.

Results

In swine, we found bilateral sympathetic trunk and ganglions run beside aorta and inferior vena cava, and thin fibers from sympathetic ganglions joined together to become the superior hypogastric nerve, which runs bilaterally as the inferior hypogastric nerves. The parasympathetic nerves joined together with inferior hypogastric nerves and formed the pelvic plexus, and we found the rectal, vesical and uterine branches of the pelvic plexus. For the functional assessment, we found regular contraction in bladder, vagina and rectum by stimulating the parasympathetic nerves. After resection of the sympathetic nerves, interval from stimulation to contraction, duration of contraction were decreased, whereas maximal pressure and frequency of contraction were increased. These results were similar to those from twelve patients with cervical cancer whose functions of the pelvic autonomic nerves were evaluated during surgery.

Conclusion

A female swine model may be adequate for the anatomical and functional assessment of the pelvic autonomic nerves of women.

GERMLINE MUTATIONS IN BREAST AND OVARIAN CANCER CASES FROM SERBIA
A. Krivokuca1, I. Boljevic1, J. Rakobradovic1, S. Jovandic2, M. Brankovic-Magic1
1Institute for Oncology and Radiology of Serbia, Department for Experimental Oncology, Belgrade, Serbia
2Military Medical Academy, Department for Molecular Medicine, Belgrade, Serbia

Aims

Rapid expansion of next generation sequencing (NGS) methods has led to a discovery of new cancer susceptibility genes. However, patients’ selection and genetic testing strategies in many countries haven’t been defined yet. The goal of this study is to identify population specific gene panel for Serbian breast and ovarian cancer patients.

Method

We tested 61 breast and 64 ovarian cancer cases using NGS 94-genes panel. The coding sequence and exon/intron boundaries were enriched using Nextera DNA Library Preparation Kit in combination with TruSight® CancerPanel (Illumina, San Diego, USA). NGS was performed on Illumina MiSeq Sequencing System according to manufacturer’s protocol.

Results

Germline BRCA1/2 mutations were found in 7(11.5%) breast and 13(20.3%) ovarian cancer cases. We found 23(18.4%) mutations in 9 other high to low-risk genes in 19 patients (15.2%). The most frequently mutated breast/ovarian cancer genes were PALB2 (n=3;2.4%), CHEK2 (n=2;1.6%), RAD51C (n=2;1.6%) and NBN (n=1;0.8%). Interestingly, we found 8 mutations (6.4%) in PRF1 gene that encodes perforin, a key effector molecule for T-cell- and natural killer-cell-mediated cytolysis, and 2 mutations (1.6%) in RET, which encodes tyrosine kinase receptor that acts as a signal transducer for cell growth and differentiation.

Conclusion

16% of breast and ovarian cancers in Serbia are related to the mutations in BRCA1/2 genes. Besides this, 6.4% of these cases showed mutations in other breast/ovarian cancer genes and 8% of cases in genes not previously associated to breast/ovarian cancers. Therefore, multigene testing increases the mutation detection rate in Serbia and improves the knowledge of the genetic structure of the population.
INHIBITION OF PHOSPHO-S6 KINASE, PROTEIN INVOLVED IN THE COMPENSATORY ADAPTIVE RESPONSE, INCREASES THE EFFICACY OF PACLITAXEL IN REDUCING THE VIABILITY OF MATRIX-ATTACHED OVARIAN CANCER CELLS

H.N. Lee¹, J.I. Choi², S.H. Park³, H.J. Lee⁴, D.W. Lee¹
¹Bucheon St. Mary's Hospital- College of Medicine- The Catholic University of Kor, Obstetrics and Gynecology, Bucheon-si, Republic of Korea
²St. Paul Hospital- Collage of Medicine- The Catholic University of Korea, Obstetrics and Gynecology, Seoul, Republic of Korea
³Bucheon St. Mary's Hospital- College of Medicine- The Catholic University of Kor, Clinical Medicine Research Institute, Bucheon-si, Republic of Korea

Aims

To identify the proteins involved the compensatory adaptive response to paclitaxel in ovarian cancer cells and to determine whether inhibition of the compensatory adaptive response increases the efficacy of paclitaxel in decreasing the viability of cancer cells.

Method

We used a reverse-phase protein array and western blot analysis to identify the proteins involved in the compensatory mechanism induced by paclitaxel in HeyA8 and SKOV3 ovarian cancer cells. We used a cell viability assay to examine whether inhibition of the proteins involved in the compensatory adaptive response influenced the effects of paclitaxel on cancer cell viability. All experiments were performed in three-dimensional cell cultures.

Results

Paclitaxel induced the upregulation of pS6 (S240/S244) and pS6 (S235/S236) in HeyA8 and SKOV3 cells. BX795 and CCT128930 were chosen as inhibitors of pS6 (S240/S244), pS6 (S235/S236). BX795 and CCT128930 decreased pS6 (S240/S244) and pS6 (S235/S236) expression in HeyA8 and SKOV3 cells. Compared with paclitaxel alone, addition of BX795 or CCT128930 to paclitaxel was more effective in decreasing the viability of HeyA8 and SKOV3 cells.

Conclusion

Addition of BX795 or CCT128930 to inhibit pS6 (S240/S244) or pS6 (S235/S236) restricted the compensatory adaptive response to paclitaxel in HeyA8 and SKOV3 cells. These inhibitors increased the efficacy of paclitaxel in reducing cancer cell viability.

⁹Sheba Medical Center, Institute of Pathology, Ramat Gan, Israel

Aims

Screening tests for high-grade ovarian carcinoma (HGOC), including serum CA125 and vaginal ultrasonography, fail to reduce disease-specific mortality, hence the universal recommendation for high-risk populations (e.g., BRCA1/2 mutation carriers) remains risk-reducing bilateral salpingo-oophorectomy (RRBSO) around the age of 40. As most HGOC arise from the fallopian tube epithelium (FTE), a ‘liquid biopsy’ may be obtained through washing of the uterine and tubal cavity, a procedure termed uterine lavage (UtL). We developed a diagnostic proteomic signature for detection of HGOC, based on microvesicles from UtL samples.

Method

Overall, 121 samples from 39 HGOC patients and 82 controls were analyzed by mass-spectrometry. Samples were divided into a discovery set (n=54) used to define the diagnostic signature, and an independent, blinded validation set (n=67).

Results

UtL microvesicle proteomics identified on average 2500 proteins per sample and more than 7000 proteins in the entire cohort. Using support vector machine algorithms, we extracted a 21-protein classifier with a high level of specificity and sensitivity, as represented in the Receiver Operating Characteristics (ROC) curve with an AUC of 0.90. Validation on an independent cohort showed an AUC of 0.74. Moreover, the signature was able to correctly diagnose all 4 early-stage lesions. RT-PCR and immunohistochemistry were able to confirm differential expression of signature proteins.

Conclusion

This proof-of-principle work demonstrates the technical feasibility of UtL, and the ability to obtain a predictive signature for HGOC, based on UtLF microvesicle proteomics. Further work is required to implement this approach for early detection in high risk populations.

Aims

Obesity is strongly associated with endometrial cancer (EC). There is extensive interaction between the sex hormone and insulin/IGF axes which both converge on the PI3K/AKT pathway. We assessed the effects of obesity and weight loss on endometrial proliferation, PTEN status and circulating and endometrial biomarkers of insulin signalling.

Method

Morbidly obese women undergoing bariatric surgery were recruited to a prospective cohort study and underwent blood and endometrial sampling at baseline, two and 12 months post surgery. Endometrial proliferation (Ki-67, pAKT), insulin receptor (IR), Insulin-like Growth Factor-Binding Protein 1 (IGFBP1) and PTEN status were assessed using immunohistochemistry.

Results

Seventy two women with median BMI 52.2kg/m² (IQR 47, 57) underwent bariatric surgery. Significant reduction in endometrial proliferation (Ki-67) and downregulation of the PI3K/AKT pathway (pAKT) were observed at 2 and 12 months post surgery. At baseline, endometrial glands were PTEN wild type in 31/35 with sufficient tissue for interpretation. Four were PTEN null at baseline; three of these had incidental atypical hyperplasia (AH) or EC. Glandular PTEN staining re-appeared with weight loss in 3 of 4 cases. Endometrial IGFBP1 expression was significantly increased 2 months post-bariatric surgery. Serum IGF1 was significantly increased and endometrial IR expression significantly decreased 12 months post-bariatric surgery.

Conclusion

PTEN loss may be a reversible feature of early endometrial carcinogenesis. Increased expression of IGFBP1 2 months post weight loss can be explained by falling circulating insulin levels. As circulating IGF1 increased after bariatric surgery the decrease in proliferation may be due to elevated IGF binding proteins.
Aims

To compare RNA-seq and microarrays of gene expression signatures that are known to be related to survival in ovarian cancer, endometrial cancer, breast cancer, colorectal cancer, renal cancer, and lung cancer.

Method

The correlation between the RNA-seq expression and reverse phase protein arrays (RPPA) in the selected genes were compared against the correlation between the microarray expression and RPPA by using the Cancer Genome Atlas data. The concordance index (C-index) in predicting overall survival was also calculated by using RNA-seq and microarrays and compared in each cancer type.

Results

In most selected genes, the correlation coefficients of RNA-seq and RPPA were comparable to those of microarrays and RPPA. Nonetheless, a number of genes showed differences in expression between RNA-seq and microarrays. Furthermore, the prognostic performance (C-index) of gene signature calculated using the microarray data were significantly higher than the prognostic performance calculated using the RNA-seq data across several cancer types.

Conclusion

It is tempting to consider that RNA-seq may outperform microarrays for clinical prediction of survival in cancer patients. However, in a number of selected genes, the correlation of microarrays and protein translation was stronger than that of RNA-seq and protein translation. It was also seen that the predictive model of survival constructed from microarrays was more accurate compared to RNA-seq in some cancers. Therefore, it is advised to carefully select the optimal methods of acquiring transcriptome data after speculating the specific genes and cancer types of interest.

7KU Leuven - VIB Center for Cancer Biology, Department of Oncology- Laboratory for Translational Genetics, Leuven, Belgium

Aims

BRCA1/2 mutations, as well as other molecular alterations, may lead to defective DNA repair by homologous recombination (HR) in approximately 50% of high-grade serous ovarian cancers (HGSOC). HR-deficiency (HRD) endows these tumors with increased sensitivity for platinum chemotherapy and PARP inhibitors. Here, we aimed to validate a genomic biomarker for HRD and correlated HRD status with clinical-pathological characteristics and outcome.

Method

SNP array profiling was performed on 207 primary HGSOC tumor samples, diagnosed between 1995 and 2011. Tumor ploidy was estimated and large-scale transitions (LSTs, i.e. chromosomal breaks between adjacent regions of at least 10 Mb) were quantified using validated ploidy-specific cut-offs. Clinical, biochemical, radiological, surgical and pathological characteristics at diagnosis, as well as outcome parameters, were retrieved from electronic patient files.

Results

HRD was detected in 128 cases (61.8%) and in 34/37 patients with BRCA mutations (91.9%). FIGO stage and residual disease did not differ between HRD and non-HRD cases, whereas median age at diagnosis was younger in the HRD group (56 versus 64 years, p=0.03). Univariate analysis showed a better overall survival for the HRD group compared with the non-HRD group (HR 0.58, CI: 0.41-0.83, p=0.003) and this prognostic effect remained significant (HR 0.67, CI: 0.46-0.98, p=0.04) after adjusting for residual disease and age at diagnosis. Univariate analysis of other clinical-pathological factors could not identify significant predictors of HRD status.

Conclusion

Genomic profiling identifies HRD in primary HGSOC, which is prognostic for survival. The presence of HRD was not related to any clinical-pathological characteristic.
CIRCULATING TUMOR CELLS: POTENTIAL MARKERS OF MINIMAL RESIDUAL DISEASE IN OVARIAN CANCER? - A STUDY OF THE OVCAD CONSORTIUM

1Medical University of Vienna, Dept. of Obstetrics and Gynecology, Vienna, Austria
2University Medical Center Eppendorf, Institute of Tumor Biology, Hamburg, Germany
3Universite de Montpellier, INSERM U1194, Montpellier, France
4Lawrence Berkeley National Laboratory, Life Sciences, Berkeley, USA
5Leuven Cancer Institute, Obstetrics and Gynecology, Leuven, Belgium
6Charité-Universtätmedizin Berlin, Gynecology, Berlin, Germany
7University Medical Center Eppendorf, Gynecology and Gynecologic Oncology, Hamburg, Germany
8University Medical Center Schleswig-Holstein, Clinical Chemistry, Kiel, Germany

Aims

In 75% of ovarian cancer patients the tumor mass is completely eradicated by established surgical and cytotoxic treatment; however, the majority of the tumors recur within 24 months. Here we investigated the role of circulating tumor cells (CTCs) indicating occult tumor load, which remains inaccessible by established diagnostics.

Method

Blood was taken at diagnosis (baseline samples, n=102) and six months after completion of adjuvant first-line chemotherapy (follow-up samples; n=78). CTCs were enriched by density gradient centrifugation. A multi-marker immunostaining was established and further complemented by FISH on CTCs and tumor/metastasis tissues using probes for stem-cell like fusion genes MECOM and HHLA1.

Results

CTCs were observed in 26.5% baseline and 7.7% follow-up blood samples. Baseline CTCs indicated a higher risk of death in R0 patients with complete gross resection (univariate: HR 2.158, 95% CI 1.111-4.191, p=0.023; multivariate: HR 2.720, 95% CI 1.340-5.522, p=0.006). Despite the drop down of CTC counts during treatment (from mean 12 to 1 CTCs per ml blood), non-responders were more likely to retain CTCs (p<0.05). Chromosomal gains at MECOM and HHLA1 loci suggest that the observed cells were cancer cells and reflect pathophysiological decisive chromosomal aberrations of the primary and metastatic tumors.

Conclusion

Our data suggest that CTCs detected by the multi-marker protein panel and/or MECOM/HHLA1 FISH represent minimal residual disease in optimally debulked ovarian cancer patients. The role of CTCs cells especially for clinical therapy stratification of the patients has to be validated in consecutive larger studies applying standardized treatment schemes.
IMMUNOHISTOCHEMICAL STUDY OF EGFR AND HER-2 ONCOPROTEIN EXPRESSION IN UTERINE CARCINOSARCOMA BY TISSUE MICROARRAY ANALYSIS

M. Sawada¹, H. Tsuda², T. Kasamatsu³, T. Kato⁴, J. Kitawaki¹

¹Kyoto Prefectural University of Medicine, Obstetrics and Gynecology, Kyoto, Japan
²National Defense Medical College, Department of Basic Pathology, Saitama, Japan
³Tokyo Metropolitan Bokutoh Hospital, Department of Obstetrics and Gynecology, Tokyo, Japan
⁴National Cancer Center Hospital, Gynecology Division, Tokyo, Japan

Aims

We comprehensively analyzed EGFR and HER-2 overexpression in uterine carcinosarcoma by tissue microarray slides to investigate whether EGFR and HER-2 oncoproteins are molecular targeting markers of uterine carcinosarcoma.

Method

This was a retrospective clinicopathological study. The present study was approved by the internal review board for ethical issues. We collected formalin-fixed paraffin-embedded tissue blocks of uterine carcinosarcoma resected from 63 patients who had undergone radical operation at the Division of Gynecology, National Cancer Center Hospital, between 1997 and 2010. We made each tissue microarray thin-section slides of epithelial and mesenchymal components of uterine carcinosarcoma, and analyzed the expression of EGFR and HER-2 oncoproteins immunohistochemically.

Results

In the epithelial component, EGFR overexpression (≥2+) was detected in 4/22 (18.2%) of endometrioid adenocarcinoma (EA), grade 1; 10/30 (33.3%) of EA, grade 2; 22/29 (75.9%) of EA, grade 3. EGFR overexpression was detected in 6/16 (37.5%) of serous adenocarcinoma. In the mesenchymal components, EGFR expression was detected in 57/78 (73.1%) (overexpression (≥2+) was detected in 43/78 (55.1%)). HER-2 overexpression (≥2+) was not detected in the epithelial or mesenchymal components.

Conclusion

EGFR oncoprotein tended to overexpress strongly in the mesenchymal component, and overexpression of EGFR oncoprotein tended to increase proportionally as the EA grading increase in the epithelial component. This study could suggest that EGFR oncoprotein would be a molecular targeting marker of uterine carcinosarcoma.
TFF3 EXPRESSION AS STRATIFICATION MARKER IN BORDERLINE EPITHELIAL TUMORS OF THE OVARY

A. El-Balat1, I. Schmeil1, T. Karn1, S. Becker1, N. Sänger1, U. Holtrich1, R. Arsenic2

1Goethe University Frankfurt, Gynecology, Frankfurt, Germany
2Charité University Hospital, Pathology, Berlin, Germany

Aims

Borderline tumors (BOT) of the ovary account for 10% to 20% of ovarian neoplasms. Like ovarian cancer, BOT encompass several different histological subtypes (serous, mucinous, endometrioid, clear cell, transitional cell and mixed) with serous (SBOT) and mucinous (MBOT) the most common. Current hypotheses suggest low-grade serous carcinoma may develop in a stepwise fashion from SBOT whereas the majority of high grade serous carcinomas develop rapidly presumably from inclusion cysts or ovarian surface epithelium. The pathogenesis of mucinous ovarian tumors is still puzzling. Molecular markers could help to better define relationships between such entities. Trefoil factor-3 (TFF3) is an estrogen-regulated gene associated with prognosis in different types of cancer. It has also been included in a recent marker panel predicting subtypes of ovarian carcinoma.

Method

We analyzed the expression of TFF3 by immunohistochemistry in a cohort of 137 BOT and its association with histopathological features.

Results

Overall expression rate of TFF3 was 21.9%. None of the BOT with serous and endometrioid histology displayed strong TFF3 expression. On the other hand, TFF3 was highly expressed in 61.4% of MBOT cases and 33.3% of BOT with mixed histology (P<0.001) suggesting a potential function of the protein in that subtypes. Associations of TFF3 expression with FIGO stage and micropapillary pattern were significant in the overall cohort but confounded by their correlation with histological subtypes.

Conclusion

The highly specific expression of TFF3 in MBOT may help to further clarify potential relationships of tumors with mucinous histology and warrants further studies.
NATURAL KILLER CELLS PREACTIVATED WITH IL-12 AND IL-18 HAVE ENHANCED FUNCTION AGAINST OVARIAN CANCER

L. Uppendahl1, M. Feliices2, L. Bendzick1, C. Ryan1, B. Koda2, K. Boylan1, A. Skubitz1, M. Geller1

1University of Minnesota, Department of Obstetrics Gynecology and Women’s Health, Minneapolis, USA
2University of Minnesota, Department of Medicine, Minneapolis, USA

Aims

Natural killer (NK) cells are therapeutically attractive lymphocytes with the ability to kill cancer cells and produce proinflammatory cytokines without prior exposure to specific tumor antigens. The milieu of the peritoneal cavity in patients with ovarian cancer impairs the functional and proliferative capacity of NK cells through a variety of mechanisms. Our objective was to investigate short-term preactivation of NK cells with IL-12 and IL-18 to enhance function and proliferation against ovarian tumor targets.

Method

NK cells from healthy donors were preactivated with IL-12/18, washed to remove cytokines, then placed against ovarian cancer targets at varying time points to assess function by flow cytometry. Direct measurement of ovarian cancer cell death was performed using automated image analysis. Preactivated human NK cells were injected intraperitoneal (IP) into a xenogeneic mouse model of ovarian cancer to evaluate control of tumor burden, NK cell function, and proliferation.

Results

Preactivation with IL-12/18 durably enhanced NK cell IFN-γ and TNF-α production against in vitro ovarian cancer targets for up to 1 week. Enriched, preactivated NK cells demonstrated a higher level of killing when measured directly in real time. Finally, preactivated human NK cells remained in greater numbers on day 25 following IP injection and decreased tumor burden within the in vivo xenogeneic mouse model of ovarian cancer.

Conclusion

Preactivation of NK cells with IL-12/18 results in persistent, enhanced functionality against ovarian cancer in vitro and in vivo. These findings suggest a potential strategy for NK cell-based therapy to circumvent the immunosuppressive nature found in ovarian cancer.
Aims

Defective DNA repair by homologous recombination (HR) is a feature of approximately 50% of high-grade serous ovarian cancers (HGSOC). Quantifying various forms of genomic damage has emerged as a biomarker for underlying DNA repair deficiencies. However, little is known on the temporal stability of these measures and whether genomic scar dynamics have predictive clinical value.

Method

Matched primary and (first) recurrent HGSOC tumor samples from 42 patients were analyzed with SNP-array profiling and (for a subset of 29) paired whole-exome sequencing. Tumor ploidy was estimated and large-scale transitions (chromosomal breaks between adjacent regions of at least 10 Mb) were quantified using validated ploidy-specific cut-offs to identify HR-deficient (HRD) cases. Mutational load was calculated as the number of single-nucleotide (exonic) variants.

Results

HRD was detected in 24/42 (57.1%) primary and recurrence samples. 22 patients remained HR-deficient at progression, whereas 2 patients switched from HR-deficient to HR-proficient and vice versa. Overall, HRD status at primary diagnosis was a significant predictor for HRD status at first recurrence (p <0.001). Deleterious somatic BRCA1/2 mutations were detected in 7/29 patients (24.1%), all in patients with a primary HR-deficient tumor. One BRCA1-mutated patient switched to HR-proficiency at relapse, but no frameshift reversion event could be documented. Median somatic mutational load was 354 at primary diagnosis and 335 at first recurrence (p=0.732) and did not differ according to HRD status at both timepoints (p=0.546 and p=0.989).

Conclusion

Genomic scars demonstrate a stable pattern through tumor progression, which may limit their predictive value at relapse.

LONG-TERM FOLLOW-UP AFTER SENTINEL LYMPH NODE BIOPSY IN EARLY-STAGE VULVAR CANCER

N. Agustí¹, A. Rodríguez-Trujillo¹, E. Mensión¹, P. Fusté¹, M. Del Pino¹, B. Gil-Ibañez¹, M. Munmany¹, I. Nicolás¹, A. Glickman¹, A. Torné¹, J. Pahisa¹

¹Hospital Clinic, ICGON, Barcelona, Spain

Aims

To evaluate the long-term follow-up in patients with early-stage vulvar cancer undergoing sentinel lymph node biopsy (SLNB).

Method

Retrospective cohort study performed in patients with squamous cell vulvar cancer ≤ 4 cm without suspected inguinofemoral lymph node metastases admitted to our center from June 1998 to July 2004 who underwent SLNB. Complete inguinofemoral lymphadenectomy was performed when SLNB was positive intraoperatively or non-detected. In midline tumors with unilateral drainage complete lymphadenectomy of the opposite side was performed. Adjuvant radiotherapy or re-excision was applied if margins were affected in histological examination. Only patients without lymph node metastases assessed by only SLNB were considered.

In order to compare the recurrence rate and disease-specific 10-year survival this cohort was compared to another cohort without lymph node metastases assessed by inguinofemoral lymphadenectomy, sharing both groups the same tumor’s characteristics and adjuvant treatment.

Results

Thirty patients had negative lymph node after performing SLNB and 51 after lymphadenectomy. The median follow-up was 62.8 months (range 2.9 – 131). We observed no significant differences in recurrence rates between patients with negative SLNB and negative lymphadenectomy (43.3% vs 51%, p=0.646) as well as in the disease-specific 10-year survival rate (76.7% vs. 84.3%, p=0.394). The location of first recurrence in negative SLNB were in 33.3%, 6.7% and 3.3% of patients, local, groin and distant recurrence respectively, being in negative lymphadenectomy 45.1%, 5.9% and 0 respectively, being these differences not significant (p=0.441).

Conclusion

SLNB seems to be, in oncological terms, as safe as inguinofemoral lymphadenectomy to assess lymph node status in early-stage vulvar cancer.
EXTENDED PELVIC RESECTIONS FOR LOCALLY INVASIVE VULVAR CANCER

N. Bacalbasa¹, I. Balescu²
¹Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania
²Ponderas Academic Hospital, Visceral surgery, Bucharest, Romania

Aims

To demonstrate the effectiveness of radical pelvic resections for locally invasive vulvar cancer

Method

We report a case series of eight patients diagnosed with locally advanced vulvar cancer in which extended pelvic resections were performed in order to achieve a good local control of the disease.

Results

The main performed procedures consisted of total infralevator pelvic exenteration in two cases, anterior pelvic exenteration in five cases and posterior pelvic exenteration in one case (Figures 1-3).
The early postoperative outcome was uneventful in all cases; however, one case developed at six weeks postoperatively an enteroperineal fistula and required re-intervention.

**Conclusion**

Pelvic exenteration can be safely performed for locally advanced vulvar cancer with acceptable rates of postoperative morbidity.

INCIDENCE OF SHORT AND LONG-TERM POSTOPERATIVE MORBIDITY RELATED TO LYMPH NODE DISSECTION FOR VULVAR CANCER

E. Barlow, N. Hacker

The Royal Hospital for Women, Gynaecological Cancer Centre, Randwick, Australia

Aims

The aim of this study was to determine the incidence of short, and long term postoperative complications, following lymphadenectomy for vulvar cancer. Specifically, the problems of groin wound dehiscence, cellulitis, lymphocyst formation, and lymphoedema were reviewed.

Method

Design: A retrospective, observational, single institution study.

All patients treated for invasive cancer of the vulva, at a tertiary hospital in Sydney, Australia, between the years 1987 to 2015, were included in the study. A retrospective analysis of the hospital medical records, including clinical charts, operative reports and pathology reports were reviewed as part of a larger study.

Results

From 1987 to 2015, 479 women were treated for vulvar cancer, with 410 eligible for inclusion in the study. Mean age was 66.7 years (range 20-95 years). Postoperatively, 6.4% of women developed cellulitis, and 10.8% experienced groin wound breakdown. Lymphocysts occurred in 42.6% (152/357) of dissected groins, following inguinal-femoral lymphadenectomy, and in 23.4% (11/47) of groins following resection of bulky positive nodes only. 43% (107/248) of women who had either unilateral or bilateral groin node dissection subsequently developed lymphoedema, compared to 11 of 47 (23.4%) women who underwent groin node debulking. Of the women who developed lymphoedema 37% developed it within 3 months of surgery.

Conclusion

Results indicate relatively low rates of groin wound breakdown and cellulitis, but high rates of lymphocyst formation and lymphoedema. More detailed analysis of the data is required to develop strategies to further reduce these complications.

ESGO7-1040

SENTINEL LYMPH NODE MAPPING FOR VULVAL CANCER: PRIOR WIDE LOCAL EXCISION DOES NOT IMPAIR NODAL MAPPING.

R. Bharathan¹, O. Devaja¹, A. Corrigan¹, M. Coutts¹, A. Papadopoulos¹, S. Montalto¹

¹West Kent Oncology Centre- Maidstone Hospital, Department of Gynaecological Oncology, Maidstone, United Kingdom

Aims

To determine the performance of sentinel lymph node (SLN) mapping technique in staging vulval cancer in women who have undergone an earlier wide local excision (WLE).

Method

Since 2005, women with vulval cancer of stage 1B or greater have undergone central surgery with SLN mapping. We have performed SLN mapping with the combined technique using Tc-99m colloid and methylene blue dye. Patients had preoperative SPEC/CT. If patients presented with clinically suspicious nodes, these nodes were debulked and subsequently treated with radiotherapy +/- chemotherapy. If the SLN was negative, then the specimen was ultra-staged by a single pathologist.

Results

Median age was 67 years and the median body mass index was 28.6. In our study of 32 patients both the SPEC/CT and gamma probe identified SLN in 100% of patients. Methylene blue identified SLN in 97% of cases. 21 patients had stage 1B disease, 4 had stage 2 and 7 had stage 3 cancer. 90% were diagnosed with squamous cell cancer. Median size of the lesion was 15 mm and depth of invasion was 2.5 mm. LVSI present in 28% of cases. LN were positive in 25% cases. The median number of SLN in central tumours was 1 per LN basin and in lateral tumours, it was 2. False negative rate was 3.1%

Conclusion

SLN is a feasible and safe technique even in those who have had prior WLE.

ICG-NIR FOR DETECTING THE SENTINEL LYMPH NODE IN EARLY STAGE VULVA CANCER: A CASE SERIES FROM A UK CENTRE
S. Rundle¹, N. Bizzarri¹, S. Natsis¹, N. Ratnavelu¹, R. O'Donnell¹, A. Kucukmetin¹, A. Fisher¹, C. Ang¹, R. Naik¹
¹Northern Gynaecological Oncology Centre, Queen Elizabeth Hospital, Gateshead, United Kingdom

Aims

Standard techniques for sentinel lymph node (SLN) biopsy in vulva cancer use a combination of blue dye (BD) and radio-labelled nanocolloid (Tc-99m) as the lymphatic tracers to enable pre and intra-operative localisation of SLNs. Indocyanine green-near infrared (ICG-NIR) fluorescence for SLN biopsy has been widely reported in cancers of the endometrium and cervix. To date, limited data on the use of ICG-NIR for SLN biopsy in early stage vulva cancer is available. Here we present updated data from a UK centre using ICG-NIR for SLN biopsy in patients with vulva cancer.

Method

Patients presenting with unifocal squamous cell cancers of the vulva of less than 4cm diameter were included. Exclusion criteria included bulky lymphadenopathy on CT or clinical examination. ICG-NIR fluorescence imaging was performed in addition to the standard combined technique for SLN detection. If sentinel lymph node detection failed, side specific lymphadenectomy was performed in accordance with the patients pre-operative counselling and consent.

Results

18 patients underwent the SLN procedure using BD/TC-99m and ICG-NIR. Of the SLN successfully detected, 96% were positive for ICG fluorescence compared to 80% for BD

Conclusion

ICG-NIR is a valid and safe technique for the detection of SLN in patients with early stage vulva cancer. ICG-NIR appears superior to BD for the intra-operative visualisation of the SLN.

ESGO7-0707

PRIMARY BIFOCAL MALIGNANT MELANOMA OF THE VAGINA. A CASE-REPORT
C. Blancafort González-Casabón¹, R. Fàbregas Xaudaro¹, F. Fargas Fàbregas¹
¹Hospital Universitario Dexeus, Gynecological Oncology Department, Barcelona, Spain

Aims

Primary melanomas of the vagina are a very rare condition, associating a much poorer prognosis than other vaginal malignancies.

Method

This case reports the clinical features and treatment procedures used in an even less common condition: a bifocal primary malignant melanoma of the vagina.

Results

A 60-year-old woman, was admitted with a chief complaint of vaginal bleeding. Clinical examination revealed two non ulcerated dark-brown masses. The biopsy of the lesions revealed malign melanoma. After extension study, the patient was treated surgically: laparoscopic colpectomy, sentinel node study and bilateral pelvic lymphadenectomy were performed, followed by a vaginal reconstruction. The tumour was pathologically staged as a IIb of melanoma according to the “2009 AJCC Melanoma Staging and classification” and the multidisciplinary committee of gynecological oncology decided to complete the treatment with inguinal and pelvic radiotherapy during 28 sessions.

Conclusion

In the last years, some studies and reviews have been published in order to improve and facilitate its management. Nevertheless, protocols haven’t been established yet, and there is even less evidence and guiding ideas on how to manage more specific cases such as bifocal presentations.

MANAGEMENT OF A BIG VULVAR CANCER RECCURENCE
E. Galati1, C. Iavazzo1, N. Blontzos1, I. Kotsakis2, E. Kostopoulos2, C. Agiannidis2, D. Korfias1, N. Kalinoglou1, G. Vorgias1
1Metaxa Memorial Cancer Hospital, Gynecologic Oncology, Pireaus, Greece
2Metaxa Memorial Cancer Hospital, Plastic-Reconstructive Surgery, Pireaus, Greece

Aims

To present the management of a big vulvar cancer recurrence.

Method

A 79-year-old woman was admitted to our Gyn-Onc department with a recurrence of vulvar cancer. She had undergone vulvectomy and left inguinal lymphadenectomy two years ago due to gr.1 vulvar carcinoma. The tumor size was 2.5cm and 1+/9 lymph nodes were found (St IIIAi). External beam radiotherapy (7000 cGy) had been given postoperatively. The recurrence was confirmed with a vulvar biopsy. The CT scan showed a lesion in the vulva measuring 7.6cm, extending to the anterior wall of the lower 1/3 of the vagina, reaching the pubic symphysis. The preoperative cystoscopy revealed infiltration of the lower urethra. No other metastasis was found in further imaging.

Results

The patient underwent extended radical vulvectomy from the pubis periosteum caudaly to ischiopubic periosteum laterally and right inguinal lymphadenectomy with excision of the outer 1/2 of the urethra. Multi frozen sections were used to establish clear margins. Reconstruction was achieved with the use of two keystone flaps type 4. A keystone flap is a perforator flap based on random musculo-cutaneous perforators from the area. Twenty one days postoperatively she developed partial left flap necrosis, which was treated with the use of a split-thickness skin graft of the anterior part of the right thigh. The pathology report described a squamous cell carcinoma grade 2-3 and inguinal lymph nodes with no signs of malignancy. Clears margins were confirmed.

Conclusion

Vulvar cancer recurrences are challenging cases which should be managed in a tertiary cancer center with a multispecialty approach.

GENOMIC CHARACTERISATION OF VULVAR (PRE)CANCERS IDENTIFIES DISTINCT MOLECULAR SUBTYPES WITH PROGNOSTIC SIGNIFICANCE

L. Nooij1, N. ter Haar2, D. Ruano3, N. Rakislova4, V. Smit5, B. Trimbos1, J. Ordi3, M. van Poelgeest1, T. Bosse2

1LUMC, Gynaecology, Leiden, The Netherlands
2LUMC, Pathology, Leiden, The Netherlands
3Barcelona Centre for International Health Research CRESIB, Pathology, Barcelona, Spain

Aims

Vulvar cancers (VC) are classified on the presence of human papilloma virus (HPV). HPV- VC are associated with TP53 mutations, but little is known about other genetic alterations. In an effort to further delineate the molecular landscape of VC, we comprehensively assessed somatic mutations in a large series of vulvar (pre)cancers.

Method

We performed targeted next generation sequencing (17 genes), p53 immunohistochemistry and HPV testing on 36 VC and 82 precursors. Subsequently, the prognostic significance of HPV and p53-status was assessed in a series of 236 VC patients (follow-up cohort).

Results

Frequent recurrent mutations were identified in HPV- VC and precursors in TP53 (42% and 68%, respectively), NOTCH1 (28% and 39%, respectively) and HRAS (20% and 32%, respectively). Mutation frequency in HPV+ vulvar (pre)cancers was significantly lower (p-value = 0.001). Furthermore, a substantial subset of the HPV- precursors (35/60, 58.3%) and VCs (9/28, 32%) were TP53 wildtype, suggesting a third molecular subtype. Clinical outcomes in the 3 different groups (HPV+, HPV-/p53-WT, HPV-/p53-abn) were evaluated in the follow-up cohort. Local recurrence rate was 5.3% for the HPV+ patients, 16.3% for HPV-/p53-wt patients and 22.6% for HPV-/p53-abn patients (p=0.044). HPV positivity remained an independent prognostic factor for favourable outcome in multivariable analysis (p=0.020).

Conclusion

HPV- and HPV+ vulvar (pre)cancers display striking differences in somatic mutation patterns. HPV-/p53wt VC appear to be a distinct clinicopathologic subgroup with frequent NOTCH1 mutations. HPV+ VC have a significant lower local recurrence rate, independent of clinicopathological variables, opening opportunities for future studies on possible reduction of overtreatment in VC.
18F-FDG PET/CT IN PREOPERATIVE NODAL STAGING OF VULVAR CANCER PATIENTS: IS IT REALLY NEEDED?

A. Buda¹, C. Crivellaro², G. Di Martino¹, F. Elisei², M. La Manna¹, S. Magni¹, P. Di Lorenzo¹, L. Guerra²

¹Gynecologic Oncology Unit- ASST-Monza- San Gerardo Hospital- University of Milano-Bicocca- Monza- Italy,
Department of Obstetrics and Gynecology, Monza, Italy
²University of Milano-Bicocca- Tecnomed Foundation-, Department of Nuclear Medicine- Monza- Italy, Monza, Italy

Aims

Aim of this study was to assess the role of PET/CT in nodal staging of vulvar cancer patients.

Method

29 pts (68 years; range 51-83) with vulvar cancer (clinical stage I-II), underwent preoperative FDG-PET/CT scan followed by radical vulvectomy and bilateral (or monolateral in case of tumour >2 cm from midline) inguinal lymphadenectomy or sentinel node biopsy. PET/CT images were analyzed by three examinators in consensus and correlated to histological findings according to a pt-based and a groin-based analyses. SUVmax of the nodal uptake of each inguinal area (if present) has been calculated and correlated to histological findings.

Results

PET/CT analysis in consensus resulted negative at inguinal LN level in 18 pts (10 TN, 8 FN) and positive in 11 pts (6 TP, 5 FP). Incidence of LN metastases resulted 48%. On pt-based analysis, sensitivity, specificity, accuracy, negative and positive predictive value of PET/CT in detecting LN metastases were 43%, 67%, 55%, 55%, 56%. On a groin-based analysis, considering overall 50 LN-sites, sensitivity, specificity, accuracy, negative and positive predictive value of PET/CT were 53%, 85%, 73%, 67%, 76% respectively. The mean value of SUVmax was 4.1 (range 0.7-9.3) for metastatic nodes, whereas 1.6 (range 0.7 – 5.4) for reactive/negative lymph-nodes (p=0.0005).

Conclusion

In vulvar cancer FDG PET/CT showed low sensitivity and moderate specificity for lymph node staging, therefore it is not an accurate tool for the nodal status assessment.

ESGO7-1009

V-Y ADVANCEMENT FLAP VERSUS LOTUS PETAL FLAP FOR PLASTIC RECONSTRUCTION AFTER SURGERY IN CASE OF VULVAR MALIGNANCIES: A RETROSPECTIVE SINGLE CENTER ITALIAN EXPERIENCE.

A. Buda¹, R. Gilardi², P.L. Confalonieri³, G. Di Martino³, J.H. Lee⁴, F. Dell'Orto⁴, M. Del Bene²

¹Unit of Gynecologic Oncology, Department of Obstetrics and Gynecology- University of Milano-Bicocca, Monza, Italy
²Unit of Plastic Surgery- San Gerardo Hospital, Department of Surgery, Monza, Italy

Aims

This study retrospectively reviewed patients with primary or recurrent vulvar malignancies that had undergone vulvoperineal reconstruction using the V-Y advancement flap and the two variant of the lotus petal flap (LPF) in terms of surgical outcome and postoperative complications.

Method

Between 2000 and 2016, 234 women operated at San Gerardo Hospital in Monza were included in the study. 128 of them having undergone V-Y flap, whereas 106 underwent LPF (58), or it tunneled variant (48). Overall, 365 flaps were harvested (214: 59% V-Y; 151: 41% LPF). Two hundred and sixty-two (262) flaps were bilateral, (47% V-Y, 24% LPF) whereas 103 flaps were monolateral (11% V-Y, 17% LPF).

Results

The average length of follow-up was 84 months (range, 6 - 180 months). Overall, postoperative complications occurred in 21.5% of patients including 27/128 (21%) of the V-Y group and in 14/106 (13%) of the LPF group. No statistically differences were recorded in terms of complications between the groups when comparing V-Y and LPF’s overall (p=0.588), or by comparing the primary (p=0.202), or the recurrent setting (p=0.281). Site of recurrence are listed in table 3. No statistically difference were found between the groups overall (p=0.974), or when comparing the primary (p=0.873), or the recurrent setting (p=0.971).

Conclusion

V-Y flap and the LPF represent two feasible techniques for vulvoperineal reconstruction after surgery for primary or recurrent vulvar malignancies. The associated rates of complications are reasonable for both procedures. LPF represents the treatment of choice in our department for vulvar reconstruction producing the best aesthetic and functional results.

OUTCOMES AND TOXICITY FOLLOWING ADJUVANT INGUINAL RADIOTHERAPY IN VULVAR CANCER; WEST OF SCOTLAND EXPERIENCE

M. Chitoni, K. Graham, N. Reed, A. Sadozye, R. Harrand

Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom

Aims

Inguinal radiotherapy with or without concomitant chemotherapy is considered standard for patients who have had wide local excision and inguinal lymphadenectomy, and are found to be node positive.

We were interested in outcomes, toxicity and patterns of failure in this group of patients.

Method

We analysed our databases for patients who had received adjuvant (chemo)radiotherapy to inguinal nodes either unilateral or bilateral.

We queried our systems (Aria and Chemocare) and collected patients from 1st January 2007 to 1st September 2015. Further details on patients were collected through case notes, Clinical Portal, SCI Store and Trakcare.

Results

We found 21 patients that fulfilled the above criteria, median age 66yrs (range 28-84 years). Sixteen patients (76%) had concomitant chemoradiotherapy. Dose of radiotherapy was 50Gy in 60% of the total cohort. About 30% of patients had grade 3 tumours and lymphovascular space invasion (LVSI) was seen in 66%.

Lymphoedema was the only late toxicity, observed in 24% of patients. There was no bowel or bladder related toxicity beyond Grade 1.

Just over half the patients are alive and disease free after a median follow up of 18 months. The median follow up for those who are disease free is 30 months.

Seven patients out of the total of 10 with any relapse, and all patients who had a distant relapse, had LVSI in their initial specimen.

Conclusion

Our results show that chemo-radiation to the inguino-femoral region is well tolerated. LVSI is a strong predictor for relapse.

VULVAR CANCER: TWO PATHWAYS WITH DIFFERENT LOCALIZATION AND PROGNOSIS

F. Hinten1, A. Molijn2, L. Eckhardt1, L. Massuger1, W. Quint2, P. Bult3, H. Bulten3, W. Melchers4, J. de Hullu1

1Radboudumc, Obstetrics&Gynaecology, Nijmegen, The Netherlands
2Delft Diagnostic Laboratory, Delft Diagnostic Laboratory, Delft, The Netherlands
3Radboudumc, Pathology, Nijmegen, The Netherlands
4Radboudumc, Medical Microbiology, Nijmegen, The Netherlands

Aims

Two etiologic pathways for vulvar squamous cell carcinoma (SCC) are described: in a background of lichen sclerosus and/or differentiated vulvar intraepithelial neoplasia and related to high-risk human papillomavirus (HPV) infection with high grade squamous intraepithelial lesion (HSIL) as precursor. The aim was to compare the predilection site and survival of HPV-related to non HPV-related vulvar SCCs.

Method

Data of patients treated for primary vulvar SCC at the Radboudumc between March 1988 and January 2015 were analyzed. All histological specimens were tested for HPV with the SPF10/DEIA/LiPA25 system assay and p16INK4a staining was performed using CINtec® histology kit. Vulvar SCCs were considered HPV-related in case of either >25% p16INK4a expression and HPV positivity or >25% p16INK4a expression and HSIL next to the tumour. Tumour localization, disease specific survival (DSS), disease free survival (DFS) and overall survival (OS) of patients with HPV-related and non HPV-related vulvar SCC were compared.

Results

In total 318 patients were included: 55 (17%) had HPV-related (Group 1) and 263 (83%) had non HPV-related vulvar SCC (Group 2). The tumours in Group 1 were significantly more often located at the perineum compared to Group 2, 30% and 14%, respectively (p = 0.001). The DSS, DFS and OS were significantly better in HPV-related than in non HPV-related vulvar SCC patients.

Conclusion

HPV-related vulvar SCCs are more frequently located at the perineum and have a favourable prognosis compared to non HPV-related vulvar SCCs. Both localization and the HPV-relation could explain this favourable prognosis. HPV-related vulvar SCC seems to be a separate entity.

³the Obstetrics and Gynecology Hospital of Fudan University, huakeqin@126.com, Shanghai, China

Aims

To compare the complications, oncological outcomes, cosmetic satisfaction and quality of life between video endoscopic inguinal lymphadenectomy (VEIL) and conventional open inguinal lymphadenectomy (COIL) in women with vulvar cancer.

Method

Patients with vulvar cancer who underwent COIL (n=27) or VEIL (n=21) in our hospital between 2003 and 2016 were included in this retrospective cohort study. The perioperative data, postoperative complications, oncological outcomes, cosmetic satisfaction and quality of life between COIL and VEIL groups were compared.

Results

20 patients (74.1%) in COIL group and 19 patients (90.5%) in VEIL group returned for their follow-up after the operation. The median follow-up time was 73 months (8-162 months) for the COIL group and 28 months (8-58 months) for the VEIL group. The inguinal lymph node yield in the VEIL group was comparable with that in the COIL group (15±5 VS 18±6, P=0.058). The VEIL group had similar recurrence rate and death rate with the COIL group. The wound complication rate is significantly lower in the VEIL group than that in the COIL group. The VEIL group had higher body image scores (16.27 ± 1.20 VS 13.16 ± 0.87, P < 0.0001) and cosmetic scores (20.13 ± 0.98 VS 16.92 ± 0.72, P < 0.0001) than the COIL group. The patients in the VEIL group had a higher life quality scores by the FACT-V questionnaire than those in the COIL group (165.9±6.3 VS 160.5±6.0, P=0.026).

Conclusion

Comparing with conventional open inguinal lymphadenectomy, video endoscopic inguinal lymphadenectomy can effectively reduce the postoperative wound complications, improve patients’ cosmetic satisfaction and life quality without compromising the therapeutic efficacy.
Aims

Study aimed to determine the rate and factors that can increase local recurrence of vulvar carcinoma.

Method

Study included all women operated due to vulvar carcinoma in Clinic of Obstetrics and Gynecology Clinical Center of Serbia during five years period (January 1st 2012. to December 31st 2016.). Upon admission to the Clinic detailed history data were taken from all patients. During gynecological examination tumor size, localisation and growth were registered. Postoperatively we noted type of performed operation, hystopathological findings and findings of excised tissue margins (clear or with residual malignancy), tumor stage and grade, local invasion depth, presence of local and distant metastases and postoperative complications (wound infection and dehiscence; lymphocele formation). All obtained data were compared according to tumor recurrence.

Results

Study included 63 patients out of which 4.8% had local recurrence of vulvar carcinoma. They in average had 67.87 +/- 11.44 years of age, 4.3 +/- 3.3 pregnancies and 25.81 +/- 4.54 BMI. The most common tumor type was squamocellular carcinoma, stage IB and grade I, with exophitic growth on labia majora or bilateraly. The mean recurrence time was 50.33 +/- 12.41 months. Out of all investigated parameters only having other gynecological illnesses (p=0.046) and metastases in ingvinal lymph nodes (p=0.039) was associated with local recurrence of vulvar carcinoma.

Conclusion

Recurrence rate of vulvar carcinoma is not frequent and the latent time is long, but influenced by gynecological comorbidities and presence of metastases in inguinal lymph nodes.
VAGINAL AND VULVAR CANCER

ESGO7-1197

LAPAROSCOPIC-ASSISTED IMMEDIATE VAGINAL RECONSTRUCTION (LAIVR) WITH PEDICLE DEEP INFERIOR EPIGASTRIC PERFORATOR FLAP (DIEP) FOR VAGINAL PRIMARY MALIGNANT MELANOMA (VPMM)

P.F. Dupré¹, C. Vigouroux¹, A. Derrien¹, D. Legoupil¹, P. Merviel¹, N. Kerfant¹
¹CHRU Brest, Finistère, Brest, France

Aims

VPMM represents 0.8% of melanomas and less than 3% of vaginal cancers

R0 excision is advised for initial stages with vaginal reconstruction as an option

Method

A 48-year-old woman presented with recurrent vaginal bleeding on account of a brown colored nodule of 25 mm of the upper third vagina

VPMM was pathologically confirmed.

Pre-treatment assessment consisted on endo-rectal ultrasound, MRI and PET-CT.

The vascular network was assessed using CT-scan.

Sentinel lymph node dissection (SLND) and radical B2 hysterectomy with two- upper-third radical colpectomy and vaginal reconstruction using DIEP flap were scheduled.

Left pedicle perforator flap was harvested distally up to the DIE artery origin and rotated into pelvic cavity following the inguinal canal.

Neo-Vagina conformation was done using laparoscopic and vaginal running sutures

Results

pN0(sn), R0 resection were achieved with a healthy margin of 25 mm, a 13 mm Breslow index and IIc AJCC stage

Vaginal healing was achieve in one month
Metastatic disease occurs at 7 months without local recurrence.

**Conclusion**

Due to rarity and unpredictable prognosis, VPMM is a challenging issue.

Immediate vaginal reconstruction using VRAM or DIEP flaps have been widely recognized.

DIEP flap and laparoscopic approach in combination allows the same results with mini invasive procedure.

Its impact on positive body image and sexual activity in a life threatening situation has to be further assessed.

EPITHELOID SARCOMA OF VULVA; REPORT OF A RARE CASE

S. Erkılınç¹, M. Gökçü¹, U. Solmaz¹, M. Bağcı¹, O. Temel¹, S. Alanyalı², M. Sancı¹
¹Teecik Education and research Hospital, Gynecologic Oncology, İzmir, Turkey
²University of Ege School of Medicine, Radiation Oncology, İzmir, Turkey

Aims

To report a epitheloid sarcoma of vulva

Method

A patient with epitheloid sarcoma of the vulva, detected in postpartum period and managed surgically was presented

Results

Epitheloid sarcoma is a rare (less than 1% of sarcomas) soft tissue tumor arising from tenosynovial tissue. A 27 year old pregnant women admitted to the hospital at 32 weeks of gestation. The patient had a painless 5 cm in diameter mass at left labium majus. A concomitant cesarean section and vulvar local excision of vulvar mass was performed. The pathologic examination revealed an epitheloid sarcoma of the vulva, lymphovascular space invasion and positive surgical margins. A radical hemivulvectomy and left inguinofemoral lymph node dissection was performed. No residual tumor was reported at final pathology. The patient discharged at fifth day of the surgery and no complication associated with surgery was encountered. A Gray external radiotherapy was administered. No recurrence occurred in 6 month postoperative follow up.

Conclusion

Gynecologists should consider the probability of epitheloid sarcoma of vulva at patients presenting with vulvar mass in younger ages. The disease can be treated with wide local excision of the lesion. The long term follow up will be presented later.
SQUAMOUS CELL CARCINOMA OF THE VULVA: A RETROSPECTIVE TUNISIAN STUDY

S. Gadria¹, M. Slimane¹, L. Charfi², H. Mansouri¹, I. Ben Saffa¹, M. Hechiche¹, F. Benna³, J. Ben Hassouna¹, K. Rahal¹
¹Salah Azaiz Institut, surgical oncology departement, tunis, Tunisia
²Salah Azaiz Institut, Pathology departement, tunis, Tunisia
³Salah Azaiz Institut, radiation therapy and oncology departement, Tunis, Tunisia

Aims

Squamous cell carcinoma of the vulva (SCCV) presents less then 4% of all genital tract malignancies. It affects mostly women in the elderly. Surgery remains the gold standard treatment. Lymph node involvement is the most significant prognostic factor for survival.

