Endometrial cancer is a clinically heterogeneous disease, and it is becoming increasingly clear that this heterogeneity may be a function of the diversity of the underlying molecular alterations. Recent large-scale genomic studies have revealed that endometrial cancer can be divided into four distinct molecular subgroups, with well-described underlying genomic aberrations. These subgroups carry significant prognostic as well as predictive information and are therefore attractive adjuncts to current clinical practice. The road towards the integration of molecular information into the current classification is not without obstacles. However, strong collaborative studies from teams across the world are tackling these issues, and a novel endometrial cancer classification integrating clinicopathological with genomic features is at the horizon. Pathologists and caretakers of endometrial cancer patients need to engage and understand the possibilities and limitations of this new molecular approach, as the technology used to determine the molecular features of endometrial cancer are becoming widely available. During this special lecture I will discuss how molecular aberrations in endometrial cancer can be assessed and how they can be exploited to refine risk-stratification strategies used by radiation oncologists. I will discuss how this information is currently used in the PORTEC-4a trial to guide the choice of adjuvant treatment in early-stage endometrial cancer. Finally, I will address how this molecular information is becoming increasingly relevant in the setting of advanced-stage or recurrent disease. Thus, although histological typing and careful pathological staging will remain crucial to clinical management, the incorporation of molecular pathology data is inevitable and should be embraced.
AGO-OVAR 12: A RANDOMIZED PLACEBO-CONTROLLED GCIG/ENGOT-INTERGROUP PHASE III TRIAL WITH CHEMOTHERAPY +/- NINTEDANIB FOR ADVANCED OVARIAN CANCER: OVERALL SURVIVAL RESULTS

Aims

AGO-OVAR12 study investigated the value of Nintedanib (N), an oral inhibitor of VEGFR, PDGFR, and FGFR in the treatment of newly diagnosed advanced ovarian cancer patients (pts). The data of final analysis of overall survival (OS) is reported here.

Method

Pts with FIGO IIB-IV ovarian cancer and upfront debulking surgery were randomly assigned (2:1) to receive six cycles of carboplatin (AUC5 or 6) and paclitaxel (175mg/m²) in addition to either 200 mg of Nintedanib (TC+N) or placebo (TC+Pl) twice daily for up to 120 weeks. Primary endpoint was investigator assessed progression-free survival (PFS) and has been reported to be significantly better previously. Here we report final OS results.

Results

1,366 patients were recruited 12/2009 – 7/2011 by 9 study groups; 911 TC+N and 455 received TC+Pl. Overall, 39% had a very high risk with FIGO III and residuals >1cm or FIGO IV while 61% had FIGO III and residuals ≤1cm or FIGO II (283 in TC-Pl, 556 in TC+N). After 605 observed deaths, OS did not show statistically significant differences (median N+TC 62.0 vs Pl+TC 62.8 months; HR 0.99; 95%CI:0.83 – 1.17; p=0.86). None of the subgroups defined by randomization strata, neither the high/low risk subgroups showed a statistically significant difference in OS between treatment groups. Adverse events leading to death occurred in 30 (3.3%) patients in TC+N and in 16 (3.6%) patients in TC+Pl.

Conclusion

Although well tolerated in combination with TC, Nintedanib combination with TC did not affect OS compared to placebo. This is the first time these data are shown.

CISPLATIN CHEMO-RADIATION VERSUS RADIATION IN FIGO STAGE III B SQUAMOUS CELL CARCINOMA OF THE UTERINE CERVIX (CRACKX TRIAL: NCT00193791)

U. Mahantshetty¹, S. Shrivastava¹, R. Engineer², S. Chopra², R. Havaldar³, V. Hande¹, R. Kerkar³, A. Maheshwari³, T. Shylasree⁵, J. Ghosh⁶, J. Bajpai⁶, L. Naidu¹, S. Gulia³, S. Gupta¹

³Tata Memorial Hospital, Clinical Research Secretariat, Mumbai, India
⁴Tata Memorial Hospital, Gynecologic Oncology, Mumbai, India
⁵Tata Memorial Hospital, Gynecologic Oncology, Mumbai, India
⁶Tata Memorial Hospital, Medical Oncology, Mumbai, India

Aims

Although concomitant chemo-radiation is standard of care for locally advanced cervical cancer, the evidence in stage IIIB disease is not robust. We report the final results of a randomized study comparing concomitant chemo-radiation (CTRT) to definitive radiation (RT) in women with FIGO stage IIIB squamous cell cervical cancer.

Method

Women in RT arm received a combination of external radiation (50 Gy in 25 fractions over 5 weeks) and brachytherapy (low dose rate or high dose rate). Women in CTRT arm received same radiation with the addition of cisplatin (40 mg/m² per week for 5 weeks). Primary and secondary end points were disease-free survival (DFS) and overall survival (OS), respectively.

Results

Between July 2003 and September 2011, 850 women were randomized (424 to CTRT and 426 to RT). At a median follow-up of 88 (IQR=61.3 – 113.1) months, there were 222 recurrences and 213 deaths in CTRT and 252 recurrences and 243 deaths in RT arms, respectively. The 5-year DFS was significantly higher in CTRT compared to RT arm (52.3% vs. 43.8%; HR for relapse or death=0.81; 95% CI=0.68–0.98, p=0.03) as was 5-year OS (54% vs. 46%; HR for death=0.82; 95% CI= 0.68–0.98, p=0.04). After adjusting for prognostic factors, CTRT continued to be significantly superior to RT for DFS and OS. There was a higher incidence of acute hematological toxicities in CTRT arm.

Conclusion

CTRT, using weekly cisplatin, results in significantly better DFS and OS compared to RT in women with stage III B squamous cervical cancer.
Changes in neoangiogenetic profile of paired primary and recurrent high-grade serous ovarian cancer (HGSOC): a study of the “Octips” consortium.

Aims

To investigate, in a large cohort of paired primary and recurrent HGSOC tissue samples, changes occurring in tumor vasculature from primary (pOC) to recurrent (rOC) disease and its implications in patients' treatment response and survival.

Method

222 pOC and rOC intra-patient paired tissue samples derived from 111 HGSOC, which were treated between 1985 and 2013 through PDS plus platinum-based chemotherapy, were assessed with immunohistochemistry for the expression of angiogenesis biomarkers (CD31, to evaluate microvessel density, and VEGF). Expression profiles were compared between pOCs and rOCs and were correlated with patients' clinicopathological and survival data.

Results

75.7%(84/111) and 19.8%(22/111) pOCs were CD31high and VEGFhigh, respectively. CD31high and VEGFhigh samples were detected in 51.4%(57/111) and 20.7%(23/111) rOCs. CD31high/VEGFhigh co-expression was found in 18.9%(21/111) and 8.1%(9/111) of pOCs and rOCs, respectively. CD31 and VEGF levels were significantly associated in pOCs (p=0.013).

Pairwise analysis showed no significant change in CD31 (p=0.935) and VEGF (p=0.086) levels from pOCs to rOCs.

No significant association between CD31 or VEGF levels and patients' clinicopathologic characteristics was observed. Nevertheless, CD31high, VEGFhigh and CD31high/VEGFhigh expression were significantly associated with better OS (p=0.019, p=0.034, p=0.020, respectively).

On multivariate analysis, VEGFhigh and CD31high/VEGFhigh expression were independent prognostic factor for OS (HR:0.343,95%CI:0.158-0.746;p=0.007 and HR:0.295,95%CI:0.130-0.672;p=0.004, respectively).

Analysis on 52 pts with known somatic BRCA status highlighted that BRCA mutations did not influence CD31 and VEGF expression.

Conclusion

The neoangiogenetic profile of HGSOC, as assessed by CD31/VEGF immunohistochemistry, did not undergo significant changes between pOC and rOC. Furthermore, higher VEGF and CD31/VEGF levels independently improve HGSOC patients' OS.

Aims

Uncontrolled, non-randomised pre-surgical window studies in endometrial cancer have shown a beneficial effect of metformin on tumour growth. Such studies recruited small numbers of women and most lacked a contemporaneous control group. The aim of this study was to assess the impact of pre-surgical metformin on endometrial tumour growth using an adequately powered randomised trial design.

Method

A multicentre, double-blind, placebo-controlled trial randomised women with atypical endometrial hyperplasia or endometrioid endometrial cancer to either metformin 850mg bd or matched placebo for 1-5 weeks prior to hysterectomy. The primary outcome was change in immunohistocchemical expression of the proliferation marker Ki-67 between pre and post-treatment endometrial biopsies and was performed according to a published protocol. Secondary outcomes included the effect of metformin on phosphorylated markers of the PI3K/Akt pathway.

Results

Eighty-eight women completed treatment, of whom 45 received metformin for a mean duration of 20.5 days (SD ±7.3 days). Most had early stage disease, although 13.6% had extra-uterine disease at presentation. Overall, metformin exposure had no effect on Ki-67 expression, when analysed using an ANCOVA model (mean difference in post-treatment Ki-67 -0.57%, 95%CI -7.57% to 6.42%, p=0.87), and neither did it decrease expression of pS6 or pAkt (mean difference pS6 -15.96, p=0.15; pAkt -5.08, p=0.51).

Conclusion

A standard diabetic dose of metformin does not reduce endometrial tumour growth when tested in an adequately powered, methodologically rigorous controlled trial. High-quality trial data demonstrating clinical efficacy are required before drugs are considered for repurposing and introduction into routine oncological practice.

Aims

GX-188E is a novel, dendritic cell targeting, DNA therapeutic vaccine encoding for HPV types 16/18- E6/E7 antigens. A previous phase I trial has been reported.

Method

72 patients were enrolled on an open-label, multicenter Phase 2 trial. Eligible patients had biopsy proven CIN3 and HPV16 and/or 18 infection confirmed by PCR. GX-188E was delivered by electroporation at weeks 0, 4, and 12. The primary endpoint was a response defined as histological regression to CIN1 or less at week 20. Safety and Immunogenicity of the vaccine were also assessed.

Results

72 patients were enrolled. 7 patients were dropped out or were found to be ineligible (data to be shown). As of March 2016, 65/72 CIN3 patients reached week 20. Of the 65 patients, 50.8% (33/65) regressed to CIN1 or less on histology at week 20. Patients with small lesion at enrollment (<50% of cervix by colposcopic inspection) were more likely to have histological regression (63.6%, 21/33) as compared to patients with lesions >50% (37.5% 12/32). The 1mg dosing group demonstrated a higher histological regression rate (59.4%, 19/32) compared to the 4 mg dosing group (42.4%, 14/33). Moreover, patients in the 1 mg group with small baseline lesions showed a regression rate of (76.9%, 10/13) and this rate increased in patients with no carcinoma in situ (85.7%, 6/7). The most common adverse events were local injection site reactions.

Conclusion

GX-188E vaccine shows promising activity and therapeutical potential for treatment of CIN3 and warrants continued investigation.
WHAT MODIFIES THE OUTCOME OF RECURRENT GRANULOSA CELL TUMORS OF THE OVARY?

1Clinica Universidade de Navarra, Ginecology, Pamplona, Spain
2Clinica Universidade de Navarra, Oncology, Pamplona, Spain
3Clinica Universidade de Navarra, Pathology, Pamplona, Spain

Aims

To evaluate the risk of death and the independent variables that define the prognosis of patients with recurrent granulosa cell tumor of the ovary (r-GCT).

Method

Articles for analysis were identified after a search of the PubMed database for articles published between 1997 and 2017. A database and a pooled analysis were designed compiling characteristics and outcomes of recurrent patients.

Results

After reviewing 204 articles, 31 were considered adequate for the research. 2386 patients diagnosed with GCT and 619 recurrent patients were included. Individual data of 146 patients was included for pooled analysis. Median follow up was 85 months. The mean disease free interval (DFI) was 68.3 months, mean post-recurrence survival 69.1 months, and mean overall survival 135.19 months. The risk of disease-related death in patients after a first relapse was 33.19%. Residual tumor at first surgery and FIGO stage were the independent variables found for predicting relapse. Multivariate analysis in the pooled population identified as independent variables modifying post-recurrence survival a DFI>60 months, secondary cytoreduction after first relapse and age <55yo.

Conclusion

Despite their indolent behaviour, r-GCT show a risk of death exceeding 30%. Age <55, DFI >60 months and surgical resection predicted a longer survival. This review compiles the largest series of r-GCT ever published.
LION – Lymphadenectomy in Ovarian Neoplasms. A Prospective Randomized AGO Study Group Led Gynecologic Cancer Intergroup Trial.

Aims

There is no level-1 evidence on the role of systematic pelvic and para-aortic lymphadenectomy (LNE) in patients with advanced ovarian cancer (AOC) with macroscopic complete resection and clinically negative lymph nodes (LN) and surgical management is very heterogeneous.

Method

Patients with newly diagnosed AOC FIGO IIB-IV with macroscopic intraperitoneal complete resection and pre- and intra-operatively clinical negative LN were randomized intra-operatively to LNE vs no-LNE. The primary endpoint was overall survival.

Results

647 patients were randomized between 12/08 and 1/12 to LNE (n=323) or no-LNE (n=324). The median number of removed LN was 57 (pelvic 35 and para-aortic 22). Microscopic LF metastases were diagnosed in 56% of the pts in the LNE arm. Median OS was 69 and 66 months in the no-LNE and LNE arm respectively (HR 1.06, 95%CI 0.83-1.34, p=0.65) and the median PFS was 26 months in both arms (HR 1.11, 95%CI 0.92-1.34 p=0.30). In the LNE arm a 64 minutes increased surgical duration (352 vs 288 min), higher blood loss (median 650 vs 500 ml), and a higher transfusion rate (67% vs 59%) were reported. Serious post-operative complications occurred more frequently in the LNE arm (e.g. rate of re-laparotomies 12.1% vs 5.9% [p=0.006], hospital re-admittance rate 8.0% vs 3.1% [p=0.006] and deaths within 60 days after surgery 3.1 vs 0.9% [p=0.049]).

Conclusion

Systematic pelvic and para-aortic LNE in patients with AOC with both intra-abdominal complete resection and clinically negative LN neither improve overall nor progression-free survival, therefore it should be omitted to reduce post-operative morbidity and mortality.

Aims

ARIEL3 (NCT01968213) evaluated rucaparib vs placebo as maintenance treatment in patients with recurrent platinum-sensitive OC.

Method

Eligibility: ≥2 prior platinum-based therapies, platinum-sensitive OC (progressive disease [PD] ≥6 months after penultimate platinum), complete (RECIST v1.1) or partial response (RECIST v1.1 or GCIG CA-125 criteria) to most recent platinum, and CA-125 less than the upper limit of normal. Patients were randomised 2:1 to oral rucaparib 600 mg BID or placebo. Investigator-assessed progression-free survival (PFS) (primary endpoint) was assessed in a step-down procedure for 3 nested groups: (1) BRCA mutant (germline or somatic BRCA mutation); (2) homologous recombination deficient (BRCA mutant or BRCA wild type/loss of heterozygosity [LOH] high); and (3) intent-to-treat (ITT) population. PFS was also assessed by blinded independent central review (key secondary endpoint) and in subgroups of the ITT population (exploratory endpoint).

Results

ARIEL3 enrolled 564 patients (375, rucaparib; 189, placebo). PFS data are summarised in the Figure. The most common grade ≥3 treatment-emergent adverse events (TEAEs) were anaemia (18.8%, rucaparib; 0.5%, placebo) and alanine/aspartate aminotransferase increase (10.5%, 0%). As of 15 Apr 2017, 13.4% (rucaparib) and 1.6% (placebo) of patients discontinued due to TEAEs (excluding PD);
1.6% and 1.1% of patients died due to AEs (including PD).

### Conclusion

Rucaparib significantly improved PFS vs placebo in all primary analysis groups, including the ITT patient population.

15Netherlands Cancer Institute, Medical oncology/DGOG, Amsterdam, The Netherlands

Aims

Cytoreductive surgery and systemic therapy are essential for newly diagnosed ovarian cancer. We conducted a multicenter, open-label phase 3 trial to study whether the addition of intraperitoneal chemotherapy under hyperthermic conditions (HIPEC) to interval cytoreductive surgery would improve outcome among patients receiving neo-adjuvant chemotherapy for stage I-II epithelial ovarian cancer.

Method

We randomly assigned patients who showed at least stable disease after three cycles of carboplatin (area under the curve 6) and paclitaxel (175 mg/m²) to receive interval cytoreductive surgery with or without HIPEC using cisplatin (100 mg/m²). Randomization was performed peri-operatively and eligible patients had a complete or optimal cytoreduction. Three additional cycles of carboplatin/paclitaxel were given post-operatively. The primary endpoint was recurrence-free survival. Overall survival, toxicity, and quality-of-life were key secondary endpoints.

Results

A total of 245 patients were randomly assigned to one of the two treatment strategies. In an intention-to-treat analysis, interval cytoreductive surgery with HIPEC was associated with longer recurrence-free survival than interval cytoreductive surgery alone (14.2 vs. 10.7 months, respectively; hazard ratio [HR], 0.66; 95% confidence interval [CI], 0.50 to 0.87; P=0.003). At the time of analysis, 44% of patients were alive, with a significant improvement in overall survival favouring HIPEC (45.7 vs. 33.9 months; HR, 0.67; 95% CI, 0.48 to 0.94, P=0.02). The number of patients with grade 3-4 adverse events was similar in both treatment arms (27% vs 25%, p=0.76).

Conclusion

Adding HIPEC to interval cytoreductive surgery is well tolerated and improves recurrence free and overall survival in patients with stage III epithelial ovarian cancer.

9University College London, Department of Oncology- UCL Cancer Institute, London, United Kingdom

Aims

Olaparib (Lynparza), an oral PARP inhibitor, significantly improved progression-free survival versus placebo in patients with PSR SOC in a randomized, double-blind, Phase II study (Study 19, NCT00753545), with the greatest benefit in patients with BRCA1/2 mutations (BRCAm). Interim overall survival (OS) analysis also suggested an advantage for olaparib-treated patients (database cut-off: 30 September 2015). We report the final analysis of long-term olaparib benefit in patients enrolled in Study 19.

Method

Patients who had received ≥2 prior regimens of platinum-based chemotherapy and were in response received olaparib (400 mg bid; capsules) or placebo until disease progression. Retrospective germline or tumour testing resulted in a known BRCAm status for 254/265 patients (96%).

Results

At final database cut-off (9 May 2016), median OS follow-up was 78.0 months. A long-term treatment benefit was shown; see Table for the final hazard ratios (HRs) for OS versus placebo (unadjusted for crossover: 13% full-analysis set [FAS] placebo patients; 23% BRCAm subgroup placebo patients). Details of BRCA wild-type (BRCAwt) patients on treatment for ≥6 years will be presented. No new safety signals or changes in the olaparib tolerability profile were seen.

Conclusion

Conclusions: This final analysis showed that olaparib provides clinically significant, long-term treatment benefit in patients with PSR SOC. A durable benefit was seen in ≥10% of BRCAm and BRCAwt patients, who continued to receive and benefit from olaparib for ≥6 years – unprecedented in the relapsed ovarian cancer setting. Olaparib was well tolerated in this population and the analysis suggested an olaparib benefit on OS in BRCAm patients.
QUALITY OF LIFE WITH WEEKLY, DOSE-DENSE VERSUS STANDARD CHEMOTHERAPY FOR OVARIAN CANCER IN THE ICON8 STUDY

Aims

To explore the impact of dose-dense chemotherapy on quality of life (QoL) in women with newly-diagnosed ovarian cancer.

Method

ICON8 is a randomised phase III trial of standard vs. weekly dose-dense chemotherapy in newly-diagnosed ovarian cancer. Patients were randomised 1:1:1 either to (1) 3-weekly carboplatin AUC5/6 paclitaxel 175mg/m², (2) 3-weekly carboplatin AUC5/6 & weekly paclitaxel 80mg/m² or (3) weekly carboplatin AUC2 & weekly paclitaxel 80mg/m². Primary analysis of progression-free survival showed no significant difference between groups. All participated in the QoL substudy and completed EORTC-QLQ-C30 and OV28 questionnaires at enrolment, before each chemotherapy cycle, 6-weekly to 9 months, then 3 monthly to 2 years. Primary QoL endpoint was global QoL at 9 months, secondary endpoints included specific function and symptom scores. Statistical significance was assessed by analysis of covariance adjusted for baseline score.

Results

17,515 QoL questionnaires were completed by 1,540 participants. There was no significant difference in global QoL (p=0.08), fatigue (p=0.42), emotional function (p=0.21) or social function (p=0.83) at 9 months between randomised groups. Significant difference was observed in peripheral neuropathy (p<0.001), with higher mean scores at 9 months in both weekly arms (27.4, 34.2, 31.3 in arms 1,2,3 respectively). Exploratory analysis indicated that this difference continued to 18 months from randomisation.

Conclusion

Self-reported 9-month global QoL, fatigue, emotional and social functioning did not differ significantly between treatment arms. However, long-term peripheral neuropathy was significantly worse in both weekly treatment groups. These findings do not support weekly, dose-dense paclitaxel within the upfront treatment of high risk ovarian cancer.
LATE BREAKING ORAL SESSION

15Greater Baltimore Medical Center-, medical oncology, Baltimore- MD, USA

Aims

Uterine serous carcinoma is a rare, aggressive variant of endometrial cancer. Trastuzumab is a humanized monoclonal antibody that targets Her2/neu, a receptor overexpressed in 30% of uterine serous carcinoma. This multi-center, randomized phase II trial compared carboplatin/paclitaxel with and without trastuzumab in patients with advanced or recurrent uterine serous carcinoma who overexpress Her2/neu.

Method

Eligible patients had primary stage III-IV or recurrent, HER2/neu-positive disease. Participants were randomized to receive carboplatin/paclitaxel (control arm) for 6 cycles with or without intravenous trastuzumab (experimental arm) until progression or unacceptable toxicity. The primary endpoint was progression-free survival. Survival differences between treatment arms were assessed for significance via 1-sided log-rank tests.

Results

From August 2011 to March 2017, 61 patients were randomized. Forty progression-free survival related events occurred among 58 evaluable subjects. Among all patients, median progression-free survival was 8.0 months (control) versus 13.3 months (experimental; p=0.014, HR 0.50 with 90% CI 0.29–0.85). Similarly, median progression-free survival was 10.9 (control) versus 17.9 (experimental) months among 41 stage III-IV patients undergoing primary treatment (p=0.028, HR 0.45, 90% CI 0.22–0.91) and 6.0 (control) versus 9.2 months (experimental), respectively, among 17 patients with recurrent disease (p=0.0029, HR 0.14, 90% CI 0.04–0.53)(Figure). Toxicity was not different between treatment arms, and no unexpected safety signals emerged.

Conclusion
Addition of trastuzumab to carboplatin-paclitaxel was well-tolerated and increased progression-free survival. This regimen may come to represent the new standard of care for women with advanced or recurrent uterine serous carcinoma who overexpress Her2/neu.

Aims

The effect of the increased awareness of the potential to treat cancer during pregnancy is currently unknown. Therefore we aimed to analyse the oncological management and the obstetrical and neonatal outcomes of patients treated in the last 20 years by members of the International Network on Cancer, Infertility and Pregnancy (INCIP).

Method

Oncologic, obstetric and neonatal outcome data of consecutive patients diagnosed with primary invasive cancer during pregnancy between 1996 and 2016 were collected from the INCIP database. These data were evaluated with descriptive and multivariable analysis for the most common obstetrical and neonatal complications (preterm pre-labour rupture of membranes (PPROM) and/or contractions, small-for-gestational-age (SGA), and neonatal intensive care unit (NICU) admission).

Results

1170 patients were included from 37 centres in 16 countries, including 955 patients with a singleton pregnancy resulting in live births. Every five years, 10% more patients were treated during pregnancy (95% CI 5 to 15), there were 4% more live births (95% CI 1 to 6), and there were 9% less iatrogenic preterm deliveries (95% CI 2 to 16). The odds ratio of chemotherapy exposure was 2.02 (95% CI 1.19 to 3.40) for PPROM and/or contractions and 1.83 (95% CI 1.21 to 2.78) for SGA. For SGA, mainly platinum-based and alkylating chemotherapy appeared to increase the incidence.

Conclusion

We observed an increased tendency to treat cancer during pregnancy, which can lead to more obstetrical and neonatal complications. We recommend the referral of pregnant cancer patients who need chemotherapeutic treatment to centres with obstetrical high care units.
The role of secondary cytoreductive surgery in platinum-sensitive recurrent ovarian cancer (PSROC) has not been defined by level-1 evidence.

Method

Pts with PSROC and 1st relapse if they presented with a positive AGO-score which selects approximately 50% of all PSROC pts. They were randomized to 2nd-line chemotherapy vs cytoreductive surgery followed by chemo. We report results of the predetermined interim analysis.

Results

409 pts were randomized 2010-2014. Platinum-free interval exceeded 12 mos in 75% and 76% pts in both arms. Complete resection was achieved in 72.5% of operated pts; 87% and 88% received a platinum-containing 2nd-line therapy. 60/180-d mortality rates were 0 and 0.5% in the surgery and 0.5 and 2.5% in the no-surgery arm. Re-laparatomies were performed in 7pts (3.5%). With the exception of myelosuppression no further significant differences were observed with respect to grade 3+ adverse events.

Median PFS was 14 mos without and 19.6 mos with surgery (HR: 0.66, 95%CI 0.52-0.83, p<0.001). Median time to start of first subsequent therapy (TFST) was 21 vs 13.9 mos in favor of the surgery arm (HR 0.61, 95%CI 0.48-0.77, p=p<0.001). Analysis of primary endpoint OS is hampered by unexpected good OS and therefore kept blinded due to immaturity.

Conclusion

Surgery in PSROC pts selected by a positive AGO-Score resulted in increase of PFS and TFST with very acceptable treatment burden. Until final OS data will definitively define the role of secondary cytoreductive surgery it should at least be considered as valuable option in pts with a positive AGO-Score.
PATTERNS OF LYMPH NODE METASTASES IN APPARENT STAGE I LOW-GRADE EPITHELIAL OVARIAN CANCER: A MULTICENTER STUDY.

Aims

To determine oncological outcomes and incidence of lymph node (LN) metastases in women who underwent systematic pelvic and para-aortic lymphadenectomy for surgical staging of apparent stage I low-grade epithelial ovarian cancer (LGEOC).

Method

A retrospective study was performed at nine institutions across Europe and USA. Patients who underwent surgical staging for presumed stage I LGEOC between 2000 and 2016 were included. A minimum number of ≥10 pelvic and ≥10 para-aortic LN was required. Patients with preoperative radiologic or clinical evidence of extraovarian or LN-disease, and those with non-epithelial histology, were excluded.

Results

The overall incidence of LN metastases was 4.3% in the 163 evaluated patients. The incidence of LN involvement in serous, endometrioid and mucinous subtypes was 10.7%, 1.5% and 0%, respectively. Upstaging due to LN involvement alone occurred in only 2.4% of the patients. Eighty-nine (54.6%) patients received adjuvant chemotherapy due to FIGO stage ≥IC disease. The five-year progression-free and overall survival was 93.2% (95%CI:89.4-97.1%) and 94.5% (95%CI:90.9-98.0%), respectively. There was no significant difference in PFS or OS between LN-negative versus LN-positive patients. However, fewer patients received adjuvant chemotherapy in the LN-negative group. Multivariate analysis did not identify any independent prognostic factor of survival.

Conclusion

The risk of LN involvement in non-serous apparent stage I LGEOC appears low with a rate of <1% in this retrospective analysis, raising questions about the value of lymphadenectomy in those patients. Larger scale prospective studies are warranted to evaluate the oncologic safety of omitting systematic LN-staging in apparent stage I non-serous LGEOC.
MUCINOUS OVARIAN CANCER (MOC) : WHAT IS THE REPRODUCIBILITY OF THE WHO CLASSIFICATION ?

⁵Hospices Civils de Lyon, Department of Pathology, Lyon, France

Aims

The WHO 2014 classification redefined the diagnostic classification of ovarian mucinous tumors: borderline mucinous tumor (BOM) and mucinous expansive (EA) and infiltrative (IA) adenocarcinoma.

Method

Retrospective study of 95 patients referred to the IGR for a borderline or malignant ovarian mucinous tumor from 1999 to 2016. All cases were reviewed by two gynecological pathologists (CG and MDS). Each pathologist interpreted the set of slides (from 1 to 4 HES per case) independently and was blinded to the interpretation of the other and to the clinical outcome of the patient.

Three types of pathological diagnoses were rendered: BOM, EA et IA. Grade of nuclear atypia and the presence of microinvasion were noted.

Results

Diagnosis was concordant between the 2 blinded independent pathologists for 87% of cases. Inter-observer diagnostic discordance was noted in 8 cases, mainly attributed to disagreement on IA vs EA with severe atypia (6/8). In 2 cases there was discordance on EA vs BOM.

Conclusion

The classification of mucinous tumors according to the WHO 2014 is difficult even for expert pathologists. The major difficulties are seen in separation of BOM from expansile adenocarcinoma. Also, the presence of severe atypia in an otherwise expansile type of invasion is interpreted differently between two pathologists (EA versus IA).