Method

We retrospectively studied women with histologically confirmed SCCV, treated in the oncological surgical department of Salah Azaiz Institute of Tunisia, between January 1994 and 2014. We collected 150 SCCV operated at our surgical department. Epidemiological, clinical characteristic and survival were analyzed.

Results

The mean age was 65 years (range 24 – 104 years). The revealing symptom was a genital lump in 70%. The mean diameter of the tumor was 35.7mm (range 10 – 120 mm). Clitoris was involved in 53% of cases. 36% had an ipsilateral inguinal node and 30% bilateral groin nodes. Tumor was classified stage I, II, III and IV in respectively 55%, 7%, 35% and 3% of all cases. Surgery consisted on a radical vulvectomy in 97% of cases. 2 patients had a pelvic exenteration. Lymph node dissection was bilateral in 89%. We omitted the lymph node dissection in a stage I A tumor. Surgery was followed by adjuvant radiation therapy in 30% of cases. 5-years and 10-years survival rate was 50.3% and 31.5% respectively. Disease free survival was 73.7%, 63.8% and 41.5% at respectively 2, 5 and 10 years.

Conclusion

Lymph node involvement is the most significant prognostic factor for SCCV survival. The survival is as good as the diagnosis and the convenient therapy is arranged early.

WHY YOU SHOULD AVOID SUPERFICIAL LYMPH NODE DISSECTION IN SQUAMOUS CELL CARCINOMA OF THE VULVA?
S. Gadria¹, M. Slimane², L. Charfi³, I. Ben Safta¹, H. Mansouri¹, F. Benna³, M. Hechiche¹, J. Ben Hassouna¹, K. Rahal¹
¹Salah Azaiz Institut, Surgical Oncology department, Tunis, Tunisia
²Salah Azaiz Institut, Pathology department, Tunis, Tunisia
³Salah Azaiz Institut, Radiation therapy and oncology departement, Tunis, Tunisia

Aims

In the aim to reduce radicality in the management of squamous cell carcinoma of the vulva (SCCV), DiSaia proposed, in 1979, superficial lymph node dissection (LND). Superficial LND was described as the « sentinel nodes procedure» of the vulva on the basis of the anatomic location of the superficial lymph nodes. In the mid 1980s, this practice became common at the Salah Azaiz Institute of Tunisia.

Method

We identified 63 SCCV with primary treatment consisting of radical vulvectomy and superficial LND

Results

The median tumor size was 29.5mm, attending mostly the Clitoris(54%). 34 women (54%) had palpable groin nodes. 52 women (82.5%) underwent bilateral superficial LND and 10 women (17.5%) underwent unilateral LND. The median number of resected nodes per groin was 7 (range 1 to 18). 4 patients (6.3%) had nodes invasion at final histological exam. Tumors were classified FIGO stage I, II and III in respectively 80%, 14% and 6% (figure). 19 patients (30%) presented postoperative surgical complications (site infection, suture leakage, lymphocele and hematoma). 5-years and 10-years survival rates were respectively 72.7% and 51.2%. Despite negative nodes on superficial LND, 12 patients (20%) had a groin recurrence. The median interval to recurrence was 43 months (range 7 – 132). After groin recurrence, 1-year survival rate was 23.6%.

Conclusion

Accurate identification of node positive patients remains a high priority in the surgical management of patients with vulvar cancer. Superficial LND didn’t show less postoperative complications. Due to the high rate of groin recurrence, this procedure isn’t safe and should be avoided.

AGGRESSIVE ANGIOMYXOMA: EXPERIENCE OF A TUNISIAN ANTI CANCER CENTER

S. Gadria, M. Slimane, S. Kacem, H. Bouaziz, S. sghaier, L. chartfi, M. Hechiche, J. Ben Hassouna, K. Rahal

Salah Azaiz Institute, Surgical Oncology Departement, Tunis, Tunisia

Salah Azaiz Institute, Pathology Department, Tunis, Tunisia

Aims

Aggressive Angiomyxoma (AAM) is a benign mesenchymal neoplasm with a myxoid and vascular components. It is characterized by a soft non-encapsulated mass with finger-like projections, infiltrating the soft tissues, slow growth, frequent recurrences and exceptional metastasis. Since Steepe and Rosai first described this tumor in 1983, only approximately 250 cases have been reported worldwide.

Method

From 1999 to 2017, 5 women with aggressive angiomyxoma were managed in the oncologic surgical department of Salah Azaiz institute, Tunisia.

Results

The average age at diagnosis was 38.2 years. The average size at diagnose was 15.4 cm. In three of five cases histopathology confirmed involved resection margins. None of the five patient received an adjuvant treatment. One patient (case no 1) showed a recurrence 24 months after initial surgery with positive margins. Despite positive margins, two women (case no 3 & 5) didn’t show any recurrence after 12 months follow up.

²Salah Azaiz Institute, Pathology department, Tunis, Tunisia

Aims

Verrucous carcinoma (VC) of the female genital tract is a rare lesion presenting less than 1% of vulvar cancer. It is a variant of squamous cell carcinoma with slow growing, rarely metastasizing to lymph nodes and impressive exophytic appearance. The aim of the study was to assess the clinico-pathological characteristics and analyze the specificity of the treatment of patients with VC of the vulva.

Method

We report 4 cases of VC treated at the surgical department of salah Azaiz Institute, Tunisia.

Results

The mean age was 66 years. All the tumors attended the clitoris with a median size of 22.5mm. All patient had a radical vulvectomy associated to bilateral inguinal lymph node dissection. Two patients (case 1 & 3) had adjuvant radiation therapy for involved histological margins and/or large tumor size. Case 1 presented a vulvar recurrence 12 months after finishing therapy, managed with a second surgery.

RV: radical vulvectomy, BLND: bilateral lymph node dissection, RT: radiation therapy, CR: complete response

Conclusion

Vulvar VC is a distinct type of vulvar carcinoma with unclear etiology. These tumors should be distinguished from giant condyloma acuminatum and well-differentiated squamous cell carcinoma. Surgery remains the most effective treatment.
VAGINAL AND VULVAR CANCER

GROIN RECURRENCE FOLLOWING STAGE IA CARCINOMA OF THE VULVA
S. Gadria1, M. Slimane1, I. Marghil1, H. Bouaziz1, H. Mansouri1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1
1Salah Azaiz Institute, Surgical oncology department, Tunis, Tunisia

Aims

Stage IA carcinoma of the vulva is associated with low risk recurrence and no groin nodes metastasis. Lymph node dissection could be omitted in this stage.

Method

We report the case of a groin recurrence 16 months after treatment for stage IA squamous cell carcinoma of the vulva (SCCV).

Results

A 49 years old woman, was referred for a 10mm left minor labia lump. Punch biopsy confirmed SCCV. The patient underwent radical vulvectomy with bilateral superficial lymph node dissection (LND). Histology confirmed a 12mm stage IA SCCV, without lymphovascular involvement or VIN. LND count 6 negative nodes each side. No adjuvant treatment were assessed. Follow up discovered a left groin recurrence 16 months after surgery. CT scan showed pathologic left iliac node without other recurrence sites. The patient underwent second surgery with inguinal and iliac LND followed by 60 Gy radiation therapy. Second recurrence appeared 3 months later treated with surgery followed by cisplatin chemotherapy. The patient were eligible for palliative care and died from disease 3 months later.

Conclusion

Several reports of groin recurrence after treatment for stage IA SCCV were published. Current management of stage IA tumors may need to be reevaluated.
VAGINAL AND VULVAR CANCER

ESGO7-1372

IMPACT OF HISTOLOGICAL TUMOR-FREE MARGIN (HTFM) AND RE-EXCISION ON SURVIVAL IN PRIMARY VULVAR CANCER WITH ADJACENT VULVAR INTRAEPITHELIAL NEOPLASIA (VIN III)

K. Gasimli1, M. Straussner1, I. Schmeil1, S. Becker1, R. Winkelmann2, K. Thomas1, A. El-Balat1

1University Hospital Frankfurt, Department of Gynecology, Frankfurt, Germany
2University Hospital Frankfurt, Institute of Pathology, Frankfurt, Germany

Aims

HTFM in vulvar cancer is an important prognostic factor. Ideally, a diameter of >8mm should be achieved after primary surgery. The role of VIN III persistence after primary surgery is still unclear. The main objective of the current study was to compare differences in disease free survival among patients with different HTFM and the role VIN III re-excision in primary vulvar cancer.

Method

Forty-one patients with remaining VIN III after primary surgery for vulvar cancer which were operated between 1996 and 2016 in our clinic were enrolled in this retrospective study. Re-excision rates for VIN III were calculated. According to the histological margin patients were divided into three group: <3mm, 3-8mm and >8mm. Univariate and multivariate survival analyses were conducted using the Kaplan-Meier method and Cox proportional hazards models, respectively.

Results

The vast majority of patients had pT1b stage (58.5%), grading G2 (70.7%) and node-negative (78.0%) disease at first diagnosis. The re-excision rate was 56.0% (23 cases). The 5-year disease-free survival (PFS) rates in patients with <3mm, 3-8mm and >8mm HTFM were 50.0%, 60.0% and 82.6%, respectively (p=0.05). The 5-year PFS rates in patients with re-excision and without re-excision for VIN III were 78.3 and 61.1%, respectively (p=0.17). Histological margin >8mm and node-positive disease were the only independent factors for PFS in multivariate analysis (p=0.01 and p=0.02, respectively).

Conclusion

HTFM is a potential prognostic indicator for PFS in vulvar cancer patients. Re-excision for VIN III could not carry any additional benefit on PFS after primary surgery.
VAGINAL AND VULVAR CANCER

ESGO7-1098

PROGNOSIS FACTORS IN PATIENTS WITH LOCALLY ADVANCED VULVAR CANCER TREATED WITH SURGERY WITH OR WITHOUT RADIOTHERAPY

M. Gomes Ferreira¹, P. Soria², J.L. Arranz³, Á. García⁴, S. García⁵, T. Rodriguez Bravo⁶, D. Beltran⁷, Á. Garcia Iglesias⁸

¹University Clinic Hospital of Salamanca, Obstetrics and Gynecology Service, Salamanca, Spain
²University Clinic Hospital of Salamanca, Radiotherapy Department, Salamanca, Spain
³University Clinic Hospital of Salamanca, Plastic Surgery, Salamanca, Spain
⁴University Clinic Hospital of Salamanca, Gynecology Service, Salamanca, Spain
⁵, , Farmacology, Madrid, Spain
⁶University Clinic Hospital of Salamanca, Gynecology Department, Salamanca, Spain
⁷, , Madrid, Spain

Aims

Vulvar cancer is rare, occupying 5% of cancers of the female genital tract. There still have a lot of lacks about the prognosis factors in the treatment of locally advanced vulvar cancer. The aim of the study was to evaluate the main prognostic factors in the effectiveness of combination of surgery and radiotherapy in the treatment of locally advanced vulvar cancer.

Method

Seventy-three cases treated with surgery plus radiotherapy were retrospective analyzed. Descriptive analysis was performed and overall survival (OS) was calculated using the Kaplan-Meier for age, location, the type of growth tumor, size and lymph node affection, in five post-treatment years. Radical vulvectomy guided by TC 99 and blue isosulfan was performed. If inguinal nodes were positive external radiotherapy was applied to the vulvar area.

Results

The most frequent location of the lesions was in the labia majora (43.83%, in the right) followed by the clitoris (28.76%). The third stage was the predominant (89.04%). Undifferentiated carcinoma was the most frequent (79.45%). Endophytic growth tumors recurred more frequently than exophytic growth. Lymph node was positive in 98.3%. Regarding the adverse effects, we find suture dehiscence (13.5%) and radiodermitis (mild in 12% and severe in 7.3%). The 5-years OS rate was 51%.

Conclusion

The tumor recurrence was more frequent two years after the treatment. The worst prognosis factors in locally advanced vulvar cancer treated with surgery plus radiotherapy are the age, clitoris location, endophytic growth tumors and bilateral lymph node affection.
VAGINAL AND VULVAR CANCER

ESGO7-0186

VULVAR ANGIOMYOFIBROBLASTOMA. A RARE CLINICAL AND SURGICAL TUMOR

C. Goudeli, V. Kouvidis, S. Patramani, I. Kokolakis, S. Koutras, E. Ziogos, A. Makrigiannakis

1University Hospital of Heraklion, Obstetrics-Gynecology, Iraklio- Creta, Greece

Aims

Angiomyofibroblastoma (AMF) is a benign tumor of the superficial soft-tissue, deriving from the mesenchymal cells of the subepithelial myxoid stromal area. We herein report a case of a 50-year-old woman surgically treated for a vaginal painless mass.

Method

A 50-year-old postmenopausal woman presented to the gynecology department due to mass-enlargement in the right part of the vulva, mainly occurring when standing. On clinical examination the lesion arise from the middle third to the right posterior vaginal wall. Her laboratory data were normal. Three years ago she was treated for a mass in left labia majora concerning a sebaceous cyst.

Results

The lesion was excised en block. The surgical specimen was firm with no areas of hemorrhage, necrosis or cystic transformation and measured 8X6X2.5cm. Microscopically, the mass had typical findings of AMF, such as hypo and hypercellular areas with thin-walled blood vessels. On immunohistochemistry, stromal cells were positive for desmin, myogenin, smooth muscle actin (SMA), S-100 and estrogen and progesterone receptors. The patient was released the day after with no post-operative problems.

Conclusion

AMF is a rare soft-tissue neoplasm of the vulva, vagina, scrotum, the inguinal area and the spermatic cord in males. It is usually described in women of reproductive age (46 years) as a painless mass causing dyspareunia and pressure. The differential diagnosis includes hernia, leiomyoma, aggressive angiomyxoma, cellular angiofibroma, bartholin gland cyst, lipoma. AMF has low recurrence potential and very rarely it can be transformed into sarcoma. The treatment is total local excision with or without embolization of its main artery.

METASTASIS OF ADENOCARCINOMA OF THE GALL BLADDER TO THE VAGINA: CASE REPORT AND REVIEW OF THE LITERATURE

M. Bouhani1, S. Haddad1, I. Zemni1, N. Boujelbene2, M. Slimene1, H. Bouzaïene1, K. Ben Mrad2, M. Hechiche1,
J. Ben Hassouna1, K. Ben Rahal1
1Salah Azaiez Institute, Surgery, Tunis, Tunisia
2Salah Azaiez Institute, Anatomy and Cytology, Tunis, Tunisia

Aims

Few cases of vaginal metastases originating from gastrointestinal carcinoma are reported in the literature. To our knowledge no cases of vaginal metastasis from gallbladder cancer were described. The aim of this article is to review the available literature to establish the clinical presentation, trends in treatment and prognosis of vaginal metastases from gastrointestinal cancer.

Method

We report a rare case of vaginal metastasis from gallbladder carcinoma with a literature search of vaginal metastasis from colorectal and gastrointestinal carcinoma.

Results

Our patient is a 68 years old woman with no medical history that presented with vaginal bleeding and pelvic pain. The clinical examination showed a solid nodule of the anterior wall of the vagina measuring 25 mm. Incisional biopsy was performed and reported well-differentiated, mucinous adenocarcinoma with a complex gland pattern. Tumor cells are immunoreactive for CK7 and CK20 suggestive of metastasis from a gastric cancer. Computed tomography showed a tumor of the gallbladder with nodules of the liver with no lesion of the gastrointestinal system.

Conclusion

Vaginal metastasis of gastrointestinal cancer should be included in the differential diagnosis of a vaginal swelling. There is no proposed standard treatment for vaginal metastases but surgical resection is an appropriate approach for local control when no disseminated metastatic disease is documented.
VAGINAL AND VULVAR CANCER

ESGO7-0977

VAGINAL SQUAMOUS CELL CARCINOMA WITH ISOLATED OVARIAN INVASION.
H. Henchiri¹, I. Zemni¹, S. Ben Othman¹, M. Hadidane¹, N. Boujelbene¹, H. Bouzaïene¹, T. Dhib¹, K. Mrad², K. Rahal¹
¹Salah Azaïz, Surgical Oncology, Tunis, Tunisia
²Salah Azaïz, Pathology, Tunis, Tunisia

Aims

Primary squamous cell carcinoma (SCCA) of the vagina counts one of the rare carcinoma with 0.35% of all cancers in women and 3.1% of gynecologic malignancies. It should only be diagnosed if other gynecologic malignancies have been excluded (especially the cervix and the vulva carcinoma). The predominant site of failure is loco regional, and the cornerstone of treatment is radiation therapy.

Method

We report a case of a single postmenopausal woman treated for a SCCA of the vagina in Salah Azaiez institute

Results

It was a 58-year-old single postmenopausal female presented with vaginal bleeding. The vaginoscopy showed a friable tumor in the first part of the vagina and the biopsy concluded to a squamous cell carcinoma. A thoracoabdominopelvic computed tomography revealed a left solid cystic ovarian mass with suspicious pelvic bilateral nodes. After radiotherapy, the patient underwent laparotomy with hysterectomy, bilateral salpingo-oophorectomy, colpectomy, partial vaginectomy, bilateral pelvic node dissection. Histology confirmed the invading of the left pelvic node as well as the left ovary by the squamous carcinoma.

Conclusion

The presence of adnexal mass in imaging can lend confusion between metastatic lesion and a synchronous cancer. In fact, it is imperative to distinguish by histology metastases from independently existing primary tumours, as prognosis and treatment differ considerably. Radiotherapy is the cornerstone of treatment. Surgery is indicated in too early stage when the only excision can be enough to eradicate the disease or after radiotherapy with persistent tumor, which is the case of our patient. Chemotherapy is more and more used in advanced stages.
VULVAR PAGET DISEASE: A REPORT OF FIVE CASES

N. Yahia¹, O. Jaidane¹, H. Hantouss¹, N. Tounsi¹, I. Sassi¹, M. Slimene¹, M. Hechiche¹, N. Boujelbene², J. Ben Hassouna¹, K. Rahal¹

¹Salah Azaiz Institute, Surgical Oncology, Tunis, Tunisia
²Salah Azaiz Institute, Anatomopathological Department, Tunis, Tunisia

Aims

Extramammary Paget disease has common manifestations to benign diseases. This leads to delay in diagnosis. The purpose of this work is to describe diagnosis, surgical treatment and outcome of a series of women with Paget's disease of the vulva.

Method

A retrospective review was performed of 5 women with Paget's disease of the vulva evaluated at a single institution: Salah Azaiz Institute, between 1993 and 2015.

Results

The results are shown in the table below.

Conclusion

This work aims to draw attention to the need for biopsy of vulvar lesions that do not respond to usual treatment. Patients should be followed up closely because of the risk of recurrence of the disease. The treatment of choice is wide excision with negative margins, which leads to functional and aesthetic sequelae,. Alternatives to surgery are needed to better care for women with this disease.

RETROSPECTIVE REVIEW OF MULTIPLE CASES OF EPITHELOID SARCOMA OF VULVA AT OUR GYNAECOLOGICAL CANCER CENTRE

M. Hruda¹, H. Robova¹, M. Halaska¹, T. Pichlik¹, L. Rob¹
¹Charles University- Third Faculty of Medicine- University Hospital Kralovske Vin, Obstetrics & gynaecology, Prague, Czech Republic

Aims

To evaluate the incidence, presentation, treatment modalities and survival rate of epithelioid sarcoma of vulva in patients treated at our centre.

Method

We performed a retrospective search for patients with epithelioid sarcoma in our histopathological database.

Results

The most recent incidence of vulvar cancer in Czech Republic is 4.16 with mortality 2.07 per 100,000. In our center we treat about 30-40 cases per year. In the past 10 years 5 patients presented with epithelioid sarcoma, the youngest was 19, the oldest 67 (mean 50.6). One of the patients had primary radical excision with IFL, 3 patients underwent primary excision followed by radical re-excision with IFL. One patient was referred with a relapse of disease after radiotherapy, we performed salvage hemivulvectomy, but due to the extent of disease she died 3 months later. Rest of the patients didn't have any further therapy and currently show no evidence of disease.

Conclusion

Epithelioid sarcoma is a rare malignant mesenchymal tumor. It presents usually with a painless subcutaneous nodule and mass with ulcerative surface. Because of these nonspecific findings it could be mistaken for benign lesions. These misdiagnoses could lead to inadequate management or treatment delay. Postoperative radiotherapy is commonly used in the distal type epithelioid sarcoma, but its role in the vulvar epithelioid sarcoma is controversial and in our case it was not successful in preventing the relapse. From our experience the best results are obtained by primary radical surgery with regional lymphadenectomy.

This work was supported by the Charles University research program PROGRES Q 28 (Oncology).
Aims

Vaginal malignant melanoma is a extremely rare non-cutaneous melanoma, and accounts for less than 5% of vaginal cancers and 0.2% to 0.8% of all malignant melanomas.
I experienced a primary malignant melanoma spreading from proximal to distal vaginal mucosa.

Method

64 years old patient visited office due to vaginal discharge. I saw black discolored mucosal lesions spreading whole vaginal surface from upper vagina to vaginal orifice and 0.5cm diameter nodular mass at the 9 o’clock position of the lower 1/3 of vaginal surface. Vaginal mass’s color was not black, same as normally appearing vaginal surface. Punch biopsy was done on several black colored vaginal surface and vaginal mass.
Pathologic report was atypical melanocytic proliferation consistent with malignant melanoma in situ for black colored vaginal surface and malignant melanoma for vaginal mass.

Results

I did laparoscopic radical hysterectomy with pelvic lymph node dissection. And via vaginal approach I did total vaginectomy with bilateral inguinal lymph node dissection.
A histologic examination revealed a 0.5x0.5cm sized nodular lesion with a depth of invasion of 700um, and a 0.2 x 0.2cm satellite lesion. Vaginal mucosal melanomas in situ were spreading all through vaginal surface. Two pelvic lymph nodes and one inguinal lymph nodes were positive.
The patient underwent adjuvant immunotherapy with a high dose of interferon alpha 2 beta and adjuvant RT.

Conclusion

Primary malignant melanoma of the female genital tract is extremely rare.
The recommended therapy for vaginal malignant melanoma is surgically excision.
Lymphadenectomy is debatable but if positive on imaging method as this case full lymphnode dissection may be needed.
VAGINAL AND VULVAR CANCER

COMPLICATIONS & POST-OPERATIVE MORBIDITY OF GROIN LYMPHADENECTOMY FOR THE STAGING OF VULVAL CANCER

R. Jones¹, J. Davies-Oliveira², F. Drews¹, E. Rzyska², R. Howells¹, K. Lim¹, A. Sharma¹

¹University hospital of Wales, Gynaecological Oncology, Cardiff, United Kingdom
²University hospital of Wales, Obstetrics & Gynaecology, Cardiff, United Kingdom

Aims

Inguinal Lymphadenectomy is a routine part of full surgical staging in cases of vulval carcinoma. Wound complications following this procedure have been quoted as high as 60%. In our centre 2 surgeons were using the modified triple incision approach & 2 were using a modified oblique incision for inguinal lymphadenectomy at the time of our study.

Our aim was to compare the modified triple incision approach versus a modified oblique incision for inguinal lymphadenectomy, looking specifically at the wound complications associated with these procedures. Method

We conducted a retrospective cohort study looking at vulval cancer patients who underwent unilateral or bilateral inguinal lymphadenectomy between 01/01/2014-31/12/2016 at University Hospital Wales, Cardiff, Wales.

Results

A total of 23 patients were identified. One or more complications occurred in 22 (95.6%). The complication rate was 17 (100%) in the modified triple incision group (seroma 9 (53%), infection 9 (53%), wound breakdown 10 (59%), lymphoedema 7 (41%), paraesthesia 4 (24%), lymphocyst 6 (35%), return to theatre 2 (18%)) versus 5 (83%) in the modified oblique incision (seroma 3 (50%), infection 2 (25%), wound breakdown 1 (17%), lymphoedema 2 (25%), paraesthesia 0 (0%), lymphocyst 3 (50%), return to theatre 0 (0%). Median modified triple incision hospital stay length 11 days versus the median modified oblique incision hospital stay 4.5 days.

Conclusion

Wound complication rates after inguinal lymphadenectomy in vulval cancer patients are high. This study suggests that an oblique incision may reduce hospital stay and overall wound complication rates. Larger numbers are required to confirm this finding.

VAGINAL AND VULVAR CANCER

ESGO7-1179

CARCINOMA OF VULVA IN A VERY YOUNG WOMAN

F. Demirkiran¹, H. Turan¹, I. Kahramanoğlu¹, T. Bese¹, M. Arvas¹
¹Istanbul University Cerrahpasa School of Medicine, Obstetrics and Gynecology, ISTANBUL, Turkey

Aims

Invasive squamous cell carcinoma (ISCC) of vulva rarely seen in women younger than age 35 years. Vulvar ISCC can be divided into two variants. One variant is the more common HPV-unrelated lesion, occurs in older women. The other variant is associated with human papillomavirus that occurs in younger women (35-65 years old). Less than 10 cases with ISCC of vulva at 18 years or younger were reported.

Method

A 18-year-old patient presented with pruritic lesion on vulva (Figure 1). There was no history of systemic disease, or tobacco-alcohol-drug use. She has been sexually active for one year. Gynecologic examination revealed an erosive lesion on clitoris. Excision biopsy was performed and keratinizing type, ISCC of vulva was diagnosed. Cervical Pap smear and HPV test resulted as negative for both. The patient underwent wide local excision and bilateral inguinofemoral lymphadenectomy (Figure 2) and staged as stage IA ISCC.
Results

Follow-up at 8 months after the surgery showed no evidence of recurrence (Figure 3).

Conclusion

Increase of incidence of ISCC of vulva in younger patients has been observed. HPV and immunosupression are implicated as main predisposing factors. Herein, we presented a very young women with vulvar cancer without any predisposing factor.
ELEVEN CASES OF MUCOSAL MALIGNANT MELANOMA OF THE GENITAL TRACT IN A SINGLE INSTITUTION DURING A 15-YEAR PERIOD

M. Kitai¹, K. Suzuki¹, A. Kogiku¹, K. Yamamoto¹, T. Sennda¹, T. Shiozaki¹, K. Matsuoka¹, T. Sudo¹, S. Nagao¹, S. Yamaguchi¹
¹Hyogo Cancer Center, Gynecology, Akashi, Japan

Aims

Mucosal melanoma is rare, and its prognosis is worse than that of melanoma arising from the skin. We herein report 11 cases of mucosal malignant melanoma of the genital tract and discuss their treatment and prognostic outcomes.

Method

A prospectively maintained database of mucosal melanoma of the vagina, vulva, and uterine cervix was analyzed. Data were collected regarding age, stage, operative outcome, progression-free survival, and overall survival.

Results

We treated 11 cases of mucosal melanoma from 2001 to 2017. The median patient age was 62 years (range, 32–80 years). Seven patients underwent a radical operation that achieved negative margins. Two patients underwent palliative operations, one patient underwent radiotherapy, and another underwent immunotherapy. Regardless of the performance of an aggressive operation, eight patients developed relapse of disease. The median progression-free survival period was 10 months (range, 1–107 months), and the median overall survival period was 39 months (range, 1–122 months).

Conclusion

Mucosal melanoma has a demonstrably worse prognosis than cutaneous melanoma. Aggressive treatment or immunotherapy may permit long-term survival of patients with mucosal melanoma.
VAGINAL AND VULVAR CANCER

VULVAR CANCER: RETROSPECTIVE ANALYSIS OF 40 CASES AT HOSPITAL SANTA MARCELINA –SAO PAULO – BRAZIL.
M. Komatsu¹, T. Almeida², M. Brandão², V. Santos², A. Sousa², C. Gomez², V. Galleto², L. Mauri²
¹Hospital Santa Marcelina, Gynaecology, Sao Paulo, Brazil
²Hospital Santa Marcelina, Gynaecology, Sao Paulo, Brazil

Aims

Analyse 40 cases of vulvar cancer, diagnosed and treated at gynecology oncology department of Santa Marcelina Hospital. The variables analyzed were: age, parity, smoking, histological type, staging, treatment and lymph nodal status.

Method

Retrospective analysis of 40 cases of vulvar cancer at period between January 2008 to March 2016.

Results

The median age of patients was 67 years, at the total 40 cases, 37 was diagnosed with spinocellular carcinoma (92.50%) the multiparous (26) represented 65%, the smokers 30.77%. The final staging was: I (15%), II (30%), III (32.50%), IV (15%), Unknown (7.50%). Thirty four patients received surgical treatment (54.28%), fifteen (37.50%) received neoadjuvant radiotherapy and/or chemotherapy. Positive lymph nodes was detected in 11 (42.30%) of 26 cases. Fourteen patients presented relapse (35%) and 19 (47.50%) died.

Conclusion

The vulvar cancer representing 5% of malignant neoplasia of female genitalia. Assaults, mainly, patients from sixth decade, there are predominance of spinocellular carcinoma as histological type. The multiparous is a frequent feature and the association with smoking was 27.50% at present casuistry. The high percentage of neoadjuvant chemotherapy in 37.5% of cases as initial treatment was performed to allow surgical approach. The high mortality at present data (47.50%) should mainly the late diagnosis, stage II and III in accordance with literature.
Aims

The application of the concept of tumour-specific markers to assess a possible disease outcome and to choose appropriate treatment options is obstructed by the limited knowledge on vulvar carcinoma (VC) biology. We aimed to identify protein markers of VC that would be indicative of a tumour that is more likely to progress.

Method

Primary tumour samples from 28 patients with early stage squamous cell VC and 14 samples of normal vulvar tissue were studied using iTRAQ analysis. The results obtained for tumour samples of VC patients that progressed during 8-12 years of follow-up period ("progVC", n=14) were be compared to those obtained for samples of patients who were disease-free at the time of last observation ("d-fVC", n=14). The differentially expressed proteins were subsequently validated using targeted proteomics methods (PRM) and immunohistochemistry using a larger sample set.

Results

5510 proteins were identified in the analysed samples. Of the proteins differentially expressed in "progVC" and "d-fVC" tumours, top 30 candidate markers were chosen for further validation. Correlation of the validation results with clinical parameters of the enrolled VSCC patients indicated that HMGA2, S100A12, FBLN5, MX1, STAT1, WARS, PRTN3 and PRELP should be considered as potential protein markers for the prediction of progression in VC patients.

Conclusion

Our findings provide evidence showing that deregulation of eight proteins' abundance is significantly associated with aggressive phenotype of VC. Their immunohistochemical assessment hold promise as a patient stratification tool.

EVALUATION OF RISK FACTORS FOR WOUND BREAKDOWN AFTER INGUINAL LYMPH NODE DISSECTION IN VULVAR CANCER

M. Kranawetter¹, C. Grimm¹, R. Schwameis², S. Polterauer¹, A. Reinthaller¹
¹Medical University of Vienna, Gynecology and Obstetrics, Vienna, Austria
²Medical University of Vienna, Gynecology and Obstetrics, Vienna, Austria

Aims

The aim of this study was to evaluate risk factors for wound complications after inguinal lymph node dissection in patients with vulvar cancer.

Method

We retrospectively identified all patients with Vulvar Cancer treated at the Medical University of Vienna between 1995 and 2015. Clinical data including age, type of operation, number of resected lymphnodes and lymphnodestatus, drainage, use of antibiotics, body mass index (BMI), co morbidities and postoperative morbidities e.g. cellulitis, wound breakdown, lymphcyst formation and lymphedema were obtained by chart review. Statistical calculations were performed using chi-square test and logistic regression analysis.

Results

147 patients and a total number of 254 groin operations were enrolled in this study. 107 patients had bilateral, 40 patients unilateral groin node dissection. The mean age was 69.5 (SD 13.0). 156 (61.4%) cases were performed as complete inguinal lymphadenectomy, 98 (38.6%) cases as sentinel node biopsies. The mean BMI was 27.6 (SD 5.8). 22 patients (8.7%) developed wound breakdown and 53 patients (20.1%) lymph cysts. Univariat analysis showed BMI >30 (p=0.004) and more than five resected lymph nodes (p=0.04) significantly correlated with wound breakdown. In multivariate analysis BMI >30 (OR 5.0 [1.6-16.0], p=0.006), diabetes (OR 3.7 [1.4-10.1], p= 0.01) and more than five resected lymph nodes (OR 4.1 [1.5-11.1], p=0.005) were shown as independent risk factors for postoperative wound breakdown.

Conclusion

Wound breakdown is a frequently seen complication after inguinal lymph node dissection. Obesity, diabetes and an extended number of removed lymph nodes were shown to be independent risk factors for developing wound complications.
DOES HUMAN PAPILLOMAVIRUS INFLUENCE CLINICAL PROGNOSIS IN VULVAR CANCER?

J.P. Lopes¹, V. Veiga², M. Bernardino¹, D. Cochicho², L. Martins², M. Cunha², A.F. Jorge¹

¹Instituto Português Oncologia - Lisboa, Serviço de Ginecologia, Lisboa, Portugal
²Instituto Português Oncologia - Lisboa, Serviço de Virologia, Lisboa, Portugal

Aims

It has been demonstrated that human papillomavirus (HPV) is one of the causes of vulvar invasive squamous cell carcinoma (VSCC), being identified in about 30-50% of those cases. However, evidence is lacking on the influence of HPV-status on the prognosis of this malignancy.

This study aims to determine the influence of HPV-status on the prognosis of patients diagnosed with vulvar SSC.

Method

We analyzed, retrospectively, the clinical files of every patient diagnosed with primary vulvar SCC submitted to surgery at our institution, from 2008 to 2014, that had a HPV genotype analysis in the surgical sample.

We evaluated and compared both groups (HPV-positive vs HPV-negative) in a three year follow-up for the following data: demographic and clinical data, first-line therapy and its clinical response, recurrence rate, disease-free interval, overall and cancer related mortality rates.

Student t test and chi-square were used for statistical analysis of the continuous and categorical variables, respectively.

Results

62 patients were included, 21 (34%) were HPV-positive and 41 (66%) HPV-negative. There were no statistically significant differences between the two groups in demographic and clinical variables. Response to first-line therapy (95% vs 96%), recurrence rate (32% vs 38%), disease-free interval (25 vs 22 months), overall (43% vs 41%) and cancer related mortality (28% vs 29%) were also similar in both HPV-positive and HPV-negative patients, respectively.

Conclusion

The prevalence of HPV in VSCC patients was similar to that described in published literature.

In our study, at a three year follow-up, the HPV status did not influenced the prognosis of disease in patients who underwent surgery.
THE PRIMARY MELANOMA OF THE VULVA: REPORT OF THREE CASES AND REVIEW OF LITERATURE

M. Bouhani, I. Zemni, S. Haddad, N. Boujelbene, S. Sakhriri, M. Slimane, A. Bouida, M. Hechiche, J. Ben Hassouna, K. Rahal

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Optimal treatments for vulvar melanomas (VM) have not been identified. VM has a poor prognosis due to late diagnosis and early dissemination. Only a limited amount of literature exists on the condition. This study elucidates the effect of current treatment.

Method

All patients diagnosed with malignant melanoma in the vulva at Salah Azaiez institute, Tunis, Tunisia, in the period from 2011 to 2017, from retrospective chart review and histologic analysis.

Results

A total of 5 patients were included. The average age at the time of diagnosis was 70 years and the median overall survival time was 12 months. The five-year survival in this study was 20%. The majority of the melanomas were nodular and four of the superficially spreading melanomas were found in the vulva only, one patient had extension on vagina. All patients underwent radical vulvectomy with bilateral inguinofemoral lymphadenectomy. Histological examinations showed free margins in all the patients.

Conclusion

Early diagnosis and staging of this cancer is important. Older women with vaginal discharge should always have a gynaecological examination. Tomography should be the standard method for staging the disease. The primary treatment is resection of the tumour, but future treatment might be a combination of resection and immunotherapy.
LEIOMYOSARCOMA OF THE VAGINA, RARE DIAGNOSIS: TWO CASES REPORT

B. Malek1, I. Zemni2, S. Haddad2, N. Boujelbene3, S. Sakhr1, M. Hechiche2, J. Ben Hassouna2, K. Rahal2

1Institut Salah Azeiz of Oncology, Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
3Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Primary leiomyosarcoma of the vagina is an exceedingly rare diagnosis. Current estimates are that this tumor could at most represent a mere 0.062% of malignant neoplasms in the female genital tract, although in actuality it is likely far less common. The aim of this study evaluate the clinical characteristics of primary vaginal leiomyosarcoma

Method

We retrospectively reviewed the clinical records of two patients with primary vaginal leiomyosarcoma treated at Salah Azaiez institute, Tunis, Tunisia, in the period from 1998 to 2003

Results

Case 1:
A 62-year-old female gravida 10 para 7 with new onset palpable vaginal mass and pink vaginal discharge is diagnosed with primary leiomyosarcoma of the vagina. She underwent a total hysterectomy with bilateral salpingo-oophorectomy and partial vaginectomy, with free margin in histological examination. She didn't receive postoperative radiation neither chemotherapy. She has been lost from sight for three years. She succumbed to her illness after, due to pulmonary metastasis of her leiomyosarcoma. Case 2:
Case Presentation. A 43-year-old female with new onset palpable vaginal mass and pink vaginal discharge is diagnosed with primary leiomyosarcoma of the vagina. She underwent local excision with free margin. She received postoperative radiation plus brachytherapy. The patient remains without recurrence nine years after surgery.

Conclusion

Vaginal leiomyosarcoma is exceedingly rare with an aggressive course, high recurrence, and undetermined ideal treatment regimen. Information on this rare tumor type is predominantly through rare case reports with collective consensus on management lacking. The gynecologic oncologist must exercise prudence in individualizing treatment regimens for this rare yet aggressive malignancy.
Primary clear cell adenocarcinomas most commonly involve the genitourinary system, including the vagina. Previously, primary clear cell adenocarcinomas of the vagina have been discussed within the context of prenatal exposure to diethylstilbestrol.

Method

We present one case of non-diethylstilbestrol-associated primary clear cell adenocarcinoma of the vagina treated at Salah Azaiez institute, Tunis, Tunisia in 2002.

Results

A 82-year-old gravida 7 para 7 single with no history of illness or prenatal DES exposure presented to the gynecology clinic with abnormal vaginal bleeding for one month duration and and weight loss. Although the patient’s mother was born in 1900 which was during the DES era, she had all previous normal and spontaneous term deliveries with no history of miscarriages. The physical exam revealed a mobile mass that measured 4 cm located in the medium anterior vaginal wall, without any lesion in the cervix. Histological exam showed a clear cell carcinoma. Chemotherapy treatment was proposed, but the patient died of pulmonary embolism.

Conclusion

Our case suggest that primary clear cell adenocarcinoma of the vagina may be unrelated to diethylstilbestrol exposure and that non-diethylstilbestrol-associated primary clear cell adenocarcinoma of the vagina.
Aims

The aim of the study is to investigate the clinical features, treatments, and prognosis of embryonal rhabdomyosarcoma of the vagina in childhood.

Method

We retrospectively reported a case of embryonal rhabdomyosarcoma of the vagina in a three years-old child treated at Salah Azaiez institute, Tunis, Tunisia, in 2015.

Results

This study has reported a 3-year-old child presented with abnormal vaginal discharge. Gynecologic examination revealed a vaginal mass in the left inferior wall of the vagina. Biopsy has performed and pathologic examination was consistent with embryonal botryoid type rhabdomyosarcoma. She has undergone the staging work up measurements including body computed tomography (CT) scan, abdominopelvic magnetic resonance imaging (MRI). Abdominopelvic MRI, showed a polypoid mass in the left inferior wall of vagina measuring 3 cm. As no metastases were detected, the girl received neoadjuvant chemotherapy, local excision with free margin. She had an ovarian transposition and adjuvant radiotherapy. The patient remains without recurrence two years after surgery.

Conclusion

This case has reminded that embryonal rhabdomyosarcoma could occur in uncommon site. Longer follow up of these cases has required due to lack of survival data for embryonal rhabdomyosarcoma of this site. The combination of surgery, chemotherapy and radiotherapy can lead to better outcomes.

GLASSY CELL CARCINOMA ARISING IN THE VAGINA
M. Bouhani1, I. Zemen1, S. Sakhri1, N. Boujellbene2, M. Hechiche1, J. Ben Hassouna1, K. Rahal1
1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Glassy cell carcinoma is a rare neoplasm that occurs most frequently in the uterine cervix. We describe a case of glassy cell carcinoma (GCC) arising in the vagina. The aim of this study is to investigate the clinical features, treatments, and prognosis of GCC of the vagina.

Method

We retrospectively reported a case of GCC of the vagina in a 24 years-old woman treated at Salah Azaiez institute, Tunis, Tunisia, in 2015.

Results

A 24-year-old Tunisian woman was admitted to our hospital for atypical genital bleeding. Gynecological examination revealed a macroscopic circumferential vaginal mass of the whole vaginal wall. The cervix was normal. The pathological diagnosis of the biopsied specimen was glassy cell carcinoma. she underwent a laparoscopic lombo-aortic node dissection, for tumour staging, with ovarian transposition. She was treated by conventional radiation therapy and chemotherapy under the diagnosis of stage I vaginal cancer (International Federation of Gynecologists and Obstetricians classification, 1986). The patient is alive, with recurrence, after three months following the radiation therapy. She underwent actually palliative chemotherapy. Glassy cell carcinoma is classified as the most poorly differentiated form of adenosquamous carcinoma. The present case illustrates the potential for glassy cell carcinoma to arise in the Mullerian epithelium throughout the female genital tract.

Conclusion

Glassy cell carcinoma is classified as the most poorly differentiated form of adenosquamous carcinoma. The present case illustrates the potential for glassy cell carcinoma to arise in the Mullerian epithelium throughout the female genital tract.
A TUMOR OF THE VAGINA NOT TO OVERLOOK, THE MESONEPHRIC ADENOCARCINOMA: ABOUT A CASE REPORT

M. Bouhani1, I. Zemni1, S. Sakhri1, N. Boujelbene2, M. Slimene1, S. Haddad1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Mesonephric adenocarcinoma of the vagina is exceedingly rare. Differential diagnosis from other aggressive tumors is complex and controversies exist in the literature regarding the biological behavior, prognosis, and optimal management strategies of these tumors.

Method

A retrospective case of mesonephrotic at Salah Azaiez institute, Tunis, Tunisia, in 2006.

Results

A 38-year-old woman presented with an ulcerated bulging mass at the antero-lateral of the vagina wall, extending to the left parameter tissue. The tumor was an adenocarcinoma with ductal and tubular pattern arising in a background of mesonephric remnants. The patient underwent neoadjuvant chemotherapy and radiotherapy and she was lost of sight for three years. The CT body scan showed a pulmonary metastasis. she underwent a palliative chemotherapy and died after eight years after the diagnosis of her vaginal pathology.

Conclusion

In spite of the aggressive biological behavior attributed in literature to mesonephric carcinomas, which is probably due to the complex differential diagnosis with other müllerian tumors, the favorable course of our patient further supports the hypothesis that malignant mesonephric carcinomas may not behave aggressively and that radical surgery alone may be curative.
VAGINAL AND VULVAR CANCER

ESGO7-1143

PRIMARY SMALL CELL NEUROENDOCRINE CARCINOMA OF VAGINA: A RARE CASE REPORT

M. Bouhani1, I. Zemni1, S. Haddad2, N. Boujelbene2, M. Slimene1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1
1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Primary small cell neuroendocrine carcinoma of vagina is an extremely rare disease. There have been less than 30 previously reported cases in literature. The aim of this case report is to investigate this tumor clinically and pathologically.

Method

We report a case of woman with the diagnosis of primary small cell neuroendocrine carcinoma of vagina, diagnosed and treated at Salah Azaiez institute.

Results

A 37-year-old female presented with complaint of irregular bleeding per vaginum of six months duration. On per speculum examination, an irregular annular growth was noted in the vagina at the level of the lower one-third. This mass was considered as a vaginal cyst. She underwent a local excision. The histological exam showed a small cell neuroendocrine carcinoma of vagina. She underwent chemotherapy and brachytherapy. Eighteen years after, she developed a pulmonary metastasis. The pulmonary lumpectomy with histological exam showed a metastazing lesion of here neuroendocrine carcinoma of vagina. The patient was lost of sight.

Conclusion

Primary small cell neuroendocrine carcinoma of the vagina has histologic, immunohistochemical, and ultrastructural features similar to those of its pulmonary counterpart. The current therapies have usually resulted in poor outcomes, and new therapeutic modalities should be explored.
VAGINAL AND VULVAR CANCER

ESGO7-1149

PERINEAL RECONSTRUCTION USING V-Y ROTATION ADVANCEMENT FLAP FOR TOTAL VULVECTOMY DEFECT OF VULVAR PAGET DISEASE

M. Bouhani1, M. Slimene1, S. Haddad1, N. Boujelbene2, H. Bouzaiene1, R. Ben Nacer1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Extramammary Paget disease (EMPD) is an uncommon malignant neoplasm that occurs in areas containing apocrine glands, and the vulva is the most commonly involved site. The treatment of Paget of vulva is mutilating. Reconstruction of total vulvectomy defect represents a challenge, and reconstructive methods include skin graft, local skin flap, musculocutaneous flap, and pedicled perforator flap.

Method

A 65-year-old woman had EMPD at the vulva in 1999. The patient was treated by minimal excision with a 2-mm safety margin and without adjuvant therapy. Seventeen years after the patient presented a large recurrence of her tumour in the vulva, anus, internal side of the left thigh. she underwent a large excision with iliac colostomy. The frozen section showed a free margin. We performed reconstruction with bilateral profunda artery perforator based V-Y rotation advancement flap. The final histological exam showed a positive margin. The patient is undergoing adjuvant treatment with the immunomodulator imiquimod.

Results

The flap survived completely without major post-operative complications with 6-months follow-up.

Conclusion

EMPD is a rare genital neoplasia where surgical excision is recommended. Profunda artery perforator based V-Y rotation advancement flap may represent a valuable option in total vulvectomy defect reconstruction. Specifically, adjuvant imiquimod is a feasible and efficacious treatment option for women with involved resection margins after surgery.

BARTHOLIN GLAND CANCER – MULTIDISCIPLINAR APPROACH
A. Mandic1, Z. Radovanovic2, N. Prvulovic-Bunovic1, B. Gutić1, B. Stojilkovic5, D. Radovanovic6
1Oncology institute of Vojvodina, Gynecological oncology, Sremska Kamenica, Serbia
2Oncology Institute of Vojvodina, Clinic for oncological surgery, Sremska Kamenica, Serbia
3Oncology institute of Vojvodina, Center for imaging, Sremska Kamenica, Serbia
4Oncology institute of Vojvodina, Gynecol oncology dept., Sremska Kamenica, Serbia
5Oncology institute of Vojvodina, Dept.for pathology and cytodiagnostic, Sremska Kamenica, Serbia
6Oncology institute of Vojvodina, Dept. of aneytegiology and intensive care, Sremska Kamenica, Serbia

Aims

Bartholin gland cancer is extremely rare type of cancer. It is only 0.001% of all gynecologic malignancies. The mean age of diagnoses is 50-60 years.

Method

We reported one case of advanced Bartholin gland carcinoma. The 62 year patient complained about a vulvar ulcer.

Results

Histopathologic (HP) finding was: squamocellular vulvar cancer. Anterior rectal wall, pelvic floor muscles and anal sphincter infiltration, positive right inguinal and left pelvic lymph nodes found by MR. She received neoadjuvant chemotherapy (NACT): Cisplatin 90 mg D1, 5-Fluorouracil D1-4 a 1500 mg, with poor response. Considering locally advanced cancer the optimal surgical approach was abdomino-perineal excision in prone position (extralevator APR). Radical vulvectomy with bilateral inguinoferoral lymphadenectomy, pelvic debulky lymphadenectomy hysterectomy and bilateral adnexectomy with resectio of rectum sec Miles in prone position was performed. Final HP was: Locally advanced Bartholin gland adenocarcinoma with positive bilateral inguinal and pelvic lymph nodes. While waiting for the adjuvant radiation, three more cycles of chemotherapy were administrated. Available protocol was: Cisplatin a 90 mg, Doxorubicin a 100 mg D1. At this point radiation therapy is in progress.

Conclusion

Three months after adjuvant chemotherapy patient is in good condition, ECOG 0, with no residual disease. The problem with patients having Bartholin gland carcinoma is that, due to low incidence, there is no consensus of treatment.
VAGINAL AND VULVAR CANCER

ESGO7-0913

EPITHELIOID SARCOMA OF THE VULVA: A CASE REPORT
E.M. Martı, S.O. Tutar, İ.E. Ertaş, M. Sancı
1 Tepecik Eğitim ve Araştırma Hastanesi, Gynecology and obstetrics, izmir, Turkey

Aims

Sarcomas of the vulva account for less than 2% of vulva malignancies with aggressive behavior and poor outcome. The predominant site of involvement is the labia majora followed by the Bartholin gland area, clitoris, and labium minus. Here in, we report a case of vulvar epithelioid sarcoma presenting in a 28-year-old in her 30 weeks pregnancy.

Method

A case report

Results

A 28-year-old white female presented to Tepecik Research and Training Hospital, Izmir, with an asymptomatic nodule involving the right vulva of 9 months duration. The patient noted an increase in the nodule size over the last two months

Conclusion

Epithelioid sarcoma is a rare soft tissue malignancy, which occurs in younger adults (mean age 26 years) with a male predilection and generally involves the distal and proximal extremities. ES involving the vulva is exceptionally rare; only 20 cases are reported in the literature and a mere 8 out of these 20 cases have supportive IHC studies. The patients ranged in age from 23 to 57 years. The clinical impression varied, with Bartholin cyst being the most common impression, followed by fibroma, dermoid cysts, viral warts, and squamous cell carcinoma. The lesions generally presented as nodular masses ranging in size from 1.5 to 6 cm. ES is considered to be of unknown line age and is often misdiagnosed as a benign lesion, especially as a benign granulomatous process.