Nevertheless, it seems important to define more reproducible histological criteria for distinction of mucinous ovarian tumors between borderline and expansile adenocarcinomas in one hand and expansile and invasive adenocarcinomas in the other hand. This study is underway in the TMRO network organized in France.
THE ROLE OF THE PERITONEAL CANCER INDEX IN SURGERY FOR ADVANCED OVARIAN CANCER
M. Rosendahl, H. Phillip, P. Sonia, A. Traut, B. Ataseven, S. Schneider, M. Sporkmann
1 Rigshospitalet, Department of Gynecology and Obstetrics, Copenhagen, Denmark
2 Kliniken Essen-Mitte, Department of Gynecology and Gynecology, Essen, Germany

Aims

The Peritoneal Cancer Index (PCI) is integrated in the ESGO Ovarian Cancer Operative Report as it describes peritoneal tumor distribution and is a predictor of residual tumor (RT).

We hypothesized that the qualitative anatomical distribution, and not the sum of PCI, predicts RT.

Method

Prospective data from 213 consecutive patients with epithelial ovarian cancer FIGO IIIB-IV undergoing upfront surgery with maximal cytoreductive effort from the Kliniken Essen-Mitte were analyzed with regards to pre-, peri-, and postoperative factors.

Results

Total PCI was significantly related to CA-125 and albumin levels, ascites, FIGO stage, surgical complexity score, duration of surgery, blood loss and number of transfusions and was predictive of RT (P<0.0001).

Complete resection rates according to PCI scores were: PCI 1-5: 100%, PCI 6-10: 85%, PCI 11-15: 70%, PCI 16-20: 42%, PCI 21-25: 47%, PCI>25: 47%. With a cut-off of 15, ROC curve analysis for RT provided an AUC of 0.75 with a sensitivity of 74% and a specificity of 67%.

There was RT in 82 patients (38%). The only limiting intra-peritoneal areas were carcinosis in the liver hilus, on the small bowel or in the mesenteric root corresponding to PCI regions 2 and 9-12 respectively (N=68 (83%).)

Seven patients had only extra-abdominal, visceral or retroperitoneal metastases not evaluable with PCI.

Conclusion

The anatomical locations and not the sum of PCI predict complete resection.

Evaluating the liver hilus and the small bowel gives adequate information of possible RT in most patients. Therefore, PCI seems of questionable clinical relevance in ovarian cancer surgery.
ORAL 01 - OVARIAN

ESGO7-0309

THE PERITONEAL CANCER INDEX (PCI): SELECTED REGIONS - AND NOT THE TOTAL PCI - ARE PREDICTIVE OF SURVIVAL IN ADVANCED OVARIAN CANCER

M. Rosendahl1, P. Harter2, C. Høgdall3

1Rigshospitalet, Department of Gynecology and Obstetrics, Copenhagen Ø, Denmark
2Klinikum Essen-Mitte, Department of Gynecology and Gynaecology, Essen, Germany

Aims

The peritoneal cancer index (PCI) describes the peritoneal cancer spread in 13 peritoneal areas (0-12) and has been shown to correlate with complete resection (CR) rates in advanced epithelial ovarian cancer (AOC).

We hypothesized that only certain PCI-areas were predictors of complete resection.

In this study we critically evaluate the usefulness of the PCI as a predictor of complete resection (CR) and median overall survival (OS) (months) in AOC.

Method

Prospective preoperative, surgical and survival data from 878 consecutive cases of AOC was obtained from the Nationwide Danish Gynecological Cancer Database.

Results

CR rate was 57%. Patients with CR had significantly longer OS compared to patients without CR: 62.6 (95% CI: 53.7-71.5) vs. 23.9 (95% CI: 19.1-28.6); p<0.0001.

Patients with PCI > median (13) had poorer OS compared to patients with PCI ≤ median: 26.7 (95% CI: 23.7-28.9) vs. 56.8 (95% CI: 49.5-64.2); p<0.0001.

In COX regression, Total PCI (HR: 1.028 (95% CI: 1.017-1.039)), Tumor Rest (HR: 1.64 (95% CI: 1.29-2.08)), Performance Status (HR: 1.31 (95% CI: 1.15-1.50)), Age (HR: 1.02 (95% CI: 1.01-1.03)) and FIGO stage (HR: 1.05 (95% CI: 1.02-1.09)) were significant cofactors for survival.

In 88% of the cases, the primary limiting factor for CR was carcinosis on the small bowel/mesenterium, stomach or hepatoduodenal ligament, corresponding to areas 2 and 9-12 in PCI (PCI 2+9-12).

ROC curve AUC for the total PCI was 81%. Selecting only PCI 2+9-12, AUC increased to 83%. In COX regression, PCI 2+9-12 had a higher HR than Total PCI (HR: 1.061 (95% CI: 1.03-1.09)).

Conclusion

Liver hilus and small bowel carcinosis are stronger predictors of CR and survival than the sum of the PCI. PCI therefore seems of limited value in the peri-operative evaluation of AOC.
HORMONAL AND FERTILITY OUTCOME AFTER FERTILITY SPARING SURGERY AND CHEMOTHERAPY FOR OVARIAN NEOPLASMS: A RETROSPECTIVE STUDY

2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33-20900 Monza, Italy
3Istituto di Ricerche Farmacologiche “Mario Negri” - IRCCS, Laboratory of Methodology for Clinical Research - Department of Oncology, Via La Masa 19-20156 Milan, Italy

Aims

Fertility sparing treatment (FST) for premenopausal women in ovarian neoplasms comprises surgical sparing of the gynecological apparatus and adjuvant chemotherapy (AC) according to risk factors. Little is known regarding the interaction between AC and the hormonal and fertility outcome in this population. We evaluated this cohort of patients in terms of during- and post-treatment ovarian function, conception and pregnancy outcome.

Method

A retrospective study was carried out in patients with epithelial (EOC) and non-epithelial (N-EOC) ovarian neoplasms undergoing FST with or without AC. Non parametric tests, univariate and multivariate (adjusted for age, histology, and relapse) logistic regression analyses were performed.

Results

573 patients (206 EOC, 367 N-EOC) treated in the period between 1980 and 2012 were included in this analysis, comprising of 40.3% patients treated with AC. Median follow-up was 12.3y with median age at diagnosis of 26.4y.

Overall, ovarian failure rates was 0.01%, childbearing desire was in 41.5%, with conception success rate of 84.5%.

At multivariate analysis, AC conferred higher risk of during-treatment amenorrhea [OR:18.45(95%CI5.19-65.62),p<0.0001], especially with platinum+etoposide+bleomycin schedule (p<0.0001), whereas post-treatment amenorrhea was rare and similar in both groups(p=0.69). Conception rate was lower in AC population (81.3%v.86.4%), yet not significant [OR:0.55(95%CI0.26-1.14),p=0.11]. Successful pregnancy rate was not affected by treatment (79.8%v.80.3%), [OR:0.94(0.51-1.75),p=0.85].

Conclusion

In this large cohort, AC affects during-treatment amenorrhea, with seemingly no significant impact on conception and successful pregnancy rates. Further follow up warrants more robust information regarding conception rates and non-surgical menopausal age. Pre-treatment counseling should discuss these risks in such young population.

ESGO7-0379

DECISIONAL VALUE OF PRETHERAPEUTIC LAPAROSCOPIC EXTRAPERITONEAL ILIO-PARAORTIC (EL-PALND) VERSUS PET-CT IN LOCALLY ADVANCED CERVICAL CARCINOMAS (LACC)

E. Leblanc1, F. Narducci1, D. Hudry1, L. Bresson1, Y. Borghesi1, S. Taleb1, A.S. Lemaire1, A. Lesoin1, H. Gauthier1

1centre oscar lambret, gynecologic oncology, lille, France

Aims

Management of LACC (FGO stage IB2-IVA) is usually based on definitive chemoradiation therapy (CRT), tailored upon the results of pretherapeutric imaging (MRI, CTscan and/or PET-CTscan). As accuracy of imaging is low especially in case of low-volume metastases. EL-PALND has been suggested to better define the indication and upper limit of CRT fields. To clarify the indications of this procedure, we prospectively compared the results of systematic pretherapeutic ilio-infraenal EL-PALND to PET-CT in LACC patients with no contra-indication for surgery, nor evidence of distant metastasis.

Method

From 2005 to 2015, all consecutive LACC patients, with normal morphological imaging (MRI and/or CTscan), were submitted to hybrid PET-CTscan, systematically followed by an ilio-infraenal EL-PALND. All PET-CT results were reviewed, then compared to those of pathological node dissections. This study was approved by our local IRB.

Results

207 informed LACC patients entered the protocol. 162 had a totally extra-uterine negative PET CT, 30 had external iliac only additional hot spots, 12 had common iliac/paraaortic and 2 distant hot spots. With a mean of 21 PA nodes, pathological involvement was found in 10/162 (6.1%), 12/40 (40%), 9/13 (70%) and 2/2 (100%) patients respectively. All except 7 had less than 5mm metastases. Overall morbidity of EL-PALND (all ≤ Clavien 3a) interested 54 (30%) patients with 50% lymphocysts, but none delayed CRT more than 2 weeks.

Conclusion

Given the significant rate of occult nodal involvement at PET-CTscan, EL-PALND seems an interesting option to tailor CRT fields, especially in case of negative PET-CT beyond the level of external iliac vessels.
Aims

Although cervical intraepithelial neoplasia grade 2 (CIN 2) is often considered the histological cut-off to proceed to conisation, a substantial proportion of CIN 2 lesions regress spontaneously, particularly in young women. We aimed to estimate the rates of regression, persistence, progression and compliance with follow-up in women with CIN 2 managed with active surveillance.

Method

Medline, Embase and CINAHL were searched from 1.1.1973 to 20.8.2016 for studies reporting on outcomes of histologically-confirmed CIN 2 in non-pregnant women, managed with active surveillance for at least three months. Data extraction and risk of bias assessments were performed independently and in duplicate. Pooled proportions for each outcome were calculated with random-effects model and inter-study heterogeneity was assessed using I² statistics.

Results

We identified 36 studies (seven control arms of randomised controlled trials, 16 prospective and 13 retrospective cohort studies) that reported on the outcomes of 3093 women. At 24 months, the regression rate was 50% (95% confidence interval (CI) 43%-67%; I² 77%), the persistence rate 32% (95%CI 23%-42%; I² 82%), while the progression rate 18% (95%CI 11%-27%; I² 90%). In a subgroup analysis of 4 studies that included 1039 women under the age of 30, the rates were 60% (95%CI 57%-63%; I² 0%), 23% (95%CI 20%-26%; I² 97%) and 11% (95%CI 5%-19%; I² 67%), respectively.

Conclusion

The majority of CIN 2 lesions regress spontaneously, particularly in young women. Close active surveillance is justified for selected young women with CIN 2 that are likely to adhere to monitoring.

ESGO7-0415

CERVICAL CANCER RELAPSE RATES IN PATIENTS WITH PARA-AORTIC NEGITIVE PET SCANS: A FIVE-YEAR ANALYSIS IN AN IRISH GYNAEONCOLOGY CENTRE

A. Rowan¹, T. Walsh¹, R. McVey¹, W. Boyd¹, D. Brennan¹
¹UCD School of Medicine- Mater Misericordiae University Hospital, Dept of Gynaecological Oncology, Dublin, Ireland

Aims

To review the rates of cervical cancer relapse in our patients with no gross metastatic spread to the para-aortic nodes (PA nodes) at initial diagnosis as defined on positron emission tomography (PET).

Method

Data contained in our gynaeoncology cancer registry was combined with hospital records. All cervical cancers over a period August 2011-July 2016 were selected for analysis. Data was collected on patients staged ≥1B2 to 4A. Patients were excluded if no PET scan was performed and diagnosis of metastasis was based on PET report.

Results

Of 105 patients, 97 had a reported PET scan. Seventy-eight percent of cases were squamous pathology. At diagnosis, 71% (n=69/97) of patients were PA node-negative. Relapse rates were higher in PA node negative patients than PA node positive 20% (n=14/69) vrs 14% (n=4/28). Of PA node-negative patients, 41% (n=28/69) had pelvic nodes positive on PET scan at diagnosis, of these 39% (n=11/28) received para-aortic radiation, 25% of patients (n=7/28) relapsed, the majority 71% (n=5/7) failing systemically. Of those negative for pelvic and PA-node disease 17% (n=7/41) relapsed, 86% (n=6/7) systemically, none received extended field radiation.

Conclusion

Although PET imaging is the standard for assessment of gross metastatic disease, overall 20% of PA node-negative patients experienced a subsequent relapse. Outcome was worse in relapsed patients who had no pelvic or PA disease at diagnosis. This review shows the importance of micro-metastasis in cervical cancer not yet identifiable by PET imaging.
IMPACT OF ADJUVANT HYSTERECTOMY ON PROGNOSIS IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER TREATED WITH DEFINITIVE CONCURRENT CHEMORADIOThERAPY: A META-ANALYSIS

S.H. Shim¹, S.H. Chae¹, J.W. Seo¹, S.N. Kim¹
¹School of Medicine - University of Konkuk, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

We investigated the effect of adjuvant hysterectomy (AH) on prognosis in locally advanced cervical cancer (LACC) patients treated with concurrent chemoradiotherapy, through meta-analysis.

Method

EMBASE and MEDLINE databases and the Cochrane Library were searched for published studies comparing LACC patients who received AH after chemoradiotherapy with those who did not, through April 2016. Endpoints were mortality and recurrence rates. For pooled estimates of the effect of AH on mortality/recurrence, random- or fixed-effects meta-analytical models were used.

Results

Two randomized trials and six observational studies (AH following chemoradiotherapy, 630 patients; chemoradiotherapy, 585 patients) met our search criteria. Fixed-effects model-based meta-analysis indicated no significant difference in mortality between the groups [odds ratio (OR) = 1.01, 95% confidence interval (CI): 0.58-1.78, \( P = 0.97 \)] with low cross-study heterogeneity (\( P = 0.73 \) and \( I^2 = 0 \)). This pattern was observed in subgroup analysis for study design, radiation type, response after chemoradiotherapy, and hysterectomy type. The pooled OR for AH and recurrence was 0.59 (95% CI: 0.44-0.79, \( P < 0.05 \)) with low cross-study heterogeneity (\( P = 0.289 \) and \( I^2 = 17.8 \)), favoring the AH group. However, this pattern was not observed in the subgroup analysis for the randomized trials. There was no evidence of publication bias.

Conclusion

In this meta-analysis, AH following chemoradiotherapy did not improve survival in patients with LACC, although it seemed to reduce the risk of recurrence. Concerning the significant morbidity of AH after chemoradiotherapy, routine use of AH should be avoided.

ESGO7-0942

ONCOLOGICAL AND OBSTETRIC OUTCOME OF ABDOMINAL RADICAL TRACHELECTOMY (ART): AN UPDATED SERIES OF CERVICAL CANCER FROM A 13-YEAR EXPERIENCE

X. Wu, J. Li, X. Li

Fudan University Shanghai Cancer Center, Dept. Gynecologic Oncology, Shanghai, China

Aims

To update the oncological and obstetric outcome of our study on ART for young patients with cervical cancer.

Method

We conducted a retrospective review of a prospectively maintained database of patients undergoing ART for cervical cancer at our institution from 04/2004 to 12/2016.

Results

Three hundred and forty-eight cases were planned for ART. Among 310 patients who successfully underwent ART, 47 had IA1 disease (with positive margin or LVSI), 27 had IA2 and 236 IB1 (123 had tumor≥2cm). Histology included 46 with adenocarcinoma, 256 squamous and 8 adenosquamous carcinoma. With a median follow-up of 48 months, 10 patients recurred and 3 died. For patients with tumors≥2 cm, 6 recurred and 3 died. The 5-year RFS and OS were 96.7% and 99%, respectively. Tumor size≥2 cm and adenosquamous carcinoma impact RFS significantly on univariate analysis. On multivariate analysis, however, only adenosquamous carcinoma retained independent predictive value. Among 103 patients who attempted to get pregnant, 21 succeeded with 23 pregnancies. Assisted reproductive technology was utilized more often recently with a success rate of approximate 60%.

Conclusion

Recurrent cases accumulated as the follow-up getting longer. However, with recurrent rate of 3.3% and 5-year OS of 99%, ART still seems to be a reasonable option for selected patients with larger tumor. Adenosquamous carcinoma may have intrinsic risk for recurrence. The unsatisfactory obstetric outcome was largely attributed by the proportion of patients who did not attempt to conceive. Assisted reproduction technology was utilized to improve obstetric outcomes.

ESGO7-1067

OUTCOMES OF ROBOTIC RADICAL HYSTERECTOMY FOR CERVICAL CANCER IN COMPARISON TO OPEN AND LAPAROSCOPIC CASES: A POPULATION BASED STUDY IN THE UNITED STATES

S. Piedimonte¹, N. Czujoh-Shulman², W. Gotlieb³, H.A. Abenhaim¹
¹Jewish General Hospital, Obstetrics and Gynecology, Montreal, Canada
²Jewish General Hospital, Epidemiology and Biostatistics, Montreal, Canada
³Jewish General Hospital, Gynecologic Oncology, Montreal, Canada

Aims

For early stage cervical cancer treated with radical hysterectomy, the robotic platform may improve visualization, ergonomics and finite dissections within the parametria. We report nationwide outcomes of robotic radical hysterectomy as compared to laparoscopic and open procedures.

Method

Using the National Inpatient Sample between 2008-2013, we performed a retrospective cohort study of all women with cervical cancer undergoing radical hysterectomy. We compared baseline characteristics, length of stay, intraoperative, postoperative and mortality outcomes between robotic, laparoscopic and open procedures. We used t-test for continuous variables, chi-square for categorical and confidence intervals using SAS.

Results

Among 33,213 women with cervical cancer, 2,999 underwent radical hysterectomy; 18.2% robotic, 6.8% laparoscopic and 74.9% open. Over time, there was a significant decline in open procedures with an increase in robotic surgeries and stable trend in laparoscopic cases. There was no difference in baseline characteristics (age, BMI, race, smoking status and comorbidities) between robotic and open cases. There was no difference in intra-operative complications. There were less cumulative post-operative complications (6.95% vs 16.4%, p<0.01), in particular less wound infections (0.37% vs 1.91%, p=0.019) and ileus (2.74 vs 9.21, p<0.01). The length of stay was significantly reduced in the robotic group (mean 1.95 days vs 4.33 open, p<0.01). There were no deaths in either group. The cost was $53,928.47 for robotic, compared to $45,620.89 for open (A1 7,983.52, p<0.01).

Conclusion

Robotic radical hysterectomy is increasingly being adopted by experienced gynecologic oncologists and leads to diminished length of stay and less post-operative morbidity at the expense of increased cost.
HOW TO IMPROVE SENTINEL LYMPH NODE MAPPING WITH INDOCYANINE GREEN (ICG) IN ENDOMETRIAL CANCER?

N. Bodé1, J. Grégoire1, M.C. Renaud1, A. Sébastienelli1, K. Grondin2, C. Morin2, M. Plante1

1Hôtel-Dieu de Québec, Gynecologic Oncology, Quebec, Canada
2Hôtel-Dieu de Québec, Pathology, Quebec, Canada

Aims

To determine the validity of sentinel lymph node (SLN) biopsy with ICG in endometrial cancer and to evaluate the factors associated with poor mapping or false negative.

Method

We reviewed all patients who underwent primary surgery for endometrial carcinoma with SLN mapping using ICG followed by pelvic lymphadenectomy, from February 2014 to December 2015. SLNs were ultrastaged on final pathology. Patients’ demographics, surgical approach, FIGO stage, cervical involvement, lymphovascular space invasion, histologic type and grade were prospectively collected. Detection rate, sensitivity and negative predictive value (NPV) were calculated and univariate analysis was performed to evaluate factors associated with failed bilateral detection of SLNs.

Results

A total of 119 patients were included in the study. The overall and bilateral detection rate were 93% (111/119) and 74% (89/119). Sensitivity and NPV were 100% in patients with bilateral detection; 95% and 99% respectively in cases with at least unilateral detection. Advanced FIGO stage (III or IV) was the only factor related to failed bilateral detection (p=0.01). In 14 hemi-pelvis, the specimen labelled as SLN did not contain nodal tissue on final pathology (only lymphatic channels), which represented 37% of the “failed detection” cases. One false negative occurred in a patient with ipsilateral suspicious enlarged lymph nodes.

Conclusion

ICG is an excellent tracer for SLN mapping in endometrial cancer. Advanced FIGO stage was correlated to failed bilateral detection (p=0.01). Care should be taken to ensure that SLN specimen actually contains nodal tissue and not swollen lymphatic channels; suspicious lymph nodes should be removed regardless of the mapping.
REFINEMENT OF HIGH-RISK ENDOMETRIAL-CANCER (HR-EC) CLASSIFICATION USING DNA DAMAGE RESPONSE (DDR) BIOMARKERS: A TRANSPORTEC INITIATIVE

Aims

The TransPORTEC consortium previously classified HR-EC into 4 molecular subtypes POLE, MSI, P53 mutated (P53m+) and no specific molecular profile (NSMP). We evaluated whether DDR biomarkers could further refine this HR-EC classification, in particular the poor prognosis NSMP and P53m+ subsets.

Method

DDR biomarkers including proteins involved in DNA damage (g-H2AX), homologous recombination (RAD51), positive or negative regulators of error-prone NHEJ (DNA-PK or FANCD2, respectively), and PARP were evaluated in 116 HR-EC by IHC using an H-score. CD8 and PD1 expression by IHC and mutation analyses were previously performed. Disease free survival (DFS) was calculated using Kaplan-Meier and Log-rank test.

Results

None of the DDR biomarkers alone were prognostic. However markers were informative within molecular subsets. Among the NSMP subset, gH2AX+ was significantly predictive of poor DFS (HR=2.56; p=0.026), and among P53m, a DNA-PK+/FANCD2- profile (favouring error-prone NHEJ) predicted worst DFS (HR=4.95; p=0.009) resulting in 5 distinct HR-EC prognostic subgroups (DFS from best to worst: "POLE/MSI" > "NSMP with no DNA damage" > "P53m+/NHEJ-" > "NSMP with high DNA damage" > "P53m+/NHEJ+"); p=0.0002. Actionable targets were also different among subsets. The P53m+/NHEJ- subgroup had significantly higher infiltration of PD1+ immune cells (p=0.003), segregating with POLE and MSI. The NSMP/gH2AX- had frequent PI3K pathway mutations and ER positivity. While the P53m+/NHEJ+ with the worst prognosis had high DNA damage and PARP expression providing a rationale for PARP inhibition.

Conclusion

The integration of DDR biomarkers further refined the TransPORTEC prognostic classification of HR-EC into 5 distinct subgroups and identified molecular subtype-specific therapeutic strategies.
IMPACT OF CONSERVATIVE MANAGEMENTS IN YOUNG WOMEN WITH GRADE 2 OR 3 ENDOMETRIAL ADENOCARCINOMA CONFINED TO ENDOMETRIUM

C. Gonthier¹, A. Tefoux-bourd¹, M. Koskas¹
¹Hopital Bichat-claude Bernard- Gynecology, Gynecology Obstetric, Paris, France

Aims

To evaluate the impact of ovarian and/or uterine preservation in young patients with grade 2 or 3 endometrial adenocarcinoma confined to endometrium.

Method

A population-based analysis was conducted. The SEER'17 Database was used to identify women younger than 45 years of age with grade 2 or 3 endometrial adenocarcinoma confined to endometrium from 1983 to 2012. A cohort of 1106 women was included: 849 underwent hysterectomy with bilateral adnexectomy, 96 underwent hysterectomy with ovarian preservation and 49 underwent uterine preservation. The demographics and survival rates according to the type of treatment administered were compared.

Results

The five-year overall survival probabilities were 94.8% (95%CI [92.8-96.2]), 93.8% (95%CI [85.8-97.4]), and 78.2% (95%CI [62.1-88.1]) for patients who underwent hysterectomy with bilateral adnexectomy, ovarian preservation and uterine preservation, respectively (p<0.001).

The five-year cancer-related survival probabilities were 99.3% (95%CI [98.6-99.9]), 98.9% (95%CI [96.9-99.9]), and 86.2% (95%CI [75.7-98.2]) for patients who underwent hysterectomy with bilateral adnexectomy, ovarian preservation and uterine preservation, respectively (p<0.001).

Patients who received uterine conservation had lower disease-specific (aHR=15.8 95%CI [5.5-45.2]) and overall survival probabilities (aHR=6.6 95%CI [3.3-13.4]) than did patients who underwent hysterectomy with or without oophorectomy. Ovarian conservation was not associated with decreased disease-specific (aHR=1.45 95%CI [0.31-6.71]) or overall survival (aHR=0.58 95% IC [0.17-1.90]).

Conclusion

Ovarian preservation has no impact on survival probability in patients with grade 2 or 3 endometrial cancer confined to endometrium. On the contrary, physicians and patients should be aware of the worse prognosis associated with uterine preservation.

3Skåne University Hospital, Department of Obstetrics and Gynecology, Malmö, Sweden
4Catholic University of Sacred Heart, Department of Gynecological Oncology, Rome, Italy
5European Institute of Oncology, Department of Gynecological Oncology, Milano, Italy
6University of Milan Bicocca, Clinic of Obstetrics and Gynecology, Monza, Italy
7Third Faculty of Medicine- Charles University, Institute for the Care of Mother and Child, Prague, Czech Republic
8Vilnius University Hospital, Center of Obstetrics and Gynecology, Vilnius, Lithuania
9Hospital Universitario Dexeus, Department of Obstetrics- Gynecology- and Reproduction, Barcelona, Spain
10Clinica Universidad de Navarra, Department of Obstetrics and Gynecology, Pamplona, Spain
11National Cancer Institute, Department of Obstetrics and Gynecology, Milano, Italy
12University of Cagliari, Department of Obstetrics and Gynecology, Cagliari, Italy
13Imperial College London, Department of Obstetrics and Gynaecology, London, United Kingdom
14Katholieke Universiteit, Department of Electrical Engineering- ESAT-SCD, Leuven, Belgium
15University Hospital Leuven, Department of Obstetrics and Gynecology, Leuven, Belgium
16Katholieke Universiteit, Department of Development and Regeneration, Leuven, Belgium

Aims

To describe the sonographic features of endometrial cancer in relation to stage, grade, and histotype using the IETA terminology.

Method

Prospective multicenter study on 1714 women with endometrial cancer undergoing a standardized transvaginal grayscale and Doppler ultrasound examination by an experienced ultrasound examiner using a high-end ultrasound system. Clinical and sonographic data were entered into a web-based protocol. Sonographic characteristics according to IETA were compared with outcome of hysterectomy, i.e. tumor stage, grade, and histotype.

Results

After excluding 176 women (no or delayed hysterectomy, final diagnosis other than endometrial cancer, or incomplete data), 1538 women were included in our statistical analysis. Mean age was 65 years (SD, 10.5), and mean BMI 30 (SD 7.1), 1378 (89.7%) women were postmenopausal, and 1296 (84.2%) reported abnormal vaginal bleeding. Grayscale and color Doppler features changed with increasing grade and stage. High-risk tumors (stage 1A, grade 3 or non-endometrioid or > stage 1B) were less likely to have regular endometrial myometrial border (difference of -23%, 95% CI -27 to -18%), whilst they were larger (mean endometrial thickness; difference of +22%, 95% CI +18 to +27%), than low-risk tumors.

Conclusion

Grayscale and color Doppler ultrasound features of endometrial tumors vary by grade and stage. This knowledge may improve preoperative ultrasound discrimination between low and high-risk cancer.
Aims

Pelvic floor functioning is a major concern for women requiring a hysterectomy for endometrial cancer and for benign conditions. This study reports the effect of hysterectomy on pelvic floor symptoms performed using an open abdominal (TAH) or total laparoscopic approach (TLH).

Method

381 women who participated in the Laparoscopic Approach to Cancer of the Endometrium (LACE) trial and required surgery for stage 1 endometrial cancer, were asked to complete the Pelvic Floor Distress Inventory (PFDI-20) before surgery, 6-months post-surgery, and yearly thereafter until 54 months follow-up. The mean change in scores in the TAH and TLH groups were compared using student t-test.

Results

At baseline, women were on average 63 years (SD 10 years), and 88% were overweight or obese. The mean PFDI-20 score was 13.5 (13.8) at baseline, indicating a low level of pelvic floor concerns among the women. Six months after surgery, women in both treatment groups reported better pelvic floor quality of life compared to baseline. Women who received a TAH reported a score of 11.01 (12.71), and women who received TLH 8.95 (11.77). The mean change in PFDI-20 score from baseline to 6-months post-surgery was not significantly different between TAH and TLH groups (0.06 (95% CI -3.18, 3.31); p=0.97).

Conclusion

Prevalence of pelvic floor symptoms in this trial was comparatively low. Surgical treatment of stage 1 endometrial cancer led to improvements in pelvic floor quality of life six months after surgery regardless of whether the surgery was performed via TAH or TLH.
FRENCH MULTICENTRIC RANDOMIZED TRIAL EVALUATING SEVERE PERIOPERATIVE MORBIDITY AFTER ROBOT ASSISTED VERSUS CONVENTIONAL LAPAROSCOPY IN GYNECOLOGIC ONCOLOGY: RESULTS OF ROBOGYN TRIAL.