5Ntra. Sra. del Rosario Hospital-Doce de Octubre University Hospital, General and Colorectal Surgery, Madrid, Spain
6Advance Techniques Cancer Center, Radiation Oncology, Madrid, Spain

Aims

Describe the surgical technique of transposition flaps, among the different types of flaps in vulvar reconstruction

Method

Retrospective study of 23 cases of vulvar cancer diagnosed between April 2008 and July 2016. We present the surgical technique: transposition flaps with surgical images and diagrams that make understandable the design and the displacement of the flap

Results

Limberg flap is very useful by allowing transpose woven from 4 different adjacent zones. It is designed with a geometric basis and are transposing the estetic-functional or loose skin that we choose the possible 4. The design consists of drawing a diamond containing tumor with angles of 60° and 120°. From one of the two angles of 120 degrees is projected an incision of length same to the distance between those angles of 120° and, from here, we can orient to one or other side according to the anatomical area and the distensibility of the skin, through another incision parallel and equal in length to the side of the rhombus. We present an example to cover the area dehiscent l after radical vulvectomy and inguinal bilateral lymphadenectomy in patient with vulvar cancer stage pTII pN0 M0 (0/19).

Dufourmentel flap is used for rhomboid defects, is but its angles are 60 degrees, but oscillating between 60°-90°. We present images of inguinal node metastases lymphadenectomy treated for squamous cell vulvar cancer, stage IIIA1 (pN0/9)

Conclusion

Transposition flaps allow excellent coverage in recurrences with big defects of vulvar cancer, with an optimal morpho-functional reconstruction

VULVAR CARCINOMA IN NORWAY: A 50-YEAR PERSPECTIVE ON TRENDS IN INCIDENCE, TREATMENT AND SURVIVAL

C.J. Meltzer-Gunnes1, M.C. Småstuen2, G.B. Kristensen3, C.G. Tropé3, A.K. Lie4, I. Vistad1
1Sørlandet sykehus, Obstetrics and Gynaecology, Kristiansand, Norway
2Oslo and Akershus University College of Applied Sciences, Department of Nursing and Health Promotion, Oslo, Norway
3The Norwegian Radium Hospital- Oslo University Hospital, Department of Gynaecological Oncology, Oslo, Norway
4Østfold Hospital HF, Center for Laboratory Medicine, Gralum, Norway

Aims

To explore trends in vulvar squamous cell carcinoma (SCC) incidence, age and stage at diagnosis, treatment and survival in Norway from 1961 to 2010.

Method

From 1961 to 2010, 2233 cases of vulvar SCC were extracted from the Cancer Registry of Norway. Data on age at diagnosis, tumor morphology, stage of the disease and treatment were analyzed. Age-standardized incidence rates, adjusted to the Norwegian standard population, were computed. Relative survival was calculated as a ratio of the observed survival in the study population over the expected survival in the background population. Multivariate Cox model was fitted to estimate hazard ratios.

Results

The overall incidence of vulvar SCC increased more than 2.5 fold (from 1.70 to 4.66 per 100,000 women/year; P<0.01) (Figure 1). Age-specific incidence rates increased among women aged ≤ 60 years (by 150% in age group 0-39 years, 175% in age group 40-49 years and 68% in age group 50-59 years). From 1971-2010, the percentage of patients receiving surgery as only treatment decreased from 81% to 61%, whereas the use of radiation and combination therapy (surgery and radiation) increased from 3% to 11% and 6% to 20%, respectively. 5-year relative survival increased significantly among women ≤ 80 years (from 72% to 83% among women aged ≤60 years and from 60% to 65% among women aged 61-80 years).

Conclusion

The incidence of vulvar SCC has increased since the sixties, particularly among women younger than 60 years. Despite less radical treatment, survival has improved.
SENTINEL LYMPH NODE BIOPSY IN VULVAR CANCER. EXPERIENCE OF A SINGLE CENTER
M. Eduard1, R.T. Adriano1, A. Núria1, F. Pere1, D.P. Marta1, G.I. Blanca1, M. Meritxell1, N. Inmaculada1, G. Ariel1, T. Aurell1
1ICGON - Hospital Clínic de Barcelona, Oncologic gynecology, Barcelona, Spain

Aims

Lymph node status represents the main prognosis factor in patients with vulvar cancer. Sentinel lymph node biopsy (SLNB) is a useful tool to assess the nodal status with a low morbidity. We describe our experience with SLNB.

Method

We included 80 patients with primary tumors ≤ 5cm without suspected inguinofemoral nodal metastases admitted to our hospital from June 1998 until July 2016 who underwent SLNB. Peritumoral injection with technetium-99 radiocolloid and methylene blue was conducted. Complete inguinofemoral lymphadenectomy was performed only in cases with intraoperative nodal metastases assessed by frozen section or in cases of non-detected sentinel lymph node. In midline tumors with unilateral drainage, lymphadenectomy of the opposite side was carried out. Nodes were postoperatively examined by histological procedure. Ultrastaging with 4µm-thick sections stained with H&E or immunohistochemically examined with antibody against cytokeratins was conducted on negative nodes.

Results

The median age was 73.1 years (range 32.1 – 95.3). Tumors had a median diameter of 1.9 cm (range 0.1 – 5) with infiltration of 4 mm (range 0.5 – 22). Forty-five (56.2%) were midline tumors. The most frequent histology was squamous cell carcinoma (64; 80%) followed by malignant melanoma (13; 16.3%). In midline tumors, bilateral detection was achieved in 26 cases (57.8%). The median nodes removed per patient was 2 (range 1 – 9). In 16 (20%) patients SLNB was intraoperatively positive and confirmed by final routine histological examination. Six (28%) positive nodes were detected by ultrastaging.

Conclusion

SLNB is a feasible procedure that should include ultrastaging in order to increase the accuracy.

IMPROVING THE ONCOLOGIC OUTCOMES. ONCOPLASTIC TECHNIQUES IN THE TREATMENT OF VULVAR CANCER.
J. Molero Vílchez1,2, E. Martínez Lamela1,2, J. Montáns Araujo1, S. Peco Adrover5, Y. Expósito Lucena6, S. Sancho Garcia7
1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, Madrid, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Pathologic Center, Pathology, Madrid, Spain
5Ntra. Sra. del Rosario, Gynecology Oncology, Madrid, Spain
6Toco-Gyn Gynecological Center, Obstetrics and Gynecology, Alcalá de Henares, Spain
7Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain

Aims

To study of outcomes and complications of the oncoplastic techniques in reconstructive surgery for vulvar cancer.

Method

Retrospective study of 23 cases of vulvar cancer. 15 cases were treated through radical vulvectomy (8), hemivulvectomy (5) and expanded lumpectomy (2). Arise with images and diagrams the technical realization of flaps fasciocutaneos, local or neighborhood, with vascular pattern axial and randomized, described according to the type of mobilization performed. Surgical variables, complications and disease-free survival (DFS) and overall survival (OS) were assessed using Kaplan-Meier survival curves and a multivariate analysis.

Results

Oncoplastic techniques for reconstruction were performed in 13 cases (86.6%). The mean age was 76.9 years, 87% of the tumors was squamous cell type and the most frequent stage was IIIA1 (26.1%), followed by stages IB and II (21.7%). The most commonly used flaps were transposition flap of interpolation, straight inner flap, flap of Martius and flaps of progress (V-Y, Z). Bilateral inguinal lymphadenectomy was performed in 9 cases and homolateral in 3 cases, with a mean removed lymph nodes of 12.8. Mean operative time was 219.6 minutes and mean blood loss was 1012 ml. There were no major complications: 3 patients had dehiscence, 1 case presented necrotizing fasciitis and another case of flap necrosis. 6 patients required re-intervention (26.1%). OS was 35.7% and DFS was 22.1% at 3 years.

Conclusion

Fasciocutaneos flaps allow a proper morpho-functional reconstruction and good local sensitivity. A protocol of perioperative management is essential to reduce the rate of complications.

ADENOID CYSTIC CARCINOMA OF THE BARTHOLIN GLAND. A CASE REPORT.
J. Molero Vílchez1,2, E. Martínez Lamela1,2, M. Rejas Gutiérrez1, R. García Alejo1, J. Montáns Araujo6
1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, Madrid, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain
5Advance Tecniques Cancer Center, Radiation Oncology, Madrid, Spain
6Pathologic Center, Pathology, Madrid, Spain

Aims

Accounting for less than 5% of all vulvar malignancies, primary carcinoma of the Bartholin gland is rare. A case of adenoid cystic carcinoma of the Bartholin gland is presented.

Method

Our patient, a 69-year-old woman, first noted a lump in the region of the introitus and labia majora in November 2015. Her only symptom was mass effect. On examination, the patient was found to have a 4 by 3 cm mass in the region of the left-sided Bartholin duct.

Magnetic resonance imaging showed 41×31 cm lobulated enhancing mass arising between the vagina and rectum which appeared to encase the anterior and left lateral walls of the rectum. Transrectal ultrasonography showed abnormal perirectal node involved the anterior portion of the anal sphincter mechanism. Computed tomography (CT) indicated no evidence of distant metastases.

The biopsy of the tumor indicated adenoid cystic carcinoma. The neoplastic cells were strongly reactive for CK 5/6, s100 and CD 117.

Results

The course of treatment included inguinal lymphadenectomy, radical hemvulvectomy and local transposition fasciocutaneous flap. Pathologic review of the resected specimen showed affected borders and postservative radiotherapy (V-MAT with IGRT) was performed to a total dose of 60 Gy in 6 fractions.
Conclusion

Physical examination showed no evidence of recurrent tumor. CT performed 6 months after surgery showed no evidence of pathologic processes.
THE USE OF A VESSEL-SEALING DEVICE DECREASES SIGNIFICANTLY THE AMOUNT OF LYMPHORRHEA IN VULVAR CANCER PATIENTS AFTER GROIN NODE DISSECTION
C. Kalantzis¹, A. Psarris¹, A. Karampelas¹, D. Papatheodorou¹
¹Anticancer Oncologic Hospital "St. Savvas", Department of Gynecologic Oncology, Athens, Greece

Aims

Many attempts to prevent complications following therapeutic groin node dissection have included modifications in surgical techniques in the past. Previous studies that enrolled heterogeneous groups of patients attempted to confirm the efficacy of some techniques such as preservation of the saphenous vein. The aim of the present study was to evaluate the efficacy of the vessel-sealing device (VSD) Ligasure™ following groin node dissection.

Method

Between October 2016 and April 2017, patients diagnosed with vulvar cancer who underwent groin node dissection, were randomized into two surgical dissection technique groups. In the first group, surgery was conducted using Ligasure™ (VSD Group). These were compared with a control group (C group) whereby ligation and monopolar electrocautery was utilized. The primary endpoint was to compare the time to drain removal and total quantity of lymphorrhea in both groups, while the secondary endpoint was to evaluate the rate of complications (infection, wound dehiscence, lymphedema) between the two groups.

Results

A total of 5 patients were enrolled in this trial, so 10 inguinal lymph node dissections were carried out. Two patients were randomly assigned to the control group (C). Significant differences were observed in terms of duration of drainage (VSS: 6.3 days - C: 11.5 days), and a significantly increased quantity of lymphorrhea was identified in control group as well (C: 792 cc VSS: 206 cc average). No other significant differences were recorded for postoperative complications, including lymphocysts, wound dehiscence and infection.

Conclusion

The use of VSS Ligasure™ offers a significant reduction in length of drain usage and in total lymphorrhea, but no significant differences for postoperative complications was observed.
VAGINAL AND VULVAR CANCER

EXPERIENCE IN INTRODUCING SENTINEL LYMPH NODE BIOPSY IN EARLY- STAGE VULVA CANCER: A SINGLE INSTITUTION BASED PROSPECTIVE STUDY

L. Paskeviciute Frøding1, V. Bahn Zobbe1, G. Oertoft Lykkegaard1, H. Claus1, T. Henrichsen Schnack1
1University hospital of Copenhagen, Obstetrics and Gynecology, Copenhagen Ø, Denmark

Aims

Primary vulva cancer (VC) is diagnosed in approximately 100 patient every year in Denmark. To improve treatment quality VC was centralized to two university centers in 2011. The current study evaluates the long-term recurrence and survival rates in early-stage VC patients after sentinel node (SN) procedure was introduced.

Method

All VC patients were prospectively registered in the Danish Gynecologic Cancer Database in the period January 2011 to July 2016. Patients with clinically stage IB (T1 < 4 cm) who had SN procedure performed were included. Inguinofemoral lymph node dissection was performed if the SN’s were not detected or in case of SN metastases.

Results

The SN procedure was performed in 164 VC patients with tumor < 4 cm and no clinical suspicious groin nodes or distant metastases. 58 patients were excluded due to stage IA or III disease. 106 patients had negative SN. Among these one patient (0.9%) experienced an isolated groin recurrence, seven (6.6 %) a localized vulva recurrence and three (2.8) distant metastases. The 5-year overall and disease-specific survival for SN negative patients were 82% and 95%, respectively. The median disease free survival in SN negative patients with recurrent disease was 19 months (CI 11.8-28.2).

Conclusion

This is to our knowledge the largest prospective single center study presenting results of SN procedure in SN negative VC patients. The study confirms the safety of SN introduction as part of the standard of care in early stage VC with low isolated groin recurrence rate and a good overall and disease-specific survival.

NEOADJUVANT ELECTROCHEMOTHERAPY IN SQUAMOUS VULVAR CANCER: PRELIMINARY RESULTS OF A PHASE II TRIAL

G. Borghese¹, A.N. Della Gatta¹, M. Feroli², M. Proccacini¹, G. Dondi¹, A. Livi¹, M. Tesei¹, B. Corti², A. Galuppi², A.G. Morganti², A.M. Perrone¹, P. De Iaco¹

¹S. Orsola-Malpighi Hospital, Unit of Oncologic Gynaecology, Bologna, Italy
²S. Orsola-Malpighi Hospital, Radiotherapy Unit, Bologna, Italy
³S. Orsola-Malpighi Hospital, Pathology Unit, Bologna, Italy

Aims

In previous studies electrochemotherapy (ECT) showed a local control of 80% in patients affected by relapse of squamous cell vulvar cancer (V-SCC). These results encouraged the use of ECT as neoadjuvant treatment in V-SCC. Aim of the study is to evaluate the effectiveness of ECT in reducing lesions in primary V-SCC and the possibility to decrease surgical aggressiveness and complication rate.

Method

The sample size was calculated based on the two-stage optimal design by Simon. The first step was planned to include 9 patients. In case of detection of at least one clinical PR, the study would enroll 8 additional patients. We enrolled patients with histological diagnosis of primary V-SCC and eligible for surgery. Accurate mapping of all lesions and ECT were performed. One month after ECT clinical response was evaluated according to RECIST criteria and the type of surgery was confirmed or modified. Surgery and pathological evaluation of surgical specimens were performed. Adjuvant therapies were prescribed based on pathological evaluation.

Results

We report the results of the first step of the trial. The average age of population was 67±10 years (mean±SD). Clinical response after therapy was observed in 7 patients (77.8%) with 1 CR and 6 PR. No peri-operative complications were recorded. Tumor downsizing led to more conservative surgery in 6 patients. With a median follow-up of 14±11 months (mean±SD) all patients are alive without disease.

Conclusion

Our preliminary analysis suggests that ECT is a suitable neoadjuvant treatment in patients with primary V-SCC. ECT may reduce tumor size and surgical aggressiveness.
VAGINAL AND VULVAR CANCER

ESGO7-1329

SENTINEL LYMPH NODE MAPPING IN EARLY STAGE VULVAR CANCER
T. Pichlík1, H. Robová1, L. Rob1, M.J. Halaška1, M. Hruda1, P. Škapa2
1Faculty Hospital Kralovské Vinohrady, Dept. of Obstetrics and Gynaecology, Praha 10, Czech Republic
2Faculty Hospital Motol, Department of Pathology, Praha 5, Czech Republic

Aims

To evaluate the oncogynaecological outcome in women with vulvar cancer up to 4 cm in the greatest diameter undergoing extirpation of groin sentinel lymph node instead of inguinofemoral lymphadenectomy.

Method

Our prospective study included 80 women with vulvar cancer stage 1B. We excluded patients with suspicion of invasion of groin lymphatic nodes, patients with multifocal tumour and patients that had been treated for other malignancy. Sentinel lymph nodes were detected according to one-day protocol. 20 MBq of radiocolloid Tc99 and 2ml of patent blau were injected intra-dermally peritumourously at different time at the day of surgery. Lymphoscintigraphy was performed. Sentinel lymph node was extirpated and sent for perioperative histopathological examination. The groin lymphatic dissection was performed in patients with positive sentinel lymph nodes.

Results

Out of 80 patients we had to excluded 3 due to the suspicion of groin lymph nodes involvement. There were identified 149 lymph nodes in 115 groins, i.e. 1.3 sentinel lymph node per one groin. 12 women had positive lymph nodes (15.6%), all of them had positive only sentinel lymph nodes with negative other lymph nodes. 6 patients had local or groin recurrence with primary negative lymph nodes, 2 patients with primary positive lymph nodes had groin recurrence.

Conclusion

Sentinel lymph node detection in vulvar tumour smaller than 4 cm decreases morbidity without any negative impact on oncogynaecological outcome.

This work was supported by the Charles University research program PROGRES Q 28 (Oncology)
To evaluate the sonographic characteristics of inguinal lymph nodes in patients with vulvar cancer.

Method

All consecutive patients with vulvar cancer planned for surgical staging of lymph nodes (LNs) at a Gynecologic oncology center were enrolled in the study. LNs were sonographically assessed using a predefined evaluation form that included topography, size, morphology and vessel architecture. The LNs were classified as not infiltrated, suspicious of metastatic involvement, and certainly metastatic. The definitive histopathology was used as a standard reference.

Results

Between 2009 and 2016, of the 75 patients included in the study, data from 131 groins were analyzed. The sensitivity and specificity of ultrasound for the detection of metastatic lymph nodes reached 86.0% and 93.2%. Ultrasound findings revealed typical findings of non-infiltrated lymph nodes as an oval shape (p<0.001), presence of hilum sign (p<0.001), and homogeneity (p<0.001). Infiltrated lymph nodes were described as having cortex asymmetry (p<0.001) or rounded shape (p<0.001), absence of hilum sign (p<0.001), heterogeneous structure (p<0.001), the presence of necrosis (p<0.001), and infiltration of the capsule (p<0.001). Regarding size, the results showed that the larger nodes (p<0.001) were related to infiltrated lymph nodes with the largest/shortest (L/S) ratio≤2.0 (p=0.044). In contrast to infiltrated LNs, non-infiltrated LNs were avascular or showed only hilar perfusion (p<0.001).

Conclusion

The typical features of an infiltrated inguinal lymph node are cortex asymmetry in early stage of metastasizing (intranodal metastases) or a rounded shape in late stage with complete node infiltration, loss of hilum sign, a heterogeneous structure with necrosis, and infiltration of the capsule.
VAGINAL AND VULVAR CANCER

ESGO7-0216

VOLUME-CONTROLLED VERSUS SHORT DRAINAGE AFTER INGUINOEMORAL LYMPHADENECTOMY IN VULVAR CANCER PATIENTS. A NATIONWIDE STUDY OF THE DUTCH GYNAECOLOGIC ONCOLOGY GROUP

1Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
2 Academic Medical Center, Center for Gynaecologic Oncology Amsterdam, Amsterdam, The Netherlands
3 Erasmus Medical Center, Obstetrics and Gynaecology, Rotterdam, The Netherlands
4 Maastricht University Medical Center, Obstetrics and Gynaecology- GROW- School for Oncology and Developmental Biology, Maastricht, The Netherlands
5 The Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital, Center for Gynaecologic Oncology Amsterdam, Amsterdam, The Netherlands
6 Radboud university medical center, Institute for Health Sciences, Nijmegen, The Netherlands
7 University Medical Center Groningen, Obstetrics and Gynaecology, Groningen, The Netherlands
8 Catharina Hospital, Obstetrics and Gynaecology, Eindhoven, The Netherlands
9 Leiden University Medical Center, Obstetrics and Gynaecology, Leiden, The Netherlands

Aims

Inguinofemoral lymphadenectomy for patients with vulvar squamous cell carcinoma is associated with significant morbidity. Inguinal drain management might influence the incidence of complications. The aim of this nation-wide prospective study (MAMBO: Morbidity And Measurement of the BOdy) was to assess the feasibility and the incidence of complications of volume-controlled versus short drainage of the groin.

Method

The MAMBO study consisted of two observational studies in all eight oncology centers in the Netherlands between 2012 and 2016. In the first study, the drain was removed when the production was <30 ml/24 hours except from the first 48 hours and for a maximum of 28 days (MAMBO-IA). In the second study the drain was removed five days postoperatively regardless the production (MAMBO-IB). Complications within eight weeks after surgery were assessed and the incidence of complications was compared.

Results

We included 141 patients (251 groins): 77 patients (139 groins) for volume-controlled drainage and 64 patients (112 groins) for short drainage. Volume-controlled drainage was associated with less lymphocele formation (10% versus 52% respectively, p<0.001). There was no difference in wound infection or primary wound breakdown. The incidence of one or more complications was 41% per groin after volume-controlled drainage versus 72% after short drainage, p=0.005.

Conclusion

This prospective study shows that volume-controlled drainage is associated with significantly less complications compared to short drainage. We advise volume-controlled drainage after inguinofemoral lymphadenectomy in patients with vulvar squamous cell carcinoma.
INTER-OBSERVER AGREEMENT FOR ASSESSING THE DEPTH OF INVASION IN VULVAR SQUAMOUS CELL CARCINOMA

Aims

The depth of invasion (DOI) is an important prognostic factor for patients with vulvar squamous cell carcinoma (SCC). Two different methods are used to assess the DOI; the conservative (recommended by The International Federation of Gynecology and Obstetrics) and the alternative method. See Figure 1. As the DOI guides the mode of treatment, there should be an uniform measurement method which best reflects clinical outcomes. The aim of this study is to assess the inter-observer agreement between pathologists using the conventional versus the alternative method.

Method

Fifty-one slides of vulvar SCC were selected, these slides represent daily practice. Five pathologists (including one resident) independently assessed all slides. Pathologists were requested to measure the DOI using both the conservative and the alternative method. The DOI was categorized into ≤1 mm and >1 mm and Light’s kappa for multi-rater agreement was calculated.

Results
**Preliminary results:** Kappa was 0.73 using the conservative method versus 0.61 using the alternative method. Pathologists were more sure about their measurement using the alternative method. Three pathologists scored the ease of use equally for both methods, two pathologists scored the conservative method more easy.

**Conclusion**

Pathologists reach substantial agreement in determining the DOI using both the conservative and the alternative method. Pathologists were more sure about their measurement using the alternative method. The number of participating pathologists will be increased.

ESGO7-0193

THE IMPACT OF WRITTEN INFORMATION AND COUNSELING (WOMAN-PRO II PROGRAM) ON SYMPTOM OUTCOMES IN WOMEN WITH VULVAR NEOPLASIA: A MULTICENTER RANDOMIZED CONTROLLED PHASE II STUDY

S. Raphaelis\textsuperscript{1}, H. Mayer\textsuperscript{1}, B. Senn\textsuperscript{2}

\textsuperscript{1}University of Vienna, Department of Nursing Science, Vienna, Austria
\textsuperscript{2}University of Applied Sciences FHS St. Gallen, Institute for Applied Nursing Sciences, St. Gallen, Switzerland

Aims

To determine if written information and/or counseling based on the WOMAN-PRO II Program decreases symptom prevalence in women with vulvar neoplasia by a clinically relevant degree and to explore differences between the 2 interventions in symptom prevalence, symptom distress prevalence, and symptom experience.

Method

A multicenter randomized controlled parallel-group phase II trial with 2 interventions provided to patients after the initial diagnosis was performed in Austria and Switzerland. Women randomized to written information received a predefined set of leaflets concerning wound care and available healthcare services. Women allocated to counseling were provided additionally with 5 consultations by an Advanced Practice Nurse (APN) between the initial diagnosis and 6-months post-surgery focusing on symptom management, utilization of healthcare services, and health-related decision making. Symptom outcomes were measured 5 times simultaneously to the counseling time points.

Results

A total of 49 women with vulvar neoplasia participated in the study. Symptom prevalence decreased in women with counseling by a clinically relevant degree, but not in women with written information. Sporadically, significant differences between the 2 interventions could be observed in individual items, but not in the total scales or subscales of the symptom outcomes.

Conclusion

The results indicate that counseling may improve symptom prevalence in women with vulvar neoplasia by a clinically relevant extent. The observed group differences between the 2 interventions favor counseling slightly over written information. The results justify testing the benefit of counseling thoroughly in a comparative phase III trial.

THE IMPORTANCE OF THE DRAINAGE SYSTEM AFTER INGUINOFLEMORAL LYMPHADENECTOMY FOR THE TREATMENT OF VULVAR CANCER: A SERIE OF 25 CASES

A. Ribeiro Dias Jr1, M.B. Santor Faria1, G. Miglino1, F. Nobrega1, M.L. Genta Dias1, M.P. Araujo1, J.C. Sadalla1, J.P. Mancusi1, C. Anton1, J. Paula Carvalho1, E. Chada Baracat1

1Instituto do Câncer do Estado de São Paulo - ICESP, Gynecology, São Paulo, Brazil

Aims

Vulvar cancer (VC) is a rare gynecologic malignancy, corresponding of 4% of all female genital cancer. This incidence is about 0.5-1.5 in 100,000 women per year, and rases continuously, mainly among women under 60, probably due to the HPV exposure. The inguinalofemoral lymphadenectomy is indicated when the stromal invasion is greater than 1 mm. Complications like lymphocele, dehiscence and infection related to the groin dissection may occur and be related to the drainage system. Our study objective to test a drainage system with the aim of avoiding lymphocele, dehiscence or infection of the operative site when the inguinalofemoral lymphadenectomy is performed for the staging and treatment of VC.

Method

25 patients from the Outpatient Clinic of Gynecological Oncology Cancer Institute of São Paulo State (ICESP) with the diagnosis of VC (stages IB to IIIC - FIGO) were submitted to the inguinalofemoral lymphadenectomy. The superficial fascia was incised, and the groin dissection were performed. After this, a Ligth Flow Silicone Drain (RUSCH Teleflex Medical - Ireland) size 14 mm was used, linked to a colostomy bag to store the drainage (pictures 1-2). Patients were instructed to compress the region where the lymphadenectomy were performed in order to promote the exit of the lymph through the drain to the colostomy bag.

Results

We did not observe any case of lymphocele, dehiscence or infection of the operative site using this drainage system.

Conclusion

The use of Ligth Flow Silicone Drain when the inguinofoemoral lymphadenectomy is performed for the treatment on VC seems to be appropriate and safe.

VULVAR CANCER IN IRELAND: ANALYSIS OF THE IRISH NATIONAL CANCER REGISTRY OVER A 20 YEAR PERIOD

A. Rowan¹, T. Walsh¹, R. McVey¹, W. Boyd¹, D. Brennan¹

¹UCD School of Medicine- Mater Misericordiae University Hospital, Dept of Gynaecological Oncology, Dublin, Ireland

Aims

To ascertain if changing practice guidelines have resulted in a change in treatments and survival in vulvar cancer in Ireland.

Method

Data was collected from the National Cancer Registry of Ireland from 1994 to 2014.

Results

A total of 816 vulvar cancer patients were identified with an average of 54 cancers diagnosed per year (range 21-58). The median age at diagnosis was 72 (range 20-85). The standardised incidence rate increased during the study, 1.08 to 2.29 during the period (figure 1). Seventy-two percent (n=591) were squamous cell carcinoma and 80% were stage 1-2 at diagnosis. The rate of surgery within 1 year of diagnosis fell from 89% to 71%, while radiotherapy rates increased from 17% to 31% during the period. Rates of smoking increased from 6% to 57%. Five year survival rates rose from 40% to 66% during the study period (figure 1).

Conclusion

This population-based study demonstrates that the incidence of vulvar cancer in Ireland is increasing, particularly in socially deprived women who smoke. The use of primary radiotherapy has significantly increased over the last two decades with increasing survival rates seen.

PRIMARY MALIGNANT MELANOMA OF THE FEMALE GENITAL TRACT
S. Sakhri1, J. Olfa1, H. Houda1, N. Lamia1, L. Boutheina1, H. Monia1, B.H. Jamel1, R. Khaled1
1salah azaiez, surgery, Tunis, Tunisia

Aims

The aim is to establish the clinical features, treatment and prognosis of primary malignant melanoma

Method

We retrospectively reviewed the clinical records of 13 patients with primary malignant melanoma of the female genital tract treated at Salah Azaiez institute, Tunis, Tunisia, in the period from 2008 to 2015

Results

13 patients with primary malignant melanoma are presented. 4 cases with melanoma of the vulva the median age was 59.5 who consulted for vaginal bleeding and a vulvar mass. An anterior pelvic exenteration with bilateral inguinal and pelvic lymphadenectomy was performed for two patients having a locally advanced tumor, the 2 other underwent a radical vulvectomy with bilateral inguinal lymph node dissection. One of the tow patients treated with pelvic exenteration died post operatively of cardiopulmonary complication, the other has developed skin metastases five months after surgery. 5 patients with vaginal melanomas the median age was 63.5. They were both treated with surgery, the other patient developed local recurrence with lung and bone metastases and she died 6 weeks later of widespread disease. Two patients with cervical melanoma were aged 50 and 47 years, both consulted for metrorrhagia, only one patient underwent CHL surgery and lomboaortic dissection followed by an exenteration. The other patient was not operated.

Conclusion

Malignant melanoma of the female genital tract is uncommon. Surgery is the best available treatment for controlling this disease. Radiotherapy is performed as an adjuvant therapy to achieve control of hidden metastases. The role of chemotherapy in patient with distant metastases has not been established.

ADENOID CYSTIC CARCINOMA OF THE VULVA
S. Sakhri1, I. Zemni1, M. Bouheni1, B. Laamouni2, N. Boujelbene1, M. Hechiche1, J. Ben Hasoouna1, K. Rahal1
1salah azaiz, surgery, Tunis, Tunisia
2salah azaiz, department of patology, Tunis, Tunisia

Aims
To study the clinical profile and outcome of the adenoid cystic carcinome of the vulva treated in the institute of Salah Azaiez Tunisia

Method
This is a retrospective, record-based study of histopathologically confirmed cases of adenoid cystic of the vulva treated in the institute of Salah Azaiez Tunisia

Results
Case 1 :
A 40-year-old women presented with a painless unilateral vulval swelling a biopsy demonstrated malignant cells consistent with adenoid cystic carcinoma. He underwent radical local excision. On follow-up after two years the patient is alive and well with no evidence of disease.

Case 2 :
A 30 years old lady presented with complaints of a slowly increasing mass in the vulva for the last 3 months. She had no evidence of metastatic disease .A biopsy was done and the histopathologic revaled the diagnostic of Adenoid cystic carcinoma. A simple vulvectomy was performed , the surgical margins were microscopically negative .On histopathologic examination confirmed the diagnosis of adenoid cystic carcinoma of the vulva. The patient was lost to view after one year in a good condition.

Conclusion
Adenoid cystic carcinoma of vulva is an extremely rare, slowly progressing neoplasm mostly involving the Bartholin’s gland. The usual treatment includes wide excision and adjuvant radiotherapy (if required). There may be late local and distant recurrence.

MAMMARY-LIKE ADENOCARCINOMA OF THE VULVA ASSOCIATED TO PAGET’S DISEASE: A CASE REPORT

M.S. Rhim¹, H. Salhi², M. Rezgani², A. Didouni¹, O. Jaidane², I. Zemni², J. Ben Hassouna², T. Dhiab², M. Hechiche², K. Rahal², A. Haddad¹, R. Faleh¹

¹Maternity Center, Department of Gynaecology and Obstetrics, Monastir, Tunisia
²Salah Azaiz Institute, Surgical Oncology Department, Tunis, Tunisia

Aims

We report a case of vulvar Paget’s disease associated with underlying mammary-like adenocarcinoma. To explore the possibility that this was a case of primary breast carcinoma of the vulva, we investigated the immunohistochemical characteristics of the tumor cells. We also review previously reported cases of primary breast-like carcinoma of the vulva with or without Paget’s disease.

Method

A 41-year-old woman, gravida 4 para 4, presented with a left vulvar labia mass.

Results

There was no previous history of malignancy or breast disease. Her family history was not remarkable for carcinomas. Physical examination found a 2 cm in diameter, erythematous and ulcerative nodule located between the left labium major and labium minor. The clitoris, right labia, vestibule and vaginal wall were intact. An enlarged fixed lymph node was palpated in each groin. An excisional biopsy specimen of the lesion was performed. Histopathological examination found a neoplastic proliferation of epithelial cells. The patient underwent a radical vulvectomy with bilateral inguinal lymph nodes dissection. The tumor measured 1.5 cm in great diameter showing the similar histopathological features seen on the biopsy specimen, described previously with numerous images of lymphatic invasion. It was confined to the vulva. Surgical margins were free of tumor. Four metastatic and bilateral regional nodes were found within the 13 sampled. The tumor was staged T1N2bM0. The patient had simple operating consequences. She’s, at present, under radiotherapy and then proposed for adjuvant chemotherapy.

Conclusion

When Paget’s disease with underlying mammary-like adenocarcinoma of the vulva is established, it is very important to perform all the pathological and immunohistochemical investigations to achieve differential diagnosis from both a metastatic lesion from an orthotopic breast cancer and a vulvar adnexal tumor.

ESGO7-1371

EPITHELIOID SARCOMA OF THE VULVA: A CASE REPORT.
I. Schmeil1, G. Honarpisheh1, S. Becker1, A. El-Balat1
1Goethe University Frankfurt, Gynecology, Frankfurt, Germany

Aims

Epithelioid sarcoma of vulva is an extremely rare tumor entity which was firstly described in 1970. Until now about 40 cases have been reported in the literature and there are no established guidelines for optimal treatment of this rare neoplasm.

Method

The present study reports a newly efficient approached case of 67-year-old female with epithelioid sarcoma of proximal type.

Results

In January 2016, a painless small nodule placed in the left labia majora was detected by the 67-year-old patient. This lump was rapidly increasing in size, ulcerating and associated with severe bleeding. The gynecological examination undertaken in April 2016 revealed a solid fixed supraclitoral mass measuring 8 x 5 cm and spanning the both labia majora. After blood transfusion, a hemivulvectomy with bilateral sentinel node biopsy was performed. Histopathological examination showed an epithelioid sarcoma of proximal type which has been successfully removed with adequate tumor free margins. The excised inguinal nodes were not affected. No postoperative adjuvant treatment was indicated. Fourteen months of follow-up the patient is well-being without recurrence or metastasis.

Conclusion

Epithelioid sarcoma is distinguished by aggressive behavior. Surgical excision constitutes weightily component in treatment of this tumor entity.

PROGNOSTIC VALUE OF LYMPH NODE RATIO AND NUMBER OF POSITIVE INGUINAL NODES IN PATIENTS WITH VULVAR CANCER

S. Polterauer1, R. Schwameis1, C. Grimm1, R. Macuks2, S. Iacoponi3, K. Zalewski4, I. Zapardiel3

1Medical University Vienna, Department of General Gynaecology and Gynaecological Oncology - Gynecologic Cancer Unit - Comprehensive Cancer Center, Vienna, Austria
2Eastern Clinical University Hospital, Latvian Oncology Center of Riga, Riga, Latvia
3La Paz University Hospital - IdiPAZ, Gynecologic Oncology Unit, Madrid, Spain
4Holycross Cancer Center, Department of Gynecologic Oncology, Kielce, Poland

Aims

To estimate the prognostic significance of lymph node ratio and number of positive nodes in vulvar cancer patients.

Method

This international multicenter retrospective study included patients diagnosed with vulvar cancer treated with inguinal lymphadenectomy. Lymph node ratio (LNR) is the number of metastatic lymph nodes (LN) to the number of removed LN. Patients were stratified into risk groups according to LNR. LNR was correlated with clinical-pathological parameters. Survival analyses were performed.

Results

This analysis included 745 patients. In total, 292 (39.2%) patients had positive inguinal LN. The mean (SD) number of resected and positive LN was 14.1 (7.6) and 3.0 (2.9), respectively. High LNR was associated with larger tumor size and higher tumor grade. Patients with LNRs 0% (N0), >0<20%, and >20% had 5-year overall survival (OS) rates of 90.9%, 70.7%, and 61.8%, respectively (P<.001 - Figure). LNR was associated with both local and distant recurrence-free survival (P<.001). Patients with 0, 1, 2, 3 or more than 3 positive lymph nodes had 5-year OS rates of 90.9%, 70.8%, 67.8%, 70.8% and 63.4% respectively (P<.001). In multivariate analysis, LNR (P=.01) and FIGO stage (P<.001), were associated with OS, whereas the number of positive nodes (P=.8), age (P=.2), and tumor grade (P=.7), were not. In high-risk patients, adjuvant radiotherapy was associated with improved survival.

Conclusion

LNR provides useful prognostic information in vulvar cancer patients with inguinal LN resection in vulvar cancer. LNR allows for more accurate prognostic stratification of patients than number of positive nodes. LNR seems useful to select appropriate candidates for adjuvant radiation.

VULVAR AND VAGINAL CANCER, VULVAR INTRAEPITHELIAL NEOPLASIA 3 AND VAGINAL INTRAEPITHELIAL NEOPLASIA 3, AN EXPERIENCE OF A REFERRAL INSTITUTE

Y. Segev†, O. Lavie†, L. Mackuli†, E. Siegler†
†Carmel Medical Center, Obstetrics and Gynecology, Haifa, Israel

Aims

To evaluate the demographic and clinical characteristics associated with Vulvar or Vaginal cancer and Vulvar and Vaginal Intraepithelial Neoplasia 3 (VIN 3), (VAIN 3).

Method

A retrospective chart review of 148 women with vulvar and vaginal malignancy and pre-malignancy was performed. Fifty nine and 19 patients with Vulvar and Vaginal Cancer respectively and 57 and 13 patients with VIN 3 and VAIN 3 respectively were evaluated between October 2008 and October 2016.

Results

The median age of vulvar cancer patients was 30 years older than VIN3 patients. HPV was found in 60% and 66.6% of vulvar and vaginal cancer respectively, and in 82.3% and 84.6% of patients with VIN 3 and VAIN 3 respectively. History of CIN (Cervical Intraepithelial Neoplasia) or warts was observed in 10% and 10.5% of vulvar and vaginal cancer respectively, and in 57.9% and 46% of patients with VIN 3 and VAIN 3 respectively. In 52.6 % of patients the vaginal cancer was metastases from other organs.

Conclusion

Most women with vulvar carcinoma are older than 70 years old. VIN3 and VAIN3 are associated with HPV infections and the most prevalent type is HPV 16. Almost half of the vaginal cancers are associated with metastases from other organs and almost half of VAIN 3 is associated with past cervical dysplasia or carcinoma.

MELANOMA OF THE CLITORIS: A CASE REPORT
D. Tomica¹, D. Haubenberger¹, E. Übermasser¹, E. Preu¹, L. Šušnjar², D. Danolić³, S. Ramić³, I. Mamić², I. Alvir², M. Puljiz²
¹General Hospital Scheibbs, Department of Gynecology and Obstetrics, Scheibbs, Austria
²University Hospital Centre Sestre Milosrdnice-University Hospital for Tumors, Department of Gynecologic Oncology, Zagreb, Croatia
³University Hospital Centre Sestre Milosrdnice-University Hospital for Tumors, Department of Oncological Pathology, Zagreb, Croatia

Aims

We present a case of 75-year old patient with melanoma of the clitoris, which is a rare neoplasm. Vulvar malignant melanoma makes less than 5% of all malignant neoplasms of the vulva and most commonly originate on the labia minora and clitoris. Median age at presentation is 70 years.

Method

A 75-year-old woman complaining of dark blue tumor of the clitoris which increased in size in the last three months. Patient underwent a complete gynecological evaluation during which a suspicious mass on her clitoris was observed. An excision of the tumor was made and a histopathological suspicion of nodular melanoma was confirmed. Thickness of tumor by Bresslow was 9 mm. TNM classification of the tumor according to IUC 2010 was pT4b NX MX R0 L1 Vo Pn1. Patient has undergone Roferon-A (Interferon alfa-2a, recombinant) therapy.

Results

18 months after diagnosis there is no evidence for neoplastic recurrence.

Conclusion

The primary treatment is resection of the tumor, chemotherapy if is indicated or combination of resection and immunotherapy. This case draws our attention to the importance of early diagnosis of this rare neoplasm of the vulva.

P16INK4A STATUS COULD STRATIFY VULVAR CANCER PATIENTS FOR IMMUNOTHERAPIES BASED ON CANCER TESTIS VACCINES AND IDO-PATHWAY INHIBITORS

J. Sznurkowski¹, K. Sznurkowska², A. Zawrocki³, W. Biernat⁴

¹Medical University of Gdansk, Oncological Surgery, Gdansk, Poland
²Medical University of Gdansk, Pediatrics, Gdansk, Poland
³Medical University of Gdansk, Pathology, Gdansk, Poland
⁴Medical University of Gdansk, Pathology, Gdansk, Poland

Aims

Recently we have found that vulvar squamous cell carcinoma (vSCC) immune surveillance as represented by Tumor Infiltrating Lymphocytes (TILs) and Tumor Infiltrating Macrophages (TAMs) depends on p16INK4-status regardless to (hr)HPV-DNA. Different immune effectors contributed to clinical outcomes in vSCC patients with positive and negative tumors for p16INK4a. Tumor immunogenicity as represented by cancer testis antigens (CTAs) and cancer induced immune tolerance as represented by expression of indoleamine 2,3-dioxygenase (IDO) were evaluated to discover the biological characteristics of the tumor microenvironment responsible for different infiltration signatures and diverse prognosis of immune cells related to p16INK4-status.

Method

Methods: Data on expression of p16INK4a, CTAs (MAGE-A1, MAGE-A4), IDO and presence of high risk (hr)HPV-DNA, were retrieved from our previous studies on cohort of 85 vSCCs. CTAs and IDO expressions were compared between tumors with different p16INK4a and (hr) HPV-DNA status. Survival analyses included the Kaplan–Meier method, log-rank test and Cox proportional hazards model.

Results

Results: p16INK4a-negative tumors revealed higher expression of MAGE-A4 (p=0.0005). Lack of difference in IDO expression was observed between p16INK4a-negative and positive tumors (p=0.2827). IDO was correlated with worse outcome in p16INK4a-positive tumors only.

Conclusion

Higher MAGE-A4 expression of p16-negative tumors could explain more dense infiltration by TILs. p16INK4a-status could stratify patients for future immunotherapies based on CT vaccines or IDO pathway inhibitors. Large cohort analyses are needed.

HUMAN PAPILLOMAVIRUS IN VULVAR INTRAEPITHELIAL NEOPLASIA

Y.H. Tang¹², H.J. Huang¹², L.Y. Yang¹, R.C. Wu¹, A. Chao¹², C.H. Lai¹
¹Chang Gung Memorial Hospital, Obstetrics and Gynecology, Taoyuan, Taiwan R.O.C.
²Chang Gung Memorial Hospital, Gynecologic Cancer Research Center, Taoyuan, Taiwan R.O.C.
³Chang Gung Memorial Hospital, Clinical Trial Center, Taoyuan, Taiwan R.O.C.
⁴Chang Gung Memorial Hospital, Pathology, Taoyuan, Taiwan R.O.C.

Aims

Vulvar intraepithelial neoplasia (VIN) is a precursor lesion of vulvar cancer. Human papillomavirus (HPV) is causative for part of VIN lesions. We aimed to analyze the distribution of HPV in VIN and its relation to treatment outcomes.

Method

We retrospectively analyzed patients who diagnosed as VIN between 1990 and 2014 in our institution. HPV DNA was extracted from formalin-fixed and paraffin-embedded samples. SPF1/GP6+ polymerase chain reaction (PCR) followed by HPV Blot and E6 type-specific PCR were performed.

Results

Of the 113 VINs (31.0% with VIN1, 18.6% with VIN2, and 50.4% with VIN3), 85.0% were positive for HPV. Patients with positive HPV was diagnosed younger than those with negative results (44.1 vs. 63.4 years, \(P = 0.008\)). HPV-positivity was significantly higher in VIN3 (94.7%) compared with VIN2 (76.2%) and VIN1 (74.3%) \(P = 0.013\). The most prevalent type was HPV16 (60.4%), followed by HPV6 (14.6%), and HPV11 (11.5%). Of the 20 patients with recurrent VIN \(n = 13\) or progression to vulvar cancer \(n = 7\), 19 had positive HPV. HPV16 was related to VIN3 \(P < 0.001\) and higher recurrent/progression rate \(P = 0.004\). All seven VINs with progression to cancer were HPV positive, six with HPV16 (one was initially VIN1 at 21 years old) and one with HPV58.

Conclusion

HPV-positivity was related to younger age in VIN. HPV16 was most prevalent genotype and significantly related to recurrence/progression. We should closely follow up VIN patients with positive HPV16, and perform biopsies for suspicious lesions despite young age.
VAGINAL AND VULVAR CANCER

ESGO7-0510

PROGNOSTIC FACTORS FOR LOCAL RECURRENCE OF SQUAMOUS CELL CARCINOMA OF THE VULVA: A SYSTEMATIC REVIEW

N.C. te Grootenhuis¹, A.W. Pouwer², G.H. de Bock³, H. Hollema⁴, J. Bulten⁵, A.G. van der Zee¹, J.A. de Hullu², M.H. Oonk¹

¹University Medical Center Groningen, Obstetrics and Gynaecology, Groningen, The Netherlands
²Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
³University Medical Center Groningen, Epidemiology, Groningen, The Netherlands
⁴University Medical Center Groningen, Pathology, Groningen, The Netherlands
⁵Radboud University Medical Center, Pathology, Nijmegen, The Netherlands

Aims

In patients treated for early-stage vulvar squamous cell carcinoma (VSCC) local recurrence is reported in up to 40%. Both clinicopathologic as well as cell biologic factors might be prognostic for local recurrence and knowledge on these factors may help to identify high risk patients and/or to develop strategies to prevent local recurrences. This systematic review aims to evaluate current knowledge on the incidence of local recurrences in VSCC related to clinicopathologic and cellbiologic variables.

Method

Relevant studies were identified by an extensive online search in March 2017. Studies reporting prognostic factors specific for local recurrences of VSCC were included. Two review authors independently performed data selection, extraction and assessment of study quality. The risk difference was calculated for each prognostic factor described by two or more studies.

Results

Twenty-two studies were included and reported mainly pathologic factors. There were differences in study quality and reported factors. Due to differences in study design, homogeneity could not be assumed. The prognostic relevance for local recurrence of VSCC of all analyzed variables remains unequivocal, including pathologic tumor free margin distance less than 8 mm, presence of lichen sclerosus, groin lymph node metastases and a variety of different tumor characteristics. Our review indicates an estimated annual local recurrence rate of 4%.

Conclusion

Current quality of data on prognostic factors for local recurrences in VSCC patients does not allow evidence-based medicine. Further research on prognostic factors, applying state of the art methodology are needed to identify high-risk patients and to develop alternative treatment strategies.
VAGINAL AND VULVAR CANCER

ESGO7-0985

RECONSTRUCTIVE PLASTIC SURGERY IN THE TREATMENT OF VULVAR CARCINOMAS
D. Tsolakidis1, A. Papanikolaou1, I. Theodoulidis1, V. Theodoulidis1, S. Pitis1, P. Pappas1, B. Tarlatzis1
1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

Vulvar reconstruction can be challenging for the gynecologist and multidisciplinary approach is necessary for better wound healing, adequate function, and acceptable appearance. The purpose of this study was to present our experience in reconstructive plastic surgery by using skin/musculocutaneous flaps after extirpation of primary or recurrent vulvar cancer in our clinic.

Method

From January 2006 to December 2016, 109 women with vulvar malignancies underwent radical vulvectomy. Thirteen of them resulted in large perineal defects and vulvar reconstruction was assisted by a plastic surgeon, including lotus flap (7 patients, average age 68.4 years), V-Y flap (5 patients, average age 67.8 years), vertical rectus abdominis musculocutaneous flap (1 patient, age 72 years). The disruption rate and length of hospital stay were evaluated and compared among those techniques.

Results

Although V-Y flaps had the highest rate of disruption (2/5), their hospitalization was the lowest (20.2 days) with 196.7° average operative duration. Lotus flaps resulted in the highest length of hospital stay (24.4 days) with 168° average operative duration. The technique with the lower rate of disruption was vertical rectus abdominis musculocutaneous flap (0%) with 300° average operative duration.

Conclusion

Study outcomes suggest that vulvar reconstructive surgery exerts benefits in patients with vulvar cancer. Multidisciplinary approach with plastic surgeon, in larger vulvar tumors is associated with a favorable oncological outcome as well as acceptable cosmetic results in vulvar cancer patients.
VULVAR PAGET DISEASE IN THE NETHERLANDS

M. van der Linden1, L. van Doorn2, J. Bulten3, E. van Dorst4, G. Fons5, C. Lok6, L. Massuger7, M. van Poelgeest8, B. Slangen9, M. Oonk9, J. de Hullu1

1Radboud University Medical Centre, Obstetrics & Gynaecology, Nijmegen, The Netherlands
2Erasmus Medical Centre, Gynaecology, Rotterdam, The Netherlands
3Radboud University Medical Center, Pathology, Nijmegen, The Netherlands
4UMC Utrecht, Gynaecology, Utrecht, The Netherlands
5Amsterdam Medical Centre, Gynaecologic Oncology, Amsterdam, The Netherlands
6Antoni van Leeuwenhoek - Netherlands Cancer Institute, Gynaecology, Amsterdam, The Netherlands
7Leiden University Medical Centre, Gynaecology, Leiden, The Netherlands
8Maastricht University Medical Centre, Gynaecology & Obstetrics, Maastricht, The Netherlands
9University Medical Centre Groningen, Obstetrics & Gynaecology, Groningen, The Netherlands

Aims

The aim of this retrospective cohort study is to assess the clinical course of vulvar Paget disease (VPD), and to study the effect of invasion and treatment on recurrence and survival.

Method

All patients with VPD were yielded from local pathology databases in all Dutch tertiary university medical centres. Data on histopathological and clinical characteristics, diagnostics, treatment and follow-up were retrieved from the medical files and pathology reports. Disease free survival (DFS) and 5-year overall survival (OS) was estimated using Kaplan-Meier curves.

Results

We analysed data of 113 VPD patients treated between 1991 to 2016. Median age was 72.5 years at time of diagnosis. Non-invasive VPD was the most common diagnosis (77%). Most patients with either non-invasive, or (micro-)invasive VPD were surgically treated. Almost 40% of the patients had one or more recurrence. Margin status did not influence the DFS. Of all patients with non-invasive VPD, 8% had an invasive recurrence or developed metastases. There were no deaths of non-invasive VPD reported. The 5 year OS was 80% in non-invasive VPD: 20% died of another causes. Five year OS in (micro-)invasive VPD is significantly worse: 60%.