Aims

In gynecologic oncology, mini-invasive surgery by laparoscopy decreases incidence of severe morbidity compared to open surgery. The robotic-assisted laparoscopy (RL) was approved by FDA in gynecology in 2005. ROBOGYN (NCT01247779) is the first multicentric randomized trial comparing severe perioperative morbidity after RL versus conventional laparoscopy (CL).

Method

Patients with a gynecologic cancer eligible for mini-invasive surgery were recruited in 13 French centers between December-2010 and December-2015. Severe perioperative morbidity was defined as Oslo grade>=Ii for per-operative complications, Clavien-Dindo grade>=II in the first 30 days, or NCI-CTCAE-4.03 grade>=3 up to 6 months after surgery, evaluated on the per-protocol dataset. Overall 374 evaluable patients were required to detect 10%-decrease of severe morbidity (15%-versus-5%) with a 90%-power (two-sided alpha=5%). Balanced randomization was stratified by center.

Results

383 patients with uterine (54%), cervical (43%) and ovarian cancer (3%) were recruited. Median age=58, BMI=25.9, WHO-0 in 83%. Per-protocol analysis includes 369 patients: 176 underwent RL, 193 CL. 208 and 92 patients had total and radical hysterectomy, respectively. A pelvic and/or iliac lymphadenectomy was performed in 186 patients, para-aortic lymphadenectomy in 71. Ten patients in each arm had a laparoconversion (p=0.83). RL was associated with a significantly longer operating time (median, 205 vs 162min, p<0.001), and higher blood loss (estimated volume, median, 100 vs 50ml, p=0.006).

Severe perioperative morbidity was reported in 48/176 for RL (27%) and 40/192 for CL (21%) (p=0.15, 1 missing data).

Conclusion

We did not observe any reduction of severe perioperative morbidity with robot-assisted laparoscopy compared to conventional laparoscopy in patients with gynecologic cancer.
PERIOPERATIVE POSITIONING MANAGEMENT IN GYNECOLOGIC CANCER SURGERY: A NATIONAL NOGGO-AGO INTERGROUP SURVEY

1Park-Klinik Weißensee, Department of Gynecology, Berlin, Germany
2Kliniken Essen-Mitte, Department of Gynecology, Essen, Germany
3Charité-Universitätsmedizin Berlin, Department of Gynecological Oncology, Berlin, Germany
4University Hospital Munich-Großhadern, AGO and Department of Gynecology, Munich, Germany
5University Medical Center Hamburg-Eppendorf, AGO and Department of Gynecology, Hamburg, Germany
6Euregio-Klinik, Department of Gynecology and Obstetrics, Nordhorn, Germany
7Donau-Isar-Klinikum, Department of Gynecology and Obstetrics, Deggendorf, Germany
8Charité-Universitätsmedizin Berlin, Department of Gynecology, Berlin, Germany
9Charité-Universitätsmedizin Berlin- Campus Virchow Klinikum, AGO and Department of Gynecology, Berlin, Germany

Aims

Approximately 4% of all medical complications are perioperative positioning injuries. Aims of the survey were the analysis of perioperative positioning management in gynaecologic-oncological surgery, the process- and structure-reliability and the implementation of current guidelines into daily clinical practice.

Method

We sent an anonymous multiple-choice questionnaire to all gynecological departments in Germany. Sixty questions were divided into five different parts: 1) descriptive information about the department, 2) focus on the pre- and 3) postoperative management, 4) on the quality management, and 5) information regarding the positioning management in the operation room based on two fictional case examples in gynecologic oncology procedures.

Results

184 of 633 departments participated in the survey (June-September 2016). 48.8% of all participating departments declared complications related to intraoperative positioning, independent from department size. Knowledge of the current guideline on positioning did not impact the incidence of complications. Positioning of the patient was mentioned in the team-time-out procedure in 66.1% of the participating departments. No difference was found between high-volume and low-volume gynecologic oncologic operative departments with regard to the use of supportive tools such as anti-thrombotic leg pumps. 92.7% included information of positioning injuries into the written informed consent. Knowledge of the guideline or a previous legal dispute did not influence the willingness to inform about possible positioning-related complications.

Conclusion

The awareness of perioperative positioning management in gynecologic cancer surgery is high throughout all departments in Germany. Almost half of all 184 participating departments report positioning-related complications in the previous 12 months, stressing the importance of this often underrated topic.
Aims

The primary aim of the survey was to investigate the expectations of European patients about maintenance therapy.

Method

A 24-item questionnaire was provided to ovarian cancer patients via internet or paper-version in 9 European countries (Austria, Belgium, France, Germany, Italy, Romania, Slovenia, Finland and Turkey). Data was captured about demographics, tumor stage and therapy after first line and/or recurrent disease and particularly about preferences of administration and expectations concerning a maintenance therapy.

Results

2101 questionnaires were evaluated. 96% of the patients had a surgery and 93% received a chemotherapy. 38% of respondents had recurrent disease. 45% patients had already heard of and 29% received maintenance therapy. 85% of the patients heard about maintenance therapy from the doctor and 10% from other patients, 9% read about it on the internet. The four most disturbing side effects of maintenance therapy were polyneuropathy (37%), nausea (36%), loss of hair (34%) and vomiting (34%). The main objective of maintenance treatment was to increase the chances of cure (73%), followed by an improvement in the quality of life (47%) and the delay of tumor growth (37%). Many patients are willing to take a maintenance therapy until tumor progression (38%). 39% would prefer an oral administration. When we performed cross country sub-analysis we observed no significant differences of expectations to a maintenance therapy.

Conclusion

There is an urgent need for more information regarding side effects and treatment goals of maintenance therapy to avoid misunderstandings by patients. This information may increase patient’s compliance for maintenance therapy in ovarian cancer.
ADVERSE EVENTS AFTER HYPERThERMIC INTRAPERITONEAL CHEMOTHERAPY (HIPEC) FOR STAGE III OVARIAN CANCER: PHASE III OVHIPEC STUDY

16The Netherlands Cancer Institute, Division of Psychosocial Research and Epidemiology, Amsterdam, The Netherlands
17The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Department of Medical Oncology, Amsterdam, The Netherlands

Aims

In the OVHIPEC study (NCT00426257), the addition of HIPEC to interval cytoreductive surgery (CRS) significantly improved recurrence-free (HR 0.68, 95% CI 0.51-0.89) and overall survival (HR 0.67, 95% CI 0.48-0.94) in patients with stage III ovarian cancer. We analysed adverse events (AEs) in OVHIPEC, the first randomized study that evaluated HIPEC in primary ovarian cancer.

Method

We randomly assigned patients who showed at least stable disease after 3 cycles of carboplatin (area under the curve 6) and paclitaxel (175 mg/m²) to receive interval CRS with (n=122) or without (n=123) HIPEC using cisplatin (100 mg/m²). Patients in both arms received 3 additional cycles of carboplatin/paclitaxel post-operatively. We describe AEs graded by CTCAE v4.0 occurring up to first follow-up, defined as 6 weeks after the end of treatment.

Results

Over 95% of patients in both arms experienced at least one AE of any grade. The number of patients with grade 3-5 AEs was 30 (24%) without HIPEC and 34 (28%) with HIPEC (p=0.71). The most common grade 3-5 AEs after HIPEC were pulmonary events, infections, abdominal pain, and ileus, all occurring in less than 10% of patients (table). Three patients died within 6 weeks after the end of treatment, 1 was treatment related (CRS only arm) and 2 were due to rapid disease progression (1 in HIPEC arm and 1 in CRS only arm).
Table. Adverse events up to 6 weeks after the end of treatment

¹ Pulmonary events include dyspnoea, hypoxia, pleural effusion, respiratory distress and tracheotomy.
² Infection events include pneumonia and other infections.
³ Thromboembolic event include venous thrombosis, pulmonary embolism and transient ischemic event.
⁴ Electrolyte disturbances include hyponatremia and hypokalemia.
⁵ Anastomosis related events include anastomosis leakage and anastomosis fistulas.

Conclusion

The addition of HIPEC to interval CRS does not increase adverse events and improves recurrence free- and overall survival in patients with stage III ovarian cancer.
IDENTIFICATION OF HIGHLY DIFFERENTIALLY EXPRESSED GENES IN PRIMARY OVARIAN CANCER AND RELATED DISTANT METASTASIS USING RNA SEQUENCING

S. Janhonen1, H. Sallinen1,2, P. Pölönen3, H. Niskanen4, J.M. Hartikainen1, M. Anttila1, M. Heinäniemi2, S. Ylä-Herttuala2, M.U. Kaikkonen1
1Kuopio University Hospital, Department of Gynecology and Obstetrics, Kuopio, Finland
2University of Eastern Finland, A.I. Virtanen Institute Department of Biotechnology and Molecular Medicine, Kuopio, Finland
3University of Eastern Finland, Institute of Biomedicine School of Medicine, Kuopio, Finland
4University of Eastern Finland, Institute of Clinical Medicine Pathology and Forensic Medicine, Kuopio, Finland

Aims

High grade serous ovarian cancer is the most common subtype of epithelial ovarian cancers (EOC) with poor prognosis. In most cases EOC is widely disseminated at the time of diagnosis. Our aim was to determine whether gene expression in distant metastasis of high grade serous EOC differ from that of primary tumors to gain better understanding of disease process.

Method

We analyzed the gene expression profile of ten primary high grade serous EOC tumors and related omental metastasis using RNA sequencing. The functions of differentially regulated genes were studied using Ingenuity Pathway Analysis and by comparing our results to TCGA data.

Results

We identified 100 differentially regulated genes between primary tumors and metastasis, majority of which were downregulated in the omental samples. Gene ontology analysis revealed that cellular functions related to embryonic development were increased within the metastasis. Many of the embryonic developmental genes were also highly expressed in TCGA ovarian cancer samples compared to any other cancer type. Interestingly, 17 of our 100 most differentially regulated genes were also found significantly altered in TCGA primary tumors that had led to metastasis formation. For survival analysis TCGA data was divided to poor and high survival according to our 100 differentially regulated genes. Our analysis identified 12 candidate genes that were significantly associated with poor survival that will be subject of future studies.

Conclusion

The gene expression of primary tumors and metastasis of high grade serous EOC exhibited significant differences. Many of the identified genes have functions in embryonic development.
ORAL 04 - OVARIAN II

ESGO7-0471

INTERVAL BETWEEN CYTOREDUCTIVE SURGERY AND ADJUVANT CHEMOTHERAPY IS ASSOCIATED WITH OVERALL SURVIVAL IN PATIENTS WITH ADVANCED OVARIAN CANCER

M. Timmermans1,2,3, M.A. van der Aa1, K.K. Van de Vijver4, R.F.P.M. Kruitwagen2,3, G.S. Sonke5
1Netherlands Comprehensive Cancer Organisation IKNL, Department of Research, Utrecht, The Netherlands
2GROW, School for Oncology and Developmental Biology, Maastricht, The Netherlands
3Maastricht University Medical Centre, Department of Obstetrics and Gynaecology, Maastricht, The Netherlands
4The Netherlands Cancer Institute, Divisions of Diagnostic Oncology and Moleculare Pathology, Amsterdam, The Netherlands
5The Netherlands Cancer Institute, Department of Medical Oncology, Amsterdam, The Netherlands

Aims

Optimal treatment for advanced epithelial ovarian cancer consists of cytoreductive surgery and (neo)adjuvant platinum based chemotherapy. The aim of this study was to evaluate whether the time to adjuvant chemotherapy (TTC) was associated with overall survival (OS).

Method

We selected all patients diagnosed with epithelial ovarian cancer (FIGO IIb-IV) between 2008 and 2015 from the Netherlands Cancer Registry. Logistic regression was used to identify factors associated with a longer TTC and multivariable Cox regression to evaluate the independent effect of treatment interval on OS. Patients receiving primary debulking surgery (PDS) and patients receiving interval debulking surgery (IDS) were analysed separately.

Results

4,143 patients were included, 1,693 underwent PDS and 2,450 IDS. Median TTC was 29 (interquartile range (IQR) 23-37) days. Perioperative complications (p<0.001), prolonged hospitalisation (p<0.001), and extended surgery (p<0.001) were independently associated with a longer TTC for both PDS and IDS. Patients who exceeded the 75% quartile of the TTC interval experienced worse survival when undergoing PDS (>37 days compared to 23-37 days; hazard rate (HR) 1.20, 95%CI 1.01-1.43) or IDS (HR 1.27(1.10-1.46)).

Conclusion

Our study provides evidence that delayed initiation of adjuvant chemotherapy is an independent prognostic factor for worse overall survival after both PDS and IDS, also when adjusting for residual disease and perioperative complications. Consequently we advise to start adjuvant chemotherapy within five to six weeks after debulking surgery.
PALB2 MUTATIONS IN HIGH-RISK WOMEN WITH OVARIAN OR BREAST CANCER

K. Metcalfe, J. Lerner-Ellis, M. Akbar, S. Narod

1University of Toronto, Faculty of Nursing, Toronto, Canada
2Mount Sinai Hospital, Genetics, Toronto, Canada
3Women's College Research Institute, Breast Cancer Research, Toronto, Canada

Aims

In the current study, we examined the frequency of PALB2 mutations in women with breast or ovarian cancer who met criteria for genetic testing for BRCA1 and BRCA2 and tested negative.

Method

DNA samples from women with ovarian or breast cancer, who met criteria for provincial BRCA1 and BRCA2 genetic testing and tested negative between the years of 2007 and 2014 were included in this study. All 13 coding exons of PALB2 plus 20 base pairs from the exon boundaries were amplified using Wafergen SmartChip technology. The amplified DNA were paired-end sequenced at 2x250 cycles using an Illumina MiSeq sequencer.

Results

2,225 women with breast cancer and 429 women with ovarian cancer were tested for PALB2 mutations. No PALB2 mutations were found in women with ovarian cancer. Seventeen deleterious PALB2 mutations were detected in women with breast cancer (0.8%). The frequency of PALB2 mutations was significantly higher in women with bilateral breast cancer (2.4%) compared to women with unilateral breast cancer (0.6%) (p=0.01). There was no significant difference in age at diagnosis between those with and without a PALB2 mutation (50.9 years vs 53.8 years; p=0.34).