Conclusion

VPD is rare and a difficult clinical diagnosis. Most patients have non-invasive VPD, which does not affect survival. However, the recurrence rate is high. Prognosis for patients with invasive VPD is worse compared to patients with non-invasive VPD. The risk of developing invasion after non-invasive disease is less than 10% in our cohort.
VAGINAL AND VULVAR CANCER

THE IMMUNE MICROENVIRONMENT IN NON-INVASIVE VULVAR PAGET DISEASE
M. van der Linden¹, J. de Hullu¹, J. Bulten², E. van der Dreef³, E. van Esch⁴, L. Massuger¹, S. van der Steen¹, T. Bosse⁴, M. van Poelgeest⁴
¹Radboud University Medical Centre, Obstetrics & Gynaecology, Nijmegen, The Netherlands
²Radboud University Medical Centre, Pathology, Nijmegen, The Netherlands
³Leiden University Medical Center, Pathology, Leiden, The Netherlands
⁴Leiden University Medical Center, Gynaecology, Leiden, The Netherlands

Aims

Non-invasive Vulvar Paget disease (VPD) is a rare skin disorder that mainly affects elderly women. Recently, cases of patients with VPD that responded to topical 5% imiquimod cream, an immune modulator, are reported. However, knowledge about the immune microenvironment of VPD is lacking. The aim of this study was to investigate the basic composition of the immune infiltrate in VPD.

Method

The immune infiltrates in 10 VPD patients were compared to those seen in either healthy controls (n=30), and the premalignancy with known response to imiquimod: vulvar high grade squamous cell intraepithelial lesions (n=43). Additional immunohistochemistry for CD4, CD8, CD14, CD20, CD56 and FoxP3 was performed.

Results

On H&E a lichenoid immune infiltrate with little interface reaction was observed in submucosal stroma of most VPD samples. Immunophenotyping showed that this stromal infiltrate mainly consisted of a variety of T-cells. B-cells, NK-cells and macrophages were also present. We noticed a great variety in the amount of cells per sample within one patient.

In the intraepithelial compartment VPD contained significantly less CD4+ and CD8+ compared to vulvar HSIL and healthy controls, and significantly less FoxP3+ cells than in HSIL cases. In contrast, the dermal compartment in VPD contained significantly more CD4+, CD8+, CD14+ and FoxP3+ cells than in healthy controls, but significantly less FoxP3+ cells in comparison to the dermal compartment of HSIL cases.

Conclusion

VPD is characterised by the presence of a dense lichenoid infiltrate, with a mixed cell population in the dermal immune infiltrate, whereas the epithelium is immunosuppressed.
VAGINAL AND VULVAR CANCER

GROIN TREATMENT IN VULVAR CANCER: IS SENTINEL LYMPH NODE DETECTION BASED ON LYMPHOSCINTIGRAPHY ENOUGH?

V. Veiga\(^1\), L. Correia\(^2\), J. Lopes\(^3\), M. Bernardino\(^2\), A.R. Sofia\(^2\), I. Santana\(^2\), A.F.J. Jorge\(^2\)

\(^1\)Centro Hospitalar de Leiria, Gynecology, Leiria, Portugal  
\(^2\)Instituto Português de Oncologia de Lisboa, Gynecology, Lisboa, Portugal  
\(^3\)Centro Hospitalar Lisboa Norte, Gynecology, Lisboa, Portugal

Aims

To evaluate if the sentinel lymph node detection (SLND) based on lymphoscintigraphy is predictive of groin nodes status, depending on tumor location.

Method

SLND performed in vulvar cancers, in Portuguese Institute of Oncology of Lisbon, between 2005 and 2016.

Ninety six unifocal invasive squamous cell carcinomas of the vulva of less than 4 cm, without suspicious groin nodes, were included.

Tumor location in relation to the midline was classified as lateral [\(>1 \text{ cm from midline}\) (n=46; 48%)], lateral ambiguous [medial border \(<1 \text{ cm from midline but not involving it}\) (n=21; 22%)], and midline (n=29; 30%).

Preoperative lymphoscintigraphy drainage pattern was evaluated and development of node metastasis in groins without initial drainage was calculated.

Results

From lateral tumors, 84.4% (n=38) had ipsilateral, 11.1% (n=5) bilateral and 4.4% (n=2) contralateral drainage. In one case SLN was not found. One patient (2%), with initial ipsilateral drainage, developed metastasis in contralateral groin.

From lateral ambiguous tumors, 71.4% (n=15) had ipsilateral and 28.6% (n=6) bilateral drainage. From those with ipsilateral drainage, no contralateral groin metastasis were identified in follow-up.

From midline tumors, bilateral drainage occurred in 52% (n=15) and unilateral in 48% (n=14). Three cases (10%), from unilateral drainage group, developed groin metastasis at the side of no drainage.

Conclusion

In our study, lymphoscintigraphy predicted groin nodes status in 96% of the cases. In midline tumors, as recommended by literature, but not in lateral ambiguous, both groins must be evaluated, as 21% (3/14) of the cases with unilateral drainage developed contralateral groin metastasis.
GROIN RECURRENCE IN VULVAR CANCERS WITH NEGATIVE SENTINEL LYMPH NODE BIOPSY

V. Veiga¹, L. Correia², M. Rocha³, A. Coelho², A. Gomes², A.F. Jorge²
¹Centro Hospitalar de Leiria, Gynecology, Leiria, Portugal
²Instituto Português de Oncologia de Lisboa, Gynecology, Lisboa, Portugal
³Instituto Português de Oncologia de Lisboa, Lisboa, Portugal

Aims

To evaluate the rate and characteristics of groin recurrences after negative sentinel lymph node (SLN) biopsy in vulvar cancer.

Method

Ninety six unifocal invasive squamous cell carcinomas of less than 4 cm, without suspicious groin nodes, submitted to SLN detection in Portuguese Institute of Oncology of Lisbon, between 2005 and 2016, were included. In all cases a combination of preoperative Tc-99m nanocolloid and intraoperative blue dye was used.

Those cases with negative SLN biopsy were divided in two groups: Group 1 – with groin recurrence and Group 2 – without it.

Patients age, body mass index, menopausal status, number of SLN, tumor pathological characteristics, local recurrence rate and indication for postoperative vulvar radiotherapy were compared between groups using non parametric tests. Significant differences were considered when p-values <0.05.

Results

The SLN detection rate was 99%.

Of the 95 SLN detected 66.3% (n=63) were negatives. From those, 8 (12.7%) groin recurrences were identified in a median time of 7 (4-47) months.

Comparing both groups, there were no statistical significant differences between them according all the characteristics analyzed.

Conclusion

In our experience, groin recurrence rate after negative SLN biopsy was 12.7% but no predictive factors were identified.

ESGO7-1087

LANGERHANS CELL HISTIOCYTOSIS LIMITED TO THE FEMALE GENITAL TRACT: A REVIEW OF LITERATURE AND REPORT OF THREE ADDITIONAL CASES

R. Wieland

University of Vermont, Pathology and Laboratory Medicine, Burlington, USA

Aims

Our aim is to provide a comprehensive review of Langerhans Cell Histiocytosis (LCH) of the gynecologic tract, including clinical presentation, pathologic diagnosis, therapy and prognosis. In addition, we report and add to the literature three new cases. LCH is a rare tumor, composed of cells sharing morphologic and immune-phenotypic characteristics of dermal Langerhans cells and can arise in the vulva, vagina, cervix or endometrium.

Method

A comprehensive search of English language literature was performed as well as a search of our institutional archives over the past twenty years. The diagnosis of our institutional cases was confirmed by review of hematoxylin/eosin stained sections as well as tumor cell immunoreactivity for immunohistochemical stains CD1a and S-100. Clinical history and follow-up information were obtained from review of medical charts.

Results

Our search revealed 32 cases of pure genital LCH. Our institutional archives provided three additional LCH cases, two vulvar and one cervical. Although therapy and outcomes reported in the literature are variable, our three patients, treated with hysterectomy (1) and excision (2) are disease free after 54, 32, and 127 months.

Conclusion

In summary, as well as a comprehensive literature review, we add to the literature three additional cases of female genital LCH. Similar to previously reported cases, LCH confined to the gynecologic tract appears to have a favorable outcome.

CORRELATION OF ISOTOPE COUNT WITH SENTINEL POSITIVITY IN VULVAR CANCER

L. Woelber1, S. Joosse2, D. Grimm1, S. Mathey1, S. Mahner3, E. Burandt4, S. Klutmann5, B. Schmalfeldt1, K. Prieske1

1University Medical Center Hamburg-Eppendorf, Department of Gynecology, Hamburg, Germany
2University Medical Center Hamburg-Eppendorf, Institute of Tumorbiology, Hamburg, Germany
3University of Munich, Department of Gynecology, Hamburg, Germany
4University Medical Center Hamburg-Eppendorf, Institute of Pathology, Hamburg, Germany
5University Medical Center Hamburg-Eppendorf, Department of Nuclear Medicine, Hamburg, Germany

Aims

Sentinel node biopsy (SNB) has become standard of care in vulvar cancer. Often several active nodes are excised per groin, as the correlation of isotope count with the presence of metastases remains unclear. This can result in increased morbidity despite of SNB. The current analysis investigates, whether resection of the hottest node could be sufficient to detect sentinel lymph node (SNL) metastasis.

Method

All patients with primary vulvar cancer receiving a SNB with radioactive tracer at the University Medical Center Hamburg-Eppendorf between 2008 and 2015 were evaluated. The day before surgery, patients received four peritumoral intradermal deposits with an overall mean dosage of 85±12MBq99mTc. Intraoperatively, a handheld gamma counter was used to identify the SNL.

Results

145 patients with 289 groins were analysed. A median of 2 (range 1-7) SNL per groin were removed. From 94/289 (32.5%) groins more than 2 SNL were excised. In 50 groins, a positive SNL was detected. The median number of positive SNL per groin was 1 (range 1-4). The SNL with the highest isotope count carried metastases in 36/46 groins (78.3%; in 4 cases highest count unknown). In 10/46 (21.7%) positive groins, the SNL with the highest count was not the metastatic SNL. Median count of these 12 SNL was 60% of the highest count with a range from 11.0% to 74.0%.

Conclusion

The highest isotope count does not reliably detect the positive SNL in vulvar cancer. To prevent groin recurrence, all SNL accumulating relevant radioactive tracer over 10% background activity should be removed.

MAMMARY LIKE GLAND ADENOCARCINOMA OF THE VULVA: A CASE REPORT
I. Yalcin, E. Sari, H. Sahin, B. Ozdal, M.M. Meydanli, T. Gungor
1Zekai Tahir Burak Women Health Care Education and Research Hospital, Gynecologic Oncology, ANKARA, Turkey

Aims

To present a case of vulvar carcinoma originating from mammary-like tissue.

Method

A 50-year old woman admitted to the outpatient clinic with the complaint of painless vulvar mass ongoing for two months. Physical examination revealed a 3×4 cm solid mass in the right hemivulva primarily located on labium minus.

Results

A punch biopsy was taken. The Immunohistochemical staining was positive for p63, CAM5.2, GCDFP15 and EMA and negative for Kromogranin and CEA. Pathologist could not reveal a definitive result and 10 days after first biopsy a wide local excision was performed. Final pathologic diagnosis revealed a mammary like gland adenocarcinoma with positive surgical margin (2.5×2×2 cm). Before a radical vulvectomy and bilateral inguinal lymphadenectomy, the patient underwent a CT scan (chest, abdomen and pelvis), mammography and a bone scintigraphy. The results showed no evidence of metastatic disease. Breast examination was unremarkable. After complementation surgery histopathological study showed that there were no residual disease and lymph node metastasis. Adjuvant treatment with cyclophosphamid and doxorubicin was planned and the patient was discharged with an uneventful postoperative course.

Conclusion

Adenocarcinoma derived from so-called mammary- like glands of the vulva are rare and represent a distinct clinicopathologic entity that must be distinguished from metastatic tumors.

INFLUENCE OF SEALING DEVICE IN THE COMPLICATION RATE AFTER AN INGUINOFEMORAL LYMPHADENECTOMY: ILSEDE PILOT STUDY

I. Zapardiel¹, I. Beamonte¹, J. Siegrist¹, M.D. Diestro¹, B. Diaz¹, A. Hernandez¹

¹La Paz University Hospital, Gynecologic Oncology, Madrid, Spain

Aims

Despite the great change and development of the surgical techniques to treat the vulvar cancer, complications following surgery are still a major issue mainly in the inguinofemoral area. Our objective was to evaluate the impact of the use of a sealing device during inguinofemoral lymphadenectomy on the reduction of postoperative complications including wound infection, wound breakdown, lymphocysts formation and lymphedema.

Method

A single institution retrospective pilot study was carried out. 15 patients with vulvar cancer underwent vulvar cancer excision and inguinal lymphadenectomy between February 2015 and December 2016. 5 of the patients underwent lymphadenectomy with a bipolar sealing device while the remaining 10 patients received the standard procedure. Postoperative complications including wound infection, seroma and lymphedema were selected as primary outcome, through which both groups were compared to each other using chi-squared and t-student tests.

Results

No differences between groups were observed regarding the baseline characteristics. Patients who underwent surgery using a sealing device showed fewer wound infection rate compare to the standard technique using monopolar energy, 0% vs 70% respectively (p=0.026). Incidence of seroma and lymphedema did not show statistically significant differences between groups.

Conclusion

In our study we found that the use of a sealing device in inguinofemoral lymphadenectomy could reduce the rate of wound infection comparing to the standard procedure. It suggests that it also may reduce the rate of seroma and lymphedema formation. A bigger study is needed in order to confirm our hypothesis and develop the most optimal procedure to reduce morbidity after inguinofemoral lymphadenectomy.

PROLIFERATION IN POSTMENOPAUSAL ENDOMETRIAL POLYPS: A POTENTIAL FOR MALIGNANT TRANSFORMATION
L. Adomaitiene1, R.J. Nadasauskiene1, M. Nickho-Amiry2, A. Cizauskas3, J. Palubinskaie4, C. Holland2, M.W. Seif2
1Hospital of Lithuanian University of Health Science, Obstetrics and Gynecology, Kaunas, Lithuania
2University of Manchester And St. Mary's Hospital, Obstetrics and Gynecology, Manchester, United Kingdom
3Hospital of Lithuanian University of Health Science, Pathology, Kaunas, Lithuania
4Hospital of Lithuanian University of Health Science, Histology and Embryology, Kaunas, Lithuania

Aims
Endometrial polyps in asymptomatic postmenopausal women are often incidentally found, yet only 1.51% are malignant. Their potential for malignant transformation has not been adequately addressed. We investigated proliferation in endometrial polyps as an indicator of their oncogenic potential in those women.

Method
Immunohistochemical studies of Ki67, using monoclonal antibodies MIB-1, were performed. Cases included 52 benign postmenopausal polyps, 19 endometrioid carcinoma with coexisting benign polyps, 12 polyps with foci of carcinoma and 4 cases of polyps which later developed carcinoma. Control included 31 atrophic endometria and 32 benign premenopausal polyps. Ki-67 was scored in 10/20 random fields, as percentage of positively-stained cells. Statistical analysis was carried out using Mann-Whitney U-test for differences between means, with significance at P < 0.05.

Results
The median Ki-67 score in postmenopausal benign polyps (2.25%) was significantly higher than in atrophic endometrium (0.90%, P<0.0001), significantly lower than in premenopausal benign polyps (6.75%, P<0.001) and endometrial cancer (4.60%, P<0.0001). Where endometrial polyps were found in association with endometrium cancer, Ki-67 was significantly higher in cancer (P<0.0001). No significant difference was found where endometrial carcinoma (2.45%) was focally detected in polyps (1.75%, P=0.37). Ki-67 expression, where polyps were resected and women later developed cancer, was not significantly different (P=0.199).

Conclusion
Polyps from asymptomatic postmenopausal women showed significantly more proliferation in both epithelial and stromal components than inactive atrophic endometrium but less than premenopausal benign polyps and/or endometrial cancer. The implication on clinical practice will be discussed.
PREDICTION OF THE OUTCOME AFTER EXCISION OF CERVICAL PRECANCER BY THE RESECTION MARGINS OR BY POST-TREATMENT HPV TESTING: A SYSTEMATIC REVIEW AND META-ANALYSIS

10Medical University of Graz, Department of Gynaecology and Obstetrics, Graz, Austria
11University of Leicester, Department of Cancer Studies, Leicester, United Kingdom

Aims

To predict failure after surgical treatment of cervical precancer

Method

We extended previous systematic reviews that assessed separately the risk of treatment failure associated with the margin status of the cervical excisions and the accuracy of post-treatment high-risk (hr) HPV testing to predict residual/recurrent cervical precancer. Information on positive resection margins and subsequent treatment failure was pooled using procedures for meta-analysis of binomial data. The meta-analysis comparing the accuracy of the margin status with post-treatment hrHPV testing was restricted to studies with i) an average follow-up of at least 18 months post-treatment and ii) treated disease and treatment outcome were histologically confirmed cervical intra-epithelial neoplasia of grade two or worse (CIN2+).

Results

The average rate of positive margins was 23% (CI=20-26%) and varied by treatment procedure and severity of the treated lesion. The overall risk of residual/recurrent CIN2+ was 7% (CI=5-8%). Treatment failure was 5 (CI=3.2-7.2) times greater with positive compared to negative resection margins. The risk of treatment failure was highest when the endo-cervical margin was positive.

The pooled sensitivity and specificity to predict residual/recurrent CIN2+ was 56% and 84%, respectively, for the margin status, and 91% and 84%, respectively, for hrHPV testing. The margin status was 41% less sensitive but not more specific than hrHPV. A negative hrHPV test post-treatment was associated with a risk of CIN2+ of 0.8%, whereas this risk was 3.7% when margins were free.

Conclusion

The risk of residual/recurrent CIN2+ is significantly greater with involved margins on excisional treatment. However, hrHPV post-treatment predicts treatment failure more accurately.

PREVALENCE OF ANAL HUMAN PAPILLOMAVIRUS (HPV) INWOVEN WITH CERVICAL OR VULVAR HIGH GRADE INTRAEPITHELIAL NEOPLASIA (PREVACO STUDY)

M. Baazeem1, N. Djimadoum1, V. Samouelian1
1University of Montreal, Gynecology Oncology, Montreal, Canada

Aims

The prevalence of anal cancer is increasing steadily especially in women. There is a paucity of data on the prevalence of anal HPV in women with high grade intraepithelial lesion (HSIL) of the anogenital tract. Our study aimed to estimate the prevalence of anal HPV infection among women with cervical and/or vulvar HSIL.

Method

Anal and cervical or vulvar swabs were collected from immunocompetent women referred to the colposcopy clinic for cervical or vulvar HSIL. All pathological HSIL specimens were reviewed. Patients without a confirmed histological diagnosis of HSIL were excluded. Swab samples were processed and tested for the presence of 36 HPV genotypes with the Linear array assay.

Results

Of the 208 women recruited in the study, 166 had confirmation of anogenital HSIL. Among the 135 patients with paired anal and cervical/vulvar valid HPV results, concurrent HPV infection was observed in 70.6% of women with cervical HSIL and 56.7% of those with vulvar HSIL (p=0.11). Among women with HPV infection on the cervix (N = 61) or the vulva (N = 49), the rate of anal infection was respectively 78.7% (48 of 61) and 77.6% (38 of 49). Oncogenic HPV types 16, 31, 51, 52, 58 and 59 were the most prevalent considering results on all samples.

Conclusion

This study provides evidence for a high prevalence of anal HPV in women with cervical or vulvar HSIL. Further studies are needed to better identify high-risk groups and develop strategies for early detection of anal HSIL and cancer in women with anogenital HSIL.

BORDERLINE OVATION TUMOR STAGING BY LAPAROSCOPIC SINGLE PORT

J. Bakenga1
1Clinique du Fief de Grimault, Gynecologic oncology, POITIERS, France

Aims

Feasability of single port staging of an ovarian borderline tumor

Method

We have selected ten consecutive cases of borderline ovarian tumor staging by conventional laparoscopy with a Gelpoint surgical technic is describe with some tips and tricks and a step by step technic
we describe à step by step technic
single port abdominal complete exploration
ovarian cystectomy or oophorectomy technic
abdominal wall biopsy and infra colic omentectomy by single port
we share pur experience of ergonomic tips and tricks

Results

All those ten cases had been done with succes
the operation duration is correct
because of a single scar
single day surgery is possible

Conclusion

borderline ovarian tumor staging by conventional laparoscopic single port is feasible without losing an amount of time
operative recovery is short
a single day surgery is possible
Aims

Inflammation plays an important role in cancer onset and progression; monocyte-to-lymphocyte ratio (LMR) is one of the most studied inflammatory markers. Aim of our study is to evaluate the prognostic role of LMR in ovarian cancer and the significance of other markers as neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR).

Method

Patients with first diagnosis of ovarian cancer admitted to our Institute between 2011 and 2016 were included. Pre-treatment complete blood count data were collected. LMR was defined as the absolute monocyte count divided by the absolute lymphocyte count; NLR was defined as the absolute neutrophil count divided by the absolute lymphocyte count; PLR was defined as the absolute platelet count divided by the absolute lymphocyte count. We correlated inflammatory index with progression free survival (PFS).

Results

94 women were enrolled. Patients with low LMR and high NLR appeared with most widespread disease; among patients treated with primary debulking surgery, 40% had low LMR versus 72% had high LMR (p=0.006), 77% had low NLR versus 54% had high NLR (p=0.023). In the univariate analysis, women with low LMR were associated with worse PFS (7 months versus 18 months, p<0.0001); conversely in patients with high NLR, PFS was 8 months versus 19 months (p=0.014). In the multivariate analysis with adjustments for age, hystotipe, grading, FIGO stage, residual tumor and chemoresponsivity, LMR was confirmed to be an independent predictor of a rich PFS (HR: 0.037, 95% CI, 0.007-0.201, p<0.0001). No correlation was found with PLR.

Conclusion

LMR and NLR could be used to predict treatment strategy and prognosis in ovarian cancer.

COMBINATION OF FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY(PET/CT) AND SENTINEL LYMPH NODE(SLN) DETECTION IN LOW-INTERMEDIATE RISK ENDOMETRIAL CANCER: A PROSPECTIVE STUDY

I. Palaia1, G. Petriglia1, A.R. Besharat1, V. Di Donato1, A. Musella1, L. Muzii1, G. Perniola1, C. Marchetti1, F. Tomao1, L. Vertechy1, P. Benedetti Panici1

1Policlinico Umberto I - Sapienza University of Rome, Department of Obstetrical-Gynecological Sciences and Urological Sciences, Roma, Italy

Aims

This study aimed to define the role of preoperative PET/CT scan evaluation in the management of clinical stage I endometrioid endometrial cancer(EEC) patients submitted to SLN detection.

Method

Fifty-seven patients with EEC who had preoperative PET/CT scan evaluation and underwent SLN mapping were prospectively collected from January 2014 to August 2016. Indocyanine green (ICG) staining was used and injected to the cervix at 3- and 9-o’clock positions (a total of 4 mL of ICG solution in a concentration of 1.25mg/mL). Pelvic lymphadenectomy was performed in all of the patients with positive lymph nodes detected on preoperative PET/CT scan. All patients who did not underwent lymphadenectomy were submitted to CT scan evaluation at 6 months.

Results

Sentinel lymph nodes were detected in 39 (68%) of 57 patients, with a mean of 2.5 SLNs. Three (5%) patients have positive pelvic node findings at PET/CT evaluation. SLN was detected in 2 of these 3 patients and in only 1 case (1.8%) the SLN resulted positive at pathological examination. The remaining 54 patients with negative PET/CT scan evaluation at 6-months follow-up showed no evidence of disease.

Conclusion

The use of preoperative PET/CT scan evaluation in low-intermediate risk EEC patients with not detected SLN may reduce the incidence of unnecessary systematic lymphadenectomy as, in this series of patients, no evidence of disease was detected at 6 months follow-up in patients with a negative PET/CT scan.

APPROACH TO THE OVARIAN CANCER PATIENT AT THE END OF LIFE: THE EOLO STUDY (END-OF-LIFE OVARIAN CANCER)

I. Palaia1, I. Sabatucci1, C. Marchetti1, F. Tomao1, A. Musella1, A. Di Pinto1, S. Boccia1, G. Perniola1, L. Muzii1, V. Di Donato1, P. Benedetti Panici1

1 Policlinico Umberto I - Sapienza University of Rome, Department of Obstetrical-Gynecological Sciences and Urological Sciences, Roma, Italy

Aims

Chemotherapy at the end of life is a complex problem on which oncologists have been questioning. Patients affected by ovarian cancer (OC) often experience a chronicization and slow progression of their disease and, as a result, chemotherapy is proposed until the end of life.

Method

We retrospectively analyzed data from patients affected by OC, treated at our department, and dead in the period between 2007 and 2017, in order to evaluate the frequency of chemotherapy until the last month of life and the chemo-related toxicity and mortality.

Results

A total of 110 OC deaths were analyzed, patients characteristics are presented on Table 1.

Of the 110 patients analyzed, 85 (77%) had undergone chemotherapy over the last three months of life and 38% had chemotherapy even during the last month of life. The chemotherapy was predominantly single-drug with weekly administration, which justifies the low percentage of chemotherapy deaths (6%). The overwhelming majority of patients (81%) needed supportive therapies (infusional, paracentesis, pain therapy and total parenteral nutrition), and long hospitalization became necessary in 20% of cases, mainly for occlusive symptoms. Despite the treatments received, the majority of patients died at home, 19% died in hospital and only 4.5% in hospice.

Conclusion

End-of-life chemotherapy in OC patients is a challenging topic. More studies and multidisciplinary approach are needed to better treat these patients.
NACT+RS is considered by many authors a good alternative to standard chemoradiation for patients affected by LACC. However there is no consensus on indications and type of adjuvant treatment. The aim of our study is to report our results in this setting of patients while proposing criteria for adjuvant treatment.

Method

Between January 2005 and November 2015, LACC patients, with FIGO stage IB2-IIB treated with neoadjuvant platinum-chemotherapy and radical surgery, were included. Adjuvant chemotherapy was proposed in case of positive nodes. Adjuvant radiotherapy was proposed in case of positive margins. Data about the time of relapse, type of retreatment and survival were collected.

Results

Among 10 years, 312 patients were found. 161 patients were excluded because of FIGO stage. A total of 151 patients were analyzed. One-hundred-thirty (92%) patients underwent surgery. Twenty-seven (19%) patients received adjuvant treatment; of these 22 received only chemotherapy and 5 received CT-RT. A total of 33 patients relapsed, 10 (37%) patients in the group of adjuvant treatment, and 23 (20%) in the group without adjuvant therapy. 5 year overall survival rate was 71%, in particular 93.8% for IB2 100% and 79.4% for stage IIA and IIB respectively.

Conclusion

NACT plus surgery in LACC FIGO stage IB2-IIB had comparable survival with RT-CT and the advantage of reducing adjuvant treatment.
IMPORTANCE OF ADVOCACY LECTURES ON WOMEN’S AWARENESS AND ATTITUDE ON CERVICAL CANCER SCREENING AND HPV VACCINATION. A PILOT OBSERVATIONAL STUDY.

J. Billod

Baguio General Hospital and Medical Center, Obstetrics and Gynecology, Baguio City, Philippines

Aims

To assess the knowledge and attitudes of women on cervical cancer screening and vaccination, and impact of lectures to their practices.

Method

Data were collected through a self-administered questionnaire before and after a lecture.

Results

200 women aged 22-59 participated with overall response rate of 70%. 100% of the knew that cervical cancer is the most common gynecologic cancer. 60% are aware that it is caused by HPV and recognizes the risk factors associated with the cancer. Of the 92% who believe that cervical cancer can be prevented by regular pap smear and gynecologic exams, only 39% had their cytology screening. Half of those without prior Pap smear is undecided for future screening. 73% believe that it can be prevented by HPV vaccination, with only 15% had their vaccination. Reasons for not receiving the vaccine are: lack of information about the vaccine, financial reasons, worried of side effects, and no motivation. Post-lecture, almost all participants improved their knowledge on risk factors, signs and symptoms, the importance of screening and vaccination. However, the same percentage still is undecided obtaining screening.

Conclusion

Knowledge on cervical cancer is fair but a major gap is depicted on preventive measures, actual acceptance of screening and vaccination. Advocacy lectures increase awareness on the disease but may not expand their acceptance to screening and vaccination. An intense effort by the health sector, public and private is needed to address women’s’ hesitancy on screening and vaccination by regular and direct health promotions and encourages accessible, affordable and affordable screening and vaccination.

A COST-EFFECTIVENESS ANALYSIS OF LAPAROTOMY, LAPAROSCOPIC AND ROBOTIC SURGERY IN ENDOMETRIAL CANCER

W. Bintiwihok¹, T. Manchana¹
¹Chulalongkorn University, Department of Obstetrics and Gynecology, Bangkok, Thailand

Aims

To compare the cost-effectiveness of laparotomy, laparoscopic and robotic surgery in Thai endometrial cancer patients.

Method

An economic analysis was conducted to compare total costs of three surgical approaches and health outcomes from both health care provider and patient perspective. Costing data were collected from clinical practice in King Chulalongkorn Memorial Hospital, Bangkok, Thailand. Health outcomes were quantified in terms of complication-free rate, derived from published data and quality of life (QOL) assessed by a Thai version of the FACT-G questionnaire at 4 weeks after surgery. Incremental cost-effectiveness ratios (ICERs) were used to compare costs per complication-free patient gained and costs per quality-adjusted life years (QALYs) gained.

Results

Minimal invasive surgery was more costly compared to laparotomy but the utility of laparoscopy was more favorable. The mean utilities of robotic surgery, laparoscopic surgery and laparotomy were 0.90, 0.96, and 0.78, respectively. The incremental cost per QALYs gained ratio (ICER) of laparoscopic surgery compared with laparotomy was 1,444 Thai baht (43.2USD)/QALY in patient expense and 28,488 Thai baht (852.9USD)/QALY in health care medical cost. ICER of robotic surgery compared with laparotomy was 141,033 Thai baht (4,222.5USD)/QALY in patient expense and 268,578 Thai baht (8,041.3USD) /QALY in health care medical cost.

Conclusion

In Thailand, laparoscopic surgery in endometrial cancer was the most favorable and cost-effective surgical approach, whereas robotic surgery was the least cost-effective.

13Addenbrooke’s Hospital, Department of Medical Oncology, Cambridge, United Kingdom
14Mount Vernon Cancer Centre, Department of Medical Oncology, Northwood, United Kingdom
15University College London, Cancer Research UK & UCL Cancer Trials Centre, London, United Kingdom
16The Christie NHS Foundation Trust, Department of Medical Oncology, Manchester, United Kingdom

Aims

To explore the impact of dose-dense chemotherapy on quality of life (QoL) in women with newly-diagnosed ovarian cancer.

Method

ICON8 is a randomised phase III trial of standard vs. weekly dose-dense chemotherapy in newly-diagnosed ovarian cancer. Patients were randomised 1:1:1 either to (1) 3-weekly carboplatin AUC5/6 paclitaxel 175mg/m², (2) 3-weekly carboplatin AUC6 & weekly paclitaxel 80mg/m² or (3) weekly carboplatin AUC2 & weekly paclitaxel 80mg/m². Primary analysis of progression-free survival showed no significant difference between groups. All participated in the QoL substudy and completed EORTC-QLQ-C30 and OV28 questionnaires at enrolment, before each chemotherapy cycle, 6-weekly to 9 months, then 3 monthly to 2 years. Primary QoL endpoint was global QoL at 9 months, secondary endpoints included specific function and symptom scores. Statistical significance was assessed by analysis of covariance adjusted for baseline score.

Results

17,515 QoL questionnaires were completed by 1,540 participants. There was no significant difference in global QoL (p=0.08), fatigue (p=0.42), emotional function (p=0.21) or social function (p=0.83) at 9 months between randomised groups. Significant difference was observed in peripheral neuropathy (p<0.001), with higher mean scores at 9 months in both weekly arms (27.4, 34.2, 31.3 in arms 1,2,3 respectively). Exploratory analysis indicated that this difference continued to 18 months from randomisation.

Conclusion

Self-reported 9-month global QoL, fatigue, emotional and social functioning did not differ significantly between treatment arms. However, long-term peripheral neuropathy was significantly worse in both weekly treatment groups. These findings do not support weekly, dose-dense paclitaxel within the upfront treatment of high risk ovarian cancer.

²Gynecologic Oncology Unit- SS Annunziata Hospital, Department of Obstetrics and Gynecology-, Chieti, Italy
³Oriental Piedmont University- Maggiore Hospital Novara- Italy, Department of Obstetrics and Gynecology, Novara, Italy
⁴Polo Scienze della Salute della Donna e del Bambino- Università Cattolica del Sacro Cuore, Fondazione Policlinico Universitario A. Gemelli-, Roma, Italy

Aims

The impact on survival of lymphadenectomy in endometrial cancer is still debate. We aimed to evaluate the survival outcomes of two different strategy in apparent confined endometrial cancer patients by comparing sentinel lymph node (SLN) mapping and selective lymphadenectomy (LD).

Method

We retrospectively reviewed women with preoperative stage I endometrial cancer underwent surgical staging with either SLN mapping, or LD in two Italian centers.

Results

Eight hundred and two women underwent surgical staging for preoperative stage I endometrial cancer were revised (145 Monza; 657 Rome). All patients underwent peritoneal washing, simple hysterectomy with bilateral salpingo-oophorectomy and nodal staging including SLN mapping, or LD. Overall 8229 lymph nodes were removed (1595 in Monza, 6634 in Rome). Pelvic lymphadenectomy was performed in 33.1% and 52.4% in Monza and Rome, respectively (p < 0.001). Patients with positive pelvic LN were 16.7% and 7.3%, in SLN and LD groups, respectively (p=0.002). Disease-free survival (DFS) curves showed a not significant difference between centers and strategies adopted (SLN mapping, LD, SLN+LD) 0.87 (95% CI 0.63-2.16; p=0.475).

Conclusion

Survival outcomes were similar for both strategies. The SLN strategy allowed to identify a higher rate of stage IIIC1 disease even with a lower median number of lymph node removed in SLN group. Applying a SLN algorithm does not impair the prognosis of endometrial cancer patients. The clinical impact and management of low volume metastasis in high-risk patients should be further clarify.

PARAORTIC LYMPHADENECTOMY IN PATIENTS WITH STAGE IB1 CERVICAL CANCER UNDERGOING RADICAL HYSTERECTOMY.
J. Burbano1, P. Rene2, F. Angelica3, A. Adriana4, T. Lin4, H. Liliana4
1Instituto Nacional de Cancerologia, Gynaecology Oncology, Bogota, Colombia
2Instituto Nacional de Cancerologia, Gynaecology Oncology, Bogota, Colombia
3Centro de Investigaciones Oncologicas Clinica San Diego, Gynaecology Oncology, Bogota, Colombia
4Hospital Simon Bolivar, Gynaecology Oncology, Bogota, Colombia

Aims

To determine the rate of paraaortic nodal involvement in patients undergoing radical hysterectomy and pelvic and paraaortic (inframesenteric) lymph node dissection in patients with stage IB1 cervical cancer.

Method

A retrospective review of all stage IB1 cervical cancer patients who underwent radical hysterectomy and lymphadenectomy at the Instituto Nacional de Cancerología in Bogotá, Colombia, between January 2009 and March 2017.

Results

A total of 94 patients met inclusion criteria. Median age was 44 (range; 26-68) The histology was squamous, adenocarcinoma, or adenosquamous carcinoma in 56 (59.6%), 29 (30.9%), and 9 (9.6%) patients, respectively. The median surgical time was 209 min (range; 95-395). The median blood loss was 400 ml (range; 20-4000). The median number of resected pelvic and paraaortic nodes were 23 (range,5-68), and 4 (range,1-25), respectively. Pelvic lymph node involvement was present in 11 (11.7%) patients. No patient had paraaortic lymph node involvement. After a median follow-up of 20.3 months (range 0.3-95), 10 patients have relapsed, 4 of them with pelvic nodal involvement;4 patients relapsed exclusively in vaginal cuff, and 1 relapsed in vaginal cuff and bone(poliostotic disease), 2 lung relapses, 2 peritoneal relapses, and 1 recurrence in the paraaortic area(At initial surgery, 18 pelvic nodes were retrieved, 2 of them positive, and 2 paraaortic negative nodes).

Conclusion

The rate of paraaortic lymph node involvement in patients with stage IB1 cervical cancer undergoing radical hysterectomy was 0%. The decision about performing paraaortic lymph node dissection in early stage cervical cancer should be individualized.

SELECTIVE UTERINE ARTERY EMBOLIZATION IN LOCALLY ADVANCED CERVICAL CANCER PATIENTS WITH VAGINAL HEMORRHAGE

J. BURBANO1, A. Almeciga1, B. Julian2, E. Jorge3, T. Lina1, P. Rene1

1Instituto Nacional de Cancerología, Gynaecologic Oncologic, BOGOTA, Colombia
2Instituto Nacional de Cancerología, Radiology, Bogota, Colombia
3Magdalena University- Magdalena- Colombia, Epidemiology, Barranquilla, Colombia

Aims

Objective: To evaluate outcomes of selective uterine artery embolization in patients with severe bleeding and locally advanced cervical cancer.

Method

Methods: A retrospective review of the medical records of all patients that underwent selective uterine artery embolization, with cervical cancer diagnosis, at Instituto Nacional de Cancerología in Bogotá, Colombia, between July 2009 and July 2017. Briefly, the procedure starts with a percutaneous access through right femoral artery, with contrast material, an assessment of pelvic vascularization is carried out; according to findings, a selective uterine artery catheterization with Cobra or Simmons catheter (5F), embolization was done with PVA or 300-500 micras under fluoroscopic visualization. Once bilateral vascular exclusion is demonstrated the procedure finishes. We built a database in Excel 2014 and statistical analysis was performed using the program STATA10.

Results

Results: A total of 52 patients were included. Median age was 45 years (range; 38-49). All the patients presented vaginal bleeding, and all of them, received blood transfusions, due to secondary anemia. The pre-transfusion median haemoglobin level was 7.12 gms/dl (range; 2.3-11.5). All the patients underwent a bilateral selective uterine artery embolization at interventional radiology service. Eight patients (15%) required a second embolization, due to bleeding persistence, after that, all the patients stopped to bleed. There were no complications or deaths associated to procedure.

Conclusion

Conclusion: Selective uterine artery embolization is an useful alternative in locally advanced cervical cancer patients with life threatening bleeding.

THE FIRST YEAR EXPERIENCE OF LAPAROSCOPY RADICAL HYSTERECTOMY AND PELVIC LYMPHADENECTOMY IN FATMAWATI HOSPITALS, JAKARTA

F.V.D. Candran1, S. Purba2

1Fatmawati General Hospital, Obstetric and Gynecology, Jakarta, Indonesia
2Cipto Mangunkusumo Central General Hospital, Obstetric and Gynecology, Jakarta, Indonesia

Aims

Minimally invasive techniques was introduced worldwide as early stage cervical cancer management since 1990s, but it was still considered as a new advance surgical technique in Indonesia. We described our first year experience of total laparoscopic radical hysterectomy and pelvic lymphadenectomy in Fatmawati Hospital, Jakarta.

Method

We enrolled the data of all patients with cervical cancer stage IB1-2A2 from Fatmawati Hospital (tertiary teaching hospital) who underwent laparoscopic radical hysterectomy and pelvic lymphadenectomy from August 2016 to August 2017.

Results

Eighteen patients were 12 squamous cell carcinoma and 6 adenocarcinoma. The mean of the biggest tumor diameter was 4 cm (1-7 cm). Seventeen patients were underwent full staging surgery, one patient had abandoned radical hysterectomy, only left lymphadenectomy was performed due to upstaging. The overall conversion rate was 0%. Four patients were stage IB1, 3 patients were stage IB2, 6 patients were stage IIA1, and 4 patients were stage IIA2. The operation median length were 408.5 (240-540 minutes), the mean hospital length of stay was 5 days. The mean estimate blood loss was 351cc (50-1000) cc. There were 2 bladder injuries, 1 rectal injury, 1 ureteral injury, and 1 stump vaginal dehiscence.

Conclusion

Beyond 1 year experience, laparoscopic radical hysterectomy and pelvic lymphadenectomy is acceptable in standard treatment of early stage of cervical cancer. An extended learning period can be required to achieve the turning point.

SURGICAL COMPLICATIONS AND THE DIFFICULTIES BEYOND THE LEARNING CURVE OF FIRST YEAR LAPAROSCOPY RADICAL HYSTERECTOMY AND PELVIC LYMPHADENECTOMY IN FATMAWATI HOSPITAL

F.V.D. Candran1, S. Purbad1
1Fatmawati General Hospital, Obstetric and Gynecology, Jakarta, Indonesia
2Cipto Mangunkusumo Central General Hospital, Obstetric and Gynecology, Jakarta, Indonesia

Aims

First year of experience was the most challenging period for a young laparoscopist. Total laparoscopic Radical Hysterectomy with Pelvic Lymphadenectomy (TLRH-PL) was introduced worldwide as early stage cervical cancer management since 1990s, but it was still considered as a new advance surgical technique in Indonesia. We describe the implementation of TLRH-PL in Indonesia, based on the complication of radical hysterectomy and pelvic lymphadenectomy in first year experience.

Method

A descriptive study was done in Fatmawati Hospital, a tertiary teaching hospital affiliated by University of Indonesia. Seventeen women with early stage cervical cancer (IB1 – IIA2, FIGO classification) who underwent TLRH-PL from August 2016 – August 2017 were enrolled for the study.

Results

Squamous cell carcinoma was found in 11 (64.7%) patients whereas adenocarcinoma (35.3%) was found with the rest. Cervical FIGO staging range from IB1(27.2%), IB2 (17.65%), IIA1(35.3%), and IIA2(23.5%). We describe five major surgical complications whom occurred in five patients, with an overall complication rate was (29.4%). There were two bladder injuries, one rectal injury, one ureteral injury and one post operative stump vaginal dehiscence. Those injuries were tackled laparoscopically and stump vaginal dehiscence was repaired vaginally.

Conclusion

Laparoscopic radical hysterectomy in was favorable for early stage cervical cancer although in our first year experience was still related with high rate complication. An extended learning period can be required for laparoscopic radical hysterectomy and pelvic lymphadenectomy to achieve the turning point.
FACTORS INFLUENCING THE ADOPTION OF THE SENTINEL LYMPH NODE TECHNIQUE FOR ENDOMETRIAL CANCER STAGING: AN INTERNATIONAL SURVEY AMONG GYNECOLOGIC ONCOLOGISTS

J. Casarin^1, F. Multinu^1, N. Abu-Rustum^2, D. Cibula^3, W. Cilbi^4, F. Ghezzi^4, M. Leitao^2, I. Konishi^5, J.H. Nam^6, D. Querleu^7, P.T. Soliman^8, K. Yost^1, A. Weaver^1, A. Mariani^1, G. Glaser^1

^7Institut Claudius Regaud- Center for the Fight Against Cancer, Surgery, Toulouse, France
^8MD Anderson Cancer, Gynecologic Oncology, Huston - Texas, USA

Aims

To explore the factors influencing adoption of the sentinel lymph node technique (SLN) for endometrial cancer (EC) staging among gynecologic oncologists.

Method

A self-administered web-based survey was sent via email (04/20/2017-05/21/2017) to all ESGO, IGCS and SGO members. Surgical and pathological practices related to SLN were investigated. Reasons for not adopting SLN were explored.

Results

Among 610 anonymous responders, results for the 489(80.2%) attending physician/consultants in gynecologic oncology are reported: 226(46.2%), 124(25.4%) and 139(28.4%) from ESGO, IGCS and SGO, respectively. Gynecologic oncologists from 69 different countries participated: 201(41.1%) from Europe, 118(24.1%) from the USA, and 117(29.9%) from other countries (10.8% country not reported). SLN is adopted by 246(50.3%) responders, with 93.1% injecting the cervix and 62.6% using Indocyanine green (ICG) dye. The NCCN SLN algorithm is followed by 160(65.0%) responders (USA:74.4%, Europe:55.4%, other countries:71.4%). However, 66.7% complete lymphadenectomy in high-risk patients. When SLN reveals isolated tumor cells (ITC), 13.8% of responders recommend adjuvant therapy. This increases to 52% if micrometastases are detected. Among the 243 not adopting SLN, the majority (126, 51.9%) perform a selective pelvic +/- para-aortic lymphadenectomy based on tumor risk factors; 50.2% cite lack of evidence and 45.3% state that
inadequate instrumentation fuel their decisions. Details reported in Table 1.

**Table 1.** Results from the survey on SLN adoption among gynecologic oncologists members of the ESGO (European Society of Gynecologic Oncology), IGCS (International Gynecologic Cancer Society, and SGO (Society of Gynecologic Oncology).

**LEGEND:**
1. Multiple answers were allowed.
2. Selective lymphadenectomy + procedure performed only if presence of tumor risk factors for lymph node metastasis.
3. Overall, 53 responders (10.8%) did not report their geographical region.

**Conclusion**

SLN mapping with a cervical injection is gaining widespread acceptance for staging of EC among gynecologic oncologists worldwide. Standardization of the surgical approach with the NCCN algorithm is applied by the majority of users. Management of ITC and the role of backup lymphadenectomy for “high-risk” cases remain areas of investigation.

7Chung Shan Medical University, School of Nursing, Taichung City, Taiwan R.O.C.
8Quemoy University, Department of Computer Science and Information Engineering, Kinmen County, Taiwan R.O.C.

Aims

In this retrospective study, we aimed to investigate the risk factors of developing SPC after breast cancer (BC) and to improve surveillance after treatment might lead to earlier detection.

Method

Eight hundred and seventy-nine patients with SPC after BC were obtained from five tumor registry centers (2000-2014). Twenty predictor variables were identified by three clinical physicians. In addition, five machine learning approaches of WEKA (Waikato Environment for Knowledge Analysis) to develop the predictive schemes for the important risk factors of new primary cancers after BC.

Results

The average age at initial and secondary cancer diagnosis was 54 years old (range 18-94) and 58.3 years old (range 35-83). The median time between initial and SPC diagnoses was 5.8 months (range 0-57.1). The overall incidence of SPC was 7.62%. The most frequent types of cancer at secondary diagnosis were gynecologic cancer (37 patients; 55.22%), contralateral breast cancer (22 patients; 32.84%), digestive cancer (8 patients; 11.94%). Experimental results illustrated that the average accuracy of RandomSubSpace (99.74%) is a superior approach. The other methods were: RandomTree (99.74%), RandomizableFilteredClassifier (99.27%), IBk (98.87%) and Kstar (98.40%).

Conclusion

Our findings suggest that Age, Tumor Size, RT surgery and Histology were the four most critical risk factors. Some specific relationships were observed between first and secondary cancer with risk factors in common, such as hormone status, tobacco use and drinking. In summary, the above information can support the important influence of personal and clinical symptom representations on all phases of guide interventions with BC in all phases of SPC trajectory.

THE ROLE OF CD 44 IN OVARIAN CANCER
I. Conic1, S. Stojnev2, L. Jankovic Velickovic2, B. Djordjevic2, I. Djordjevic2, A. Ristic-Petrovic2, D. Krtinic1, M. Krstic2
1Clinical center Nis, Clinic of oncology, Nis, Serbia
2Institute of Pathology, Faculty of Medicine- University of Nis, Nis, Serbia

Aims

The aim of this study is to examine the expression of CD44 in ovarian cancer, its correlation with clinical and pathological factors, and to evaluate the impact of expression of CD44 expression in tumor samples concerning disease prognosis, treatment and survival rate of patients.

Method

Tumor samples of 270 patients with ovarian carcinoma (ovarian cancer in FIGO stage I, FIGO stage II, FIGO stage III and FIGO stage IV), treated at the Clinic for Oncology Clinical Center Nis during the period from 2005 to 2011, were analyzed immunohistochemically for expression of CD44. Testing of the correlation with clinical and pathological parameters was done in the statistical data processing program SPSS 20.0.

Results

In patients with the expression of CD44 up to 10%, metastases were significantly present (p <0.05). In FIGO stage I, in most cases, high expression of CD44 (p <0.05) was recorded, whereas low expression of CD 44 (p <0.05) was recorded in FIGO stage IV. Mean survival was significantly longer in patients with the expression of CD 44 over 10%. (p <0.01). The death rate was significantly higher in patients with lower expression of CD 44 (p <0.05)

Conclusion

CD 44 could be used as a prognostic marker for ovarian cancer. The unfavorable clinical course of the ovaries was associated with the absence or low expression of CD 44.

NEW BIOMARKERS IN THE DIAGNOSIS OF OVARIAN PATHOLOGY
A. Coosemans¹, T. Baert¹, C. Landolfo², P. Busschaert⁵, A. Vanderstichele¹, D. Timmerman¹, I. Vergote¹
¹University Hospitals Leuven, Gynaecology and Obstetrics, Leuven, Belgium
²KU Leuven, Department of Development and Regeneration, Leuven, Belgium
³KU Leuven, Department of Oncology, Leuven, Belgium

Aims

This project on new diagnostic biomarkers focusses on three pillars: proteins, cfDNA (cellfree DNA resulting from apoptotic tumor cells) and immune profiles.

Method

Serum, plasma and peripheral blood mononuclear cells (PBMC) were collected of 269 women. In 157 of them (68 benign cysts, 13 borderline tumors, 43 invasive ovarian cancers, 33 healthy controls) an immune profile analyses based on the presence of CD4, CD8, MDSC (myeloid derived suppressor cells) and Treg (regulatory T cells) was performed. In 39 invasive ovarian cancer patients, immune profile was monitored during disease progression.

Results

Most striking were the differences in monocytic MDSC (mMDSC), as their presence increased with growing malignancy potential (benign vs borderline vs invasive) (Fig 1). This graded difference remained (p=0.006), but rendered the invasive cancers more pronounced as a separate group, if mMDSC were PDL1 positive. The presence of these cells resulted in poor overall survival (Fig 2) and their increase after neoadjuvant platin-based chemotherapy (NACT) and interval debulking surgery (IDS) resulted in an increased chance of relapse.
Conclusion

Immune profiling in blood for ovarian pathologies holds much promise. For the first time in literature, a clear involvement of mMDSC in ovarian cancer is shown. This finding might have important clinical consequences in the selection of patients and the timing of immunotherapy.
THE INFLUENCE OF ITGBL1 PROTEIN ON OVARIAN CANCER CELLS PROLIFERATION AND CHEMORESISTANCE

A.J. Cortez1, K.A. Kujawa1, P.A. Tudrej1, K.M. Lisowska1

1Maria Sklodowska-Curie Institute - Oncology Center- Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland

Aims

In our previous microarray study we analyzed gene expression profile of 72 high grade serous ovarian cancers (HG-SOC) [1]. We identified two molecular subgroups of HG-SOC with distinct gene expression profiles and survival [2]. Among differentially expressed genes was an Integrin beta-like1 gene (ITGBL1). ITGBL1 is a poorly characterized protein, structurally cognate with integrin β. Our aim was to study whether and how ITGBL1 can influence the phenotype of ovarian cancer cells.

Method

ITGBL1 coding sequence was PCR-amplified from cDNA and cloned into pLNCX2 vector. Retroviral system was used to obtain two ovarian cancer cell lines: OAW42/ITGBL1(+) and SKOV3/ITGBL1(+) with overexpression of ITGBL1. Control cell lines were obtained by transduction with empty vector. Proliferation and cytotoxicity were analyzed using MTS and crystal violet assay.

Results

We compared proliferation of control OAW42 and SKOV3 cells with isogenic cell lines containing ITGBL1 construct. The results indicate that ITGBL1 overexpression has no effect on proliferation of ovarian cancer cells. We also evaluated an influence of ITGBL1 protein on ovarian cancer cells sensitivity to cisplatin and paclitaxel, and both cell lines overexpressing ITGBL1 were significantly more resistant to cisplatin and to paclitaxel, as compared to the control lines.

Conclusion

Our results indicate that although ITGBL1 has no effect on ovarian cancer cells proliferation rate, it may however increase their resistance to cisplatin and paclitaxel. These results are in line with our previous observation that patients with HG-SOC showing higher ITGBL1 mRNA expression have significantly shorter OS [2].

Acknowledgments: Polish National Science Center grant 2012/04/M/NZ2/00133 to K.M.L.
We observed an increased tendency to treat cancer during pregnancy, which can lead to more obstetrical and neonatal complications. We recommend the referral of pregnant cancer patients who need chemotherapeutic treatment to centres with obstetrical high care units.
ENHANCED RECOVERY AFTER SURGERY (ERAS) STRATEGY IN MAJOR GYNECOLOGIC SURGERY – OUR EXPERIENCE AND COMPARISON WITH CLASSIC PERIOPERATIVE PROTOCOL

M. Pakšć, A. Dovnik, S. Dobnik
1University Clinical Centre Maribor, Department of Gynecologic Oncology and Oncology of Breasts, Maribor, Slovenia

Aims

ERAS is a multimodal strategy to reduce perioperative stress response allowing enhanced postoperative recovery and includes no extensive bowel preparation, early feeding, multimodal analgesia with avoidance of opioid analgesia, early mobilisation, no drainage use, active management of nausea and vomiting.

Method

Prospective data of all consecutive patients who underwent major surgery for pelvic organ tumors in the Department of gynecologic and breast oncology, Maribor, Slovenia, over a 6-month period (41), were collected and compared with a historical consecutive cohort of patients, treated in 6-month period in 2005 (40), before implementation of ERAS.

Results

There were no differences regarding diagnosis and intraoperative complications. The results are shown in Table 1.

Table 1: Comparison of postoperative period between patients undergone ERAS and those having classic perioperative protocols.

Conclusion

Patients undergoing ERAS had reduced length of hospital stay, less postoperative blood transfusion rate, antibiotic use, complication rate, shorter intravenous and opioid analgesia. ERAS is not only safe, it was shown to be superior to classic perioperative approach and should be implemented in every day clinical practise for major gynaecologic surgery.
PATIENTS’ AND PHYSICIANS’ EXPECTATIONS DIFFER SIGNIFICANTLY DURING THE FOLLOW UP PERIOD AFTER GYNECOLOGIC OR BREAST CANCER TREATMENT

M. Pakiz1

1University Clinical Centre Maribor, Department of Gynecologic Oncology and Oncology of Breasts, Maribor, Slovenia

Aims

The follow up period after completion of primary treatment for gynecologic or breast malignancy might be long. We explored and compared the patients' and physicians' expectations and preferences during the follow up period.

Method

This prospective study included 122 patients after gynecological or breast cancer treatment at the Department of Gynecological and Breast Oncology, Maribor, Slovenia, and 72 primary level gynecologists/general practitioners in our region. A questionnaire was used to compare the expectations/preferences of patients and physicians regarding the center and location of follow-up, the prognosis revealed, attitudes towards examinations, and sense of safety and stress.

Results

Patients consider it more important to be followed-up at the center of treatment, closest to their home, and to be exactly informed about the prognosis. Unlike their physicians, patients consider the sense of safety and stress caused by regular visits as more important, and many of them would rather visit the physician when symptoms occur as opposed to on a regular basis.

Conclusion

Given the lack of evidence-based improvement of survival with regular follow-up, in accordance with our results, individualization of scheduling follow-up visits with the lowest acceptable frequency and intermediate nurse consultations might be associated with meeting patients’ expectations without compromising survival outcomes.

DISSEMINATED PERITONEAL LEIOMYOMATOSIS AND METASTATIC GIST : A MANAGEMENT DILEMMA REGARDING MULTIPLE NODULAR SEROSAL LESIONS

A. El-Agwany¹, M. Meleis²
¹Faculty of Medicine - Alexandria University, Obstetrics and Gynecology, Alexandria, Egypt

Aims

We aim to discuss cases with GIST and LPD regarding their diagnosis and surgical management with pitfalls related. We also aim to focus on management of multiple nodular serosal lesions.

Method

A 60 years old woman was suspected with advanced ovarian cancer on CT and ultrasound imaging by multiple nodular peritoneal lesions and adnexal masses. Another case was 55 years old, diagnosed with multiple fibroid uterus on ultrasound and a huge subserous one. Tumor markers were normal in both cases. Both were scheduled for exploratory laparotomy.

Results

Midline laparotomy was done for the first case where total hysterectomy with bilateral salpingo-oophorectomy and resection anastomosis for the small intestine with removal of macroscopic lesions were done. Midline line laparotomy was done for the second case where total hysterectomy with bilateral salpingo-oophorectomy and omentectomy with resection anastomosis of the small intestine and removal of macroscopic lesions seen were done. By intraoperative findings and histopathological evaluation, the first case was diagnosed as Disseminated Peritoneal Leiomyomatosis. The other case was diagnosed with multiple uterine fibroid and metastatic GIST in patient with neurofibromatosis type I.

Conclusion

Disseminated Peritoneal Leiomyomatosis and metastatic GIST can be similar on imaging and operative findings. Also, they are similar to peritoneal carcinomatosis. These pathologies should be kept on mind when encountering multiple solid nodular masses in the visceral and parietal wall peritoneum on imaging and intraoperatively. Surgical and postoperative management differ according to the pathology. These pathologies should be confirmed by histopathology and immunohistochemistry.

INTRAPERITONEAL CHEMOTHERAPY USING PORT-A-CATH : A WAY FOR PREVENTION OF LOCAL RECURRENCE IN ADVANCED EPITHELIAL OVARIAN CANCER

A. El-Agwany1, M. Meleis1
1Faculty of Medicine - Alexandria University, Obstetrics and Gynecology, Alexandria, Egypt

Aims

We aim to evaluate intraperitoneal chemotherapy using Port-A-Cath for prevention of local recurrence in advanced ovarian cancer.

Method

From July 2015 to December 2015, fifty patients with stage III epithelial ovarian cancer who had optimal surgical cytoreduction underwent Port-A-Cath insertion during laparotomy for intraperitoneal chemotherapy administration using Cisplatin and IV taxol for six cycles. Follow-up was done over one and half year.

Results

Patient age was about 50-70 years. Forty five patients (90%) received 3-4 cycles only due to intolerable GIT troubles. Three cases dropped out on follow-up and two cases didn’t continue therapy due to port related complications. HIPEC was done in two cases only. Five patients out of 47 cases (10%) had port related complications as back flow of fluid around the port site that occurred in two cases where one case was transient and the tube was removed due to malfunctioning in the other one. Infection at port site occurred in one case that was transient and peritoneal treatment was continued. Catheter displacement occurred in two cases that was transient in one case and was removed in the other case. Forty one patients (91.1%) out of 45 cases were disease free on follow up. Local recurrence occurred in 4 cases (8.8%).

Conclusion

Intraperitoneal chemotherapy in optimally cytoreduced stage III epithelial ovarian cancer is associated with high success with low recurrence. It is recommended to be adjuvant with HIPEC. It is associated with low complications.
VALUE AND BEST WAY FOR DETECTION OF SENTINEL LYMPH NODE IN ENDOMETRIAL CANCER: A SURGICAL ALGORITHM FOR LYMPHADENECTOMY

A. El-Agwany1, M. Meleis1

1Faculty of Medicine - Alexandria University, Obstetrics and Gynecology, Alexandria, Egypt

Aims

We aim to evaluate the value and techniques for SLN mapping in early stage endometrial cancers and whether selective or systematic lymphadenectomy is needed.

Method

Between June 2016 and December 2016, 120 patients underwent surgical staging for early stage endometrial cancer. Patients were classified equally according to SLN mapping technique used. Group A included hysteroscopic guided intra-lesional methylene blue injection, Group B included transcervical injection, Group C included uterine subserosal injection and Group D included combined transcervical and subserosal injection. Blue nodes and enlarged ones were removed and frozen section was done then pelvic and lower para-aortic node dissection was done and sent for pathological examination. We evaluated the role of SLN according to relation of metastatic disease in blue and large nodes in relation to other ones.

Results

SLN count with metastatic disease was more with hysteroscopic technique than combined one. Large nodes with metastatic disease were lower than SLN.

Conclusion

SLN in endometrial cancer has no role due to multiple lymphatic drainage except if direct intra-lesion dye injection. Best technique is hysteroscopic guided injection. We recommended the following algorithm for lymphadenectomy. Systemic bilateral pelvic and lower para-aortic lymphadenectomy if no blue or large metastatic nodes. If positive blue or large nodes, same side lymphadenectomy is needed. If blue or large nodes are negative for metastasis, there is no role. This approach can help patients avoid the side effects associated with a complete lymphadenectomy.

BRCA MUTATIONAL STATUS TO PERSONALIZE MANAGEMENT OF RECURRENT OVARIAN CANCER: A MULTICENTRE STUDY.

C. Marchetti1, A. Musella1, R. De Leo2, M. Dindinosante2, E. Capoluongo2, G. Scambia2, P. Benedetti Panici1, A. Fagotti2

1 Sapienza University of Rome, Department of Gynecological and Obstetrical Sciences and Urological Sciences, Rome, Italy
2 Catholic University of the Sacred Heart, Department of Obstetrics and Gynecology - Division of Gynecologic Oncology, Rome, Italy

Aims

To assess the correlation between BRCA mutational status and disease presentation at recurrence, treatment strategy, and post-recurrence survival in a large multicentre series of high grade serous ovarian cancer (HGSOC) patients.

Method

A consecutive series of 126 recurrent HGSOC patients, with full or partially platinum sensitive disease, tested for BRCA 1/2 germline mutational status. Women received surgery or chemotherapy according to disease spread and patient general health condition.

Results

Seventy-eight (62%) wild-type BRCA (BRCAwt), and 48 (38%) BRCA 1 or 2 mutation carriers (BRCAm) were analysed. Rates of partially and fully platinum-sensitive patients were superimposable between groups. Involvement of multiple anatomic sites and distribution of peritoneal carcinomatosis were also similar. Secondary cytoreductive surgery (SCS) was successfully completed in a larger group of BRCAm (67%) patients compared to BRCAwt (49%, p=0.06). With a median follow-up of 28 months, non-mutated patients showed a shorter median PRS, compared to BRCA carriers (60 months vs not reached; p= 0.01; Fig. 1), with 5-years PRS of 41% and 89%, respectively. In the subgroup of patients who received complete SCS, 5-years PRS was significantly longer in BRCAm compared with BRCAwt (92% vs 43%, p= 0.03). At multivariate analysis, BRCA germ-line mutational status was the only independent prognostic factor for duration of PRS after primary recurrence (p= 0.059).

Conclusion

BRCA mutational status is useful to find out an effective tailored treatment for recurrent HGSOC patients.
A RARE CASE OF MALIGNANT PERIPHERAL NERVE SHEATH TUMOR OF THE VAGINA

M. Fam², J. Neymeyer¹, J. Sehouli¹, J. Barinoff¹
¹Charité Universitätsmedizin Berlin Campus Benjamin Franklin, Gynaecology, Berlin, Germany
²Charité Universitätsmedizin Berlin Campus Benjamin Franklin, Urology, Berlin, Germany

Aims

Malignant peripheral nerve sheath tumors (MPNSTs) are sarcomas, which originate from peripheral nerves or from cells associated with the nerve sheath, such as schwann cells, perineural cells, or fibroblasts. The incidence is 1 / 1 million people per year; the most common localizations are extremities, trunk, head and neck. MPNST arising from female external genitalia is extremely rare. There is only one published case from 2009 in Saudi Arabia.

Method

A 52-year-old- G0- female admitted to our hospital with complaint of rapidly growing mass located in the anterior vaginal wall. Our Patient had 1999 an early cervical cancer. She was treated by radical hysterectomy with R0 resection. Neither postoperative radiation nor chemotherapy had been performed.

Results

A biopsy of the mass showed MPNST of the vagina. The patient underwent removing of the mass as en bloc resection with clitoris and distal 2/3 of the urethra. There were no distal metastases. The Tumor was 2 cm and was classified as grade 2. After an additional resection, R0 status has been achieved. Immunohistochemistry: strong expression for S100, no expression of desmin und SMA. Proliferation rate (Ki 67) was 40%.

Conclusion

Due to rarity of the condition, there is no consensus about optimal treatment of MPNST. Currently the first step of treatment is surgical resection of the tumor with adequate clear margins. It is strongly recommended, that the cases of MPNST should be registered for appropriate data bank. Our patient is recruited for REGSA (German registry for gynecological sarcoma by Charité ).

FUSION ULTRASOUND IN GYNECOLOGICAL MALIGNANCIES: A REAL-TIME VIRTUAL NAVIGATION IN PET/CT 3D VOLUMES FOR LYMPH NODE EVALUATION

G. Garganese1, S.M. Fragomeni1, S. Bove1, M.T. Evangelista1, F.P. Ieria2, A. Giordano2, A.C. Testa1, G. Scambia1

1Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome, Italy
2Università Cattolica del Sacro Cuore, Nuclear Medicine, Rome, Italy

Aims

The fusion virtual navigation (FVN) is an advanced technology of the “precision oncology” that customize the diagnostic process by merging multimedia images from different standard methods. This pilot study evaluated the efficacy of the FVN to identify sonographically the 18F FDG-PET/CT suspicious lymph nodes in women with gynecological malignancies.

Method

From March to June 2017, 21 lymph nodal sites (13 inguinal, 5 pelvic and 3 axillary) were studied from 14 consecutive patients with vulvar (8), breast (3), uterine (2) and ovarian cancer (1) with PET/CT positive or suspicious and ultrasound uncertain lymph nodes. All exams were performed using the Virtual Navigator System software (by Esaote S.P.A., Genova). PET/CT scans were uploaded in DICOM format to the ecograph. A co-registration completed the synchronization, using the following landmark: 1) pubic symphysis (groin and pelvic lymph nodes) and 2) sternum xyphoid process (axillary nodes). PET/CT target lymph nodes were virtually marked and automatically reported during US navigation.

Results

The co-registration was successfully achieved for all the study sites and the FVN guide allowed to identify target lymph nodes in ultrasound. In 16 patients a FNA was performed under FVN guide: 5 negative were addressed to follow up; 11 positive underwent further treatment (3 surgical and 8 medical). 5 patients were directly addressed to surgery, after placement of a tissue marker clip under FVN guide to recognize the target nodes by intraoperative x-ray (3 negative and 2 positive).

Conclusion

FVN is a feasible complementary tool for target therapy, potentially avoiding unnecessary diagnostic surgeries and systemic treatments.
HEALTH-RELATED QUALITY OF LIFE (HRQOL) AND PATIENT-CENTRED OUTCOMES WITH OLAPARIB MAINTENANCE POST-CHEMOTHERAPY IN PATIENTS WITH GERMLINE BRCA-MUTATED PLATINUM-SENSITIVE RELAPSED SEROUS OVARIAN CANCER (PSR SOC)

18National Cancer Center Hospital, Department of Breast and Medical Oncology, Tokyo, Japan
19Université Paris Descartes- AP-HP, Medical Oncology Department, Paris, France

Aims

In the Phase III, randomized, double-blind, SOLO2 trial (ENGOT Ov-21; NCT01874353), maintenance olaparib after response to chemotherapy led to significant improvement in progression-free survival (PFS) versus placebo in patients with germline BRCA-mutated PSR SOC (hazard ratio 0.30, 95% CI 0.22, 0.41; P<0.0001; median 19.1 vs 5.5 months; 63% data maturity). Our a priori hypothesis was that maintenance olaparib would not impact HRQOL compared with placebo and would be associated with additional patient-centred benefits to support PFS prolongation (SOLO2 primary endpoint).

Method

HRQOL was evaluated by the Functional Assessment of Cancer Therapy-Ovarian Trial Outcome Index (FACT-O TOI) in all 295 patients. The primary HRQOL analysis was change from baseline in FACT-O TOI score during the first 12 months (mixed model repeated measures). Secondary planned analyses included duration of ‘good quality of life’ by time without symptoms of disease or toxicity (TWiST) and quality-adjusted PFS (QAPFS; a single measure of PFS and QoL outcomes).

Results

Olaparib had no significant detrimental effect versus placebo on HRQOL analysed by change from baseline in FACT-O TOI score (–3.1–2.9, respectively, difference [olaparib–placebo] –0.2; 95% CI –2.4, 2.1; P=0.88). TWIST (15.0/7.7 months, difference 7.3; 95% CI 4.7, 9.0; P<0.001) and QAPFS (mean 14.0/7.3 months, difference 6.7; 95% CI 5.0, 8.5; P<0.0001) significantly improved for olaparib patients.

Conclusion

Maintenance olaparib did not detrimentally impact HRQOL versus placebo. The significant improvement in PFS with olaparib was associated with additional patient-centred benefits, including a longer duration without symptoms of disease or treatment toxicity and longer QAPFS.

8AstraZeneca, Oncology Global Medicines Development, Macclesfield, United Kingdom
9University College London, Department of Oncology- UCL Cancer Institute, London, United Kingdom

Aims

Olaparib (Lynparza), an oral PARP inhibitor, significantly improved progression-free survival versus placebo in patients with PSR SOC in a randomized, double-blind, Phase II study (Study 19, NCT00753545), with the greatest benefit in patients with BRCA1/2 mutations (BRCAm). Interim overall survival (OS) analysis also suggested an advantage for olaparib-treated patients (database cut-off: 30 September 2015). We report the final analysis of long-term olaparib benefit in patients enrolled in Study 19.

Method

Patients who had received ≥2 prior regimens of platinum-based chemotherapy and were in response received olaparib (400 mg bid; capsules) or placebo until disease progression. Retrospective germline or tumour testing resulted in a known BRCAm status for 254/265 patients (96%).

Results

At final database cut-off (9 May 2016), median OS follow-up was 78.0 months. A long-term treatment benefit was shown; see Table for the final hazard ratios (HRs) for OS versus placebo (unadjusted for crossover: 13% full-analysis set [FAS] placebo patients; 23% BRCAm subgroup placebo patients). Details of BRCA wild-type (BRCAwt) patients on treatment for ≥6 years will be presented. No new safety signals or changes in the olaparib tolerability profile were seen.

Conclusion

Conclusions: This final analysis showed that olaparib provides clinically significant, long-term treatment benefit in patients with PSR SOC. A durable benefit was seen in ≥10% of BRCAm and BRCAwt patients, who continued to receive and benefit from olaparib for ≥6
years – unprecedented in the relapsed ovarian cancer setting. Olaparib was well tolerated in this population and the analysis suggested an olaparib benefit on OS in BRCAm patients.
PREDICTING RISK OF OVARIAN MALIGNANCY IMPROVED SCREENING AND EARLY DETECTION FEASIBILITY STUDY (PROMISE-FS)

Aims

To evaluate feasibility of undertaking a study to stratify a general population on the basis of their predicted ovarian cancer (OC) risk and offer risk management options of screening and prevention.

Method

Design: Multi-centre, prospective, pilot, cohort study (ISRCTN54246466).

Inclusion-criteria: Women ≥18 years.

Exclusion-criteria: Women with history of ovarian/tubal/primary peritoneal cancer or previous genetic testing for OC genes.

Recruitment: Through GP surgeries/primary care. Interested women will be directed to an online ‘Decision Aid’ and telephone help line. Consent will be obtained via telephone. Consenting individuals will provide a blood sample and complete questionnaires at baseline/post-recruitment/7 days/3 months/6 months post results.

Primary outcome: Acceptability and uptake.

Secondary outcomes: Use of helpline; satisfaction/regret; follow-up completion rate; risk perception; cancer worry; psychological health; quality of life (QoL); usefulness of decision aid; stratification of OC-risk category; uptake of risk management options.

Panel genetic testing looking for mutations in BRCA1/BRCA2/RAD51C/RAD51D/BRIP1/OC-SNPs will be performed. Genetic and epidemiological data will be used in a validated risk-algorithm to predict an individual’s lifetime OC-risk. Validated questionnaires will collect data on psychological health, QoL, satisfaction/regret; decision aid and helpline use. Intermediate-risk (≥5%<10% lifetime OC-risk) and high-risk (≥10% lifetime OC-risk) women will be offered options of OC screening (biomarker and USS) and prevention. Mutation carriers/increased risk women will be seen in a high-risk gynaecological cancer clinic and by clinical genetics.

Results

Study is currently in recruitment phase.

Conclusion

PROMISE-FS will help guide future research and planning of a larger study on population based testing and risk stratification for OC prevention.

ESGO7-1417

THROMBOCYTOSIS AS A PROGNOSTIC MARKER IN PATIENTS WITH OVARIAN CARCINOMA

A. Ganovska1, S. Kovachev1
1Military Medical Academy, Department of gynecology, Sofia, Bulgaria

Aims

The aim of our study was to determine the dependence of preoperative thrombocytosis and clinical stage in patients with ovarian carcinoma as well as the dependence on the serum level of CA 125.

Method

The study is one-central, retrospective for one year (2016-2017). Thirty two patients aged 35 to 81 years with histological (intraoperative and postoperative) ovarian carcinoma were included. All patients were subjected to total hysterectomy with ovaries and uterine tubes, omentectomy and pelvic and paraaortic lymph node dissection. Immediately prior to surgical intervention, laboratory tests were performed by platelet counts and CA 125.

Results

The mean age of patients was 58.43 years (35 to 81 years). In 27 patients, platelet counts were in baseline and platelet count was 5 (15.62%). All patients with thrombocytosis have a disseminated tumor process (III and IV stage according to FIGO). The distribution is as follows: III Stage - 3 (9.38%); IV Stage - 2 (6.25%). In 24 (75%) patients, elevations of tumor marker CA 125 were found, and in 8 (25%) it was in reference values. All patients with thrombocytosis have elevated tumor markers.

Conclusion

The presence of thrombocytosis in ovarian malignancies is associated with an advanced tumor process, a low degree of differentiation and extremely poor prognosis with respect to the treatment effect. The number of platelets prior to surgery may be a prognostic factor.
USEFULNESS OF THE SENTINEL LYMPH NODE BIOPSY IN PATIENTS WITH ENDOMETRIAL CANCER

T. Gómez Rodríguez1, S. Sanz Viedma2, L.F. González García1, F.M. Ana María1, C.M. Luis Miguel1, O.P. Jose Luis1, E.L. Irene1, E.M. Agustin Jose1, R. Omar1, S.D.C. Gonzalo1, O.J. Maria Victoria1, E.R. Maria Pilar4, D.L.T.B. Marina1, S.U. Irene1, R.P. Raquel1

1Hospital Universitario Virgen de la Victoria, Oncoginecología, Málaga, Spain
2Hospital Universitario Virgen de la Victoria, Medicina Nuclear, Málaga, Spain
3Hospital Universitario Virgen de la Victoria, Anatomía Patológica, Málaga, Spain
4Hospital Universitario Virgen de la Victoria, Ginecología, Málaga, Spain

Aims

Analyze if sentinel lymph node biopsy could be considered as an efficient lymphatic assessment technique in cases of low and medium-risk endometrial cancer, reflecting the true status of the lymph region.

Method

35 patients with preoperative diagnosis of endometrial carcinoma type 1 were included. Day before surgery 99mTc-nanocolloid was injected in cervix and a SPECT/CT lymphoscintigraphy were carried out. Blue dye was injected at same location intraoperatively. A gamma probe was used to identify SNs. An intraoperative biopsy of SNs was performed. A complete pelvic lymphadenectomy was performed in all cases. Lymphadenectomies were analyzed by conventional techniques (H&E) while SNs were analyzed by ultrasection and immunohistochemistry techniques (ultrastaging).

Results

SN detection rate was 74.3%. False negative rate was 0%. Negative predictive value were 100%. There were no surgical complications resulting from sentinel node sampling. 88.9% of lymphadenectomies performed in low and medium-risk cases were negative.

Definitively, 22% of the patients presented a higher staging than the one supposed according to MRI and biopsy data. A discordance of 20% was recorded for biopsy and 58% for MRI.

The overall incidence of metastasis was 17.1%. By groups, was 13.3% at low risk, 8.3% at medium risk and 37.5% at high risk.

Ultrasataging techniques in SN increased 50% the detection of lymph node metastases.

Conclusion

SLN procedure is a safe and feasible method. It seems to increase the diagnostic accuracy of lymphatic status. Larger series are needed to obtain conclusions, however, the results being published allow us to be optimistic in this line of research.

FLABRA, FRONTLINE APPROACH FOR BRCA TESTING IN OVARIAN CANCER (OC) TREATMENT NAÏVE POPULATION. A LATIN AMERICA (LA) EPIDEMIOLOGIC STUDY

1AstraZeneca Argentina, Medical Department, Buenos Aires, Argentina
2Instituto Alexander Fleming, Oncology, Buenos Aires, Argentina
3Instituto do Cancer do Estado de Sao Paulo, Clinical Oncology, Sao Paulo, Brazil
4Instituto Nacional de Cancerología, Oncology, Ciudad de Mexico, Mexico
5CORI, Oncology, La Rioja, Argentina
6Oncomédica - IlMAT, Oncology, Montería, Colombia
7Hospital Nacional Alberto Sabogal, Oncology, Callao, Peru
8CEMIC, Oncology, Buenos Aires, Argentina
9Hospital Alemán, Oncology, Buenos Aires, Argentina
10Instituto Nacional de Cancerología, Oncology, Bogotá, Colombia
11Clínica Vida, Oncology, Medellin, Colombia
12Fundación Investigar, Clinical Research, Buenos Aires, Argentina
13Instituto Oncologico Nacional, Oncology, Panama City, Panama
14Hemato Oncólogos Cali, Oncology, Cali, Colombia

Aims

Majority of OC cases are sporadic, but in approximately 17% germline mutations in BRCA1 or BRCA2 genes can be identified. While in breast cancer, several clinical factors can raise suspicion for an inherited susceptibility, this is not the case for OC. BRCA mutated OC has distinct clinical characteristics, increased sensibility to platinum and non-platinum drugs, and to DNA repair targeting agents like PARP inhibitors. Additionally, somatic BRCA mutations (BRCAm) could be identified in additional 6% patients. In many areas of the world, prevalence of germline BRCAm nor of additional somatic BRCAm has been well characterized. LA population is a paradigm of poly-ethnicity, with a mixture of Native, Spanish, Italian, Portuguese and Jewish ancestries.

Method

Archived tumor blocks will be used for BRCA testing in 480 patients diagnosed with OC within the last 120 days. After having provided consent, demographics, ethnicity and cancer family history, as well as data relevant to OC diagnosis, counseling approach, and treatment plan will be collected. Blood samples will also be analyzed in positive patients to determine if the mutation is from germline or somatic origin.

Results

We present the results of somatic and germline BRCAm prevalence from first 10% of the sample.

Conclusion

FLABRA is a multi-center, study designed to determine the prevalence of germline and somatic BRCAm in newly diagnosed OC patients, and to describe current counselling and treatment approach at front line with a new approach of starting BRCA testing in tumor, expanding the benefits of new therapeutic options and possible outcomes to more patients.
PROGNOSTIC VALUE OF DYNAMIC EVALUATION OF HE 4 IN PATIENTS WITH CA 125-NEGATIVE OVARIAN CANCER

O. Gotko¹, V. Prokhorova¹, L. Derzhavets², A. Pletnev³, L. Zaitseva¹

¹N.N. Alexandrov National Cancer Center of Belarus, Diagnostic department with radiodiagnosis group, Minsk, Belarus
²N.N. Alexandrov National Cancer Center of Belarus, Clinical diagnostic laboratory, Minsk, Belarus
³N.N. Alexandrov National Cancer Center of Belarus, Laboratory of oncogynecology, Minsk, Belarus

Aims

The aim of the work was to estimate the prognostic value of the HE4 marker in ovarian cancer patients with normal CA125 values after the 3rd cycle of chemotherapy.

Method

53 patients with I-IV stage ovarian cancer, who underwent primary cytoreductive surgery and 6 cycles of standard combination of platinum and taxane chemotherapy, were included in study groups. HE4 concentrations were measured before the start of treatment and each cycle and at the end of chemotherapy. The selection criterion for the study was CA125 <35 U/ml after 3 cycles of chemotherapy. In group 1 (n=24), values of HE4 after 3 cycles of chemotherapy were within the normal range, in group 2 (n=29) they exceeded the normal values. The follow-up period was 3 years. In 26 of 53 patients, tumor progression was diagnosed, 27 had remission.

Results

A statistically significant decrease in HE4 concentration was revealed (p<0.001). In group 1, one-year progression-free survival (PFS) was 100%; the three-year PFS was 80.8%. 39.6% of patients in group 2 progressed during the first year of follow-up, the three-year PFS was 29.4%. Statistically significant differences in one- and three-year PFS between the study groups (p=0.001 and p<0.001, respectively) were revealed, which allows to speak of an unfavorable prognosis in patients with normal CA125 and elevated HE4 after 3 cycles of chemotherapy.

Conclusion

Dynamic evaluation of the HE4 level might serve as a prognostic factor in patients with normal CA125 values after 3 cycles of chemotherapy.

ANALYSIS OF ASSOCIATION OF OVERALL SURVIVAL IN STAGE III-IV OVARIAN CANCER WITH THE COMPLETENESS OF CYTOREDUCTIVE SURGERY

O. Gotko¹, A. Pletnev², V. Prokhorova¹, L. Derzhavets², L. Zaitseva¹
¹NN Alexandrov National Cancer Center, Diagnostic department with group of radiodiagnosis, Minsk, Belarus
²NN Alexandrov National Cancer Center, Laboratory of oncogynecology, Minsk, Belarus
³NN Alexandrov National Cancer Center, Clinical diagnostic laboratory, Minsk, Belarus

Aims

The aim of the study was to analyze the relationship between the completeness of cytoreductive surgery and one-, three- and five-year overall survival (OS), and determine its prognostic significance in patients with stage III-IV ovarian cancer.

Method

119 patients with advanced ovarian cancer were included in this study: 102 patients with stage III and 17 patients with stage IV disease. Complete cytoreduction was achieved in group 1 (n = 50), optimal – in group 2 (n = 51) and suboptimal / non-optimal – in group 3 (n = 18).

Results

Analysis of the relationship between the completeness of cytoreduction and one-, three- and five-year OS in patients with stage III-IV ovarian cancer showed that one-year OS was 100% in group 1 and 2, an 92.9% in group 3. The three-year OS was 93.0% in group 1, 60.2% in group 2, and 66.1% in group 3. The five-year OS in the study groups was 60.7%, 47.4% and 36.7%, respectively. Statistically significant differences in the three- and five-year OS were revealed between groups 1 and 2 ($P_{log-rank} = 0.004$ and $P_{log-rank} < 0.038$, respectively) and between groups 1 and 3 ($P_{log-rank} = 0.043$ and $P_{log-rank} < 0.028$, respectively). Analysis of the one-year OS with regard to the completeness of cytoreduction in patients with stage III-IV ovarian cancer revealed no significant differences between the study groups.

Conclusion

This study revealed that completeness of cytoreductive surgery was crucial for OS and prognosis in patients with stage III-IV ovarian cancer.

DIFFERENCES IN ENDOMETRIAL CANCER MOLECULAR PORTRAITS BASED ON ETHNICITY IN THE CANCER GENOME ATLAS

D. Guttery1, K. Blighe1, K. Polymeros1, P. Symonds2, S. Masic3, E. Moss1

1University of Leicester, Leicester Research Centre, Leicester, United Kingdom
2University of Leicester, Department of Gynaecological Oncology, Leicester, United Kingdom
3University of Leicester, Department of Molecular and Cell Biology, Leicester, United Kingdom

Aims

It is clear that racial/ethnic differences in endometrial cancer (EC) incidence, age at presentation and survival exist; however, it is unclear whether this disparity is driven by inherent genetic alterations in the primary tumour.

Method

We investigated the molecular features of EC using data in the TCGA, including somatic mutations, gene expression, DNA methylation and copy-number aberrations (CNAs) and contrasted them between BoAA, Caucasian and Asian women.

Results

There were 503 patients with EC, including 374 Caucasian, 109 Black or African American (BoAA), and 20 Asian patients. Asian women were more likely to be diagnosed at younger age ($P = 0.011$), whereas BoAAs were more likely to have serous type tumors ($P = 0.008$) and higher BMI ($P = 0.0008$). No difference in overall or disease-free survival was evident. Mutation and somatic copy number alteration (SCNA) analysis revealed an enrichment of $TP53$ mutations in BoAAs; whereas $POLE$ and $RPL22$ mutations were more frequent in Caucasians. We also found Asian women to harbour more than double the number of mutations per tumour. Major recurrent SCNA racial differences were observed at chr1q, chr8, chr10, and chr16, which distinguished BoAA tumours into 4 groups and Caucasian tumours into 5. Finally, we observed a significantly higher frequency of mutations in DNA mismatch repair genes associated with Lynch syndrome in Asians.

Conclusion

We have highlighted clinically-relevant molecular differences that intrinsically characterise EC racial disparities, potentially forming the basis for molecular targeted therapies, and also explaining why Asians are frequently diagnosed at an earlier age, potentiating future screening studies.

CLINICAL EFFICACY ANALYSIS OF PREOPERATIVE NEOADJUVANT CHEMOTHERAPY WITH HIGH DOSE DENSE PACLITAXEL PLUS CISPLATIN IN STAGES IB2, IIA2, IIB CERVICAL CANCER IN IRAN

F. hashemi1, A.S. mousavi2
1Tehran University of Medical Sciences, imam khomeini hospital-valieasr hospital, tehran, Iran

Aims

The study was done to analyze the efficacy of the NACT with high dose-dense paclitaxel and cisplatin before radical surgery on cure rate, survival rate, and the progression of free survival rate of bulky tumor of cervical cancer in Stages IB2, IId A2, and IIB.

Method

Fifty-two patients with cervical cancer in Stages Ib2, IIA2, and IIB were selected, and responding patients to chemotherapy were scheduled to undergo radical hysterectomy and bilateral pelvic lymphadenectomy with or without para-aortic lymphadenectomy.

Results

Fifty out of 52 patients with a median age of 50 years were evaluable for clinical response. Thirty-two patients (64%) responded to the NACT including six (12%) with a complete clinical response. There was no statistical relationship between clinical response, tumor stage and size, and parametrical involvement, however, patients with higher grade of tumor, adenocarcinoma or tumor in upper 2/3 of vagina showed a higher probability of no response to chemotherapy. Downstaging after NACT in all stages was statistically significant regarding pathologic findings and clinical response (p = 0.002). Five-year survival was 88% and factors affecting survival and disease-free survival were pathological response and tumor site based on cox-regression analysis. Overall recurrence rate was 20% and tumor size was the only significant relevant factor for recurrence (p = 0.017).

Conclusion

Combined regimen of chemotherapy in locally advanced cervical cancer proved to be valuable and efficacious without any late complications.

COMPARATIVE MiRNA MICROARRAY PROFILING INDICATES MiR-363 PROMOTES CHEMoresistance IN OVARian CANCER CELLS BY TARGETING THE HIPPO MEMBER, LATS2

M. Hassan1, Z. Mohamed2, S. Okasha3, H. Watari4, S. EL-Khamisy5
1Zewail City for Science and Technology, Center for Genomics, Port Said, Egypt
2Aswan Inive., Zoology Dept., Aswan, Egypt
3Aswan Unive., Zoology Dept., Aswan, Egypt
4Hokkaido Unive.- Graduate School of Medicine, Gynecology Dept., Sappor, Japan
5Zewail City for Science and Technology, Center for Genomics, Giza, Egypt

Aims

To study the comparative microRNA profiling between the ovarian cancer cells, KF, and their taxane-resistant counterpart, KF-TX to get novel markers for ovarian cancer taxane-resistance.

Method

Microarray profiling was performed in KF and KF-TX cells. Quantitative-PCR was used to evaluate expression of miR-363 and LATS2 in ovarian cancer cells and tumor tissues. Plasmid-based expression was used to overexpress miR-363. MiR-363 inhibitor and siRNA transfection followed by viability were used to validate the relationship between miR-363 and LATS2. Viability assay, clonogenic assay and western analysis were used to validate the differential response of different clones to TX. Dual luciferase assay was used to validate that miR-363 targets LATS2

Results

qRT-PCR indicated that miR-363 was upregulated in KF-TX cells, while introducing miR-363 into sensitive ovarian cancer cells confers TX-resistance in the responsive cells. MiR-363 inhibitor restored the response to TX. In addition, miR-363 was found to bind to the 3′-UTR of LATS2 mRNA, confirming direct targeting to LATS2. RT-PCR-based evaluation of miR-363 in of human ovarian tumours revealed its upregulation in most of the tumour tissues identified as resistant, while downregulation of the same gene the tissues identified as sensitive ones. Moreover, higher levels of miR-363 in human ovarian cancer specimens were significantly correlated with TX chemoresistance and poor prognosis.

Conclusion

Our study concludes that miR-363 is associated with TX-resistance. Targeting miR-363 may sensitize chemoresistant ovarian cancer to taxane.
BRUSH CYTOLOGY OF THE FALLOPIAN TUBE FIMBRIA AND ITS CORRELATION WITH THE HISTOLOGY OF HIGH GRADE SEROUS CARCINOMA IN FALLOPIAN TUBE

J. Hausnerova1, V. Weinberger2, L. Zlamalikova1, J. Presl3, P. Ovesna4, M. Bednarikova5, R. Slunecko6, E. Jandakova1, M. Chalova1, L. Minar2, M. Felsinger2, M. Anton2

4Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic
5University Hospital Brno, Department of Hematology and Oncology, Brno, Czech Republic
6University Hospital in Pilsen, Department of Pathology, Pizen, Czech Republic

Aims

Recent studies show that a significant percentage of high grade serous carcinoma (HGSC) arises in the fimbria of the fallopian tube (FT). Stage of the disease is a crucial prognostic factor and there is still no reliable tool for early detection available. The aim of this study is to evaluate cellularity, cytomorphology and immunocytochemistry of brush cytology from FT with respect to histologically proved tubal HGSC.

Method

Prospectively, consecutively cells were sampled via cytobrush from the fimbria of surgically removed FT. Cellularity (inadequate/low/moderate/high), cytomorphology (anisonucleosis, small or large nucleolus, hyperchromasia, mesothelial-like sheets and three dimensional clusters of cells) were evaluated in liquid based cytology samples. Immunocytochemistry using p53, Ki67 antibodies were evaluated. Final results were classified as benign, suspicious and malignant. FTs were sampled with the SEE-FIM protocol. Local ethical committee approved study and informed consent was signed by all patients.

Results

We examined 135 FTs from 90 patients. Sufficient cellularity was presented in 98.5% of samples. Tubal HGSC was histologically diagnosed in 13 patients. Cytology was evaluated in nine samples as malignant, in two as suspicious, in one as benign and one was non-diagnostic. Atypical p53 expression was established in 9 samples and high Ki67 index in 8 samples among 11 malignant or suspicious cytology cases.

Conclusion

Study demonstrates excellent cellularity of FT cytology as well as very good correlation between cytomorphology and immunocytochemistry with histology of HGSC in FT. Our findings support further research of FT brush cytology in early detection of HGSC using for instance hysteroscopy.

MASPIN EXPRESSION IN CERVICAL DYSPLASIA AND CERVICAL CANCER, AND ITS RELATION WITH SURVIVAL OF THE DISEASE

E. İsci Boztan1, I. Guler2, O. Erdem3, C. Taskiran4, M.A. Onan1
1Gazi University Faculty of Medicine, Gynecologic Oncology, Ankara, Turkey
2Gazi University Faculty of Medicine, Obstetrics and Gynecology, Ankara, Turkey
3Gazi University Faculty of Medicine, Pathology, Ankara, Turkey
4Koc University School of Medicine, Gynecologic Oncology, Istanbul, Turkey

Aims

Mammary serine protease inhibitor (maspin), acts as a tumor suppressor through the inhibition of cancer cell invasion and metastasis. Paradoxically, maspin levels are increased in some types of malignant cells. This would be related with the specific microenvironment of carcinoma cells and also about the genetic background. The aim of this study was to investigate the maspin expression in cervical dysplasia and cancer, and also to analyse the relation with survival.

Method

Maspin expression was assessed by immunohistochemistry (IHC), and labelled streptavidin biotin method (LSAB) was used to determine cytoplasmic and nuclear maspin expressions, respectively, in 30 cases of cervical intraepithelial neoplasia grade 1 (CIN1), 30 cases of CIN2, 30 cases of CIN3, and 29 cases of cervical cancer.

Results

Maspin expression was detected in only seven patients of all patients with cervical intraepithelial neoplasia (n=90). In patients with cervical cancer, maspin expression was detected in 20 patients. No significant relation was noted between maspin expression and overall survival rates of the patients with cervical cancer (p=0.19). Contrast to this we detected significant correlation with nuclear maspin staining and overall survival (p=0.03, Figure 1).

Conclusion

There are very few studies about maspin and cervical cancer in the literature. This study shows that nuclear maspin expression is related to survival rates in cervical cancer. Further series will clarify the role of maspin expression in cervical cancer.
EVALUATION OF UTILITY OF SOLUBLE MESOTHELIN-RELATED PEPTIDE AND FOLATE RECEPTOR ALPHA IN DIAGNOSIS OF OVARIAN CANCER
Ł. Janas¹, E. Głowacka², K. Zimna¹, K. Szyłło¹, M. Nowak¹
¹Polish Mother's Health Center Research Institute, Department of Operative Gynecology and Oncological Gynecology, Łódź, Poland
²Polish Mother’s Health Center Research Institute, Centre of Medical Laboratory Diagnostics, Łódź, Poland

Aims

Despite well-established position of Human Epididymis Protein 4 (HE4) and Risk of Ovarian Malignancy Algorithm (ROMA) in diagnosis of adnexal tumors, still large effort is made to discover new potential biomarkers of ovarian cancer. The purpose of the study was to evaluate the utility of Soluble Mesothelin-Related Peptide (SMRP) and Folate Receptor Alpha (FRA) in diagnosis of ovarian cancer.

Method

Serum samples were collected from 107 patients qualified for surgery due to pelvic mass (68 pre- and 39 postmenopausal). 33 of them suffered from ovarian cancer, 74 had benign ovarian tumors. Samples were analyzed to determine the levels of SMRP and FRA. Finally, results were compared with histological outcome of tumors, taken during surgery.

Results

The levels of FRA were significantly higher in sera of women suffering from ovarian cancer compared with patients with benign disease, when the groups of all patients (p=0.0003) and postmenopausal patients (p=0.001) were considered. Concentrations of FRA in sera of patients with serous ovarian cancer were significantly higher than in other histopathological types of ovarian cancer. In premenopausal group, FRA levels did not differ between patients with malignant and benign tumors. As far as SMRP is concerned, its concentrations in sera showed no relevant difference between patients with ovarian cancer and benign disease (p=0.1104).

Conclusion

FRA shows elevated levels in sera of patients with ovarian cancer (especially serous type). Therefore, it reveals some potential to become a biomarker of ovarian malignancy. SMRP did not prove its utility in the diagnosis of ovarian cancer.

ESGO7-1497

SENTINEL LYMPH NODE DETECTION IN VULVAR CANCER BY USING MAGNETISATION OF THE IRON OXIDE PARTICLES
G. Jelenek¹, R. Feranec¹, C. Tomáš¹, J. Chovanec¹
¹Masaryk Memorial Cancer Institute, Gynecological Oncology, Brno, Czech Republic

Aims

Aim of this abstract is to show the feasibility of the new sentinel lymph nodes detection system in a vulvar cancer by using magnetic susceptometry, generating a magnetic field which transiently magnetises the iron oxide particles in comparison to the method when radioisotope with gamma probe is used.

Method

We have used two systems, standard lymphatic mapping with radioisotope and also the magnetic susceptometry system in a radical vulvectomy to detect sentinel lymph nodes. During the inguinal lymphadenectomy sentinel lymph nodes were preferably identified with magnetic susceptometry system. The gamma probe was used only at the end of the surgery to verify whether all sentinel lymph nodes had been harvested.

Results

The results by the use of a magnetic susceptometry system in comparison to the standard method with a radioisotope and a gamma probe would most likely be identical. The sentinel lymph node with the highest magnetic value ex vivo was the same node as the one with the highest radioactivity.

Conclusion

The magnetic detection method of the sentinel lymph nodes seems to be feasible and safe. It is necessary to compare the method to standard procedures of sentinel lymph node detection. The magnetic susceptometry system could potentially be used in cases when the nuclear medicine department is not available or when blue dye could not be used.
A case report of primary small cell ovarian carcinoma of pulmonary type

E. Kalampokas¹, V. Sharma², T. Gagliardi³, I. Miller², F. Payne², M. Gurumurthy¹
¹Aberdeen Royal Infirmary, Gynaecologic Oncology, Aberdeen, United Kingdom
²Aberdeen Royal Infirmary, Pathology, Aberdeen, United Kingdom
³Aberdeen Royal Infirmary, Radiology, Radiology, United Kingdom

Aims

Primary small cell ovarian cancer of pulmonary type (SCCOPT), is a highly aggressive tumor with an incidence of less than 1% of all ovarian cancers. A preoperative diagnosis is usually not obtained and is commonly interpreted as an epithelial ovarian cancer at presentation. To date, only 8 cases of “pure” primary SCCOPT have been reported in literature.

Method

We report a case of a 77-year old Caucasian woman who presented initially with a one-week history of abdominal discomfort. Blood tests were normal apart from slightly raised inflammatory markers and Ca125 of 50 u/ml. Calcium levels were normal. The RMI was found to be 450, hence a CT of the chest-abdomen-pelvis was performed and discussed at the MDT meeting (Figure 1). As there was no evidence of disease beyond pelvis, with no lymphadenopathy, upfront surgery was performed in a gynaecologic oncology center. Total abdominal hysterectomy with bilateral salpingo-oophorectomy and omentectomy was performed uneventfully.

Results

Histology showed a tumour comprising areas of classical small-cell carcinoma morphology, showing cells with scant cytoplasm, stippled chromatin and nuclear moulding (Figure 2). However, other areas of the tumour were comprised of spindled cells and epithelioid cells with more abundant cytoplasm. Immunohistochemistry showed that the lesion was positive with the neuroendocrine markers CD56 and PGP 9.5, and showed dot-like positivity with the cytokeratin EMA, including in the spindled and epithelioid components.
Conclusion

There is no clear consensus for management and optimal regime for postoperative chemotherapy. In general, adjuvant chemotherapy with carboplatin and etoposide combination is offered.
IS TOTAL LAPAROSCOPIC HYSTERECTOMY AN ACCEPTABLE OPTION FOR THE TREATMENT OF EARLY STAGE ENDOMETRIAL CANCER?

J. Kaur

1King’s College London, Gynaecology, LONDON, United Kingdom

Aims

To assess the frequency and types of complications experienced by women undergoing TLH. We performed an analysis of complications associated with total laparoscopic hysterectomy (TLH) for early stage endometrial cancer in a cancer unit in the UK.

Method

We conducted a retrospective analysis of women who had undergone surgery for endometrial cancer, specifically looking at those women who had TLH as the primary procedure or conversion from TLH.

We assessed the number of women who had an operative procedure that started as a TLH, we assessed the number of procedures converted to laparotomy and any other complications experienced.

The women were then followed up at eight weeks post operatively and then after one year with a telephone consultation.

Results

Over an eighteen month period, 31 women had their procedure listed as TLH. The average age was 51 years. There were no entry complications at laparoscopy. Five procedures were converted to laparotomy due to adhesions from previous surgery in four cases and haemorrhage in one case.

Post operatively two women complained of umbilical pain that resolved months after their procedures.

28% of women could not be contacted by phone.

Conclusion

A small number of women experienced complications which increased their hospital stay and post operative recovery.

From our study the results suggest, that for the majority of patients, TLH to treat early stage endometrial cancer is indeed an acceptable option.
**Aims**

The objective of this study was to assess the knowledge of Cervical Cancer transmission, prevention and HPV vaccine among mothers of daughters aged below 10 years.

**Method**

A cross sectional descriptive study has been conducted among the mothers of daughters aged below 10 years, live in the Mohakhali ‘Sat Tola’ slum area of Dhaka city. The pre-tested questionnaire was used to collect information from the respondents by face to face interview at house-hold level. Convenient sampling technique was used to select the sample. The sample size was 100 in number. The total questions on knowledge was 22. Knowledge score was divided into 3 category: poor, average and good knowledge.

**Results**

Majority respondents’ age was 21 to 29 years. Respondent’s mean age at marriage was 15 years and mean age was 17 years when their first child born. The respondents’ mean knowledge score was 7.19 out of 22. In total, 55% respondents had poor knowledge, 45% respondents had average knowledge and 2% respondents had good knowledge. Among them 98% respondents heard about cancer, 77% respondents heard about Cervical Cancer, 8% respondents knew about sign and symptom and only 2% respondents knew the causes of Cervical Cancer. Around 18% respondents heard about HPV vaccine but nobody knew in which age this vaccine should be administered.