Conclusion

Genetic testing for PALB2 should be considered for high-risk women with breast cancer, especially those who present with bilateral breast cancer. However, PALB2 does not appear to contribute to ovarian cancer which has implications for counselling women who are identified with a PALB2 mutation.
ORAL 05 - VAGINAL AND VULVAR CANCER

ESGO7-0962

PROGNOSTIC VALUE OF LYMPH NODE RATIO AND NUMBER OF POSITIVE INGUINAL NODES IN PATIENTS WITH VULVAR CANCER

S. Polterauer1, R. Schwameis1, C. Grimm1, R. Macuks2, S. Iacoponi3, K. Zalewski4, I. Zapardiel3
1Medical University Vienna, Department of General Gynaecology and Gynaecological Oncology- Gynecologic Cancer Unit - Comprehensive Cancer Center, Vienna, Austria
2Eastern Clinical University Hospital, Latvian Oncology Center of Riga, Riga, Latvia
3La Paz University Hospital - IdiPAZ, Gynecologic Oncology Unit, Madrid, Spain
4Holy Cross Cancer Center, Department of Gynecologic Oncology, Kielce, Poland

Aims

To estimate the prognostic significance of lymph node ratio and number of positive nodes in vulvar cancer patients.

Method

This international multicenter retrospective study included patients diagnosed with vulvar cancer treated with inguinal lymphadenectomy. Lymph node ratio (LNR) is the number of metastatic lymph nodes (LN) to the number of removed LN. Patients were stratified into risk groups according to LNR. LNR was correlated with clinical-pathological parameters. Survival analyses were performed.

Results

This analysis included 745 patients. In total, 292 (39.2%) patients had positive inguinal LN. The mean (SD) number of resected and positive LN was 14.1 (7.6) and 3.0 (2.9), respectively. High LNR was associated with larger tumor size and higher tumor grade. Patients with LNRs 0% (N0), >0<20%, and >20% had 5-year overall survival (OS) rates of 90.9%, 70.7%, and 61.8%, respectively (P<.001 - Figure). LNR was associated with both local and distant recurrence-free survival (P<.001). Patients with 0, 1, 2, 3 or more than 3 positive lymph nodes had 5-year OS rates of 90.9%, 70.8%, 67.8%, 70.8% and 63.4% respectively (P<.001). In multivariate analysis, LNR (P=.01) and FIGO stage (P<.001), were associated with OS, whereas the number of positive nodes (P=.8), age (P=.2), and tumor grade (P=.7), were not. In high-risk patients, adjuvant radiotherapy was associated with improved survival.

Conclusion

LNR provides useful prognostic information in vulvar cancer patients with inguinal LN resection in vulvar cancer. LNR allows for more accurate prognostic stratification of patients than number of positive nodes. LNR seems useful to select appropriate candidates for adjuvant radiation.
PROGNOSTIC FACTORS FOR LOCAL RECURRENT OF SQUAMOUS CELL CARCINOMA OF THE VULVA: A SYSTEMATIC REVIEW

N.C. te Grootenhuis¹, A.W. Pouwer², G.H. de Bock³, A.G. van der Zee¹, J.A. de Hullu², M.H. Oonk¹

¹University Medical Center Groningen, Obstetrics and Gynaecology, Groningen, The Netherlands
²Radboud University Medical Center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
³University Medical Center Groningen, Epidemiology, Groningen, The Netherlands
⁴University Medical Center Groningen, Pathology, Groningen, The Netherlands
⁵Radboud University Medical Center, Pathology, Nijmegen, The Netherlands

Aims

In patients treated for early-stage vulvar squamous cell carcinoma (VSCC) local recurrence is reported in up to 40%. Both clinicopathologic as well as cell biologic factors might be prognostic for local recurrence and knowledge on these factors may help to identify high risk patients and/or to develop strategies to prevent local recurrences. This systematic review aims to evaluate current knowledge on the incidence of local recurrences in VSCC related to clinicopathologic and cellbiologic variables.

Method

Relevant studies were identified by an extensive online search in March 2017. Studies reporting prognostic factors specific for local recurrences of VSCC were included. Two review authors independently performed data selection, extraction and assessment of study quality. The risk difference was calculated for each prognostic factor described by two or more studies.

Results

Twenty-two studies were included and reported mainly pathologic factors. There were differences in study quality and reported factors. Due to differences in study design, homogeneity could not be assumed. The prognostic relevance for local recurrence of VSCC of all analyzed variables remains unequivocal, including pathologic tumor free margin distance less than 8 mm, presence of lichen sclerosus, groin lymph node metastases and a variety of different tumor characteristics. Our review indicates an estimated annual local recurrence rate of 4%.

Conclusion

Current quality of data on prognostic factors for local recurrences in VSCC patients does not allow evidence-based medicine. Further research on prognostic factors, applying state of the art methodology are needed to identify high-risk patients and to develop alternative treatment strategies.
Aims

To ascertain if changing practice guidelines have resulted in a change in treatments and survival in vulvar cancer in Ireland.

Method

Data was collected from the National Cancer Registry of Ireland from 1994 to 2014.

Results

A total of 816 vulvar cancer patients were identified with an average of 54 cancers diagnosed per year (range 21-58). The median age at diagnosis was 72 (range 20-85). The standardised incidence rate increased during the study, 1.08 to 2.29 during the period (figure 1). Seventy-two percent (n=591) were squamous cell carcinoma and 80% were stage 1-2 at diagnosis. The rate of surgery within 1 year of diagnosis fell from 89% to 71%, while radiotherapy rates increased from 17% to 31% during the period. Rates of smoking increased from 6% to 57%. Five year survival rates rose from 40% to 66% during the study period (figure 1).

Conclusion

This population-based study demonstrates that the incidence of vulvar cancer in Ireland is increasing, particularly in socially deprived women who smoke. The use of primary radiotherapy has significantly increased over the last two decades with increasing survival rates seen.
Esgo7-0687

Vulvar carcinoma in Norway: a 50-year perspective on trends in incidence, treatment and survival

C.J. Meltzer-Gunne1, M.C. Småstuen2, G.B. Kristensen3, C.G. Tropé4, A.K. Lie4, I. Vistad1
1Sørlandet sykehus, Obstetrics and Gynaecology, Kristiansand, Norway
2Oslo and Akershus University College of Applied Sciences, Department of Nursing and Health Promotion, Oslo, Norway
3The Norwegian Radium Hospital- Oslo University Hospital, Department of Gynaecological Oncology, Oslo, Norway
4Ostfold Hospital HF, Center for Laboratory Medicine, Gralum, Norway

Aims

To explore trends in vulvar squamous cell carcinoma (SCC) incidence, age and stage at diagnosis, treatment and survival in Norway from 1961 to 2010.

Method

From 1961 to 2010, 2233 cases of vulvar SCC were extracted from the Cancer Registry of Norway. Data on age at diagnosis, tumor morphology, stage of the disease and treatment were analyzed. Age-standardized incidence rates, adjusted to the Norwegian standard population, were computed. Relative survival was calculated as a ratio of the observed survival in the study population over the expected survival in the background population. Multivariate Cox model was fitted to estimate hazard ratios.

Results

The overall incidence of vulvar SCC increased more than 2.5 fold (from 1.70 to 4.66 per 100 000 women/year; P<0.01) (Figure 1). Age-specific incidence rates increased among women aged ≤ 60 years (by 150% in age group 0-39 years, 175% in age group 40-49 years and 68% in age group 50-59 years). From 1971-2010, the percentage of patients receiving surgery as only treatment decreased from 81% to 61%, whereas the use of radiation and combination therapy (surgery and radiation) increased from 3% to 11% and 6% to 20%, respectively. 5-year relative survival increased significantly among women ≤ 80 years (from 72% to 83% among women aged ≤60 years and from 60% to 65% among women aged 61-80 years).

Conclusion

The incidence of vulvar SCC has increased since the sixties, particularly among women younger than 60 years. Despite less radical treatment, survival has improved.
EXPERIENCE IN INTRODUCING SENTINEL LYMPH NODE BIOPSY IN EARLY-STAGE VULVA CANCER: A SINGLE INSTITUTION BASED PROSPECTIVE STUDY

L. Paskeviciute Frøding, V. Bahn Zobbe, G. Oertoft Lykkegaard, H. Claus, T. Henrichsen Schnack

1University hospital of Copenhagen, Obstetrics and Gynecology, Copenhagen Ø, Denmark

Aims

Primary vulva cancer (VC) is diagnosed in approximately 100 patients every year in Denmark. To improve treatment quality VC was centralized to two university centers in 2011. The current study evaluates the long-term recurrence and survival rates in early-stage VC patients after sentinel node (SN) procedure was introduced.

Method

All VC patients were prospectively registered in the Danish Gynecologic Cancer Database in the period January 2011 to July 2016. Patients with clinically stage IB (T1 < 4 cm) who had SN procedure performed were included. Inguinofemoral lymph node dissection was performed if the SN’s were not detected or in case of SN metastases.

Results

The SN procedure was performed in 164 VC patients with tumor < 4 cm and no clinical suspicious groin nodes or distant metastases. 58 patients were excluded due to stage IA or III disease. 106 patients had negative SN. Among these one patient (0.9%) experienced an isolated groin recurrence, seven (6.6%) a localized vulva recurrence and three (2.8%) distant metastases. The 5-year overall and disease-specific survival for SN negative patients were 82% and 95%, respectively. The median disease free survival in SN negative patients with recurrent disease was 19 months (CI 11.8-28.2).

Conclusion

This is to our knowledge the largest prospective single center study presenting results of SN procedure in SN negative VC patients. The study confirms the safety of SN introduction as part of the standard of care in early stage VC with low isolated groin recurrence rate and a good overall and disease-specific survival.
INCIDENCE OF SHORT AND LONG-TERM POSTOPERATIVE MORBIDITY RELATED TO LYMPH NODE DISSECTION FOR VULVAR CANCER

E. Barlow¹, N. Hacker¹
¹The Royal Hospital for Women, Gynaecological Cancer Centre, Randwick, Australia

Aims

The aim of this study was to determine the incidence of short, and long term postoperative complications, following lymphadenectomy for vulvar cancer. Specifically, the problems of groin wound dehiscence, cellulitis, lymphocyst formation, and lymphoedema were reviewed.

Method

Design: A retrospective, observational, single institution study.

All patients treated for invasive cancer of the vulva, at a tertiary hospital in Sydney, Australia, between the years 1987 to 2015, were included in the study. A retrospective analysis of the hospital medical records, including clinical charts, operative reports and pathology reports were reviewed as part of a larger study.

Results

From 1987 to 2015, 479 women were treated for vulvar cancer, with 410 eligible for inclusion in the study. Mean age was 66.7 years (range 20-95 years). Postoperatively, 6.4% of women developed cellulitis, and 10.8% experienced groin wound breakdown. Lymphocysts occurred in 42.6% (152/357) of dissected groins, following inguinal-femoral lymphadenectomy, and in 23.4% (11/47) of groins following resection of bulky positive nodes only. 43% (107/248) of women who had either unilateral or bilateral groin node dissection subsequently developed lymphoedema, compared to 11 of 47 (23.4%) women who underwent groin node debulking. Of the women who developed lymphoedema 37% developed it within 3 months of surgery.

Conclusion

Results indicate relatively low rates of groin wound breakdown and cellulitis, but high rates of lymphocyst formation and lymphoedema. More detailed analysis of the data is required to develop strategies to further reduce these complications.
STATHMIN, A PREDICTIVE BIOMARKER FOR TAXANE RESPONSE IN BREAST CANCER?

1University of Bergen, Section of Oncology- Department of Clinical Science, Bergen, Norway
2University of Bergen, Center for Cancer Biomarkers CCBIO - Department of Clinical Science K2, Bergen, Norway
3Haukeland University Hospital, Department Of Gynaecological Oncology, Bergen, Norway

Aims

There are no clinically applicable predictive biomarkers for taxane response in (breast) cancer. Stathmin, a critical modulator of microtubule dynamics, has been suggested in preclinical and retrospective studies. We aimed to investigate if stathmin (STMN) or phosphostathmin (pSTMN) expression are linked to response to paclitaxel in a large breast cancer series, and if such treatment response effects are mirrored in differences in survival.

Method

We used data from an open label multicentre study with long follow-up including 223 patients. Patients were stratified to either paclitaxel (n=114) or epirubicin (n=109) neoadjuvant monotherapy prior to surgery/radiation. STMN and pSTMN levels were determined by immunohistochemistry and mRNA expression levels. Response was graded by the UICC system. Immunohistochemistry data for hormone receptors (oestrogen and progesterone) were available. An independent dataset (GSE21997) with mRNA microarray data (STMN005563) was used for validation.

Results

High STMN/pSTMN expression was associated with improved response to paclitaxel (p=0.04; p=0.006), but not epirubicin treatment. Subgroup analysis showed this effect was more pronounced in hormone receptor positive patients (p=0.008 and p=0.005). However, high STMN expression was associated with worse recurrence free and disease specific survival in paclitaxel (p=0.04; p=0.03) but not epirubicin treated patients (p=0.40; p=0.73). The independent dataset confirmed a lower residual cancer burden in patients with high vs. normal stathmin levels after paclitaxel but not doxorubicin treatment (p=0.01; p=1.00).

Conclusion

High STMN/pSTMN levels are associated with improved response to paclitaxel but not epirubicin treatment. This effect is enhanced in hormone receptor positive patients. However, high stathmin levels are associated with worse survival.
ORAL 06 - PREVENTION, DIAGNOSTICS AND PREINVASIVE DISEASE

MRI-BASED PREDICTIVE FACTORS OF AXILLARY LYMPH NODE METASTASES IN BREAST CANCER

D. Atallah1, M. Moubarak1, W. Arab2, N. EL Kassis1, G. Chahine3, M. Ghossain4, C. Salem4
1. Beirut, Lebanon
2. Saint Joseph University, Beirut, Lebanon
3. Oncology, Beirut, Lebanon
4. Radiology, Beirut, Lebanon

Aims

To determine the accuracy of MRI in detecting axillary lymph nodes (ALNs) metastases preoperatively and to define predictive characteristics of ALN involvement in patients with invasive breast cancer.

Method

Breast MR (3 Tesla) examinations of 169 patients with invasive breast cancer were reviewed at Hôtel-Dieu de France Hospital. Morphological parameters in addition to apparent diffusion coefficient (ADC) value were compared with pathological nodal status.

Results

The sensitivity and specificity of MRI in detecting ALN involvement were 87.5% and 55.6% respectively. The negative and positive predictive value of MRI was 81.64% and 66.34% respectively. The mean size of metastatic ALN was larger than that of negative ALN (13.9 mm vs. 10.9 mm, p = 0.000). ALNs larger than 12 mm were associated with higher risk of metastases (p = 0.000). The asymmetry of size between ipsilateral and contralateral ALNs was more significant in positive ALNs on pathology (p= 0.008 vs. 0.043). In a univariate analysis, the round shape of ALN, loss of fatty hilum, irregular contours and hypo-intensity/heterogeneous intensity on T2-weighted sequence were significantly predictive of lymph node metastasis (p = 0.000 for the four characteristics). In a multivariate analysis, only the round shape of lymph node and the hypo-intensity/heterogeneous intensity on T2-weighted sequence were significantly associated with lymph node metastasis (p=0.01 and p=0.018 respectively). The ADC value of ALN did not aid the differentiation between benign and metastatic lymph nodes (p= 0.862).