**Conclusion**

The knowledge of Cervical Cancer transmission, prevention and HPV vaccination among mothers who live in slum of Dhaka city is poor. Providing knowledge to these mothers is essential.

AGE-RELATED SPECIFICITIES OF ENDOMETRIAL PROLIFERATION/STEM CELL INDEX DISTRIBUTION
N. Kikalishvili, R. Beriashvili, T. Muzashvili, G. Burkadze
1Tbilisi State Medical University, Department of Pathology and Cytopathology, Tbilisi, Georgia

Aims

The aim of our study was to explore the age-related specificities of endometrial proliferative/stem cell index distribution under normal and hyperplasia conditions. The detection of the relationship between stem cell distribution specificities and proliferative activity under the age norm and endometrial hyperplasia can become one of the assisting diagnostic criterion in morphology diagnostic algorithm.

Method

The study represents a retrospective research. 2 study groups “Norm” and “Endometrial Hyperplasia” (30 cases) were selected from material data of Acad. N. Kipshidze Central University Clinic. HE technology and immunohistochemistry with proliferation marker ki67 and stem cell marker CD146 was performed. The proliferative/stem cell index was calculated by the ratio of Ki67-positive cell percentage value divided by CD146-positive cell percentage value.

Results

In the study group “Norm” the proliferative/stem cell index ranges within the interval 8-16.5 and in the study group “Endometrial Hyperplasia” within the interval 15-23. Its mean average value in the age distribution subgroups accounts for: 1.1) reproductive age – 10.6; 1.2) menopause – 4.5; 1.3) post-menopause – 1, 2.1) reproductive age – 18; 2.2) menopause – 18.2; 2.3) post-menopause – 18.5.

Conclusion

The proliferative/stem cell index in the study group “Norm” progressively decreases with aging, while in the study group “Endometrial Hyperplasia” it behaves opposite and increases with age. Moreover, the proliferative/stem cell index in endometrial hyperplasia cases with regard to norm increases significantly and most markedly differs from the norm in post-menopause period.

Project was supported by scientific grant PhDF2016_42 for PhD scholarships of Shota Rustaveli National Science Foundation.
ATTITUDE AND INTENTION OF HPV VACCINATION AMONG KOREAN UNIVERSITY STUDENTS

H.W. Kim

Seoul National University, College of nursing, Seoul, Republic of Korea

Aims

This study is aimed to examine the attitude toward the HPV vaccination to prevent cervical cancer and intention to receive the vaccine against HPV in Korean university students.

Method

Convenient sample of 273 students was recruited in one university. Self administered questionnaire was used to collect the data. Attitude toward HPV vaccine consisted of 3 items for measuring related beneficial effects and safety concern and the intention to receive the HPV vaccination was measured with 6 items. Descriptive statistics were analyzed using SPSS statistical package.

Results

The mean ages of the students were 20.51±0.82 years. 25.4% responded as they had heard about HPV. 67.0% responded as both men and women are necessary to be vaccinated. Relatively Korean students perceived that the HPV vaccine would be effective for preventing their cervical cancer. In regard to the intention to receive the HPV vaccine, the role of health professional's recommendation was highly perceived (3.77±0.89; maximum 5.0)

Conclusion

To promote HPV vaccination among Korean university students, nurses' and doctors' influences should be reinforced. Still awareness about HPV should also increased in the university setting.

CLEAR CELL CARCINOMA ARISING FROM ABDOMINAL WALL ENDOMETRIOSIS WITH LYMPH NODE METASTASIS – A RARE CASE REPORT AND REVIEW OF THE LITERATURE.

S. Kim, K.J. Min, S. Lee, J.H. Hong, J.K. Lee, N.W. Lee, J.Y. Song

Korea University Medical Center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Abdominal wall endometriosis represents 1-2% of all endometriotic lesions. The malignant transformation of abdominal wall endometriosis is rare, though it can occur. Herein we report a rare case of clear cell adenocarcinoma arising from abdominal wall endometriosis with extensive lymph node metastasis.

Method

In this case, a 51-year-old woman presented with a growing mass in the right periumbilical area. Computed tomography scan revealed a 5 cm-sized solid mass located on the right rectus muscle.

Results

A punch biopsy of the abdominal lesion was performed and histology showed metastatic adenocarcinoma of unknown origin. She had a surgical history of laparoscopic subtotal hysterectomy with right salpingo-oophorectomy. The patient underwent radical excision of the mass, trachelectomy, left salpingo-oophorectomy, and lymph node dissection. The abdominal wall mass showed clear cell adenocarcinoma arising from endometriosis on histology. There were extensive lymph node metastases. The patient underwent adjuvant chemotherapy.

Conclusion

Both lymphatic and local invasion are key routes of clear cell adenocarcinoma arising from abdominal wall endometriosis. Extensive lymph node metastasis could be associated with poor prognosis.
COMPLETE CLINICAL REMISSION OF STAGE IV BREAST CANCER WITH BONE AND LYMPH NODE METASTASIS COMBINING LOW-DOSE CHECKPOINT INHIBITORS WITH INTERLEUKIN-2 (IL-2) AND FEVER RANGE HYPERTHERMIA

R. Kleef1, H. Bojar2, R. Moss3, D. McKee4

2Next Gen Oncology, Molecular Biology, Duesseldorf, Germany
3Cancer Decisions, Cancer Decisions, Lemont- PA 16851, USA
4Scientific Advisory Board for the Mederi Foundation, Science, Ashland- OR 97520, USA

Aims

Locally advanced stage inoperable metastatic breast cancer has a poor prognosis.

Method

FD: 09/2016 the 65y female noticed the tumor 10 years ago. She first presented in 09/2016 with massive fungating exulcerating right breast carcinoma deeply infiltrating the anterior right chest wall with metastatic right axillary lymph adenopathy and metastasis to the right iliac bone and vertebral body L5 and T8. Tru-Cut biopsy revealed invasive ductal carcinoma of no special type, G3, cT4 N1 M1 (bone), ER 100% and PR 40% positive, Ki–67 19%, HER-2/NEU (c-erbB-2) neg. confirmed by FISH, Score 2+: the cancer was luminal A, EGFR neg., Tp53 neg., AR neg., PD-L1 and CTLA-4 overexpressed, CA 15-3 was elevated at 42 kU/l. She underwent emergency palliative radiation 5 x between in 11/2016 with 25 Gy TD at 5 Gy SD; she then underwent immunotherapy as described previously combining low-dose checkpoint inhibitor ipilimumab–nivolumab in combination with low dose interleukin (IL-2) treatment parallel to local regional and whole-body hyperthermia. Additionally low-dose metronomic chemotherapy was performed twice combining gemcitabine (800mg/m2) and vinorelbine (30mg/m2).

Results

Restaging at the end of 01/2017 performed with clinical examination, bone scintigram, and CT thorax/abdomen and full laboratory workup proved complete remission of the primary large fungating breast cancer, complete remission of bone metastasis and massive shrinkage of lymphadenopathy with normal tumour markers. Current (09/2017) follow-up time 13 months. Photo documentation will be presented.

Conclusion

This unexpected remission of advanced metastatic breast cancer following immunotherapy including low-dose checkpoint inhibitors, hyperthermia and metronomic chemoradiation therapy warrants further clinical studies.
FINAL VALIDATION OF ProMisE MOLECULAR CLASSIFIER IN A LARGE POPULATION BASED SERIES: NEW ERA IN ENDOMETRIAL CARCINOMA DIAGNOSIS AND TREATMENT.

3Im Medizin Campus Bodensee, Institute of Pathology, Friedrichshafen, Germany
4University of British Columbia, Department of Pathology and Laboratory Medicine- Genetic Pathology Evaluation Center, Vancouver, Canada
5University of British Columbia and British Columbia Cancer Agency, Department of Pathology and Laboratory Medicine, Vancouver, Canada
6Tuebingen University Hospital, Institute of Pathology, Tuebingen, Germany
7LKH Graz West, Institute of Pathology, Graz, Austria
8University of British Columbia and Vancouver General Hospital, Department of Pathology and Laboratory Medicine, Vancouver, Canada
9University of British Columbia, Department of Gynecology and Obstetrics- Division of Gynecologic Oncology, Vancouver, Canada

Aims

Based on The Cancer Genome Atlas, we previously developed and confirmed a pragmatic molecular classifier for endometrial cancers; ProMisE (Proactive Molecular Risk Classifier for Endometrial Cancer). ProMisE identifies four prognostically distinct molecular subtypes, and can be applied to diagnostic specimens (biopsy/curettings), enabling earlier informed decision-making. We have strictly adhered to the Institute of Medicine (IOM) guidelines for the development of genomic biomarkers, and herein present the final validation step of a locked-down classifier prior to clinical application.

Method

We assessed a large retrospective cohort of women from the Tübingen University Women’s Hospital treated for endometrial carcinoma between 2003-13. Primary outcomes of overall, disease-specific and progression-free survival were evaluated for clinical, pathological, and molecular features.

Results

Complete clinical and molecular data were evaluable from 452 women. Patient age ranged from 29–93 (median 65) years, and 87.8% cases were endometrioid histotype. Grade distribution included G1 (n=282), G2 (n=75), and G3 (n=95) tumors. 276 patients had stage IA disease, with the remaining stage IB (n=89), stage II (n=26), and stage III/IV (n=61). ProMisE was a prognostic marker for progression-free (p=0.001) and disease-specific (p=0.03) survival even after adjusting for known risk factors.

Conclusion

We have developed, confirmed and now validated a pragmatic molecular classification tool (ProMisE) that provides consistent categorization of tumors and identifies four distinct prognostic molecular subtypes. ProMisE can be applied to diagnostic samples and thus could be used to inform surgical procedure(s) and/or need for adjuvant therapy. Based on the IOM guidelines this classifier is now ready for clinical evaluation through prospective clinical trials.

AMYLOIDOSIS ASSOCIATED WITH MULTIPLE MYELOMA MIMICKING PERITONEAL CARCINOMATOSIS: A VERY UNUSUAL CASE REPORT

O. Komurcu Karuserci1, S. sucu1, Z. bozdag2, O. balat1, H.C. ozcan1, B. agar1
1gaziantep university, ob&gyn, gaziantep, Turkey
2gaziantep university, pathology, gaziantep, Turkey

Aims

Background: Extracellular deposition of fibrous protein in various tissues and organs is defined as amyloidosis. It has a coincidence with multiple myeloma in approximately 12-15% of cases. Omental amyloidosis is very uncommon, and a small number of cases of omental amyloidosis associated with multiple myeloma (MM) have been reported.

Case Report: We reported a 61-year-old woman with omental amyloidosis associated with multiple myeloma who presented with abdominal ascites and pleural effusion as initial symptoms. Patient was diagnosed as peritoneal carcinomatosis with elevated CA 125 levels at first evaluation. Exploratory laparotomy was performed. Histopathological examination revealed omental amyloidosis. Postoperative systematic assessment of amyloidosis was relevant with MM after the bone marrow biopsy which was performed and evaluated by hematology department which in turn explained the unusual accumulation of amyloid in omentum.

Method

Figure Legend:

Fig1. Axial upper abdominal CT without intravenous contrast medium demonstrating intraabdominal ascites (red arrow), pleural effusion at the right side of the lung (black arrow) and diffuse infiltrative omental mass (white arrow).

Fig2. Macroscopic appearance of the omentectomy specimen.

Fig3. Amorphous and homogenous eosinophilic material accumulation around the vessel wall and adipose tissue, Hex200.

Fig4. Positive staining of the amorphous material with Congo red, x200.

Results

this is a case report

Conclusion

In this report we represented a very unusual case; omental amyloidosis with abdominal ascites and pleural effusion associated with MM that can be confused with peritoneal carcinomatosis. We should keep in mind the possibility of amyloidosis in the differential diagnosis of abdominal ascites and pleural effusion.

THE ROLE OF COLPOSCOPIC INDEXES IN THE PREDICTION OF CERVICAL DYSPLASIA

E. Kúdela 1, M. Nachajova 1, K. Biringer 1, P. Zubor 1, J. Visnovsky 1, J. Danko 1

1 Jessenius Faculty of Medicine - Comenius University, Clinic of Obstetrics and Gynaecology, Martin, Slovak Republic

Aims

Colposcopic scoring indexes provide an objective tool in the diagnosis of uterine cervix pathologies. The basic systems include Reid colposcopic index with its variants and the Swede score as the latest modality. The aim of our study was to evaluate the relevance of both indexes in the prediction of CIN2+ lesions.

Method

We included 386 patients who underwent a colposcopic examination because of a suspicious cytological result: ASCUS - 77 (19.9%), LSIL - 182 (47.1%), ASC-H - 39 (10.1%) - 71 (18.4%) and AGC - 17 (4.4%). HPV status was verified by the Hybrid Capture 2 test and the colposcopic finding was evaluated based on the Reid index and the Swede score for each patient. Pregnant patients and patients after surgery on the uterine cervix were excluded from the study.

Results

Reid colposcopic index with the cut off value ≥ 2 showed excellent parameters for the detection of CIN2+ lesions: sensitivity 90.78%, specificity 82.04%, PPV 74.42% and NPV 93.92%. Swede score with cut off value ≥ 4 achieved comparable results: sensitivity 88.65%, specificity 89.39%, PPV 82.79%, NPV 93.19%. The HPV DNA assay showed excellent sensitivity: 96.1%, but low specificity (30.0%) for the detection of CIN2+ lesions.

Conclusion

Swede score showed in our study the best combined sensitivity and specificity for CIN2+ lesion detection. Both scoring systems, however, confirmed a high efficiency in differential diagnosis of cervical pathologies. The accuracy of non-invasive screening for cervical dysplasia can be enhanced by combining the colposcopic examination with molecular markers.

OVARIAN CANCER CELLS SHOW ENHANCED RESPONSE TO THE NOVEL FGFR INHIBITOR CPL-304-110

K. Kujawa¹, A. Rusin¹, M. Obryt¹, P. Tudrej¹, A. Cortez², A. Stanczak², M. Wieczorek², K. Lisowska¹
¹Maria Sklodowska-Curie Institute – Oncology Center, Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland
²Celon Pharma Inc., Innovative Drugs R&D Department, Mokra 41a, 05-092 Lomianki/Kielpin, Poland

Aims

No selective inhibitor targeting Fibroblast growth factor receptor (FGFR) tyrosine kinases has been clinically approved, so far, although few are tested in preclinical and clinical studies. A novel selective FGFR inhibitor, CPL-304-110, was recently synthesized by Celon Pharma S.A. We tested this inhibitor against several ovarian cancer cell lines.

Method

Commercially available ovarian cancer cell lines (A2780, ES2, OAW42, OVCAR3, SKOV3) and our own newly established OVPA8 line, were used. CPL-304-110 was tested in the 0.0001–10 µM concentrations, for 72 hours, and compared to the control inhibitor AZD4547. Cell viability was determined using AlamarBlue assay (data analysis: GraphPad Prism).

Results

Ovarian cancer cell lines were much more sensitive to the novel CPL-304-110 inhibitor (IC50 between 0.98 – 3.51 uM) than to the control inhibitor (IC50: 7.66 – 14.88 uM). SKOV3 cells were the most sensitive (IC50 0.98 uM for CPL304-110, 7.66 uM for control inhibitor). Most sensitive cell lines from other cancers had following IC50 values: gastric line SNU-16: 0.21 nM and 0.09 nM, respectively; lung line DMS114: 0.063 uM and 0.043; bladder line UM-UC-14: 0.031 uM and 0.094 uM.

Conclusion

Although some cell lines derived from other cancers show greater sensitivity against both inhibitors, in the ovarian cancer cell lines we observed evident trend toward enhanced efficacy of our novel FGFR inhibitor over the control one. This suggests that FGFR inhibitor effective against ovarian cancer can be synthesized.

Acknowledgments

The research was co-financed by the Polish National Center of Research and Development and pharmaceutical company CelonPharma S.A., project "CELONKO" (STRATEGMED2/266776/17/NCBR/2015)
LSF EXPRESSION IN HPV-POSITIVE CERVICAL CANCER AND ENDOMETRIAL CANCER

W. Kwasniewski¹, J. Broniarczyk², J. Kotarski¹, A. Gozdziacka-Jozefiak²

¹Medical University, I Department of Gynaecological Oncology and Gynecology, Lublin, Poland
²Adam Mickiewicz University in Poznan, Department of Molecular Virology, Poznan, Poland

Aims

The transcription factor LSF is expressed in a variety of tissues and is involved in many biological processes such as: regulation of cellular and viral promoters, cell cycle, and DNA synthesis. The LSF modulates expression of specific genes which regulate invasion of cancer, angiogenesis, chemoresistance, and senescence. Its overexpression was detected in human hepatocellular carcinoma (HCC) and during colorectal cancer (CRC) tumorigenesis and progression.

The aim of the present study was to analyze mRNA level of LSF transcription factor in HPV dependent cervical cancer and endometrial cancer. RNA was isolated from cervical cancer cells, endometrial cancer cells, and non-cancer cells collected from patients undergoing gynecological surgical procedures.

Method

Total RNA (1 µg) was reversely transcribed to cDNA and used as a template in quantitative polymerase chain reaction (qPCR). qPCR was performed using SYBR Green PCR master mix and appropriate primers. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as a reference gene.

Results

qPCR analysis showed elevated expression of LSF mRNA in HPV-dependent cervical cancers compared to endometrial cancers. The increased expression of LSF gene was particularly observed during cervical cancer progression.

Conclusion

The further studies are needed to clarify the mechanism by which LSF can be involved in the development of studied cancers.
PHYSICAL ACTIVITY DURING ADOLESCENCE AND YOUNG ADULTHOOD AND THE RISK OF BREAST CANCER IN BRCA1 AND BRCA2 MUTATION CARRIERS

J. Lammert1, J. Lubinski2, S.J. Kim3, S. Armel4, A. Eisen5, W.S. Meschino6, C. Eng7, H.T. Lynch8, M. Kiechle1, S.A. Narod9, J. Kotsopoulos1

6North York General Hospital, Genetics Program, Toronto, Canada
7Cleveland Clinic, Genomic Medicine Institute and Center for Personalized Genetic Healthcare, Cleveland, USA
8Creighton University School of Medicine, Department of Preventive Medicine and Public Health, Omaha, USA

Aims

Physical activity is inversely associated with the risk of pre- and postmenopausal breast cancer among women in the general population and remains one of the most important modifiable risk factors. It is not clear whether or not physical activity is associated with the risk of breast cancer among BRCA mutation carriers.

Method

We conducted a case-control study of 1,413 BRCA mutation carriers. Detailed information regarding physical activity from ages 12-13, 14-17, 18-22, 23-29 and 30-34 was collected by questionnaire. Multivariate logistic regression analysis was used to estimate the odds ratios (OR) and 95% confidence intervals (CI) of physical activity and breast cancer risk. Analyses were stratified by menopausal status at breast cancer diagnosis and BRCA mutation type.

Results

Moderate-intensity exercise between ages 12-17 was associated with a 36% decreased risk of premenopausal breast cancer (highest vs. lowest quartile, OR=0.64; 95% CI 0.44-0.92; P-trend=0.006) and moderate-intensity exercise from ages 18-22 was associated with a 39% decreased risk of premenopausal breast cancer (highest vs. lowest quartile, OR=0.61; 95% CI 0.41-0.90, P-trend=0.013). Strenuous physical activity from ages 23-29 was associated with a 33% decreased risk of premenopausal breast cancer (2nd highest vs. lowest quartile, OR=0.66, 95% CI 0.45-0.98, P=0.041, P-trend=0.16). Physical activity was not associated with the risk of postmenopausal breast cancer risk (P>0.09). The associations did not vary by BRCA mutation type.

Conclusion

These findings suggest that physical activity during adolescence and early adulthood is associated with a reduced risk of premenopausal breast cancer among BRCA mutation carriers. Future prospective analyses are warranted.
A PHASE IIA STUDY OF TISOTUMAB VEDOTIN ((HuMax®-TF-ADC) IN PATIENTS WITH RELAPSED, RECURRENT AND/OR METASTATIC CERVICAL CANCER: UPDATED SAFETY AND EFFICACY

20MD Anderson Cancer Center, Oncology, Houston, USA

Aims

There are limited therapeutic options for patients (pts) with advanced/metastatic cervical cancer. Tisotumab vedotin (Tv) is an antibody-drug conjugate (ADC) composed of a Tissue Factor human IgG1 monoclonal antibody conjugated to a microtubule disrupting agent Monomethyl Auristatin E (MMAE), tested in the Ph I/IIa dose-escalation study (NCT02001623) in pts with locally advanced and/or metastatic solid tumors. Preliminary results from the cervical expansion cohort were presented at ESMO 2017. Updated safety and efficacy including PFS and ORR by central imaging will be presented.

Method

Key eligibility criteria include previously treated advanced/metastatic cervical cancer, adequate organ function and ECOG 0-1. Tv 2.0 mg/kg q3w was administered until progression, toxicity, or withdrawal. Efficacy and toxicity were assessed according to RECIST 1.1 and CTCAE 4.03.

Results

34 pts with advanced cervical cancer were enrolled. Median age 43 (21-73) and median prior lines 2 (0-4). Prior treatment consisted of platinum (91%), taxane (91%), bevacizumab (71%). 17 pts (50%) experienced Gr 3 TEAE(s) related to GI (7 pts), anemia (3 pts), infections (2 pts), neuropathy (3 pts), bleeding (3 pts), conjunctivitis (1 pt), other (11 pts). No Gr 4 or 5 AEs were reported. The response rate was 32%, including 9 confirmed responses. Median DOR was 8.3 months in the confirmed responders. Response by central imaging and PFS will be available at the time of presentation.

Conclusion

Preliminary data demonstrated a manageable safety profile and encouraging efficacy in previously treated, advanced/recurrent cervical cancer. These data warrant further investigation of tisotumab vedotin in previously treated recurrent/advanced cervical cancer.

Aims

ARIEL3 (NCT01968213) evaluated rucaparib vs placebo as maintenance treatment in patients with recurrent platinum-sensitive OC.

Method

Eligibility: ≥2 prior platinum-based therapies, platinum-sensitive OC (progressive disease [PD] ≥6 months after penultimate platinum), complete (RECIST v1.1) or partial response (RECIST v1.1 or GCIG CA-125 criteria) to most recent platinum, and CA-125 less than the upper limit of normal. Patients were randomised 2:1 to oral rucaparib 600 mg BID or placebo. Investigator-assessed progression-free survival (PFS) (primary endpoint) was assessed in a step-down procedure for 3 nested groups: (1) BRCA mutant (germline or somatic BRCA mutation); (2) homologous recombination deficient (BRCA mutant or BRCA wild type/loss of heterozygosity [LOH] high); and (3) intent-to-treat (ITT) population. PFS was also assessed by blinded independent central review (key secondary endpoint) and in subgroups of the ITT population (exploratory endpoint).

Results

ARIEL3 enrolled 564 patients (375, rucaparib; 189, placebo). PFS data are summarised in the Figure. The most common grade ≥3 treatment-emergent adverse events (TEAEs) were anaemia (18.8%, rucaparib; 0.5%, placebo) and alanine/aspartate aminotransferase increase (10.5%; 0%). As of 15 Apr 2017, 13.4% (rucaparib) and 1.6% (placebo) of patients discontinued due to TEAEs (excluding PD);
1.6% and 1.1% of patients died due to AEs (including PD).

**Conclusion**

Rucaparib significantly improved PFS vs placebo in all primary analysis groups, including the ITT patient population.
CLEAR CELLS ADENOCARCINOMA OF CÉRVIX

J. Mariconde1, O. Rosato2
1IMGO, GYNECOLOGY ONCOLOGY, Cordoba, Argentina
2IMGO, gynoncology, Cordoba, Argentina

Aims

Cervix adenocarcinoma accounts for 10% to 20% of cervical carcinomas. Clear cell cervical adenocarcinoma (ACCC) usually occurs around age 50, and is rare in young women. Intrauterine exposure to diethylstilbestrol (DES) is one of the most frequently cited causes in the literature for the etiology of the disease in young patients (75% of cases). In early stages, it has a favorable prognosis. A notable difference between that of clear cells compared to the rest is that the vast majority are endophytic and tend to have deep infiltration of the cervix; they also tend to spread to the uterine body more frequently than other carcinomas.

Method

In surgery as a first step, the identification of 5 colored sentinel lymph nodes (2 right hypogastric and 3 left) is performed (through the use of patent blue), in addition to bilateral classic lymphadenectomy; as a second step, and with absence of lymphatic involvement in the intraoperative, abdominal radical trachelectomy is performed with preservation of uterine arteries and superior pedicles.

Results

Expectant control is decided, without adyuvancia therapy.

After 8 years of surgery, the patient is free of disease and normal menstrual cycles.

Conclusion

CONCLUSIONS: conservative surgery of fertility has become an important option to consider in cases of young patients with unsatisfied fertility.

⁸ImmunoGen- Inc., Clinical Development, Waltham, USA
⁹Massachusetts General Hospital Cancer Center, Division of Gynecologic Oncology, Boston, USA
¹⁰The University of Oklahoma, Stephenson Cancer Center, Oklahoma, USA

**Aims**

Mirvetuximab soravtansine is an ADC, comprising a FRα-binding antibody linked to the tubulin-disrupting maytansinoid, DM4. Here we report on an expansion cohort of patients with advanced endometrial cancer treated with mirvetuximab soravtansine as part of a phase I monotherapy trial.

**Method**

Patients with advanced or recurrent endometrial cancer, and confirmation of tumor FRα positivity by immunohistochemistry, were eligible to enroll. Patients were administered mirvetuximab soravtansine intravenously once every three weeks at 6 mg/kg based on adjusted ideal body weight. Responses were assessed according to RECIST 1.1 and adverse events (AEs) evaluated by CTCAE v4.0.

**Results**

A total of 24 heavily pretreated (median of 3 previous systemic treatments) patients were enrolled. The most commonly reported AEs were fatigue, nausea, diarrhea, decreased appetite, hypomagnesemia, and blurred vision; the majority of which were grade 1-2. Six patients (25%) experienced drug-related grade 3 events, the most frequent of which was diarrhea (3 patients), and grade 4 thrombocytopenia occurred in one individual. Two patients (8%) discontinued for related AEs (grade 2 peripheral neuropathy or pneumonitis). Two confirmed partial responses were seen for an overall response rate of 8%. In addition, 4 patients had stable disease ≥12 weeks. A greater depth and duration of tumor reduction were observed in tumors with serous histology.

**Conclusion**

Mirvetuximab soravtansine exhibited a manageable safety profile in advanced endometrial cancer patients. In this cohort, antitumor activity was more pronounced in individuals with serous-type tumors compared to those with endometrioid histology.

MORTALITY REDUCTION BY OPEN ABDOMEN TO PREVENT COMPARTIMENTAL SYNDROME AFTER CYToreDUCTION SURGERY COMPLICATIONS IN PERITONEAL CARCINOMATOSIS.

C. Martínez Gómez1, M. Decuyper2, M. Ángeles Fité3, L. Gladieff1, J. Ruiz1, A. Martínez1, G. Ferron1

1Institut Claudius Regaud, Surgery, Toulouse, France
2Institut Claudius Regaud, Medical Oncology, Toulouse, France
3Institut Claudius Regaud, Intensive Care and Reanimation, Toulouse, France

Aims

Many years ago, the idea of intentionally leaving the abdomen of a surgical patient open after laparotomy was not contemplated by most of surgeons in order to prevent intra-abdominal hypertension, an elevation of intra-abdominal pressure above 12 mmHg, which could conduced to an abdominal compartimental syndrome (ACS) and multiorgan failure. Thus Open Vacuum-Pack Abdomen technique have been used in abdominal surgery, there are no notions about its results in peritoneal carcinomatosis.

Method

We include retrospectively 28 patients who required an oncological surgery with peritoneal carcinomatosis between 2006 to 2016 at the Institut Claudius Regaud of Toulouse who required to be treated by Open Vacuum-Pack Abdomen technique caused by a intra-abdominal hypertension to avoid a compartimental syndrome.

Results

Patients were operated by ovarian, intestinal cancer, pseudomyxoma peritonei or mesotheliome. PCI was 17 and those with a high peritoneal carcinomatosis index had radical to supraradical cytoreduction including extended peritonectomy, mesenteric and intestinal vaporisation or intestinal resection. The Open Vacuum-Pack Abdomen technique was applied at a median post-operative delay of 9 days (Range: 1-73), and it was changed every 48 to 72 hours during a median of 20 days (range: 1-73). Primary fascial closure was obtained in 26 patients (92%); 6 patients presented persistent or de novo complications during the application and 14 patients (50%) were extubated on the same day of the first VAC application. Actually, ten patients are alive.

Conclusion

According to our experience, open vacuum-pack technique decreases morbi-mortality and improve results in case of postoperatory compartimental syndrome in peritoneal carcinomatosis.

10Institut Bergonie, Surgery, Bordeaux, France
11Institut Bergonie, Surgery, Bordeaux, France
12Institut Claudius Regaud- Institut Universitaire du Cancer, Surgery, Toulouse, France

Aims

Aim of the study was to assess quality of life during the first year after pelvic exenteration for gynecologic malignancy performed with curative intent.

Method

A French multicentric prospective study was performed by including patients who underwent PE. Quality of life by measuring functional and symptom scales was assessed using the EORTC QLQ-C30 (version 3.0) and the EORTC QLQ-OV28 questionnaires prior to surgery, and at baseline, 1, 3, 6, and 12 months after the procedure.

Results

A total of 97 patients were included. Quality of life including physical, personal, fatigue, and anorexia reported in the QLQ-C30 were significantly reduced one month postoperatively and improved at least to baseline level one year after the procedure. Body image was also significantly reduced one month postoperatively. Global health, emotional, dyspnoea, and anorexia items were significantly improved one year after surgery compared to baseline values. Unlike younger patients, elderly patients did not regain physical and social activities after PE.

Conclusion

Deterioration of QOL was most significant during the first three months after surgery. Elderly patients were the only group of patients with permanent decreased physical and social function. Preoperative evaluation and postoperative follow-up should include health-related QOL instruments counselling by a multidisciplinary team to cover all aspects concerning stoma care, sexual function and long-term concerns after surgery.
THE ROLE OF MRI AS AN INTERVAL ASSESSMENT TOOL OF RESPONSE TO CHEMORADIATION IN LOCALLY ADVANCED CERVICAL CANCER

A. martinez1, P. Baissas2, A. Lusque3, M. Delannes4, G. Balague5, G. Ferron1, E. Meny2, D. Querleu7, E. Leblanc7

1Institut Claudius Regaud - Institut Universitaire du Cancer - Toulouse Oncopole, Surgery, Toulouse, France

6Institut Claudius Regaud - Institut Universitaire du Cancer - Toulouse Oncopole, pathology, Toulouse, France
7Institut Bergonie, Surgery, Bordeaux, France
8Centre Oscar Lambret, Surgery, Lille, France

Aims

Main objective was to determine the predictive value of 45 Gy MRI evaluation in LACC patients without para-aortic lymph node involvement treated with concurrent chemoradiation.

Method

Patients with locally advanced cervix cancer (LACC) treated at

Claudius Regaud Center in Toulouse, France and at Oscar Lambret Center in Lille, France,

were included. In order to specifically investigate the role of imaging on local control, only patients with no distant metastasis, and no paraaortic lymph node involvement, were included. Patients underwent pelvic external beam radiotherapy combined with platinum-based chemotherapy.

Results

185 patients were included in the study. Tumor size post chemoradiation and tumor reduction rate were statistically predictive of OS and DFS. However, MRI performed prior to brachytherapy modified treatment strategy in only 6% of patients. Patients who underwent surgery in case of poor response after chemoradiation had non-significant decreased survival compared to those treated with brachytherapy.

Conclusion

MRI assessment after 45 Gy external radiotherapy with chemosensitization showed a prognostic predictive role. Tumor reduction rate superior to 60% between pre and 45 Gy post-radiotherapy MRI were significantly associated with improved OS. Post-radiotherapy MRI modified treatment strategy in a small proportion of patients. However, enables brachytherapy optimization with dose-volume-adaptation and dose escalation with a better assessment of gross tumor volume. 60% in reduction of the maximum diameter can be considered as a prognostic cut-off.
LATE BREAKING

ESGO7-1408

RADIOLOGICAL ENDOVASCULAR EMBOLIZATION OF SMALL PEVIS ARTERIES IN PATIENTS WITH COMPLICATED UTERINE CERVIX CANCER: A SINGLE CANCER CENTER EXPERIENCE OVER 15 YEARS

V. Matylevich
NN Alexandrov National Cancer Centre, Gynecologic Oncology Department, MINSK, Belarus

Aims

To conduct the efficacy of radiological endovascular embolization (REE) of small pelvis arteries in patients with locally advanced and recurrent uterine cervix cancer (UCC).

Method

81 patients were included: 68 (84%) primary and 13 (16%) – with UCC recurrences, who underwent REE of small pelvis arteries regarding vaginal bleeding.

Results

Distribution of primary patients according to FIGO stages was: IIB stage – in 4 (6%), IIIB – in 44 (65%), IV – in 20 (29%). In the result of the procedure hemorrhage was stopped in 76 (94%) patients.

During follow-up period, 67 (83%) patients died from the underlying disease, 4 (5%) from other reasons. The adjusted 1-year survival was 41.4% (SE 5.6%), 5-year – 17.9% (SE 4.5%), median adjusted survival – 8.4 months. Survival of 22 (32%) patients who was not treated further, and 46 (68%) patients who continued the treatment was significantly differed clinically and statistically. 1-year adjusted survival was 15.2% (SE 8.1%) and 53.5% (SE 7.4%), respectively, no patient survived to 5 years in the first subgroup, in the second subgroup a 5-adjusted survival was 24.0% (SE 6.8%), median adjusted survival for the first subgroup was 5.4 months, for the second – 12.8 months (p<0.001).

Conclusion

REE is an effective method of arrest of hemorrhage in patients with locally advanced and recurrent UCC in 94% of cases. Conduction of this procedure in primary complicated locally advanced UCC patients allowed to perform radiotherapy treatment in 68% of cases and can be used at any stage of treatment.

3Kliniken Essen-Mitte, Department of Gynecology and Gynecologic Oncology, Essen, Germany
4Ruhr University Bochum, Department of Obstetrics and Gynecology, Bochum, Germany

Aims

To evaluate the efficacy of a collagen-fibrin patch (Tachosil®) in prevention of symptomatic lymphoceles after pelvic lymphadenectomy in women with gynecological malignancies.

Method

In the multicentre randomised trial, women with pelvic lymphadenectomy were randomized either to bilateral pelvic application of collagen-fibrin patches (Tachosil®) or no intervention. The main outcome was incidence of symptomatic lymphocele diagnosed within four weeks after surgery. Secondary outcomes included asymptomatic lymphoceles and need of medical or surgical interventions within four weeks after surgery. The study hypothesis was an absolute decrease in symptomatic lymphocele incidence with Tachosil® of at least 66%.

Results

164 women with cervical (n=64), ovarian (n=53), and endometrial cancer (n=47) were included. 75 women were randomized to Tachosil® and 89 to the control group. In total, 40 lymphoceles were observed among 164 women (24%). There was no significant difference between study groups in the primary study outcome. Symptomatic lymphoceles were observed in 7/75 (9%) women in the intervention group and 4/89 (4%) women in the control group (p=0.22). The secondary outcome was observed in 14 (18%) women in the intervention group compared to 15 (16%) in the control group (p=0.27). In a multivariate logistic regression model, study center, patient’s age, cancer type, surgical access, number of lymph nodes, and occurrence of intraoperative complications did not influence the risk of developing a symptomatic lymphocele.

Conclusion

Lymphoceles are a frequent complication of lymphadenectomy. If symptomatic, lymphocele requires intervention potentially delaying subsequent oncological treatment. Intraoperative application of Tachosil® does not reduce the incidence of symptomatic lymphoceles after pelvic lymphadenectomy.

OVARIAN OR APPENDIX CARCINOMA? THE CHALLENGING DIAGNOSIS

J. Moreira-Barros¹, I. Vaz², A. Günther³

¹Hospital Pedro Hispano, Obstetrics and Gynecology, Marco de Canaveses, Portugal
²Luzerner Kantonsspital, Frauenklinik, Luzern, Switzerland

Aims

Introduction: Carcinoma of appendix is rare, corresponding to 0.4% of gastrointestinal cancers and 1% of appendix specimens. There is no characteristic clinical presentation and often mimics acute appendicitis. Management is not consensual: besides appendectomy some defend right colectomy and in some cases adjuvant FU-based chemotherapy. In intraperitoneal disseminated disease, selected patients may benefit from aggressive surgical cytoreduction and HIPEC. Benefit of systemic chemotherapy is unknown.

Method

Case report: 60 years-old postmenopausal patient, obese and with hypertension complained of intermittent lower abdominal pain and bowel habit changes for 1 month. She referred loss of 8kg/1month, although under diet, with no other complaints. On physical examination cervix was ventrally pushed by a mass in the cul-de-sac. Ultrasound showed a cystic-solid mass occupying the small pelvis, about 15cm with increased blood flow. The CT supported its gynecological origin, with ascites and bilateral pyelocalycectasy. Mamography, thorax X-ray, colonoscopy were normal. PET-CT described “a large, but low FDG-avidity ovarian carcinoma with peritoneal carcinomatosis and suspected retroperitoneal lymph node metastases.” CA-125 and CA 72-4 were elevated. The patient was submitted to a comprehensive staging debulking laparotomy.

Results

The final pathology report revealed a “poor differentiated Adenocarcinoma of Appendix Vermiformis” with invasion of all layers and serosa perforation (pT4 pN0 i+ (0/29) pM1a (Ovar, Peritoneum) L0 V0 G3). On a multidisciplinary discussion, patient was then proposed for right colectomy and HIPEC.

Conclusion

Appendix carcinoma can represent a challenge for diagnosis and management. No standard of care is established due to its infrequency.

THE ROLE OF CHEMOTHERAPY IN LOW-GRADE SEROUS OVARIAN CARCINOMA: REPORT OF TWO CASES

J. Moreira-Barros¹, I. Vaz², A. Günther²
¹Hospital Pedro Hispano, Obstetrics and Gynecology, Marco de Canaveses, Portugal
²Luzerner Kantonsspital, Frauenklinik, Luzern, Switzerland

Aims

Low-grade serous carcinoma is an uncommon subtype of ovarian/peritoneum carcinoma. Comparing to high-grade, low-grade serous carcinoma is characterized by younger age at diagnosis, chemoresistance, prolonged overall survival and aberrations within the MAP kinase-signaling pathway. The existing data have suggested relative chemoresistance in multiple settings.

Method

Case Report

Results

Case 1: 60 years old patient was diagnosed with ovarian carcinoma FIGO IIB, submitted to maximal debulking surgery – including sigmoid resection followed by Hartmann procedure (pT2b pN0(0/28) M0 G1). The surgery was complicated by iatrogenic left ureter damage, managed with Double-J catheter insertion and followed by multiple revision laparotomies due to anastomosis insufficiency and rectal and vaginal wounds leakage, which prevented the patient from adjuvant chemotherapy beginning. Two years later, patient has no signs of disease recurrence.

Case 2: 45 years old patient diagnosed with low-grade ovarian carcinoma FIGO IIIC was submitted to tumor debulking surgery, including sigmoid resection/anastomosis and splenectomy (pT3c pN1(6/38) M0 G1). The post-operative period was complicated by anastomosis insufficiency and multiple intra-abdominal fistula formation, followed by several laparotomies, double-J catheter placement on the right ureter and nephrostomy on the left. A pulmonary embolism also occurred. Consequently, standard adjuvant chemotherapy was avoided. One year later underwent correction of recto and vesicovaginal fistulas, keeping urinary derivation and two ostomies without disease recurrence.

Conclusion

In both cases chemotherapy could not be performed due to postoperative complications and no tumor recurrence is seen after 1-2 years' follow-up. This highlights the idea of a potentially unnecessary and harming intervention in low-grade tumors, which show per se a poor response to chemotherapy.
PRETERM BIRTH FOLLOWING LLETZ: PREVIOUS OBSTETRIC HISTORY HAS A GREATER ASSOCIATION WITH GESTATION AT DELIVERY THAN DEPTH OF CERVICAL EXCISION

T. Motiwale1, M. Viskaduraki2, O. Barney3, P. McParland3, E. Moss1

1University of Leicester, Cancer Research Centre, Leicester, United Kingdom
2University of Leicester, Core Biotech Services, Leicester, United Kingdom
3University Hospitals of Leicester, Obstetrics and Gynaecology, Leicester, United Kingdom

Aims

To investigate the pregnancy outcomes in women who have undergone a large loop excision of the transformation zone (LLETZ) for cervical intraepithelial neoplasia.

Method

A retrospective cohort study of singleton pregnancies attending a specialist antenatal clinic (2009-2016). Data was collected on interventions (cerclage/cyclogest), obstetric history, LLETZ depth and 20-week cervical length (CL). Analysis was performed comparing: LLETZ-only (no previous preterm birth (PPTB)); LLETZ+PPTB; PPTB-only.

Results

Cerclage was inserted in 25 (4%) of all the LLETZ cases (n=631), 19 for CL<25mm. A further 23 (3.6%) women were prescribed cyclogest. The median gestation at delivery in women who did not undergo an intervention during pregnancy was 40+0 weeks in the LLETZ-only group (n=520), 38+1 weeks in the LLETZ+PPTB (n=63) and 38+3 weeks in the PPTB-only group (n=467), regression p<0.001. In the LLETZ groups (n=583) the birth gestation reduced significantly with the depth of excision (p=0.004), however the median was above 37-weeks in all the depth categories (<10mm: 40+0; 10-19mm: 39+6; 20-29mm: 39+1; >30mm: 38+6). Total LLETZ depth was not associated with 20-week CL (p=0.167). Univariate analysis of LLETZ-only and LLETZ+PPTB cases (no intervention) identified PPTB, BMI and total LLETZ depth as significant risk factors for PTB. Only PPTB and total LLETZ depth remained significant on multivariate analysis, p<0.001 and p=0.03 respectively.

Conclusion

Our results indicate that PPTB appears to be more strongly associated with gestation at delivery compared to depth of cervical excision. Further work is needed to quantify the risk in order for patients and clinicians to plan appropriate pre/antenatal care.
PLATELET-DERIVED GROWTH FACTOR RECEPTORS EXPRESSION AND ITS CORRELATION WITH ANGIOGENESIS FACTORS IN OVARIAN CANCER PATIENTS

S. Szubert1, R. Moszynski2, D. Szpurek1,2, M. Nowicki3, A. Frankowski4, A. Lojewski5, S. Sajdak1, S. Michalak6

1Poznan University of Medical Sciences, Division of Gynecological Surgery, Department of Gynecology Obstetrics and Gynecologic Oncology, Poznań, Poland
2Leszno Regional Hospital, Department of Obstetrics and Gynecology, Leszno, Poland
3Poznan University of Medical Sciences, Department of Histology and Embryology, Poznan, Poland
4Gynecologic and Obstetrical University Hospital, Department of pathomorphology, Poznan, Poland
5Leszno Regional Hospital, Department of Obstetrics and Gynecology-, Leszno, Poland
6Poznan University of Medical Sciences, Department of Neurochemistry and Neuropathology-, Poznan, Poland

Aims

The aim of the study was to analyze the correlations between expression of Platelet-Derived Growth Factor Receptors alpha and beta (PDGFR-alpha and PDGFR-beta) with microvessel density (MVD) and factors of angiogenesis: VEGF, bFGF and EMMPRIN in epithelial ovarian cancers (EOCs) patients.

Method

Analysis concerned 53 samples of EOCs, 37 samples of benign ovarian tumors (BOTs), and 21 samples of normal ovaries. The study was performed in the Division of Gynecological Surgery, Poznan University of Medical Sciences.

Results

PDGFR-alpha was found in tumor cells in 17 (32%) of samples of EOCs and 7 (20%) of BOTs, while, there were no PDGFR-alpha receptor in epithelium of normal ovaries (P = 0.001). PDGFR-alpha receptor was present in the stroma of 21 (39%) EOCs, 20 (58%) BOTs and 15 (83%) normal ovaries (P = 0.004). There were no significant differences in the expression of PDGFR-beta between the studied groups. The expression of both PDGFR receptors was not related with FIGO stage, grade and histopathological type of EOCs. Neither PDGFR-alpha expression nor PDGFR-beta expression was correlated with MVD assessed with anti-CD31, anti-CD34 and anti-CD105 antibodies. The expression of PDGFR receptors did not influence VEGF, bFGF and EMMPRIN expression.

Conclusion

The expression of PDGFRs is not correlated with vascularization and the expression of VEGF, bFGF and EMMPRIN in EOCs patients.

EXPRESSION OF CD44 (CANCER STEM CELL MARKER) AS RECURRENCE PROGNOSTIC FACTOR IN STAGE III EPITHELIAL OVARIAN CANCER

P mulawardhana1, P. hartono2, I. yuliat2, K. sudiana3, M. pascawardhana4
1airlangga university-dr. soetomo general hospital-airlangga university general hospital, obstetrics and gynaecology- oncology subdivision, Surabaya, Indonesia
2airlangga university-dr. soetomo general hospital, obstetrics and gynaecology- oncology subdivision, Surabaya, Indonesia
3airlangga university, pathology anatomy, Surabaya, Indonesia
4airlangga university-dr. soetomo general hospital-airlangga university general hospital, obstetrics and gynaecology, Surabaya, Indonesia

Aims

Recent investigations have unravelled CSC (Cancer Stem Cell) role in cancer recurrence and therapeutical resistance, CD44 has been reported as a CSC marker in EOC (Epithelial Ovarian Cancer), investigator wanted to analyse CD44 as recurrence prognostic factor in stage III EOC.

Method

Hystorical Cohort, CD44 Immunohystochemistry examination performed on the pathological EOC sample diagnosed with PR (Platinum Resistant) and PS (Platinum Sensitive) recurrence. CD44 expression measured, the role as recurrence prognostic factor evaluated, influence towards earlier recurrence analysed.

Results

20 PR and 20 PS subjects were involved in the research. Mean CD44 expression in PR group was 36.80±29.54; while in the PS was 7.05±9.58; there was significant difference between 2 groups (p=0.000). There was a strong correlation between CD44 with recurrence timing (p=0.894). With the cut off 12.5; 85% PR subject had CD44>12.5; 85% PS had CD44<12.5; with 85% sensitivity and 85% specificity as a good recurrence prognostic factor. RR of CD44 is 5.667, RR of tumor residue post surgical staging is 2.513. Patient with CD44>12.50 has possibility of earlier recurrence (< 6 months) 48,487 times, patient with tumor residue of<1cm has possibility of earlier recurrence 13,013 times.

Conclusion

CD44 expression can be used as recurrence prognostic factor in stage III EOC, CD44 was significantly higher in the PR group, there was negative correlation between CD44 with the timing of recurrence. CD44 as recurrence prognostic factor was not influenced with grade and pathologic type, but influenced by stage. Expression of CD44 and tumor residue post surgical staging are good predictors for recurrence timing.
Aims

Perivascular epithelioid cell tumours (PEComas) are neoplasms of uncertain histogenesis that arise in various anatomic sites. Uterine PEComas are rare neoplasms described as being characterized by spindled and/or epithelioid cells with clear-acidophilic cytoplasm and myomelanocytic differentiation. mTOR pathway activation, mainly through TSC1/2 genetic alterations, is reported to be important in the pathogenesis of PEComas. Here, we sought to investigate the somatic genetic alterations in uterine PEComas.

Method

Eighteen tumours were diagnosed as PEComas (12/18 as malignant PEComas) by specialist gynaecological pathologists based on routine histological sections and immunohistochemistry. DNA extracted from tumours and matched normal tissue (n=15), and from tumour only (n=3), was subjected to massively parallel sequencing targeting all exons of 410 cancer genes. Somatic single nucleotide variants, small insertions/deletions and copy number alterations were defined using state-of-the-art bioinformatics algorithms.

Results

Tumours were sequenced at a median coverage of 794x (306x-1326x). Six PEComas did not harbor any non-synonymous mutations in the analyzed genes. In the remaining 12 tumours, the genes most frequently affected by non-synonymous somatic mutations were TP53 (4/18, 22%); ATRX, KDM6A, ATM, BRD4 (each 2/18, 11%); MED12 (hotspot) and DICE1R1 (each 1/18, 6%). Only two PEComas harbored TSC2 mutations (2/18, 11%). At the copy number level, homozygous deletions of BRCA2 (3/18, 17%), RB1, FOXO1 and a histone gene cluster on chromosome 6p22 (each 2/18; 11%) were most common.

Conclusion

Uterine PEComas histologically diagnosed as PEComas harbor a diverse repertoire of somatic genetic alterations, which suggests that these tumours may represent a heterogeneous group of neoplasms rather than a genetically distinct entity.

METHYLATION ANALYSIS OF SELECTED GENES IN ENDOMETRIAL CARCINOGENESIS

M. Nachajova¹, P. Zubor¹, T. Biešk¹, P. Slavík², S. Mersakova³, D. Dvorska⁴, D. Brany⁴, Z. Dankova³, J. Danko¹

¹Jessenius Faculty of Medicine and University Hospital, Obstetrics and Gynecology, Martin, Slovak Republic
²Jessenius Faculty of Medicine and University Hospital, Pathology, Martin, Slovak Republic
³Jessenius Faculty of Medicine, Division of Oncology- BioMed, Martin, Slovak Republic
⁴Jessenius Faculty of Medicine, Division of Molecular Medicine- BioMed, Martin, Slovak Republic

Aims

Initiation, progression and metastasis of the endometrial carcinoma are controlled by genetic and epigenetic events. The most common epigenetic modification is methylation of DNA that is involved in the activation and deactivation of genes and such can impact their biological activity. The aim of this study was evaluation of the methylation changes in genes HTR1B, HS3ST2 and MME in particular groups of patients with endometrial carcinoma, atypical hyperplasia and benign endometrium and determination of their sensitivity, specificity and ability to differentiate carcinomas from healthy endometrial tissue.

Method

Analysis conducted at the Department of Obstetrics and Gynecology of the Jessenius Faculty of Medicine and University Hospital in Martin in collaboration with the Department of Pathology, Division of Oncology and Molecular Medicine.

Results

ROC curves and AUC were analyzed for individual genes to discriminate carcinoma from benign endometrium. HTR1B gene showed 90.6% sensitivity and 100% specificity, AUC = 0.955, p<0.0001, HS3ST2 showed 81.2% sensitivity and 100% specificity, AUC = 0.924, and p<0.0001 and gene MME showed 62.5% sensitivity and 72.5% specificity, AUC = 0.716, p<0.0001. The risk of endometrial carcinoma was determined as follows: HTR1B (OR 420.4, 95% CI 23.9-7386.1, p<0.0001), HS3ST2 (OR 40, 95% CI 2.3-682.7, p<0.01) and MME (OR 9.6, 95% CI 0.23-91.6, p=NS).

Conclusion

There were significantly higher methylation levels in cancer tissue compared to a healthy endometrium for individual genes. The study demonstrated that these genes can be used as methylation biomarkers in differentiation of women with endometrial cancer from women without malignancy.

POST-OPERATIVE RECOVERY ASSESSMENT OF URINARY TRACT DYSFUNCTION FOLLOWING RADICAL HYSTERECTOMY FOR CERVICAL CANCER PATIENTS

L. Nuranna1, K. Sang1, A. Andrijono1, T. Utami1
1RSCH, Oncology Gynecoogy, Jakarta, Indonesia

Aims

To assess the length of recovery phase in urinary tract dysfunction following radical hysterectomy for cervical cancer patients in Cipto Mangunkusumo Hospital.

Method

This survey study was conducted in Cipto Mangunkusumo Hospital from September 2016 to May 2017. Subjects were cervical cancer patients from stage IA2 to IIA2 who underwent radical hysterectomy. Suprapubic catheter (SPC) was inserted to observe the urine production after procedure. Patients were then directed for bladder training protocol involving clamping and opening SPC. Sensation of bladder fullness followed by spontaneous micturition were recorded. Measurement of post voiding residual (PVR) urine volume after spontaneous micturition until less than 100 ml was considered as resolution of urinary tract dysfunction. The average days of every achieved phase were then calculated.

Results

Twenty-nine subjects underwent radical hysterectomy during observation period. But only 21 subjects continued the bladder training protocol and recorded for the recovery phases. The average time needed to obtain sensation of bladder fullness and spontaneous micturition were 7.57 ±4.78 days (median 5 days, minimum 3 days, maximum 22 days) and 8±5.21 days (median 6 days, minimum 3 days, maximum 23 days). The objective PVR urine became less than 100ml was obtained after 21.42±18 days (median 18 days, minimum 7 days, maximum 74 days).

Conclusion

Following radical hysterectomy, recording the recovery phase of urinary tract dysfunction is essential to ensure complete resolution. Complete resolution of the urinary dysfunction is achieved after 21.42±18 days in average (median 18 days, minimum 7 days, maximum 74 days).

THE FEASIBILITY AND THE VALUE OF THE IDEAL AMBULATORY SETTING OF ONE STOP CLINIC FOR POSTMENOPAUSAL BLEEDING (PMB) IN CUMBRIA THE ARGUMENT; HYSTEROSCOPY REPLACING PIPELLE

A. Oudair

West Cumbria Hospital, OG, Cockermouth, United Kingdom

Aims

• To analyse the PMB one year referrals (2015) in West Cumbria to assess the potential of creating a continuous integrated pathway

Method

212 PMB new fast tract referrals in Whitehaven in 2015 were analysed. The data input included, trigger symptoms, clinical assessment, investigations and clinic output. Later the information about results and interventions were coded into the database.

Results

26 cancers were diagnosed investigating PMB including; 3 urinary system, 2 cervical and the rest was endometrial cancer. There were 13 cases of endometrial hyperplasia. There was also one case of fistula and 9 cases of endometritis.

The pickup rate of any cancer by investigating PMB was 26/212 (12.26%). The pickup rate of endometrial cancer was 21/212 (9.9%). The ultrasound picked 7 adnexal cysts and three were complex and one of them was an ovarian cancer associated with an endometrial cancer. Endometrial sampling was attempted in 138 cases (65.1%) and the attempt was abandoned in 20. In this abandoned cases follow hysteroscopy picked up an endometrial cancer and one case of hyperplasia. Follow up hysteroscopy pick up six endometrial cancers in the group where pipelle was not even attempted. In the successful attempts of 118 cases it picked up 12 endometrial cancers. The pipelle missed two cancers diagnosed later by outpatient hysteroscopy.

Hysteroscopy diagnosed the 9 of the 21 endometrial cancers and three were under GA. There were no cases of failed outpatient hysteroscopy.

Conclusion

The presented data will support the argument in setting a service where hysteroscopy replaces the pipelle after ultrasound risk assessment of the case.

RARE CASE OF INVERTED PAPILLOMA OF THE CERVIX

A. Oudai

West Cumberland Hospital, Obstetrics and Gynaecology, Cockermouth, United Kingdom

Aims

To demonstrate the clinicopathological features of a case of inverted papilloma of the cervix with review of the literature.

Method

52 year postmenopausal nulliparous woman referred to the fast tract gynaecology clinic in Whitahaven, UK with history of postmenopausal bleeding and dysparunia. Past history included conservative treatment for CIN1 three years ago, anxiety and hernia repair. Clinical examination indicated thick elevated vascular lesion involving the anterior lip of the cervix. Biopsy was taken under local anaesthesia after photodocumentation of the lesion. Given the suspicious features MRI was requested and was discussed in the regional cancer network meeting. The recommendation was for loop biopsy which was done under GA.

Results

MRI indicated a suspicious lesion confined to the cervix very suggestive of early stage cervical cancer. Histology indicated completely excised exophytic squamoproliferative lesion with PSA negative and exhibiting wild type p53 immuoreactivity with focal staining with EMA. These features could represent association with HPV42. There are no features of invasion or significant atypia and specimens were discussed and reviewed by many pathologists. Clinically the lesion disappeared and frequent follow up over two years confirmed no residual abnormality.

Conclusion

This is a benign case with rare reporting in the literature. Inverted papilloma in the lower female genital tract is extremely rare. This may be associated with low risk HPV. So far there is no indication from the limited literature of progression into cancer and no consensus on follow up. This case created clinical suspicion of cancer and MRI features identical to malignancy. Photodocumentation and case sharing and reporting contribute to further knowledge.

2APHP hôpital Tenon, Gynecology, Paris, France
3CHIC, Gynecology, Creteil, France
4CHU reims, Gynecology, reims, France
5APHM chu marseille, Gynecology, Marseille, France

Aims

The impact of a single intracapsular lymph node metastasis is unclear and the potential role of inguino femoral radiotherapy in women with vulvar squamous cell carcinoma (VSCC) is currently of unclear significance.

The purpose of this study was thus to review the clinical impact of groin metastatic nodal disease within a French multicentre cohort of women with VSCC.

Method

Data of women with surgically treated VSCC treated between January 2005 and December 2015 were retrospectively abstracted from five French institutions with prospectively maintained databases.

Results

During the study period, 636 were documented as having received primary surgical treatment for VSCC of whom, 508 underwent surgical groin nodal staging. 176 (34.6%) had at least one positive LN.

Five-year OS rates were 65.8% in women with one intracapsular, 58.3% in women with one extracapsular, 60.6% in women with two, 33.6% and 28.6% in women with more than three positive lymph nodes.

5-year RFS rates were 54.9% in women with one intracapsular, 44.2% in women with one extracapsular, 35.5% in women with two, 24.5% and 0% in women with more than 3 positive lymph nodes.

Looking at the impact of radiation adjuvant therapy in 1) women with one intracapsular positive node, a benefit could not be identified 2) women with LVSI, RFS and groin LN RFS rates were statistically significantly higher for women with adjuvant inguino-femoral radiotherapy regardless to the number of affected nodes.

Conclusion

inguino femoral radiation seems to have a role in women with VSCC having one intracapsular groin metastases and LVSI

1CHU Bretonneau, Gynecology, Tours, France
2CHU Bretonneau, Radiology, Tours, France
3Chu Bretonneau, Pathology, Tours, France

Aims

the aim of this study was to determine whether there is predictive factors of discordance between MRI and histological sizes of invasive lobular breast carcinoma

Method

we included all women managed in our institution for an invasive breast lobular carcinoma between January 2007 and December 2016. univariate and multivariate analyses were performed to evaluate the association between demographic and pathological factors and discordance

Results

During the study period, 384 women were included. we had all MRI data for 246 of them. when evaluating concordance with a level of 20mm, significant factors in univariate analysis were: statut menopausal status (OR 2,34 [1,06 – 5,17], p=0,04), histological size (OR 0,98 [0,96 – 0,99], p=0,01), the histological size of associated inset component (OR 0,94 [0,87 – 1,01], p=0,03), a neoadjuvant chemotherapy (OR 0,14 [0,06 – 0,37] p<0,001) and hormone receptor status (p=0,06). in multivariate analysis, histological size and neoadjuvant chemotherapy were independent predictive factor of a discordance >20mm

Conclusion

this work permitted to identify independent predictive factors of discordance > 20 mm between MRI and histological sizes of invasive lobular breast carcinoma

⁵CHU reims, Gynecology, Reims, France
⁶CAC dijon, Surgery, Dijon, France
⁷CHU Lille, Gynecology, Lille, France

Aims

Predicting the pattern of recurrence can aid in the development of targeted surveillance and treatment strategies. The objectives of this study were to identify patterns of recurrence in women with operable endometrial cancer (EC) and to identify high-risk periods for recurrence in function of age.

Method

The data of 1153 women who received primary surgical treatment for stage I-III EC between January 2001 and December 2013 were abstracted from a prospectively maintained multicentre database. The time to first recurrence was calculated from the date of diagnosis, and the associated hazard function was examined to determine the peak risk period of recurrence. We categorized age at diagnosis as <65 and ≥65 years old and analysed the hazard ratio (HR) by stratifying age groups.

Results

Women with EC aged ≥65 years maintain a significant recurrence rate during follow-up whatever the stratification (locoregional recurrence, distant recurrence, ESMO/ESGO/ESTRO subgroup).

Multivariable Cox proportional hazard regression showed that the increased risk of recurrence of EC was associated with advanced age, advanced disease ESMO/ESGO/ESTRO subgroup but not with initial treatment received.

Conclusion

The annual HR of recurrence is not uniformly distributed over time but is dynamic and markedly determined by prognostic factors at diagnosis.

8 CH jean verdier, Bondy, France
9 CH poissy, Gynecology, Poissy, France
10 Paris, France
11 Tours, France

Aims

Patterns of distant metastatic failure of endometrial cancer (EC) by specific anatomic site are not well described in the literature. In this work, we evaluated the metastatic patterns of EC cancer and analysed the potential distribution of metastatic disease.

Method

A total of 1444 women with EC treated between 2000 and 2013 were identified. Of which we extracted women with locoregional and distant recurrence or with distant recurrence alone. Women were scored based on first site of metastasis: multiple versus one site: bone, brain, lung, liver or sus diaphragmatic lymph nodes.

Results

110 women developed distant metastatic disease with (n=37(33.6%)) or without (n=73(66.4%)) locoregional recurrence after definitive treatment, including 39 women with exclusive first site of metastatic disease and 34 with multiple sites of metastatic disease. When considering all women, the most common exclusive first site of metastasis was lung (42.8%), bone (15.9%), liver (14.3%), brain (9.5%), sus diaphragmatic lymph nodes (14.3%) and other (3.2%). The median time to develop distant metastases was shorter after the completion of treatment for exclusive brain metastatic disease compared with other sites of metastatic disease (7 months vs, 9 for lung, 10 for liver, 19 for bone and 27 months for sus diaphragmatic LN; P=0.004). The rate of 3-year overall survival was higher in the sus diaphragmatic LN metastase group (83.3% vs 50.6% for lung, 37.3% for bone, 16.7% for brain and 0% for liver; P=0.0059), but there was no significant difference in the median survival after the occurrence of distant metastases regardless of additional treatment (P=0.34).

Conclusion

The present study has demonstrated the site-specific patterns of metastases.

CENTRALIZATION of MAMOGRAPHY REPORTING WITH MOBILE TRUCKS: TURKISH EXPERIENCE
1Hacettepe University Faculty of Medicine, Obstetrics and Gynecology, Ankara, Turkey
2Kecioren Training and Research Hospital - Ministry of Health, Radiology, Ankara, Turkey
3Turkish Ministry of Health - Public Health Institute, Cancer Control Department, Ankara, Turkey
4National Mammography Report and Control Center, National Mammography Report and Control Center, Ankara, Turkey

Aims

To report the initial results and the effectiveness of new Turkish population breast cancer screening program including the females aged 40-49; out-sourcing mobile trucks and national central report center.

Method

The study is conducted prospectively for one year (March 2016-March 2017) in all 81 provinces of Turkey. Mammography images were transferred via internet to central report unit and are evaluated in a double blind manner.

Results

Totally, images of 414,802 patients were transferred from 155 KETEMs. Of these patients; 95,872 (23.1%) were aged between 40-44; while 84,851 (20.5%) were 45-49, 157,901 (38.1%) were 50-59 and remaining 76,178 (18.3%) were between 60-69 years of age. Among all images, 21,999 (5.3%) were BI-RADS 0-4-5, 391,123 (94.35%) were BI-RADS 1-2 while remaining 1,680 (0.4%) had insufficient views for BI-RADS scoring. Totally recall rate of the national center was 5.7%. BI-RADS scores did not show a significant correlation with respect to age, NUTS regions, KETEM type, mammography device except for breast patterns. daily number of screened patients was significantly higher in out-sourcing mobile trucks compared to stationary KETEMs (38.2 vs. 8.9; P<0.05).

Conclusion

This is the first and largest breast cancer screening study from a developing country evaluating a central report center, mobile trucks and screening for ages 40-49. Initial results show the feasibility and effectiveness of these strategies for similar countries having difficulties in breast cancer screening programs. However, final validation and follow up data should be seen for final conclusions.

UTERINE SARCOMAS: REVIEW OF THE INCIDENCE

J. Pérez Martínez¹, L. Gonzalez-Gea², P. Garbayo-Sesma³, D. Martínez-Campo², B. Santacruz³

¹Hospital Universitario de Torrejón, Gynecological Oncology, Madrid, Spain
²Hospital Universitario de Torrejón, Oncological Department, Torrejón de Ardoz, Spain
³Hospital Universitario de Torrejón, Gynecological Oncology, Torrejón de Ardoz, Spain

Aims

To review the incidence and characteristics of uterine sarcomas in our population.

Method

We analyzed the incidence of uterine sarcomas at the Hospital de Torrejón in a population of 140,000 habitants since 2011 to date.

Results

Until May 2017, we diagnosed 72 cancers of the uterine body, of which 13.8% were uterine sarcomas (10 cases). Of the uterine sarcomas, 4 were leiomyosarcomas, 3 carcinosarcomas, 2 endometrial stromal sarcoma and 1 adenosarcoma.

According to the classification of FIGO 2009 and by histological grade, the stages were: 60% IBG3, 10% IAG1, 10% IIIC1G2 and 20% IVB both high-grade sarcoma.

Hysterectomy and double annexectomy were performed in all patients. Lymphadenectomies were performed prior to 2014 when a protocol was published by the Spanish Society of Gynecology and Obstetrics in which only hysterectomy and double-annexectomy were sufficient for the treatment of these tumors. Complete surgery was performed on the carcinosarcomas. The 2 patients with high-grade stage IVB sarcomas had to have an emergency hysterectomy due to uncontrollable acute bleeding. The surgeries were performed via laparoscopy and had to be reconverted to laparotomy. In six patients, laparotomy was performed due to uterine size.

One patient presented a bilateral ureteral lesion as an intraoperative complication, it was an emergency surgery for acute bleeding without specialized equipment. We had another case of postoperative surgical wound infection.

Conclusion

Despite the limited series, it is striking that sarcomas account for 13.8% of all malignant uterine tumors in our population, and therefore we should study possible risk factors and the appearance of new cases.
COMPLETE CYTOREDUCTION AFTER SIX CYCLES OF NEO-ADJUVANT CHEMOTHERAPY CONFERS A SURVIVAL BENEFIT IN ADVANCED OVARIAN CANCER.

1City Hospital, Pan-Birmingham Gynaecological Cancer Center, Birmingham, United Kingdom

Aims

To assess the impact of neoadjuvant chemotherapy (NACT) and cytoreductive outcomes on overall survival (OS) in patients undergoing interval debulking surgery (IDS) for advanced ovarian cancer.

Method

We undertook a retrospective review of patients receiving NACT followed by IDS between 2007-2017. Patients were analysed according to number of NACT cycles received: group 1 consisted of patients receiving ≤4 cycles and group 2 consisted of those receiving ≥5 cycles. Outcomes were stratified by cytoreductive outcome, surgical complexity, stage and chemotherapy exposure.

Results

231 patients in group 1 and 167 in group 2 were identified. In group 1, the OS for those achieving R0, R1 and R2 was 51.1, 36.1, and 34.3 months respectively. Statistically significant differences in survival were seen in patients achieving R0vR2 (p<0.019) but not in R0vR1 (p=0.125) or R1vR2 (p=0.358). In group 2, the OS for those achieving R0, R1 and R2 was 53.0, 24.7, and 22.1 months respectively. Statistically significant differences were seen between R0vR1 and R0vR2 (p<0.00001) but not between R1vR2 (p=0.917). No difference in OS was seen between groups 1 and 2. In patients achieving R1, there was a trend towards decreasing OS with increasing exposure to NACT from 36.1(95%CI 32.0-40.2) months with 3 cycles to 24.3(95%CI 14.4-34.2) months with ≥6 cycles.

Conclusion

Surgery with utilisation of cytoreductive procedures to achieve complete clearance should be offered to all patients irrespective of NACT exposure if R0 can be achieved. R1 cytoreduction has questionable value in those receiving ≤4 cycles and no value in those receiving ≥5 cycles.

CLINICAL PATHWAYS OF RECOVERY AFTER SURGERY FOR ADVANCED OVARIAN/TUBAL/PERITONEAL CANCER – A NSGO-MANGO INTERNATIONAL SURVEY IN COLLABORATION WITH AGO AUSTRIA. A FOCUS ON SURGICAL ASPECTS

E. Piovano1, A. Ferrero2, P. Zola3, C. Marth4, M.R. Mirza5, K. Lindemann6,7
1Regina Montis Regalis Hospital, Obstetrics and Gynecology Unit, Mondovi, Italy
2Mauriziano Hospital, Academic Department of Gynecology and Obstetrics, Torino, Italy
3University of Turin, Department Surgical Sciences, Torino, Italy
4Innsbruck Medical University, Department of Obstetrics and Gynecology, Innsbruck, Austria
5Rigshospitalet- Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark
6Oslo University Hospital, Department of Gynecologic Cancer- Division of Cancer Medicine, Oslo, Norway
7University of Oslo- Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway

Aims

ERAS (Enhanced Recovery After Surgery) principles are gaining ground in gynae-oncology. Patients undergoing surgery for advanced ovarian cancer may in particular benefit from a standardized, multidisciplinary perioperative management. This survey aimed at assessing current practice in Scandinavia, Italy and Austria to understand to what extent ERAS principles have been implemented.

Method

In July 2017, a web-based questionnaire (SurveyMonkey Inc. Palo Alto, CA, USA) was sent to centres conducting surgery for advanced ovarian cancer within NSGO-MaNGO and other Italian institutions-AGO Austria (n=100). Descriptive statistics were used.

Results

Overall response rate was 61%. Only a third of the centres in Italy and Austria follow a written ERAS protocol compared to 60% of the Scandinavian centres. Only a minority of centres have completely abandoned bowel preparation, with the highest proportion in Scandinavia (36%). Prolonged fasting for fluids of ≥6 hours prior to surgery is routinely practiced in Italy (79.5%), less frequent in Scandinavia and Austria (27% and 29%, respectively). Carbohydrate loading is only inconsistently administered, ranging from 10% in Italy to 67% in Scandinavia. Peritoneal drainage is used by 22% routinely, by 61% in case of bowel resection/lymphadenectomy or peritonectomy. Early feeding with a light diet on day 0 or 1 is standard of care in Scandinavia and Austria, but not in Italy.

Conclusion

The degree of implementation of ERAS protocols varies across cooperative groups. Centralization of care seems to facilitate standardization of perioperative protocols. The high heterogeneity may challenge a multicentre, international approach to generate procedure specific evidence for ERAS protocols in ovarian cancer.
This survey assessed current perioperative practice to understand to what extent ERAS (Enhanced Recovery After Surgery) principles have been implemented in advanced ovarian cancer (OC) surgery. Here, we present the results on anesthesiologic aspects of ERAS.

Method

In July 2017, a web-based questionnaire (SurveyMonkey Inc. Palo Alto, CA, USA) was sent to centres conducting surgery for advanced OC within NSGO-MaNGO, other Italian institutions and AGO Austria (n=100). Descriptive statistics were used.

Results

The most common premedication in Italy (77%) and Austria (100%) are benzodiazepines. The vast majority of institutions (89%) utilize intraoperative warming devices. Fluid management, analgesia and anesthesia varies, between and within countries. Only 52% of the institutions follow a written protocol for perioperative fluid management. Liberal (22%), restricted (22%) and zero-balance (38%) regimens are used. Total IV anesthesia (TIVA) with target-controlled infusions of propofol and/or remifentanil is used in the majority of centres in Italy and Austria, while less than half of the NSGO centres use TIVA. Epidural is the predominant opioid sparing analgesia in Scandinavia (78.5%) and Austria (83%), but is less frequently used in Italy (53%). Postoperative nausea and vomiting prophylaxis is often prescribed (83%), but is rarely multimodal.

Conclusion

Key elements of ERAS are managed by anaesthetists. These showed a high grade of heterogeneity in clinical practice in our survey. This may reduce the full benefit of ERAS despite otherwise standardized pathways. Close collaboration with anaesthetists in research and clinical practice is crucial to establish and implement an optimal ERAS pathway for OC patients.

LOCAL RECURRENCE IN VULVAR CARCINOMA; INCIDENCE AND PROGNOSTIC IMPACT OF PATHOLOGICAL MARGIN DISTANCE AND LICHEN SCLEROSUS

A.W. Pouwer1, N.C. te Grootenhuis2, G.H. de Bock3, H. Hollema4, J. Bulten5, A.G.J. van der Zee2, J.A. de Hullu1, M.H.M. Oonk2

1Radboud university medical center, Department of Obstetrics and Gynaecology, Nijmegen, The Netherlands
2University of Groningen- University Medical Center Groningen, Department of Obstetrics and Gynaecology, Groningen, The Netherlands
3University of Groningen- University Medical Center Groningen, Department of Epidemiology, Groningen, The Netherlands
4University of Groningen- University Medical Center Groningen, Department of Pathology, Groningen, The Netherlands
5Radboud university medical center, Department of Pathology, Nijmegen, The Netherlands

Aims

To determine the incidence of local recurrence of vulvar squamous cell carcinoma (SCC) and the prognostic significance of pathological margin distance and lichen sclerosis.

Method

Patients, surgically treated in our two centers for primary vulvar SCC between 2000 and 2010, were eligible for this study. All pathological slides were reviewed in a standardised way by two expert gynaecopathologists. Local recurrence was defined as any recurrent disease located on the vulva. Time to first local recurrence was compared for different subgroups.

Results

Preliminary results: Data were analysed from 163 patients with a median follow-up time of 77 months (range 0-202). The actuarial local recurrence rate for all patients at 10 years was 40%, see Figure 1. Pathological margin distance did not influence the risk on recurrence (HR 1.02 (95%CI 0.96-1.09), neither using a cutoff of eight millimeters (HR 0.93 (95%CI 0.52-1.77) or five millimeters (HR 1.05 (95%CI 0.49-2.26). Ninety-eight patients were treated with wide local excision (WLE) and 65 were treated with a (partial) vulvectomy; no difference in local recurrence rate was observed (HR 0.70 (95%CI 0.40-1.25). Only in the WLE group, patients with histologically confirmed lichen sclerosus had significant more local recurrences compared to patients without (HR 3.30 (95%CI 1.43-7.60)), see Figure 2.

Conclusion

Local recurrences frequently occur in patients with primary vulvar SCC (40% after 10 years) and are associated with lichen sclerosus, especially in patients treated with WLE.

MODIFIED CERVICOGRAPHY AND VISUAL ACETOACID INSPECTION AS AN ALTERNATIVE SCREENING FOR CERVICAL PRE-CANCER LESION
G. Purwoto1, H. Dianika2, L. Nuranna1, S. Purbadi1
1Faculty of Medicine Universitas Indonesia/RSUPN Cipto Mangunkusumo, Oncology Gynecology Division- Obstetrics and Gynecology Department, Central Jakarta, Indonesia
2Faculty of Medicine Universitas Indonesia/RSUPN Cipto Mangunkusumo, Obstetrics and Gynecology Department, Central Jakarta, Indonesia

Aims
To compare the diagnostic accuracy between visual inspection with acetic acid (VIA) and modified cervicography as an alternative screening for cervical cancer lesion.

Method
We performed a diagnostic cross-sectional study carried out at Dr. Cipto Mangunkusumo National Referral Hospital from February until April 2015. We collected samples from the Gynecologic Outpatient Clinic who sequentially underwent VIA examination, modified cervicography, and colposcopy.

Results
A total of 185 patients were included in this study. From VIA examination, we obtained positive VIA result of 7%, while modified cervicography had 7.6% positive results. On the other hand, there was 5.4% of patients who were found to have abnormal colposcopy results. From those results, we obtained that sensitivity and specificity of VIA were 96% and 90.9%. Meanwhile, sensitivity and specificity of modified cervicography were 97.7% and 90.9%, respectively, compared to colposcopy as a gold standard.

Conclusion
Modified cervicography and VIA are reliable tools for cervical cancer screening, with comparable sensitivity and specificity. Modified cervicography can be used as a supplementary tool to improve the documentation of VIA, as an alternative to VIA.
LYNCH SYNDROME ASSOCIATED ENDOMETRIAL CARCINOMAS: PRIMED FOR IMMUNE STIMULATION

N.C. Ramchander1, N.A. Ryan2,3, E.J. Crosbie2,4
1University of Manchester, Medical School, Manchester, United Kingdom
2University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom
3University of Manchester, Division of Evolution and Genomic Medicine, Manchester, United Kingdom
4Central Manchester University Hospitals NHS Foundation Trust, Department of Obstetrics and Gynaecology, Manchester, United Kingdom

Aims

Lynch syndrome-associated endometrial carcinomas (LSAECs) are hyper-mutated tumours caused by inherited DNA mismatch repair (MMR) deficiency. They are characterised by an abundance of immunogenic neoantigens. We hypothesised that LSAECs have more tumour infiltrating lymphocytes (TILs) than sporadic MMR intact cancers. Furthermore, we hypothesised that high densities of regulatory T-cells, PD-1+ immune cells, and intra-tumoural PD-L1-expressing cells impede anti-tumour cytotoxicity in this cohort.

Method

LSAECs (n=22) were histology, stage and grade matched with sporadic MMR intact endometrial carcinomas (n=29). CD3+ and CD8+ T-cells, FoxP3+ regulatory T-cells, PD-1+ immune cells, and intra-tumoural expression of PD-L1 at the tumour centre (CT) and invasive margin (IM) were quantified. CD3+ and CD8+ T-cell densities were used to generate an immunoscore for each tumour.

Results

A significantly higher proportion of LSAECs had high immunoscores than sporadic tumours (72% vs. 18%, p<0.001). CD3+ and CD8+ T-cell densities correlated strongly with PD-1+ (both p<0.0001), and FoxP3+ expression (both p<0.001). FoxP3+ (p=0.02) and PD-1+ (p=0.0001) expression was significantly higher in LSAEC compared to MMR intact tumours. There was a trend towards higher PD-L1 expression in LSAECs compared to MMR intact tumours (39% vs. 24%, p=0.2). High PD-L1 expression was correlated with high IM CD3+ and CD8+ T-cell densities (both p<0.01), and PD-L1 expression was associated with high histological grade (p=0.03).

Conclusion

LSAECs are characterised by high TIL densities, however FoxP3+ regulatory T-cells and the PD-1/PD-L1 axis likely facilitate immune evasion. Reversal of immune evasion with immune-checkpoint inhibition may thus be especially relevant to this cohort.

BOTRYOID Rhabdomyosarcoma: A Case Report

I. Rasjidi¹, C. Christine Susanto¹, J.C. Mulia¹
¹Pelita Harapan University, Obstetric Gynecology, Tangerang, Indonesia

Aims

According to The International Rhabdomyosarcoma Study Group’s, tumor staging criteria includes tumor of 5 cm or more, invasion to tissues nearby, lymph nodes, or metastasis. Better prognosis has been found on early stage, young age, embryonic type, and exoffitc.

Method

Results

Considering that the patient is still in the reproductive age and have plans of getting married next month, radical surgery, the classic treatment of rhadomyosarcoma, has to be avoided, and replaced with fertility-sparing surgery as an alternative, with further treatment of lasso ligation to stop the bleeding followed by debulking of the tumor mass. An incomplete resection would leave out tumor at local or surrounding tissues. A treatment plan will be to conduct chemotherapy. Referring to study guidelines by the IRS, the patient is in the Group III Stage 1 so that the appropriate therapy recommendation is 3 chemotherapy regimens: Vincristine + dactinomycin + cyclophosphamide (VAC) and radiotherapy.

Standard regimens for treating rhabdomyosarcoma are:

Vincristine + actinomycin-D + cyclophosphamide (VAC)

Ifosfamide + vincristine + actinomycin-D (IVA)

According to IRSG, patient with gross residual after initial surgery (group III) have 5-years survival rate of 70% compared to group I that have 5-years survival rate of 90% and group II of 80%.

Conclusion

Rhabdomyosarcoma, one of a kind of soft tissue sarcoma, is a rare malignancy that comes from mesenchyme or mesoderm tissue. This patient undergone fertility-sparing surgery as an alternative treatment, and then continued with chemotherapy. Prognosis for this patient as mentioned in five-years survival rate is 70%.
BOTRYOID RHABDOXYOSARCOMA: A CASE REPORT

I. Rasjidi¹, C. Christine Susanto¹
¹Pelita Harapan University, Obstetric Gynecology, Tangerang, Indonesia

Aims

About 1% case of malignancy in adults is sarcoma whereas in this age group less than 5% of them is rhabdomyosarcoma. Rhabdomyosarcoma is a rare tumor found in humans, with incidence rate of around 1% in adult and 6-7% in children. Better prognosis has been found on early stage, young age, embryonic type, and exofitic.

Method

case study

Results

A 28 years old unmarried woman with a mass protruding from her vagina, causing urinating difficulty since 5 hours prior admission. On physical examination, we found a 9 x 5 x 8 cm dense lump, blackish-brown colored, spongy, smooth surfaced with no tenderness. The histopathologic test result is botryoid type embryonic rhabdomyosarcoma.

Considering that the patient is still in the reproductive age and have plans of getting married next month, the further treatment of lasso ligation to stop the bleeding followed by debulking of the tumor mass. An incomplete resection would leave out tumor at local or surrounding tissues. A treatment plan will be to conduct chemotherapy. Referring to study guidelines by the IRS, the patient is in the Group III Stage 1 so that the appropriate therapy recommendation is 3 chemotherapy regimens: Vincristine + dactinomycin + cyclophosphamide (VAC) and radiotherapy.

Conclusion

Rhabdomyosarcoma, one of a kind of soft tissue sarcoma, is a rare malignancy that comes from mesenchyme or mesoderm tissue. This patient undergone fertility-sparing surgery as an alternative treatment, and then continued with chemotherapy. Prognosis for this patient as mentioned in five-years survival rate is 70%.

INTENSITY MODULATED RADIATION THERAPY BOOST IN LOCALLY ADVANCED CERVICAL CANCER: IS IT A SAFE AND FEASIBLE ALTERNATIVE WHEN BRACHYTHERAPY IS NOT PRACTICABLE?

G. Riva1, R. Lazzari1, O. Alessandro1, C.M. Francia1, M. Augugliaro1, D.P. Rojas1, S. Comi2, F. Cattani3, R. Orecchia3, B.A. Jereczek-Fossa1

1European Institute of Oncology, Radiotherapy, Milan, Italy
2European Institute of Oncology, Medical Physics, Milan, Italy
3European Institute of Oncology, Scientific Directorate, Milan, Italy

Aims

Standard treatment in locally advanced cervical cancer is External Beam Radiotherapy (EBRT) concomitant to platinum based chemotherapy, followed by intracavitary/interstitial brachytherapy. We questioned whether an Intensity Modulated Radiation Therapy (IMRT) boost is safe and feasible in patients clinically or radiologically unfit for brachytherapy boost.

Method

We retrospectively analyzed 22 patients with cervical cancer who underwent IMRT boost with BrainLabVERO® between 7/2014 and 12/2016. Toxicity, local control (LC), progression free survival (PFS) and overall survival (OS) were assessed. Acute and late toxicity were evaluated by CTCAE Version 4.1. Pre boost MRI was performed in all but one patients. Clinical Target Volume (CTV) drawn considering the initial extent of the disease and Planning Target Volume achieved adding 3-5 mm to CTV. Constraints to organs at risk were borrowed from the brachytherapy ones. Image Guided Radiotherapy (IGRT) was performed at every fraction.

Results

Patients’ characteristics are listed in table 1. All patients underwent EBRT to pelvis+lumbo-aortic lymph-nodes with a median dose of 50.4 Gy (range 43.2-50.4), all but one received concomitant chemotherapy. Contraindications to BRT were technical limitations, comorbidity or claustrophobia. Boost treatment was homogeneously performed to a total dose of 25 Gy in 5 fractions (alternating days). Median follow-up was 21 months (range 4–58.2). Results are shown in table 2.

Conclusion

Conclusion
Our preliminary data show the safety and feasibility of IMRT boost in terms of toxicity. LC, OS and PFS are coherent to the cohort of patients (48% stage IV disease). IMRT boost seems to be reasonable alternative when brachytherapy is not practicable.
PREOPERATIVE ASSESSMENT OF MYOMETRIAL INVASION IN LOW-RISK ENDOMETRIAL CANCER BY 3D ULTRASOUND AND DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING

A. Rodriguez Trujillo¹, M. Munmany¹, C. Martí¹, M. Del Pino¹, B. Gil Ibañez², A. Glickman¹, I. Nicolás¹, P. Fusté¹, A. Tomè²

¹Hospital Clinic de Barcelona, Gynecology Oncology, Barcelona, Spain
²Hospital Clinic de Barcelona, Gynecology Oncology, Barcelona, Spain

Aims

To compare the usefulness of 3-dimensional (3D) ultrasound and diffusion-weighted magnetic resonance imaging (DW-MRI) in the preoperative assessment of myometrial invasion in patients with low-risk endometrial cancer.

Method

Retrospective study performed in patients with proven endometrioid adenocarcinomas FIGO grade 1 or 2 who underwent surgery at the Hospital Clinic of Barcelona between January 2012 and March 2017. We compared the assessment of myometrial invasion (<50% or ≥50%) by 3D ultrasound by the subjective impression of the examiner and DWI-MRI with final pathologic evaluation on hysterectomy specimens.

Results

A total of 111 patients were included in the study. Evaluation of the depth of myometrial invasion with 3D ultrasound had a sensitivity, specificity and accuracy of 71.9% (95% CI 54.6%-84.4%), 86.1% (95% CI 76.8%-92%) and 82% (95% CI 73.8%-88%), respectively. Evaluation of the depth of myometrial invasion with DW-MRI had a sensitivity, specificity and accuracy of 71.9% (95% CI 54.6%-84.4%), 88.6% (95% CI 79.7%-93.9%) and 83.8% (95% CI 75.8%-89.5%), respectively. Association of both techniques reached 84.4% (95% CI 68.2%-93.1%) sensitivity, and decreased specificity and accuracy to 79.7% (95% CI 69.6%-87.1%) and 81.1% (95% CI 72.8%-87.3%), respectively.

Conclusion

Association of 3D ultrasound and DW-MRI had the highest sensitivity to assess myometrial invasion in low-risk endometrial cancer, decreasing false negative rate. These two techniques combined allow the clinicians to consider more patients at high risk of metastatic lymph node. This preoperative assessment could help to plan more accurate the surgery, thus these patients would benefit of a staging lymphadenectomy.

ESGO7-1515

ASSESSMENT OF MYOMETRIAL INVASION IN LOW-RISK ENDOMETRIAL CANCER BY INTRAOPERATIVE BIOPSY WHEN 3D ULTRASOUND AND DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING HAVE DISCORDANT RESULTS

A. Rodriguez Trujillo1, M. Munmany1, C. Martí1, D.P. Marta1, B. Gil Ibañez1, P. Fusté1, A. Glickman1, I. Nicolás1, A. Torné1

1Hospital Clinic de Barcelona, Gynecology Oncology, Barcelona, Spain

Aims

To describe the diagnostic efficacy of intraoperative biopsy in the assessment of myometrial invasion in patients with low-risk endometrial cancer when 3-dimensional (3D) ultrasound and diffusion-weighted magnetic resonance imaging (DW-MRI) have discordant results.

Method

Retrospective study performed in patients with proven endometrioid adenocarcinomas FIGO grade 1 or 2 who underwent surgery at the Hospital Clinic of Barcelona between January 2012 and March 2017. 3D ultrasound and DW-MRI were routinely performed before the surgery and if the two imaging studies were discordant in the assessment of myometrial invasion, intraoperative biopsy was carried out. Intraoperative biopsy was performed by frozen section and 3D ultrasound by the subjective impression of the examiner. The results were compared with final pathologic evaluation of histerectomy specimens.

Results

A total of 58 patients were included in the study. Intraoperative biopsy had a sensitivity, specificity and accuracy of 75% (95% CI 40.9%-92.8%), 98% (95% CI 89.5%-99.6%) and 94.8% (95% CI 85.9%-98.2%), respectively. 3D ultrasound had a sensitivity, specificity and accuracy of 62.5% (95% CI 30.6%-86.3%), 92% (95% CI 81.2%-96.8%) and 87.9% (95% CI 77.1%-94%), respectively. DWI-MRI had a sensitivity, specificity and accuracy of 50% (95% CI 21.5%-78.5%), 90% (95% CI 78.6%-95.6%) and 84.5% (95% CI 73.1%-91.6%), respectively.

Conclusion

Intraoperative biopsy had a good diagnostic efficacy to the assessment of myometrial invasion in low-risk endometrial cancer. In cases of disagreement of the imaging techniques in the preoperative assessment, the intraoperative pathological evaluation of the hysterectomy specimen seems to be a good tool for a correct staging.

COMPARATIVE RESULTS OF PROLONGED LYMPHORRHEA AND LYMPHOCELE FORMATION AFTER LAPAROSCOPIC PELVIC LYMPHADENECTOMY IN EARLY CERVICAL AND ENDOMETRIAL CANCER

I. Gladchuk1, N. Rozhkovska1, V. Kozhakov1, Y. Petrovskiy1
1Odessa National Medical University, Obstetrics&Gynecology#1, Odesa, Ukraine

Aims

The aim of this study was to compare the results for preventing prolonged lymphorrhea and lymphocele formation by using laparoscopic ultrasonic and electrocautery technique of radical hysterectomy with pelvic lymphadenectomy in early stages of cervical and endometrial cancer.

Method

Study represents a retrospective review of 64 patients with laparoscopically managed preoperative clinical stage IA-IB endometrial cancer (endometrioid adenocarcinoma) and IA-IB1 cervical cancer (squamous cell carcinoma). Patients were randomly assigned for lymphadenectomy in 1 side of the pelvis using the ultrasonic scalpel (Bowa, Germany), whereas, in the other side, the bipolar coagulation (Karl Storz, Germany) to seal lymphatic vessels was used.

Results

There were no differences in age, clinical stage, histologic type, body mass index in two groups. Operation time (160,2±18,4) min and (147,7±15,2) min, number of removed lymph nodes (from 6 till 11), rate of complications (1 case in each group), were similar in both groups. Positive pelvic lymph nodes were detected in 4 cases in 1st group and 3 cases in 2nd group. We used postoperative drainage after lymphadenectomy during 5-7 days until the amount of lymphorrea had markedly diminished (less than 50 ml). Prolonged lymphorrhea (after 7-8 postoperative days) was detected in every third patients of each group, lymphocele formation - in about 10 % cases in each group. There were also no differences for disease recurrence and survival rate in two groups.

Conclusion

There were no significal differences in prolonged lymphorrhea and lymphocele formations after laparoscopic ultrasonic and bipolar electrosurgical pelvic lymphadenectomy in early endometrial and cervical cancer.
SUPRARENAL PARAORTIC LYMPH NODE INVOLVEMENT IN ADVANCED CERVICAL CANCER AND THE IMPACT OF REMOVAL ON SURVIVAL

I.B. Runnebaum - MD, L. Eisold - MD, H. Diebolder - MD
Jena University Hospital, Women's Hospital- Klinik u. Poliklinik für Frauenheilkunde u. Fortpflanzungsmedizin, Jena, Germany

Aims

Lymph node involvement is an important prognosticator in cervical cancer. The resection of metastatic infrarenal paraaortic lymphnodes has been demonstrated to be of therapeutic value. This study investigates the frequency of involvement and the impact of the removal proximal to infrarenal nodes on survival.

Method

Patients with locally advanced cervical cancer (n=) were treated by radical hysterectomy with pelvic and infrarenal paraaortic lymphadenectomy between 2006 and 2013 in the ESGO training center at the Jena University Women’s Hospital by the same surgical team, 44 of which received in addition a suprarenal node dissection around the renal vessels, the coeliac truncus, the superior mesenteric artery and the hepatoduodenal ligament. The other 43 matched patients served as controls.

Results

The median number of removed nodes was 85 (103 vs 72), 65% of the 44 patients had suprarenal lymph node metastases. Median FU was 14 vs 21 months in the control group. Chylus ascites was observed 50% in the suprarenal group (25% infrarenal). Patients after suprarenal dissection needed more blood transfusion. Suprarenal lymph node metastases were found when at least 25% of the paraaortic infrarenal nodes were positive. Median overall survival was increased after suprarenal node dissection (28 vs 42 months), not statistically significant. Patients with suprarenal lymph node metastases had worst overall survival.

Conclusion

Suprarenal lymph node dissection was feasible and detected a high rate of involvement. Removal of involved nodes may be beneficial for the survival of cervical cancer patients. Strength: First study on suprarenal LND with a large patient number. Limitation: Retrospective design.
TEN YEARS REVIEW OF GESTATIONAL TROPHOBlastic DISEASE (GTD) IN BANGABANDHU SHEIKH MUJIB MEDICAL UNIVERSITY OF BANGLADESH

K. Sabera
Bangabandhu Sheikh Mujib Medical University, Obstetrics & Gynaecology, Dhaka, Bangladesh

Aims

Gestational Trophoblastic Disease (GTD) comprises a spectrum of disorders from the pre-malignant conditions of complete (CHM) and partial (PHM) hydatidiform moles through to the malignant invasive mole, choriocarcinoma (CC) and very rare placental site trophoblastic tumour (PSTT/ETT). The incidence of GTD in South Asian region is 200-500/lac pregnancies (0.3%). Bangladesh is a low income country of this region. There is a specialized GTD centre in BSMMU. GTD cases from all over the country are referred in this centre. Two MOLAR CARDS are filled up at 1st visit. One is kept at the centre and another is given to the patient. During follow-up, Persistent Gestational Trophoblastic Neoplasia (PGTN) cases are diagnosed on the basis of weekly or monthly serum β-hCG level.

To register and to give effective management of Gestational Trophoblastic Disease (GTD) in BSMMU

Method

This retrospective analysis done at the Gynaecologic Oncology Division of BSMMU from the records of "MOLOR CARD" from 2007 to 2016 among 500 cases. Following variables were studied

Results

Prevalence of GTD was 2%, age group 21-25 years (33%), 39.32% nil parity, primigravida 31.58%, income <100$/month in 53% cases, amenorrhoea >8 weeks in 67.24% cases, 64.56% were from outside city. Pre-evacuation β-hCG was estimated in 75.73% cases. Diagnosis by USG in 84.84%. Evacuation done within <1 month in 87.59%. Histopathology was available in 57.25%. 48 hours post evacuation β-hCG was available in 28.08%. Post-evacuation USG done in 37.70%. Mortality was nil.

Conclusion

A "MOLOR CARD" is an essential tool for follow-up of GTD cases.

ACHIEVEMENTS AND FURTHER GOALS OF PATIENTS’ ADVOCACY TO DEVELOP CANCER CARE IN THE COUNTRY OF GEORGIA

E. Sanikidze1
1Georgia Patients’ Union, Oncology Group, Tbilisi, Georgia

Aims

To evaluate achievements of GPU advocacy, communication and social mobilization (ACSM) activities to improve oncology patients’ diagnosis, treatment, prevention, support and care in Georgia.

Method

1. Study and assessment of Cancer care challenges and gaps via analysis of statistical data, official reports and questionnaires/interviews
2. Collaborate with medical facilities, medical staff, managers, psychologists and social workers, patients and their family members, various NGOs, especial women organizations, famous persons etc. via communication and social mobilization methods to elaborate and implement advocacy plan
3. Conduct advocacy activities to achieve changes in the gynecological oncology (GO), Cancer Care strategy (CCS) development and fundraising for needed services.
4. Elaborate concrete recommendations and models on base of own results and experience of other countries in the field of Cancer Care in general and GO concretely.

Results

In collaboration with Tbilisi Cancer Center, NCDC, MoH, Tbilisi State Medical University, “Rights to health” organization, Roche and others, gaps were identified in the following areas: low referral to screening programs, lack of timely detection tests and activities, including genetic tests, lack of target- and immunotherapy, palliative care, psycho-social support programs and hospices in our country. On base of ACSM activities, problems description and special interventions were added to National Cancer Strategy.

Conclusion

For timely implementation of strategy in patients’ life, development of human and financial resources, some legislative and regulatory changes should be provided (Like organizational vaccination, obligatory screening, distress screening,. pre cancer conditions control, education, implementation of special approaches for timely detection and modern diagnostic methods, including genetic testing e.t.c)
ASSESSMENT OF QUALITY OF LIFE, URINARY AND SEXUAL FUNCTION AFTER RADICAL HYSTERECTOMY IN LONG TERM CERVICAL CANCER SURVIVORS

F. Plotti¹, G. Scaletta¹, C. Terranova¹, S. Capriglione¹, S. Crispino¹, A. Li Pomi², A. Miranda¹, D. Luvero¹, C. De Cicco¹, R. Montera¹, R. Angioli²
¹Campus Bio-Medico University of Rome, Obstetric and Gynecology, Rome, Italy

Aims

The aim of this study was to evaluate long-term quality of life, urinary and sexual function in long-term cervical cancer survivors previously treated with radical hysterectomy (RH) type C2/type III.

Method

All patients submitted at Campus Bio-Medico of Rome to radical hysterectomy type C2/type III for cervical cancer were considered eligible for this retrospective study protocol. We included exclusively patients with complete response to primary treatment with at least 36 months of follow up. Included subjects were interviewed with the European Organization for Research and Treatment of Cancer (EORTC) QLQ-CX24 Questionnaire, EORTC QLQ30 and an Incontinence Impact Questionaire-7 (IIQ-7).

Results

From January 2004 to June 2014, 251 patients affected by locally advocated cervical cancer were treated at Campus Bio-Medico of Rome treated with type C2/ type III RH. At time point of March 2017, 90 patients were included with a median follow-up of 49 months. The symptoms of fatigue, nausea and vomiting, appetite loss, pain, insomnia, and dyspnea as well as a negative financial impact were reported as not frequent and rarely disabling.

On the contrary, patients frequently reported gastrointestinal complaints. Concerning sexual activity, data indicated a good level of sexual enjoyment with a slight worsening of sexual activity. Incontinence was reported in 28% of cases and appeared to be mild and rarely disabling.

Conclusion

Waiting for ongoing RCTs, this study confirmed that RH may be considered as an useful treatment plan, according to its negligible long-term impact on QoL, urinary disfunctions and sexual function.

EPIDEMIOLOGY OF THE VAGINAL CANCER IN BELARUS. STATISTIC REPORT FOR 2006-2015 YEARS.
A. Shushkevich¹, A. Evmenenko¹, A. Pletnev¹, S. Maevrichev¹
¹Belarus National Cancer centre of Belarus, Onco gynecology, Minsk, Belarus

Aims

The aim of the study is to evaluate morbidity and mortality of vaginal cancer in Belarus for the period 2006-2015.

Method

Cases of vaginal cancer between 2006-2015 were analyzed using Belarusian cancer register database.

Results

For this period 371 cases of vaginal cancer were detected in Belarus. 270 (72.8 %) cases were detected among urban population, 101 (27.2 %) cases were detected among rural population. On average in the Republic of Belarus 37 new cases of vaginal cancer are detected per a year. 33.24 % cases of vaginal cancer were detected in stage I, 35.43 % in stage II, 15.65 % in stage III and 12.36 in stage IV. Five-year overall survival rate for the period 2010-2015 was 94.5 % in stage I, 54 % in stage II, 54 % in stage III, 0 % in stage IV.

Conclusion

The morbidity of vaginal cancer in Belarus is only 3 % from all diagnosed cases of malignant neoplasms of the female reproductive system and most of them 68.67 % of vaginal cancer were diagnosed in early stage. On average in Belarus 37 new cases of vaginal cancer are detected per a year.

ESGO7-1445

CONTRAST-ENHANCED ECHOGRAPHY IN THE DIAGNOSTICS OF CERVICAL CANCER AND EVALUATION OF THE EFFICIENCY OF NEOADJUVANT CHEMOTHERAPY

I. Meshkova1, I. Berlev1, A. Petrova1, A. Sidoruk1
1Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia

Aims

To study the possibilities of contrast echography in the diagnostics of the primary tumor of cervix and the prospects for its application in assessing the effectiveness of neoadjuvant chemotherapy.

Method

The results of contrast echography with bolus administration of contrast Sonovju, data of 30 patients with cervical cancer 1b-2a stages were studied. The features of the accumulation of the contrast by neoplasm before and after the treatment were evaluated. The control group-5 patients with histologically verified uterine myoma.

Results

In 27 patients (90%) a rapid accumulation of contrast with a tumor was recorded (the time of accumulation of contrasts (RI) was 19.2 sec), the average time of passage of contrast (MTT) was 12 with the formation of washout effect - type 3 of the curve. The maximum intensity of accumulation of contrast (Imax) was 95. Benign nodes in all patients accumulated contrast slowly from the periphery to the center without forming the washout effect - type 1 curve. Changes in the features of accumulation of contrast after chemotherapy were detected in 23 (76,7%) patients and showed an increase in RI to 32.3 and a decrease in Imax to 48.2, the washout effect in these observations was absent.

Conclusion

The use of the contrast-enhanced echography method increases its specificity in the differential diagnosis of malignant and benign cervical lesions. The change in the features of the tumor time-intensity curves, increase from RI and MTT, disappearance of the contrast washout effect, decrease in Imax are important additional characteristics for evaluating the effectiveness of neoadjuvant chemotherapy.