Conclusion

Conventional MRI using the ALN shape and the signal intensity in T2-weighted sequences can evaluate the axilla with high sensitivity.

14CHU Tenon, Gynecologic department, Rennes, France

Aims

BACKGROUND: The standard of care of endometrial cancer involves complex procedures such as pelvic and para-aortic lymphadenectomy and omentectomy, particularly for high-risk endometrial cancer. Few data are available about these complex surgical procedures and adjuvant therapy in elderly women. We aim to examine treatment and survival of elderly women diagnosed with high-risk endometrial cancer.

Method

STUDY DESIGN: We performed a case-control study of women diagnosed between 2001 and 2012 with high-risk endometrial cancers. Women older than 70 years (n=198) were compared with patients <70 years (n=198) after matching on high-risk for recurrence and LVSI status.

Results

RESULTS: Elderly patients had lymphadenectomies less frequently compared with younger patients (76% vs 96%, p<0.001) and no adjuvant treatment more frequently (17% vs 8%, p=0.005) due to less chemotherapy being administered (23% vs 46%, p<0.001). The 3-year DFS, CSS and OS of patients ≥70 years was 52% (43-61), 81% (74-88) and 61% (53-70), respectively. These were significantly lower than the 3-year DFS, CSS, and OS of younger patients, which was 75% (68-82) (p<0.001), 92% (87-96) (p<0.008) and 75% (69-82) (p=0.018), respectively. Cox proportional hazard models found that elderly women had 57% increased risk of recurrence (hazard ratio 1.57, 95% CI 1.04-2.39) compared with younger patients.

Conclusion

CONCLUSION: Although we found an independently significant lower DFS in elderly patients with high-risk endometrial cancer when compared with young patients, elderly women are less likely to be treated with lymphadenectomy and chemotherapy. Specific guidelines for management of elderly patients with high-risk endometrial cancer are required to improve their prognosis.

POTENTIAL CLINICAL IMPACT OF THE INTRODUCTION OF THE NONAVALENT HUMAN PAPILLOMAVIRUS VACCINATION: AN ANALYSIS OF 13,665 PATIENTS OVER A 18-YEAR STUDY PERIOD

G. Bogani1, A. Ditto1, F. Martinelli1, M. Signorelli1, V. Chiappa1, D. Lorusso1, R. Francesco1

1National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To test the theoretical utility of the incorporation of quadrivalent and nonavalent vaccination against HPV into a clinical setting.

Method

Data of consecutive patients undergoing sampling for HPV DNA testing from 1998 to 2015 were retrospectively searched in order to identify changes in HPV prevalence during three study periods (T1, 1998-2003; T2, 2004-2009; and T3, 2010-2015).

Results

We enrolled 13,665 patients: 1361, 5130, 7174 patients, in T1, T2 and T3, respectively. Potentially, the quadrivalent vaccine protected against HPV infection in 71.5%, 46.5% and 26.5% of patients tested in T1, T2 and T3, respectively (p-for-trend<.001). While, the nonavalent vaccine protected against HPV infection in 92.5%, 72.3% and 58.1% of patients tested in T1, T2 and T3, respectively (p-for-trend<.001). The proportion of patients with genital dysplasia grade2+, not related to HPV types covered by quadrivalent vaccine (13% in T1, 21% in T2 and 34% in T3) and nonavalent vaccine (3% in T1, 12% in T2 and 19% in T3) increased over the time (p-for-trend<.001). For all study period the nonavalent vaccine was superior that quadrivalent vaccine in protect against HPV infection (p<.001). The figure displays the prevalence of dysplasia related to HPV 16-18 and to high-risk HPV infection other than 16-18.

Conclusion

Nonavalent vaccine would improve protection against HPV infections and HPV-related genital dysplasia2+. Moreover, we can speculate that cross protection of nonavalent vaccine will be related to a highest coverage against other HPV types.
IMPLEMENTATION OF AN ENHANCED RECOVERY AFTER SURGERY (ERAS) PROGRAM: THE MD ANDERSON CANCER CENTER EXPERIENCE

G. Salvo¹, L. Meyer¹, J. Lasala¹, M. Iniesta¹, N. Sheh¹, M. Munsell², A. Rodriguez-Restrepo¹, C. Corzo¹, P. Ramirez¹

¹The University of Texas- MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston- TX, USA
²The University of Texas- MD Anderson Cancer Center, Biostatistics, Houston- TX, USA

Aims

To evaluate perioperative outcomes of patients undergoing exploratory laparotomy for gynecologic indications in an Enhance Recovery after Surgery (ERAS) program and compare to those receiving traditional perioperative care (pre-ERAS)

Method

All consecutive patients managed under an ERAS program undergoing exploratory laparotomy between 11/3/2014 and 10/26/2016 were compared to historical controls (May to October, 2014). Interventions included, allowing oral intake of fluids up to 2 hours before induction of anesthesia; perioperative euvolemia as well as opioid-sparing analgesia; and ambulation and regular diet on the day of surgery. Wilcoxon rank-sum and Fisher’s exact tests were used

Results

A total of 518 enhanced recovery patients were compared with 74 patients in the control group (pre-ERAS). ERAS resulted in a 1-day reduction in hospital stay (median LOS pre-ERAS: 4 days [range, 2-27] vs. ERAS: 3 days [range, 1-43], p<0.01) with stable readmission rates (pre-ERAS: 14.1% vs. ERAS: 12.9%, p=0.85). ERAS resulted in a 73.6% reduction in median postoperative morphine equivalents during the first 3 days after surgery with no significant difference in mean pain scores between the pre- and post ERAS cohorts. No differences were observed in postoperative complications between pre-ERAS and ERAS groups respectively (29.6% vs. 25.7%, p=0.47; GU: 21.1% vs. 18.3%, p=0.63; Hematologic: 16.9% vs. 11.8%, p=0.25). Overall compliance with all components of the ERAS protocol was 70% (range, 40-85%)

Conclusion

Implementation of an ERAS program was associated with reduced LOS with stable readmission and perioperative complication rates and reduced overall opioid consumption. Further study is warranted to determine impact on progression free survival
LONG TERM RESULTS FROM RT3VIN: A MULTI-CENTRE, RANDOMISED, PHASE II TRIAL OF CIDOFOVIR OR IMIQUIMOD TREATMENT FOR VULVAL INTRAEPITHELIAL NEOPLASIA 3

Aims

Vulval intraepithelial neoplasia (VIN) is a chronic condition, which, if untreated, may become cancerous. Currently standard treatment for VIN is surgery, but this does not guarantee a cure and can cause significant physical and psychological problems. The RT3 VIN trial demonstrated that topical treatment with cidofovir and imiquimod are effective in 46% of patients with acceptable levels of adverse events. This study reports the long-term (24 month) follow up of these patients.

Method

Participants with complete response were followed up for a further 24 months. Events were either “new lesion” (any new lesion either biopsied or not biopsied) or “new VIN” (biopsied lesions with histologically proven VIN). All statistical analyses were pre-planned and conducted using Stata SE 14.

Results

Median length of follow up was 18.4 months. At 18 months, 50% on imiquimod (95% CI: 33.6%-64.5%) and 69% of patients on cidofovir (95% CI: 51.2-82.0) remained lesion free. At 18 months, 71.6% on imiquimod (95% CI: 52.0-84.3) and 94% of patient on cidofovir (95% CI: 78.2-98.5) remained VIN free. There were no grade 4+ adverse events reported and the number of grade 2+ events was similar between treatment arms (imiquimod: 24/42 (57%) vs. cidofovir: 27/41 (66%), χ²=0.665, p=0.415).

Conclusion

Long-term data indicates that response is maintained for longer following treatment with cidofovir compared to imiquimod with no difference in the rates of adverse events between the two drugs. Overall, the levels of adverse events and the absence of grade 4 events, indicates acceptable safety of use of these drugs in this setting.
THE ANALGESIC EFFICACY OF FORCED COUGHING DURING CERVICAL PUNCH BIOPSY: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY

Y. Segov1, O. Lavie1, E. Balan2, A.T. Goldstein3, E. Siegler1
1Carmel Medical Center, Obstetrics and Gynecology, Haifa, Israel
2Carmel Medical Center, Anesthesiology, Haifa, Israel
3Schneider’s Children Medical Center, Department of Pediatrics, Petah Tikva, Israel

Aims

To assess the efficacy of forced coughing as a pain-reducing technique during cervical punch biopsy compared to a control group.

Method

The study is a prospective randomized-control trial. The study group comprised 90 women who underwent cervical punch biopsies during investigation of abnormal Pap smear test results. The women were randomly assigned to “cough” and control groups. Pain was measured on a 10-cm visual analogue scale (VAS) during different stages of the procedure, and compared to assess the effect of forced coughing on pain level during biopsy.

Results

VAS pain score during biopsies was significantly lower in the “cough” group. The median pain level in the “cough” group was 1.5, compared to 4 in the control group. Eighty percent of the women in the “cough” group reported a pain level of 2 or less compared to 40% of the women in the “control” group (P = 0.0002). In the second biopsy, 69% of the women reported VAS ≤ 2 in the cough group compared to 28% of the patients in the control group. Forced coughing was shown both to reduce anxiety regarding the prospect of future cervical procedures and to decrease patients’ desire for future pain management. This was true for 32% of the women in the “control” group compared to 12% of the women in the “cough” group (P=0.05).

Conclusion

Forced coughing provides significant pain relief during cervical punch biopsy and reduces the patients’ fear and desire for pain medications in future procedures.

SENSITIVITY OF NON-INVASIVE PRENATAL FOR CANCER DETECTION AND TREATMENT MONITORING IN PREGNANT WOMEN

L. Lenaerts, J. Vermeesch, M. Verheecke, L. Dehaspe, N. Brison, F. Amant

1KU Leuven - Gynaecologic Oncology, Oncology, Leuven, Belgium
2KU Leuven, Department of Human Genetics, Leuven, Belgium
3University Hospitals Leuven, Gynaecological Oncology, Leuven, Belgium
4KU Leuven, Genomics Core Facility, Leuven, Belgium

Aims

We recently developed a massive parallel sequencing-based analysis pipeline for non-invasive prenatal testing (NIPT), allowing genome-wide detection of foetal and maternal chromosomal imbalances. On cell-free DNA samples of 20,000 asymptomatic pregnant women we incidentally identified 7 genomic imbalance (GI) profiles reminiscent of cancer-related copy number variations. Six women were subsequently diagnosed with cancer. We now aim to explore the sensitivity of routine NIPT testing for cancer detection and treatment monitoring in pregnant women, potentially contributing to enhanced prognosis.

Method

Pregnant women (≤ 40 years) diagnosed with breast, ovarian, cervical or haematological cancer (the 4 most prevalent cancer types encountered during pregnancy) are recruited in UZ Leuven or via the International Network on Cancer, Infertility and Pregnancy. A plasma sample is taken for GI-profiling. In case of an aberrant GI-profile, consecutive samples are taken to assess treatment response.

Results

Of the 23 pregnant cancer cases included, cell-free plasma DNA of 9 cases showed chromosomal abnormalities (either segmental or genome-wide). Sensitivity of cancer detection was highest for haematological (67%) and breast cancers (40%). No GIs were detected in cell-free DNA of the ovarian (n=1) and cervical (n=4) cancer cases. For the true positive cases, GI-profiling of tumor biopsy DNA showed comparable genomic imbalances as seen in cell-free plasma DNA. Furthermore, GI-profiling of cell-free DNA was able to follow treatment response.

Conclusion

Primary results indicate that GI-profiling of circulating cell-free DNA is able to detect cancer in a proportion of cancer cases. Further recruitment is ongoing and supplementary analyses are planned to understand false negative results.
**Aims**

The aim of this study was to determine the risk of HPV-related carcinomas and premalignancies in women diagnosed with cervical intraepithelial neoplasia grade 3 (CIN3). Knowledge on this risk is important to consider HPV vaccination and/or increased attention on other HPV-related carcinomas and premalignancies when CIN3 is identified.

**Method**

Women diagnosed with a CIN3 between 1990 and 2010 were identified from the Dutch nationwide registry of histopathology and cytopathology (PALGA) and matched with a control group without CIN3. Subsequently, all hrHPV associated high-grade lesions and carcinomas in the ano-genital region and oropharynx between 1990 and 2015 were extracted. Incidence rate ratios (IRR) were estimated for carcinomas and premalignancies of the vulva, vagina, anus and oropharynx.

**Results**

178,036 women were identified; 89,018 with a previous diagnosis of CIN3, and 89,018 matched controls without a history of CIN3. Women with a history of CIN3 showed increased risk of HPV-related carcinomas and premalignancies with IRRs of: 3.85 (95%CI of 2.32-6.37) for anal cancer, 6.68 (95%CI 3.64-12.25) for AIN3, 4.97 (95%CI 3.26-7.57) for vulvar cancer, 13.66 (95%CI 9.69-19.25) for VIN3, 86.08 (95%CI 11.98-618.08) for vaginal cancer, 25.65 (95%CI 10.50-62.69) for VAIN3, and 5.51 (95%CI 1.22-24.84) for oropharyngeal cancer. This risk remained significantly increased, even after long-term follow-up, up to 20 years.

**Conclusion**

This population-based study shows a long-lasting increased risk for HPV-related carcinomas and premalignancies of the ano-genital and oropharyngeal region after a CIN3 diagnosis. Studies investigating methods to prevent this increased risk in this group of patients, like intensified screening or vaccination, are warranted.
Aims

Early menopause leads to an increased cardiovascular risk. Cardiovascular risk assessment based on traditional risk factors often underestimates the actual risk in middle-aged women. Measures of atherosclerosis such as carotid intima-media thickness (CIMT) and pulse wave velocity (PWV) could help to predict future cardiovascular events in this group. BRCA1/2 mutation carriers are generally exposed to an earlier menopause due to risk-reducing salpingo-oophorectomy (RRSO) around the age of 40 to reduce their elevated ovarian cancer risk. Until now, cardiovascular risk in BRCA1/2 mutation carriers after RRSO is not yet studied. The aim was to investigate if time since RRSO in BRCA1/2 mutation carriers is related to advanced signs of subclinical atherosclerosis measured by CIMT and PWV.