SENTINEL LYMPHADENECTOMY IN CERVICAL CANCER USING NEAR INFRARED FLUORESCENCE FROM INDOCYANINE GREEN COMPARED TO TECHNETIUM-99M-NANOCOLLOID

P. Soergel¹, P. Hillemanns¹, J. Kirschke¹, R. Klaptod², T. Derlin², H. Hertel¹
¹Hannover Medical School, Department of Obstetrics and Gynaecology, Hannover, Germany
²Hannover Medical School, Department of Nuclear Medicine, Hannover, Germany

Aims

In the last years, indocyanine green (ICG) has been evaluated for sentinel diagnostic in different tumor entities. ICG is a fluorescent molecule which emits a light signal in the near infrared band after excitation. Our study aims to evaluate ICG compared to the gold standard Tc-99m-nanocolloid.

Method

Between 5/2015 – 3/2017, we included patients with primary cervical cancer FIGO IA – IIA with the indication for sentinel lymphadenectomy in this prospective trial. Sentinel diagnostic was carried out using Tc-99m-nanocolloid, ICG and patent blue. We examined each pelvic site for near infrared light signals using the Storz ICG System, for radioactivity and blue staining. All sentinel lymph nodes, defined as being Tc-99m-nanocolloide positive, and all fluorescent lymph nodes were excised and tested; then sent to histologic examination. All additional pelvic lymph nodes were excised and examined, too.

Results

33 patients were included in this study. We dissected 996 pelvic lymph nodes, 211 of them being sentinel lymph nodes (Tc99m-positive). Only four of them showed no ICG fluorescence, so that the sensitivity of ICG for detecting a Tc99m-positive lymph node was 98.1% (CI95% 94.9-99.4%). As one pelvic site was detected being tumor infiltrated in a lymph node that was ICG positive, but Tc99m negative, ICG identified even more pelvic sites with nodal infiltration than Tc99m. Of the 785 Tc99m-negative pelvic lymph nodes, 160 showed ICG fluorescence, so that the specificity of ICG was 79.6% (CI95% 76.8-82.3%).

Conclusion

ICG is a promising approach for pelvic sentinel identification in cervical cancer with a similar sensitivity as Tc-99m-nanocolloid.

BE AWARE OF INCOMPLETE EXCISION OF ENDOCERVICAL MARGINS

P. Stanciu1, B. Ganesh1, A. Sanusi1, M. Padwick1

1West Hertfordshire Hospitals NHS Trust, Obstetrics and Gynaecology, Watford, United Kingdom

Aims

Large Loop Excision of the Transformation Zone (LLETZ) is currently the most common treatment of cervical high grade dyskaryosis. The purpose of this procedure is to remove the abnormal cervical cells with minimal damage to healthy tissue, facilitating accurate histological diagnosis of the excision margins. It is known to reduce the risk of invasive cancer of the cervix, but often positive CIN margins are followed up only by surveillance with repeated cervical smear and colposcopy.

Method

From June 2016 to June 2017 we had 353 LLETZ procedures within our trust. In four cases the endocervical excision margins were positive for CIN3 and follow up smear test showed persistent abnormal cells. Three of the patients have repeated LLETZ procedures and one had LAVH.

Results

Two specimens were reported as invasive squamous cells cervical cancer 1A1, one was 1B and another one was 2B.

Conclusion

Patients with a background of cervical dysplasia have an increased risk of developing invasive cancer. Intensive follow up picked up the residual disease and prompt treatment assured complete excision of the invasive cancer with accurate staging. Consideration should be given to repeat surgical excisional treatment rather than routine smear follow up for all incomplete endocervical excisions.

10University Medical Center Groningen, Gynaecology, Groningen, The Netherlands
11UMC Utrecht Cancer Centre, Gynaecological Oncology, Utrecht, The Netherlands
12Leiden University Medical Centre, Obstetrics and Gynaecology, Leiden, The Netherlands
13Maastricht University Medical Centre, Obstetrics and Gynaecology, Maastricht, The Netherlands
14Elisabeth-Tweesteden Hospital, Gynaecologic Oncologic Center South, Tilburg, The Netherlands
15AMC, Gynaecological Oncology Amsterdam CGOA, Amsterdam, The Netherlands
16Radboud University Medical Center, Scientific Institute for Quality of Healthcare, Nijmegen, The Netherlands

Aims

Risk-reducing salpingo-oophorectomy (RRSO) around the age of 40 is currently recommended to BRCA1/2 mutation carriers resulting in premature menopause. The TUBA-study (NCT02321228) investigates Quality of life between standard RRSO and early risk-reducing salpingectomy (RRS) with delayed oophorectomy (RRO). In this abstract we focus on patient decision making.

Method

A multicentre non-randomised trial in 10 oncology centres. Premenopausal BRCA1/2 mutation carriers choose between RRSO at age (35-40 (BRCA1) or 40-45 (BRCA2)) and the innovative strategy (RRS after completion of childbearing and RRO at age 40-45 (BRCA1) or 45-50 (BRCA2)).

Results

Of the first 200 participants, 95 (47.5%) chose RRSO and 105 (52.5%) to delay RRO. Women choosing for delayed RRO were more likely to be conjoined in a relationship and to have their BRCA mutation diagnosed longer ago. Most important reasons to delay RRO: the opportunity to delay premature menopause, the trust in the TUBA-hypothesis and the willingness to participate in research for the next generation. For choosing RRSO the known safety of RRSO and fear of ovarian cancer are defining factors.

Conclusion

More understanding of key factors in the process of decision making between RRSO and RRS with delayed RRO can enhance patient satisfaction. We invite more countries to take an initiative such as the TUBA-study; pooled data will eventually learn us not only about quality of life and decision making of BRCA1/2 carriers, but also about the safety of salpingectomy with delayed RRO in cancer prevention.
FIRST EVIDENCE FOR INCREASED NECRPTOTIC CELL DEATH AFTER HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC) IN OVARIAN (CANCER) CELL LINES

E. Steindl1, V. Seebacher1, C. Bekos2, S. Aust2, M. Sachet3, A. Reinthaller2, T.W. Grunt4, D. Pils1

1Medical University of Vienna, Section for Clinical Biometrics- Center for Medical Statistics- Informatics- and Intelligent Systems CeMSIIS & Department of Surgery, Wien, Austria
2Medical University of Vienna, Department of Obstetrics and Gynecology, Wien, Austria
3Medical University of Vienna, Department of Surgery, Wien, Austria
4Medical University of Vienna, Department of Medicine I and Comprehensive Cancer Center CCC, Wien, Austria

Aims

Serous ovarian cancer is difficult to treat with highest mortality of all gynecologic malignances. Peritoneal tumor spread is the major challenge and most patients die on local – mostly chemotherapy resistant – recurrences. To improve outcome, aggressive therapies are discussed, e.g. hyperthermic intraperitoneal chemotherapy: Local chemotherapy can be tolerated at higher concentrations and hyperthermia could increase tissue penetration and toxicity. Nevertheless, the concrete mode of action is unknown, therefore we merged recent findings of different cell death and stress mechanisms to a hypothesis (Fig.1): Heat induced stress reactions, including tRNA fragment synthesis – known to inhibit apoptosis – could shift cells from the non-immunogenic apoptosis to the immunogenic necroptosis and therefore increases patients’ survival.

Method

We treated ovarian (cancer) cell lines with hyperthermic or normothermic chemotherapy and stained immunofluorescently for necroptotic (pMLKL, RIPK3), apoptotic (M30), and stress markers (hsp90), scanned and quantified stainings with CellProfiler. Colocalization of pMLKL/RIPK3 – and interestingly Hsp90 in cells at 42°C – at cell borders was shown by confocal microscopy and judged as sign for necroptosis.

Results

In some cell lines, ES2 (Fig.2) and IOSE 364, an increase of double stained cells in the 42°C compared to the 37°C condition was seen, whereas in other cell lines no (CaOV3) or only little (TYK-nu) increase was seen.
Conclusion

We show first evidence for increased necroptosis (defined as high colocalized pMLKL/RIPK3 abundance) after hyperthermic compared to normothermic chemotherapy in some ovarian (cancer) cell lines.
Aims

Ovarian cancer remains an important health issue in gynecologic oncology. Cancer recurrence is present in 75% of patients after initial treatment. Studies show that elevated HE4 protein is a sensitive marker of ovarian cancer recurrence and it precedes elevation of CA125 by 5-8 months. The aim of this study is to evaluate the use of HE4 marker in prediction of the course of the disease in female patients with ovarian cancer who have finished the first line chemotherapy.

Method

The study is retrospective. The studied group will comprise 50 female patients with recurrent ovarian cancer. For each patient, test results for CA125 and HE4 will be analyzed retrospectively, the tests being performed at the time of diagnosis, during and after finishing chemotherapy, as well as during follow-up visits.

Results

We found significantly higher serum concentrations of HE4 and CA125 after the first-line chemotherapy in platinum-resistant patients. The area under the curve for CA125 and HE4 depending on the platinum-sensitivity are AUC=0.87 and AUC=0.7 respectively. HE4 and CA125 levels are elevated during the time of diagnosis of the first and the second recurrence. HE4 was elevated respectively at a frequency of 77% and 95% for the first and the second recurrence. CA125 was elevated at a frequency of 77% and 84% respectively for the first and the second recurrence. We found shorter disease-free survival in patients with elevated levels of HE4 and CA125.

Conclusion

It seems that HE4 protein may constitute a useful biomarker in prediction of therapeutic outcomes in patients with advanced recurrent ovarian cancer. Its greater specificity and high sensitivity may result in HE4 being more useful than currently used CA125.
Ki67 AND CD44 INDICES DEPENDS ON P16 STATUS OF VULVAR CANCER TISSUE. HIGH INDEX OF CD44 POSITIVE CANCER CELLS PREDICTS WORSE OUTCOME OF PATIENTS

J. Sznurkowski1, A. Żawrocki2, K. Sznurkowska3, W. Biernat2
1Medical University of Gdansk, Oncological Surgery, Gdansk, Poland
2Medical University of Gdansk, Pathology, Gdansk, Poland
3Medical University of Gdansk, Pediatrics- Pediatric gastroenterology- Hepathology and Nutrition, Gdansk, Poland

Aims

To evaluate proliferative power and metastatic potential of vulvar squamous cell carcinoma as represented by Ki67 and CD44 indices respectively, to extend the biological characteristics of the primary tumor microenvironment related to p16INK4a and high-risk HPV-DNA statuses.

Method

Data on p16INK4a and high-risk HPV-DNA statuses, were retrieved from our previous studies on cohort of 85 vulvar cancer patients. Expression of Ki67 and CD44 were evaluated by immunohistochemistry and percentage of positively stained cancer cells was calculated for each case. Indices of Ki67 and CD44 were compared between tumors with different p16INK4a and high-risk HPV-DNA status. Survival analyses included the Kaplan–Meier method, log-rank test and Cox proportional hazards model.

Results

Higher indices of CD44 were observed among p16INK4a-negative tumors (p<0.001) while high risk HPV-DNA status did not influenced on percentage of CD44 positive cancer cells (p=0.082). Higher indices of Ki67 were observed among p16INK4a and high-risk HPV-DNA positive tumors (p<0.001 and p<0.001, respectively). CD44 index was found to be independent negative prognostic factor for overall survival of vulvar cancer patients (p=0.004, 2.72 HR 95%CI 1.38-5.33).

Conclusion

This study highlights the importance of comprehensive assessment of all biomarkers both in p16INK4a-negative and positive vulvar cancer tumors regardless to high risk (hr)HPV-DNA-status. Widespread incorporation of CD44 index into pathological examination could be used in future studies for calculation of cut-off value indicating patients requiring more extensive management.
BENCHMARKING OF UTILIZATION RATES OF BREAST CANCER TREATMENT MODALITIES INDICATES LACK OF ADHERENCE TO TREATMENT GUIDELINES IN POMERANIAN VOIVODESHIP (POLAND).

J. Sznurkowski1, A. Ohler2
1Medical University of Gdansk, Oncological Surgery, Gdansk, Poland
2Cancer Treatment Center of Gdynia- Polish Red Cross Hospital- Gdynia- Poland, Gynecologic Oncology Ward, Gdynia, Poland

Aims

To calculate utilization rates of surgery, chemotherapy and radiotherapy within population of breast cancer patients living in Pomeranian Voivodeship, Poland (2 million people reflecting polish demography) and to compare with evidence based estimated (appropriate) rates.

Method

Utilization rate of treatment modality was defined as proportion of new cases treated with particular method at least once during the course of their illness. Data for 2013 were extracted from National Health Fund. An appropriate utilization rates for breast cancer (reflecting current guidelines) were extracted from available publications.

Results

1065 patients underwent oncological treatment for breast cancer in 2013 in Pomeranian Voivodeship. The 5-year relative survival rate for this cohort was 68%. Overproduction of surgery and chemotherapy (15.9% and 29.9% respectively) was notified. Utilization of radiotherapy was found to be 36.5% below appropriate one.

Conclusion

Benchmarking of utilization rates could serve as useful tool for prediction of quality of treatment. Significant differences between current and appropriate utilization rates in Pomeranian Voivodeship may explain, worse long-term results of breast cancer treatment. The identification of reasons for which differences occur and the improvement in adherence to the guidelines would ensure better patients outcomes.
SURGICOPATHOLOGIC OUTCOME OF LAPAROSCOPIC RADICAL HYSTERECTOMY AND PELVIC LYMPHADENECTOMY, FIRST YEAR EXPERIENCE IN FATMAWATI HOSPITAL JAKARTA

G. Tanamas¹, F.V.D. Candran², S. Purba³
¹Cipto Mangunkusumo Central General Hospital, Obstetrics and Gynecology, Jakarta, Indonesia
²Fatmawati General Hospital, Obstetrics and Gynecology, Jakarta, Indonesia

Aims

Radical hysterectomy (type III) and pelvic lymphadenectomy for early stage invasive cervical cancer can be performed both by minimally invasive or open technique. The aim of this study was to describe surgicopathologic outcome of our first year experience in laparoscopic radical hysterectomy for treatment of early-stage cervical cancer in Fatmawati Hospital Jakarta.

Method

All specimens of laparoscopic radical hysterectomy were measured manually and examined in pathological anatomy department. Size of tumor, parametrial length, number of lymph node, tumor border in vagina was measured manually by one examiner.

Results

This study describes surgicopathologic outcome of 17 patients underwent laparoscopic radical hysterectomy and pelvic lymphadenectomy. Patient’s age was 35 until 59 years old, (median 46 years old). Body mass index was 16.4 until 32.4 kg/m² (median 24.5 kg/m²). Cancer stage was evenly distributed in our patients, the lowest stage was stage IB1 and the highest stage is IIA2. Most of histologic type of cervical cancer is squamous cell carcinoma (62.5%). The median of tumor size 4 cm (1-7 ). Left parametrium width was 6 cm (3-8) and right parametrium width was 5 cm (3-6). Number of left lymph node yield was 8 (5-12) and right lymph node was 8 (5-12). Most of vaginal border was free of tumor (56.3%).

Conclusion

The characteristic of cervical cancer in our study is not differ from other studies. Laparoscopic approach for early stage cervical cancer is new experience in our center. We need more cases to be able to analyze the outcome of laparoscopic radical hysterectomy in our center.
NERVE-SPARING RADICAL HYSTERECTOMY IN PATIENTS WITH INFILTRATIVE CERVICAL CANCER

T. Dermenzhyn, V. Svintsitskiy

\textsuperscript{1}Clinical Center, Clinical Oncology, Kyiv, Ukraine
\textsuperscript{2}National Cancer Institute, Gyneacologic Oncology, Kyiv, Ukraine

**Aims**

The study was aimed on improvement of treatment effectiveness and quality of life of the patients with infiltrative cervical cancer (ICC) by improving radical hysterectomy via using nerve-sparing method.

**Method**

The dissertation is based on analysis of retrospective data on 120 patients with ICC cured during the last 10 years by combined method in accordance with the standards and prospective data on clinical observation and treatment results of 90 patients with ICC treated in the Department of Oncogynecology of National Cancer Institute in 2012–2016 by nerve-sparing radical hysterectomy (NSRE, the main group, n = 45), and radical hysterectomy III (RHE III, the control group, n = 45).

**Results**

It has been shown that 3-year survival index in the group with NSRE was (81.0 ± 10.6) % versus (73.7 ± 16.2) % in the group with RHE III. The conduction of NSRE in the patients with ICC has allowed to decrease significantly the rate of complications of genitourinary system which usually develop after convenient RHE III: difficulty with urinary bladder emptying in RHE III group was significantly increased compared with NSRE group (3.93 ± 0.06) and (1.09 ± 0.04) (p < 0.05); dyspareunia – (4.69 ± 0.07) and (2.87 ± 0.07) (p < 0.05) respectively.

**Conclusion**

After conduction of NSRE there were observed no changes in the degree of bladder wall compliance and its volume, the changes of detrusor pressure were not registered that allowed to provide an adequate urination and continence, and did not worsen the quality of life of the patients.
To evaluate the concordance of Pap smear, colposcopy and histopathology in patients with cervical intraepithelial neoplasia established during cervical screening in a tertiary care hospital.

Method

It was a retrospective study conducted in Department of Gynecology I. Patients with abnormal Pap smear, undergoing Large Loop Excision of Transformation Zone (LLETZ) or conisation during the period from January 2013 to July 2017 were included in the study. Case records were reviewed regarding demographic and clinical data, Pap smear reports, colposcopy findings and histopathology reports (HPR) following cervical excision. Conventional and liquid-based cytology were reported adopting Bethesda system and biopsies routinely processed and stained with H&E.

Results

Total number of cases analysed were 352. The mean age of patients was 40.875 years (range of 21 to 71 years). Concordance rate with Pap smear for CINI was 65.4% and for CINII and CINIII was 56%. Concordance rate with colposcopy for CINI was 64.9% and for CINIII was 53.6%. For cases with ASC-H we had at histopathological exam CINI 4 cases, CINII 16 cases, CINIII 9 cases, and cervical cancer 3 cases. Detection rate for cancer at patients with ASC-H was good for colposcopy (P value 0.001).

Conclusion

In our study agreement between colposcopy and HPR was higher than Pap smear and HPR. 7,082 women with cervical intraepithelial neoplasia at Pap smears had normal biopsies. For HSIL we had 26 cases with underrated CIS diagnosis and 4 with invasive cancer at excision.
AN ULTRASOUND STUDY FOR PREDICTION OF ENDOMETRIAL CANCER USING IETA TERMINOLOGY

M.C. Tirnovanu1, M. Onofriecu2, A.M. Cozoreanu3, A.R. Cara3, S. Pasat3, C. Mucelinita3, S.D. Tirnovanu4
1"Gr. T. Popa" University of Medicine and Pharmacy, Obstetrics and Gynecology, Iasi, Romania
2"Gr. T. Popa" University of Medicine and Pharmacy, Obstetrics and Gynecology, Iasi, Romania
3University Women’s Hospital Cuza Voda, Obstetrics and Gynecology, Iasi, Romania
4Student University of Medicine and Pharmacy “Gr. T.Popa”, General Medicine, Iasi, Romania

Aims

To use terms and definitions described by the International Endometrial Tumor Analysis group (IETA) in evaluating the endometrium on gray scale ultrasound and Doppler imaging for testing the validity of these ultrasound variables in addition to patients clinical variables to identify the best predictors of endometrial cancer.

Method

A prospective study was done on 58 patients with abnormal uterine bleeding and diagnosis at histopathological exam of endometrial cancer. TVS and color Doppler were used. Myometrial invasion was evaluated by subjective assessment (<50% or ≥50%).

Results

The mean age of patients was 61.52±2.3 years (range of 40 to 78 years). The best predictors for endometrial cancer were endometrial thickness 24.75 +/- 4.403mm, heterogeneous endometrium echogenicity 100% sensitivity (Se) (95% CI: 0.6756 to 1) and 38.60% specificity (Sp) (95% CI: 0.2706 to 0.5157), irregular endometrial midline 100% Se and 47.37% Sp, hyperchogenicity of endometrium 50% Se and 50.88% Sp, ill-defined endometrium-myometrium interface 100% Se and 98.25% Sp, multiple global vessels 50% Se and 94.74% Sp, Doppler score >2. The ability of the colour score to discriminate between benign and malignant changes was assessed by the ROC curve analysis. The AUC was 0.899 (95%CI 0.809 to 0.996) giving the best cut-off value for malignancy of ≥ to 1.5, with 87.5% Se and 79% Sp.

Conclusion

Terms used by IETA group were clinically valuable and reasonable in assessment of preoperative endometrial malignancy. The subjective ultrasound evaluation of myometrial invasion had a good accuracy in our study.

RELATIONSHIPS OF NUCLEAR, ARCHITECTURAL AND FIGO GRADING SYSTEMS IN ENDOMETRIAL CANCER

T. Toptas¹, E. Pestereli², S. Bozkurt³, G. Erdogan², T. Simsek⁴

¹Saglik Bilimleri University- Antalya Research and Training Hospital, Gynecologic Oncology, Antalya, Turkey
²Akdeniz University School of Medicine, Gynecopathology, Antalya, Turkey
³Akdeniz University School of Medicine, Biostatistics and Medical Informatics, Antalya, Turkey
⁴Akdeniz University School of Medicine, Gynecologic Oncology, Antalya, Turkey

Aims

To examine correlations among nuclear, architectural and FIGO grading systems, and their relationships with lymph node (LN) involvement in endometrioid endometrial cancer.

Method

Histopathology slides of 135 patients were reviewed with respect to grade and LN metastasis. Notable nuclear atypia was defined as grade 3 nuclei. FIGO grade was established by raising architectural grade (AG) by one when tumor is composed of cells with nuclear grade (NG) 3. Correlations between the grading systems were analyzed by Spearman’s rank correlation coefficients, and relationships of grading systems with LN involvement were assessed using logistic regression analysis.

Results

Correlation analysis revealed a significant and strongly positive relationship between FIGO and architectural grading systems ($r=0.885$, $P=0.001$); however, correlations of nuclear grading with architectural ($r=0.535$, $P=0.165$) and with FIGO grading systems ($r=0.589$, $P=0.082$) were moderate and statistically non-significant. LN involvement rates differed significantly between tumors with AG1 and those with AG2, and tumors with FIGO grade 1 and those with FIGO grade 2. In contrast, while the difference in LN involvement rates failed to reach significance between tumors with NG1 and those with NG2, it was significant between NG2 and NG3 ($P=0.042$). An independent relationship between the grading systems and LN involvement could not be established in multivariate analysis.
Conclusion

Nuclear grading is correlated neither with architectural nor with FIGO grading systems. On the other hand, none of the grading systems is an independent predictor of LN involvement.
LATE BREAKING

PREDICTION OF SHORT-TERM SURGICAL COMPLICATIONS IN WOMEN UNDERGOING PELVIC EXENTERATION FOR GYNECOLOGICAL MALIGNANCIES

L. Tortorella¹, J. Casarin¹, K. Mara², A. Weaver³, F. Multinu¹, W. Cliby¹, G. Glaser¹, G. Scambia³, A. Mariani¹, A. Kumar¹

¹Mayo Clinic, Division of Gynecologic Surgery, Rochester, MN, USA
²Mayo Clinic, Department of Biomedical Statistics and Informatics, Rochester, MN, USA
³“Policlinico Gemelli” Foundation-Catholic University of the Sacred Heart, Department of Obstetrics and Gynecologic, Roma, Italy

Aims

Pelvic exenteration (PEx) is an extensive surgery associated with high postoperative morbidity and mortality rates. The absence of well-defined preoperative selection criteria to identify patients eligible for PEx prompted the assessment of predictors of 30-day major surgical complications.

Method

Demographics and surgical characteristics of 138 patients undergoing PEx in a single institution between 01/2004-12/2016 were reviewed. Postoperative complications were graded using the Accordion grading system. Logistic regression was used to analyze potential risk factors for grade 3/4 complications. Major complications were defined as Accordion grade 3.

Results

A total of 138 patients were included in the analysis. The median age was 62.7 years, 31.1% of patients were obese, and 54.6% had an ASA score > 3. Forty-five patients underwent total PEx, 52 anterior PEx, and 41 posterior PEx. Accordion Grade 3-4 complication was experienced by 37/138 patients (40.2%), and 3 patients (2.2%) experienced death within 90 days. The most frequent Grade 3 complications were: complications of urinary reconstruction (n=15, 41.7%), wound dehiscence (n=9, 25%), and abdominal abscess (n=6, 16.7%). On univariate analysis, the following were associated with Grade 3/4 complication: pre-operative hemoglobin < 10 mg/dl, presence of 3+ comorbidities, BMI>35, type of exenteration, infralevator versus supralevator PEx, pelvic floor reconstruction, estimated blood loss (EBL) > 750ml. On multivariable analysis, independent predictors of early complications were type of exenteration and EBL>750ml. (Figure 1)

Conclusion

Major complications after exenteration are common, and the complexity of surgery plays a considerable role in predicting complication. These data can be used to better risk stratify patients undergoing PEx.

SENTINEL LYMPH NODE (SLN) BIOPSY WITH CERVICAL INJECTION OF INDOCYANINE GREEN (ICG) IN APPARENT EARLY STAGE ENDOMETRIAL CANCER (EC): PREDICTORS OF UNSUCCESSFUL MAPPING

L. Tortorella1, J. Casarin1, F. Multinu1, M. McGree2, A. Weaver2, C. Langstraat1, G. Keeney3, A. Kumar1, G. Scambia4, A. Mariani1, G. Glaser1

1Mayo Clinic, Division of Gynecologic Surgery, Rochester - MN, USA
2Mayo Clinic, Department of Biomedical Statistics and Informatics, Rochester - MN, USA
3Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester - MN, USA
4“Policlinico Gemelli” Foundation- Catholic University of the Sacred Heart, Department of Obstetrics and Gynecologic, Roma, Italy

Aims

To identify predictors of unsuccessful SLN mapping in patients with apparent early stage EC undergoing surgical staging with SLN biopsy and cervical injection of ICG

Method

Consecutive patients with attempted SLN biopsy between June 2014 and June 2016 were analyzed. Successful procedure (SP) was defined as the bilateral identification of SLN, while unsuccessful procedure (UP) included unilateral or no SLN mapping. The association between patient’s disease characteristics and having a UP were evaluated using logistic regression

Results

Among 328 patients included in the analysis, 257 (78.4%) had a SP while 71 (21.6%) had an UP (14.9% with unilateral SLN mapping and 6.7% no mapping). An increase in the rate of SP was observed over the 8 calendar year quarters, as representing the learning curve (p=0.06), increasing from 57.7% to 83.3% in the first and last quarters. Independent predictors of UP were volume of dye injected <3 mL, longer operative time, lysis of adhesions at the beginning of surgery, and presence of enlarged lymph nodes. The presence of lymph node metastases was not associated with UP (8.2% in SP vs. 12.7% in UP respectively, p=0.24). In addition, 6 of 14 (42.9%) patients with cervical stromal invasion had UP compared to 65 of 314 (20.7%) patients without cervical stromal invasion (p=0.06). (Table 1)

Conclusion

The rate of UP is influenced by length of surgery, adhesions from previous surgery, enlarged lymph nodes, and volume of dye. Given that low volume of dye injected (<3 mL) was associated with UP this should be standardized to avoid this.

Table 1. A summary of predictors of unsuccessful procedure (unilateral or no SLN mapping). Data are presented as unadjusted OR and 95% CI, with adjusted OR and 95% CI of predictor variables, compared to center (OR, 95% CI).

PRIMARY PREVENTION OF CERVICAL CANCER: FACTORS OF SUCCESS
N. Tsip¹, J. Napolska², M. Lyzogub³
¹National Cancer Institute, Oncogynaecology, Kyiv, Ukraine
²Khmelnitsky regional oncological hospital, Oncogynaecology, Khmelnitsky, Ukraine
³Bogomolets National Medical University, Student, Kiev, Ukraine

Aims

Despite visual localization, cervical cancer remains one of the most common malignant tumors in women. In Ukraine, cervical cancer ranks 5th in frequency and 6th in mortality from malignant tumors in women, and in the age group 30-54 years - the 2nd place in both incidence and mortality.

To analyze the awareness of students of higher educational institutions about the risk factors of the development of cervical pathology.

Method

800 questionnaires were handed out. 657 female students of 12 higher non-medical and 3 medical-biological higher educational institutions of Ukraine took part in the anonymous questionnaire. The age of the respondents ranged from 16 to 25 years and averaged 19.3 ± 1 years.

Results

16.9% of respondents were informed about HPV-associated development of cervical cancer. Among medical and biological universities – 50.7% and the highest level among biologists – 85.7%.

Conclusion

A well-organized information campaign among young women is the main factor that influences the success of the national screening program for the prevention of cervical cancer.

Students of higher medical and biological educational institutions are an important potential of information campaigns.
DETECTION OF CANCER STEM-LIKE CELLS IN ESTABLISHED OVARIAN CANCER CELL LINES AND TUMORS

1Maria Skłodowska-Curie Institute - Oncology Center - Gliwice Branch, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland
2Maria Skłodowska-Curie Institute - Oncology Center - Gliwice Branch, Department of Bone Marrow Transplantation and Oncohematology, Gliwice, Poland
3Maria Skłodowska-Curie Institute - Oncology Center - Gliwice Branch, Tumor Pathology Department, Gliwice, Poland
4Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Pathology and Laboratory Diagnostics, Warsaw, Poland

Aims

Cancer stem-like cells (CSLC) are defined as a slow cycling, undifferentiated and highly chemoresistant cells. Many studies are aimed to better characterize CSLC and search for targeted therapy against CSLC. Additionally, high expression of CSLC markers in the tumors correlate with worse prognosis of cancer patients.

Method

Our newly established ovarian cancer cell line (OVPA8) and five commercially available lines (A2780, ES2, OAW42, OVCAR3, OVPA8, SKOV3) were used in this study. We also analyzed a collection of over 100 ovarian cancer PFPE samples. Cell surface markers were detected by flow cytometry assay with CD44-FITC and CD133-PE; side population was detected using Hoechst 33342. Detection of CD44 and CD133 in paraffin sections was done by immunohistochemistry.

Results

The majority of cell lines contained about 0.1% of CD133+/CD44+ cells. CD133+ cells were very rare (up to 2%). CD44+ population was highly variable between cell lines (0% to 90%). These results were confirmed also in paraffin sections: CD133 staining was very rare, while CD44 was more ubiquitous. Our preliminary results suggest, that CD44 expression was correlated with patients survival.

Conclusion

It seems that CD133+/CD44+ population of putative CSLC accounts for about 0.1% in established ovarian cancer lines. Side population does not correspond to CD133+/CD44+ population. CD133 is rare, while CD44 is present on much greater fraction of cells. In tumor samples from ovarian cancer patients CD44 expression seems to correlate with worse prognosis.

FACTORS PREDICTING RECURRENCE IN PATIENTS WITH STAGE IA ENDOMETRIOID ENDOMETRIAL CANCER: WHAT IS THE IMPORTANCE OF LVSI?

I. Ureyen, A. Karalok, O. Turkmen, G. Kimyon, Y. Aktas Reis, A. Akyol, T. Tasci, T. Turan

1Antalya Training and Research Hospital, Gynecological Oncology, Antalya, Turkey
2Etlik Zubeyde Hanım Women’s Health Training and Research Hospital - Department of Gynecological Oncology - Ankara - Turkey

Aims

The aim of this study is to define the clinical and pathological prognostic factors for recurrence and to evaluate recurrence patterns and adjuvant therapies used in this group of patients with stage IA endometrioid type endometrial cancer (FIGO 2009).

Method

Among the patients with epithelial endometrial cancer operated on between January 1993 and May 2013 in a single institution, 720 patients with stage IA endometrioid endometrial cancer were included. Patients with a tumor type of serous, clear cell, mucinous, undifferentiated and mixed type and with a tumor containing sarcomatous component and the patients with a secondary primary cancer were excluded from the study.

Results

LVSI was present in 60 (8.3%) patients. Pelvic and paraaortic lymphadenectomy was performed in 266 (36.9%) patients. Median follow-up time was 48 months (range, 3-240). Recurrence occurred in 23 (3.4%) patients and 6 (0.9%) died of disease. The median TTR was 24 months (range, 4-52 months) in the patients with recurrence. LVSI was associated with recurrence in the univariate analysis (Figure 1). Five-year DFS decreased from 96.8% to 80.1% in the presence of LVSI (p=0.001). This association couldn’t be shown in patients who had had lymphadenectomy (p=0.136). Extra-pelvic recurrence occurred in 6.7% and 1% of the patients with and without LVSI, respectively (p=0.001). Any independent prognostic factor couldn’t be detected in the multivariate analysis.

Conclusion

Only LVSI and tumor grade were associated with DFS and DSS, respectively in the 686 patients with stage IA endometrial cancer in the univariate analysis, since these associations couldn’t be shown in multivariate analysis.

13Netherlands Cancer Institute, Division of Psychosocial Research and Epidemiology, Amsterdam, The Netherlands
14Netherlands Cancer Institute, Pathology, Amsterdam, The Netherlands
15Netherlands Cancer Institute, Medical oncology/DGOG, Amsterdam, The Netherlands

Aims

Cytoreductive surgery and systemic therapy are essential for newly diagnosed ovarian cancer. We conducted a multicenter, open-label phase 3 trial to study whether the addition of intraperitoneal chemotherapy under hyperthermic conditions (HIPEC) to interval cytoreductive surgery would improve outcome among patients receiving neo-adjuvant chemotherapy for stage III epithelial ovarian cancer.

Method

We randomly assigned patients who showed at least stable disease after three cycles of carboplatin (area under the curve 6) and paclitaxel (175 mg/m2) to receive interval cytoreductive surgery with or without HIPEC using cisplatin (100 mg/m2). Randomization was performed per-operatively and eligible patients had a complete or optimal cytoreduction. Three additional cycles of carboplatin/paclitaxel were given post-operatively. The primary endpoint was recurrence-free survival. Overall survival, toxicity, and quality-of-life were key secondary endpoints.

Results

A total of 245 patients were randomly assigned to one of the two treatment strategies. In an intention-to-treat analysis, interval cytoreductive surgery with HIPEC was associated with longer recurrence-free survival than interval cytoreductive surgery alone (14.2 vs. 10.7 months, respectively; hazard ratio [HR], 0.66; 95% confidence interval [CI], 0.50 to 0.87; P=0.003). At the time of analysis, 44% of patients were alive, with a significant improvement in overall survival favouring HIPEC (45.7 vs. 33.9 months; HR, 0.67; 95% CI, 0.48 to 0.94, P=0.02). The number of patients with grade 3-4 adverse events was similar in both treatment arms (27% vs 25%, p=0.76).

Conclusion

Adding HIPEC to interval cytoreductive surgery is well tolerated and improves recurrence free and overall survival in patients with stage III epithelial ovarian cancer.

5Institut Claudius regaud - Institut Universitaire du Cancer - Toulouse Oncopole, Pathology Department, Toulouse, France
6CHU - Institut Universitaire du Cancer - Toulouse Oncopole, Oncologic and Gynecologic Surgery, Toulouse, France

Aims

Aim of this study was to assess the therapeutic and prognostic role of functional pretherapeutic FDG-PET/CT parameters in patients treated with radiochemotherapy (RCT) for locally advanced cervix cancer (LACC) without paraaortic involvement.

Method

LACC patients treated with RCT and with surgical staging paraaortic lymphadenectomy without macrometastatic involvement were included. All patients had received at least 45 Gy radiotherapy and 5 cycles of platinum-based chemotherapy. High-risk histologies were excluded. A senior nuclear physician expert in oncogynecology reviewed FDG-PET/CT imaging for all patients. SUVmax, MTV, TLG were extracted from cervical tumor and from pelvic lymph nodes when positive. Medical charts were reviewed for clinical, pathology and survival data.

Results

93 patients were included (table 1), with a median follow-up of 40,5 months. Figures 1 and 2 show survival data. Cervical SUVmax and TLG were significantly associated with response to RCT (respectively, p=0,0299 and p=0,0175; table 2). In univariate analysis, FIGO stage and cervical SUVmax were significantly associated with both OS and PFS (respectively p=0,005 and p=0,014). In multivariate analysis, cervical SUVmax was the main predictive factor for OS (p=0,029).

Conclusion

Cervical tumor SUVmax demonstrated to be a predictive biomarker for response to treatment and survival in LACC patients without paraaortic involvement. Metabolic parameters should be evaluated in further trials to determine their role in clinical practice.
RECURRENT CANCER IS ASSOCIATED WITH DISSATISFACTION WITH CARE; A LONGITUDINAL ANALYSIS IN OVARIAN AND ENDOMETRIAL CANCER PATIENTS

7Netherlands Cancer Institute, Division of Psychosocial Research and Epidemiology, Amsterdam, The Netherlands
8The Netherlands Comprehensive Cancer Organisation, CoRPS- Department of Medical and Clinical Psychology, Utrecht, The Netherlands

Aims

The primary aim of this study was to assess the longitudinal impact of a recurrence of gynecological cancer on satisfaction with information provision and care. The secondary aim was to assess the impact of a recurrence on illness perceptions, anxiety and depressive symptoms and health-related quality of life (HRQoL).

Method

This study is a longitudinal analysis from the ROGY Care trial, conducted between 2011 and 2014, including patients with endometrial (N=215) and ovarian (N=149) cancer. Patients were invited to complete questionnaires directly after initial treatment and after 6, 12 and 24 months. Patient-reported outcomes were compared before and after the recurrence. Linear mixed model analysis was performed to assess the differences in patient-reported outcomes of patients with a recurrence compared to patients without a recurrence.

Results

During 2-year follow-up, 25 patients with endometrial cancer (12%) and 64 patients with ovarian cancer (43%) had recurrent disease, of whom 9 endometrial and 26 ovarian cancer patients completed at least one questionnaire after their recurrence. Patients with a recurrence reported lower satisfaction with care after the diagnosis of recurrent disease (doctor interpersonal skills, exchange of information between caregivers and general satisfaction with care), more threatening illness perceptions, more anxiety and depressive symptoms and worse HRQoL compared to patients without recurrence.

Conclusion

After diagnosis of recurrent disease, endometrial and ovarian cancer patients were less satisfied with care compared to patients without a recurrence. Our findings suggest that patients with recurrent cancer are in need of care that is better tailored to their needs.

INCIDENCE AND PATTERN OF SPREAD OF METASTATIC LYMPH NODES IN PATIENTS WITH LOW GRADE SEROUS OVARIAN CANCER

M. Wafa1, J.P. Grabowski1, E.I. Braicu1, E. Taube2, M.Z. Muallem1, J. Sehouli1

1Charité Medical University Berlin- Berlin Germany, Department of Gynecology- Virchow Campus Clinic- Tumor Bank Ovarian Cancer Network TOC, Berlin, Germany
2Charité Medical University Berlin- Berlin Germany, Institute of Pathology- Virchow Campus Clinic, Berlin, Germany

Aims

The aim of this study was to determine the incidence and pattern of distribution of metastatic lymph nodes (LN's) in patients with low-grade serous ovarian cancer (LGSOC).

Method

Retrospective analysis of patients with primary LGSOC, who underwent primary surgery including systematic lymphadenectomy. Analysis of the affected LNs along with the pattern of lymphatic spread was performed.

Results

Forty-eight patients from which who received systematic pelvic and para-aortic lymph node dissection were identified. The median age was 50 years old (range: 21-76). The majority of patients had FIGO stage III (89.6%). Mean of 45.5 lymph nodes were resected. Lymph nodes metastasis were found in 31 (64.6%) patients. In 15 (31.3%) patients both pelvic and para-aortic LNs were affected concomitantly, para-aortic were affected in 5 (10.4%) patients, isolated pelvic lymph nodes were affected in 8 (16.7%) of patients. The most frequently affected region was the right obturator fossa (51%), found in 14 (29.2%) patients, followed by left obturator fossa (40.7%) found in 11 patients (22.9%).

Conclusion

Low-grade serous ovarian cancer is alike potential for metastatic spread with more confinement to the pelvis compared to the para-aortic region.

Aims

The malignant mixed mullerian tumors (MMMTs) of uterus are composed of an admixture of both malignant epithelial (carcinomatous) and mesenchimal (sarcomatous) components. MMMTs of the uterine cervix are rare and unusual neoplasms, accounts for only 0.005% of all cervical malignancies, and approximately 60 well documented cases have been reported. Due to the limited experience, the clinicopathologic features, therapeutic approach and prognosis of these tumors has not been well determined. Here, we report a case of MMMT of cervix was succesfully treated by surgery and adjuvant chemoradiotherapy.

Method

A 46 year old multiparous woman, admitted to our clinic because of intermittant vaginal bleeding. Speculum examination shows a fragile tumoral mass appeared to originate from the endocervical canal. Bilateral parametria were free. The biopsy revealed malignant mesenchimal tumor. MRI confirmed a 44x17 mm, well defined heterogeneous mass in the cervix, without parametrial invasion and without extension into the bladder or rectum. She underwent type III radical hysterectomy with pelvicparaortic lymphadenectomy and omentectomy, upon diagnosis of a FIGO clinical stage 1B2 cervix tumor. Histopathological analysis revealed a MMMT with epithelial and mesenchimal components in the uterine cervix. The patient start to receive six cycles of adjuvant chemoradiotherapy containing weekly cisplatin and radiotherapy. She is currently well conditioned, free of the disease and showed no evidence of recurrence 18 months after the surgery.
Conclusion

MMMTs composed of an admixture of both carcinomatous and sarcomatous components. MMMTs of cervix staged according to FIGO clinical staging for cervical cancer. The treatment is mainly, radical surgery and adjuvant chemoradiotherapy.
Aims

Atypical polypoid adenomyomas (APAs) are rare, benign and noninvasive uterine lesions that composed both epithelial and mesenchimal components. Although they are considered to be benign diseases, they can coexist with endometrial carcinomas or atypical endometrial hyperplasias. Here, we report a case of coexistence of APA and endometrial adenocarcinoma.

Method
Results

A 35 year old nulliparous woman admitted to our hospital with primary infertility. Transvaginal ultrasonography showed a thick and irregular endometrial thickness. We performed endometrial curettage with sharp curettes under ultrasonographic guidance. Pathology report revealed a coexistence of atypical polypoid adenomyoma and well differentiated endometrioid adenocarcinoma. Because of her childbearing and her young age, she underwent medroxyprogesterone acetate treatment. After the MPA treatment, endometrial control biopsy was normal and then she underwent IVF treatment twice, but she could not become pregnant. 2 years later than first curettage, an endometrial biopsy showed recurrence of atypical polypoid adenomyoma with well differentiated endometrial adenocarcinoma. Patient desired definitive treatment and we performed TAH BSO. Final pathology report revealed same result: coexistence of atypical polypoid adenomyoma and Grade 1 endometrial adenocarcinoma with myometrial invasion less than % 50. There is no recurrence or distal metastasis during the 20 month follow-up.

Conclusion

Recurrence can be seen despite agresive curettage and MPA treatment, for patients who has a coexistence of APAS and endometrial carcinomas. Close follow up with control biopsies must be done.

4Babol University of Medical Sciences, Obstetrics & gynecology, Babol, Iran

Aims

This report is about a 56-year-old menopause woman with a history of breast cancer treatment with tamoxifen.

Method

The case report includes a 56 years old woman with severe uterine bleeding and a large 80*60 mm mass in the uterine cavity referred to the gynecology ward of Ayatollah Rouhani Hospital of Babol in 2016. The patient has been diagnosed with breast cancer since 9 years ago and treated by mastectomy and chemotherapy and then used tamoxifen for 5 years; she had TAH & BSO surgery in Aug 2015, in which the pathology reported the mostly necrotic endometrial polyp (Fig 1). Five months after hysterectomy, she came back with vaginal bleeding and soft and necrotic massive mass filled all the vaginal space; the vaginal mass was removed. In ultrasonography and CT scans of the abdomen and pelvis, a large mass of 90 * 100 mm was observed inside the pelvis. The pathology of the vaginal mass was reported a low grade endometrial stromal sarcoma (Fig 2).

Results

After consultation with an oncologist, the patient was underwent chemotherapy and then laparotomy, in which a solid 100 * 100 mm mass with severe adhesion to the intestines was observed. It was underwent mass resection with omentectomy. On histopathological study mostly necrotic mass with foci of high grade sarcoma is noted (Fig 3) the patient was received chemotherapy until July 2017.

Conclusion

Patients with breast cancer, who are treated with tamoxifen, are exposed to the risk of carcinoma and endometrial stromal sarcoma and should be monitored for endometrial cancer symptoms.
INCREASED FREQUENCY OF HLADRhi REGULATORY T CELLS WITH HIGHLY IMMUNOSUPPRESSIVE PROPERTIES IN CERVICAL SQUAMOUS CELL CARCINOMA AND ITS CLINICAL IMPLICATIONS
S. Ye1, J. Wu1, S. Goswami2, X. Pei1, L. Xiang1, X. Zhang2, H. Yang1

2Institute Pasteur of Shanghai- Chinese Academy of Sciences, Unit of Innate Defense and Immune Modulation- Key Laboratory of Molecular Virology and Immunology, Shanghai, China

Aims
Regulatory T cells (Treg) are composed of different subsets and involved in tumor immune escape and cancer progression. The study aims to investigate the frequency, phenotype and functions of Treg subsets in patients with squamous cell carcinoma (SCC) of the uterine cervix and to identify their clinical implications.

Method
Flow cytometry was used to analyze Treg cell subsets in peripheral bloods from 80 SCC, 42 pre-cancer patients and 50 healthy subjects and in surgical specimens from 35 SCC patients. Their phenotypic and functional features as well as clinical association were further explored.

Results
SCC patients had a remarkably increased proportion of HLADRhi Treg subset in peripheral blood, which exhibited a unique phenotypic feature, including high expression of activation and inhibitory markers. In addition, HLADRhi Treg subset expressed high amounts of Ki-67 and pro-apoptotic molecules. Consequently, this subset underwent more apoptosis in vitro regardless of IL-2 addition, indicating that this subset is highly cycling with strong apoptosis potential. Further studies demonstrated that the HLADRhi Treg subset harbored highly suppressive function. The frequency of HLADRhi Treg subset was strongly increased in the tumor microenvironment compared to the blood counterparts in SCC patients. Prognostic analysis showed that patients with recurrence showed a tendency of increased HLADRhi Treg subset in both blood and tissue, although statistical significance was not achieved.

Conclusion

The frequency of HLADRhi Treg cells was increased in SCC patients. They had unique phenotype and highly suppressive function. The possible prognostic implication merits further exploration by enlarging the sample size.
UBIQUITIN SPECIFIC PROTEASE-17 (USP17) RELATED GENES ARE POTENTIAL TARGETS FOR EPITHELIAL-MESENCHYMAL TRANSITION IN HIGH-GRADE SEROUS OVARIAN CANCER

Aims

To investigate gene expression differences between primary tumor, malignant cells in the ascites and metastatic implant on the peritoneal surface in high-grade advanced stage serous ovarian cancer.

Method

Biopsies from primary tumor, peritoneal implant and ascites were collected from 10 patients operated primarily for high-grade, advanced staged serous ovarian cancer. After total RNA isolation (RNeasy mini-prep, Qiagen, Valencia, CA, USA), total RNA expression profile (GeneChip® Human Gene 2.0ST Array, Affymetrix, CA, USA) were measured in tissue biopsies and fluid samples. mRNA expressions of three different groups were compared with the help of bioinformatic analysis.

Results

There were significant differences in 7 gene expressions between primary tumor and peritoneal implant, 1041 gene expressions between primary tumor and malignant cells in the ascites, 648 gene expressions between peritoneal implant and malignant cells in the ascites. Functional analyses of candidate genes were carried out by gene ontology and pathway analysis. Genes related with three processes which are protein deubiquitination, ubiquitin-dependent protein catabolism and apoptotic processes were significantly differentially expressed between primary tumor & peritoneal implant and malignant cells in the ascites. All of those genes were belong to USP17 gene family.

Conclusion

Gene expression difference between primary tumor and the peritoneal implant is not as much as the difference between primary tumor and free cells in the ascites. These results show that, malignant cells return into its genetic origin after they invade on peritoneum. This is the first study that offers USP17 as a potential target for epithelial-mesenchymal transition. Further studies will elucidate the importance of USP17 and other deubiquitinating enzymes in metastasis of ovarian cancer.
LEARNING CURVE AND SURGICAL NODAL RETRIEVAL OUTCOME FOR TOTAL ABDOMINAL HYSTERECTOMY WITH LYMPHADENECTOMY IN TREATMENT OF ENDOMETRIAL CANCER

Aims

Staging surgery in patients with endometrial cancer is important in management and have a great impact on overall survival. The more competent surgeon, the less under/overstaged surgeries occurs. Thus, our aim was to determine learning curve for total abdominal hysterectomy (tAH) with lymphadenectomy (pelvic/paraaortal) for surgical treatment of endometrial cancer and feed-back for assessment of extent of lymphadenectomy and surgical management.

Method

Retrospective analysis including 303 patients, mean age 64.1 yrs (35-90). The learning curve of surgical procedure was estimated with respect to chronologic order. Surgeries were performed by surgeons with different level of oncosurgical skills, divided into two groups (experienced - Group A) and in residency (trainees - Group B).

Results

There were performed 183 tAH with adnexectomy (bilateral/unilateral), 114 tAH with adnexectomy and pelvic lymphadenectomy and 6 tAH with adnexectomy and pelvic-paraaortic lymphadenectomy. Mean number of total retrieved lymph nodes was 11.7 (1-35), from both fossa obturatoria 5.8 (0-19), both parailiac 9.4 (0-24) and paraaortic areas 4.2 (1-9), respectively. Surgeons in group A removed more lymph nodes compared to group B (mean 15.1 vs 10.3, p<0.05), achieved less complications (p<0.05) and shorter operation time (p<0.01). Similarly, they did it for fossa obturatoria clearance 6.7 vs 3.4 nodes (p=0.0041), respectively. Surgeons in group A showed stable operative outcomes, 55% of surgeons in group B improved their surgical skills when comparing first half-pool of operated patients to the second half. Achievements have been noted in reduction of total operative time (p=0.026), rate of surgical complications (9% vs 0.8%, p=0.031) and total number of lymph nodes removal (8.6 vs 10.7, p<0.05).

Conclusion

The learning curve for tAH with lymphnode dissection is an important guide for education, clinical training and quality feedback for every surgeon participating in surgical management of endometrial cancer.