Method

We performed a cohort study in 165 BRCA1/2 mutation carriers (aged 40 to 63 years) who underwent RRSO at age ≤ 45 years and at least five years previously. Main study endpoints were CIMT and PWV, and traditional cardiovascular risk factors were collected by questionnaires and single cardiovascular screening visit.

Results

The mean CIMT was 0.69 mm (SD 0.087), and the PWV was 6.40 m/s (SD 1.42). After adjustment for systolic blood pressure, insulin resistance, total cholesterol and body mass index, no association was found between age-adjusted CIMT and time since RRSO. Age-adjusted PWV and time since RRSO were also not associated, after adjusting for systolic blood pressure, total cholesterol and waist hip ratio.

Conclusion

Time since RRSO is not related to CIMT and PWV in BRCA1/2 mutation carriers. However, a longer follow-up period is needed.

ESGO7-0820

LONG-TERM EFFICACY AND IMMUNOGENICITY OF THE 9-VALENT HUMAN PAPILLOMAVIRUS VACCINE: FINAL ANALYSES OF A DOUBLE-BLIND, RANDOMIZED CLINICAL STUDY

E. Joura

1Medical University of Vienna, Department of Gynecology- Comprehensive Cancer Center, Vienna, Austria

Aims

The 9-valent human papillomavirus (9vHPV) vaccine targets the four HPV types (HPV6/11/16/18) covered by the quadrivalent HPV (qHPV) vaccine, with the addition of the five oncogenic types most commonly associated with cervical cancer after HPV16/18 (HPV31/33/45/52/58). Analyses of 9vHPV vaccine efficacy and immunogenicity were conducted in a clinical trial (V503-001; NCT00543543) in young women aged 16-26 years.

Method

Participants (N=14,215) were randomized to receive a three-dose series of 9vHPV or qHPV (control) vaccine. Cervical and external genital swabs for HPV-DNA testing and cervical cytological samples for Papanicolaou staining were collected regularly. Tissue samples from biopsy or cervical definitive therapy (loop electrosurgical excision procedure, conization) were tested for HPV DNA. Serum antibody responses to the nine vaccine HPV types were assessed.

Results

Prophylactic efficacy against HPV31/33/45/52/58-related outcomes was 100% (95% CI: 39.4, 100) for cervical intraepithelial neoplasia Grade 3 (CIN 3); 97.7% (93.3, 99.4) for cervical, vulvar, and vaginal disease; 96.0% (94.6, 97.1) for 6-month persistent infection; 92.9% (90.2, 95.1) for Pap test abnormalities; and 90.2% (75.0, 96.8) for cervical definitive therapy. Efficacy was high against each HPV type and in subgroups defined by age, race, and geographic region. Incidences of HPV6/11/16/18-related infection, cytological abnormalities, disease, and definitive therapy were similar in both vaccine groups. Antibodies to vaccine HPV types persisted through 5 years following vaccination.

Conclusion

The 9vHPV vaccine prevents HPV31/33/45/52/58-related infection and disease and provides similar protection against HPV6/11/16/18 as the qHPV vaccine. Vaccine efficacy was sustained for up to 6 years.

DEVELOPMENT AND PRE-TESTING OF THE EORTC QUALITY OF LIFE QUESTIONNAIRE FOR VULVA CANCER PATIENTS – THE SIGNIFICANCE OF PATIENT INVOLVEMENT

P. Jensen1, L. Froeding2, E. Greimel3, A. Lanceley4, A. Nordir5, A. Obergunngerer6, I. Vistad7

1Odense University Hospital, Department of Gynecology, Odense, Denmark
2Copenhagen University Hospital, Gynecology, Copenhagen, Denmark
3Medical University of Graz, Obstetrics and Gynecology, Graz, Austria
4UCL, Dept. of Women’s Cancer, London, United Kingdom
5East Kent Hospital, Gyencyology, Kent, United Kingdom
6Department of Psychology, University of Innsbruck, Innsbruck, Austria
7Soelandet Hospital, Gynecology, Arendal, Norway

Aims

Objective: Patients with vulva cancer (VC) and health care professionals representing Northern, Central, and Southern Europe participated in the development of an EORTC Quality of Life (QoL) Group VC specific questionnaire. The objective of phase 3 is to pre-test the provisional questionnaire to identify and solve potential conceptual and operational problems to ensure broad cross-cultural adaptation.

Method

Methods: The provisional questionnaire underwent rigorous forward-backward translation and was then administered to VC patients representative across age, stage, treatment modality, and country. A structured interview was conducted after questionnaire completion to assess the patient’s perspective on clarity and acceptability. Response questionnaire- and debriefing interview data were collected and audited by a multinational collaborative module team. Standardized decision rules for deletion, addition, and changing of the wording were applied.

Results

Results: A well-balanced sample of 77 patients from nine European countries was included. Most items, 32/36 (89%) satisfied decision rules and showed a high compliance, >95% for 31/36 (86%) items. Three items displayed serious patient concern. Weighting the patients’ comments, final pre-testing resulted in the deletion of five items, re-phrasing of three items while five items on sexuality, 4 on urological problems and 2 on proctitis were made conditional. Preliminary explorative psychometric analyses suggested a structure of 9 multi-items scales and one single item

Conclusion

Conclusion: The EORTC QoL group has developed and pre-tested a VC specific questionnaire. Debriefing interviews supplemented the quantitative test results and appeared to add highly significant information leading to substantial and relevant changes for final field testing in phase 4.

PREDICTION MODEL FOR 30-DAY MORBIDITY AFTER GYNECOLOGICAL MALIGNANCY SURGERY

S.H. Chae¹, S.H. Shim¹, S.J. Lee¹, J.H. Suh¹, S.N. Kim¹, S.B. Kang¹, J. Kim²
¹Konkuk University Medical Center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Konkuk University Medical Center, Research Coordinating Center, Seoul, Republic of Korea

Aims

The potential risk of postoperative morbidity is important for gynecologic cancer patients because it leads to delays in adjunctive therapy and additional costs. We aimed to develop a preoperative nomogram to predict 30-day morbidity after gynecological cancer surgery.

Method

Between 2005 and 2015, 533 consecutive patients with elective gynecological cancer surgery in our center were reviewed. Of those patients, 373 and 160 patients were assigned to the model development or validation cohort, respectively. To investigate independent predictors of 30-day morbidity, a multivariate Cox regression model with backward stepwise elimination was utilized. A nomogram based on this Cox model was developed and externally validated. Its performance was assessed using the concordance index and a calibration curve.

Results

Ninety-seven (18.2%) patients had at least one postoperative complication within 30 days after surgery. After bootstrap resampling, the final model indicated age, operating time, and serum albumin level as statistically significant predictors of postoperative morbidity. The bootstrap-corrected concordance index of the nomogram incorporating these three predictors was 0.656 (95% CI, 0.608–0.723). In the validation cohort, the nomogram showed fair discrimination [concordance index: 0.674 (95% CI = 0.619–0.732] and good calibration (P = 0.614; Hosmer-Lemeshow test).

Conclusion

The 30-day morbidity after gynecologic cancer surgery could be predicted according to age, operation time, and serum albumin level. After further validation using an independent dataset, the constructed nomogram could be valuable for predicting operative risk in individual patients.

7Paul Scherrer Institute, Center of Proton Therapy, Zürich, Switzerland
8University Hospital Center Rijeka, Department of Obstetrics and Gynecology, Rijeka, Croatia
9Sorlandet Hospital, Department of Obstetrics and Gynaecology, Sorlandet, Norway
10Copenhagen University Hospital Rigshospitalet, Department of Gynecology and Obstetrics, Copenhagen, Denmark
11Odense University Hospital, Department of Gynecology and Obstetrics, Odense, Denmark

Aims

Vulva cancer (VC) treatment causes severe morbidity that may negatively impact the patient’s Quality of Life (QoL). The aim of the present review was to evaluate available patient reported outcome measures (PROMs) to assess disease and treatment related effects in VC patients.

Method

A systematic literature search was performed to identify studies using PROMs in the assessment of disease and treatment related effects in VC patients. The systematic review was conducted in accordance with the PRISMA statement. This review comprises part of phase one in the development of a European Organisation for Research and Treatment of Cancer QoL questionnaire for VC patients.

Results

No randomized controlled trials were identified. Eleven of 2299 articles were selected including 535 women with VC. The selected studies exhibited great heterogeneity. Twenty one different instruments were used to assess QoL in VC patients. Most of the questionnaires were generic. Different issues (sexuality, lymphedema, body image, urinary and bowel function, vulva specific symptoms) were reported as potentially important but results were not systematically collected. One VC specific questionnaire was identified but did not allow assessment and reporting on scale level.

Conclusion

The present review identified several QoL domains of potential relevance for VC patients but a lack of a robust and sensitive PROM to validly assess effects of disease and treatment. Most studies relied on self-constructed non-validated questions. Our study confirms a need to develop a VC specific questionnaire that allows broad cross-cultural adaptation for use in clinical trials.

PROSPECTIVE CLINICAL COHORT STUDY FOR EFFICACY ASSESSMENT OF TOPICAL TREATMENT WITH OLIVOLEINA ON POST-SURGICAL SCARS IN PATIENTS UNDERGOING RADIOTHERAPY FOR GYNECOLOGIC CANCERS

J. Molero Vílchez1-2, E. Martínez Lamela1,2, S. Sancho García4, B. Castro Rodríguez5, J.L. Prieto Alonso6
1Ntra. Sra. del Rosario Hospital, Gynecology Oncology, MADRID, Spain
2Toco-Gyn Gynecologic Center, Gynecology Oncology, Alcalá de Henares, Spain
3Infanta Leonor University Hospital, Obstetrics and Gynecology, Madrid, Spain
4Ramon y Cajal University Hospital, Radiation Oncology, Madrid, Spain
5Carris Skin Laboratory, Pharmacy, Madrid, Spain
6Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain

Aims

Evaluate the effectiveness of the topical treatment with olivoleina on the post-surgical quality of healing in patients treated with radiotherapy for gynecologic cancers.

Method

Prospective Cohort study (case/control) (Canadian Task Force classification IIa) in 100 patients operated for gynecologic cancers. The study was carried out by Gynecological Oncologic Unit from January 2014 to July 2016. A comparative analysis of the healing response to topical treatment with olivoleina was carried out in patients who received radiotherapy, with a monitoring at 3, 6 and 12 months. The features of the scars were assessed according to the Vancouver Scale, Manchester Scale and Posas Scale.

Results

52 patients took part in the radiotherapy group, divided into: Group 1- 36 cases(69.2%) with topical treatment and 16 control-cases. Group 2- 48 patients who didn’t receive radiotherapy, divided into 30 cases (62.5%) with olivoleina topical treatment and 18 control-cases. The quality of the healing in patients treated with radiotherapy for gynecological cancers and after that, treated with olivoleina was significantly better (p<0.01). The tolerance was good –very good in 96.9% of the cases. The dermatological effects studied, were good-very good in 95.2% of the cases in relation with the wound hydration, in 73% in relation with the restoring of the skin barrier and in 76.5% in the anti-inflammatory action.

Conclusion

The topical application of olivoleina can be introduced within the therapeutic options of abnormal healing prevention in patients who have received radiotherapy.
Aims

To describe the trajectory of leg swelling and leg symptoms from before, to 24 months after, gynaecological cancer surgery, the association of leg swelling with symptoms and the severity of those symptoms.

Method

Women (n = 408) diagnosed with gynecological cancer (235 uterine, 114 ovarian, 69 cervical, vulvar, or vaginal cancer; respectively) were enrolled in the prospective longitudinal Lymphoedema Evaluation in Gynecological cancer Study (LEGS). Eligibility included: 18 years and older, treated in one of six Queensland hospitals, and diagnosed from June 1, 2008 to February 28, 2011.

Results

Data from 281 women with complete data contributed to the trajectory analyses. Up to 19% of patients reported leg swelling at baseline before surgery. The swelling trajectory of women after surgery was diverse, including 38% of women who continued to have no swelling over the next two years, 32% of women who had low and decreasing trajectory of swelling, and women who had either low (14%) or high (15%) swelling at baseline whose swelling increased further. Women who reported swelling had 4 times increased odds of reporting 12 other symptoms including pain, numbness and weakness. Women in the increasing swelling trajectories had more severe other leg symptoms.

Conclusion

This study adds to previously available leg swelling prevalence estimates by showing that distinct trajectories exist after gynaecological cancer surgery. It furthermore found that persistent or increased swelling is associated with greater odds of also having up to 12 other leg symptoms, most prominently pain, numbness or weakness.
THE NEW NORMAL; SEXUAL FUNCTION AFTER OVARIAN CANCER FOR SURVIVORS AND PARTNERS COMPARED TO NORMDATA

Aims

Because of the lack of quantitative data on sexual function after ovarian cancer, both for survivors and their partners, it is difficult to counsel patients on expected effects. We hypothesized that ovarian cancer may cause sexual problems, not only for survivors, but also for partners. The purpose of this study is to compare sexual function after ovarian cancer for survivors and partners with normdata in age-matched controls.

Method

After an average of six years after their primary treatment, patients with ovarian cancer (n=275) and their partners (n=137) conducted surveys for HR-QoL and sexual function with the EORTC-QLQ C30 and OV-28. Normdata for age-matched controls were gathered through the PROFILES-registry. Scores on the questionnaires were linearly transformed. Differences between the groups were compared and correlations were calculated.

Results

Sexual function showed a non-normal distribution. Median level of sexual function of survivors was 83 (minimum 17 – maximum 100). Hundred (36%) of 275 survivors had undisturbed sexual function. For partners, the median level of sexual function was 43 (0-100) with only 2 persons reported undisturbed function and 21 with a score of 0. Normdata showed a median sexual function for female age-matched controls 17 (0-100) and for male age-matched controls 50 (0-100). Sexual function between survivors and partners correlated strongly (Spearman’s rho .617, p<0.01).

Conclusion

An effect on sexual function for survivors of ovarian cancer is present in the majority of cases. However when compared to age-matched controls, the effect seems limited. Further exploration of sexual function in ovarian cancer survivors is warranted.
Aims

To compare oncological outcomes between conservative and radical surgery in the treatment of stage I granulosa cell tumors of the ovary (GCT).

Method

Data from 240 patients with stage I GCT were retrospectively collected among MITO centers (Multicenter Italian Trials in Ovarian cancer and gynecologic malignancies) and analyzed.

Results

Mean age was 48.95 ±15.3 in the entire cohort; 36±12.1 and 56.1 ±11 in the conservative and radical surgery cohorts, respectively (p=0.001). 19 patients were affected by juvenile GCT (7.5%), 222 (92.5%) by adult type GCT. Stage 1A, 1B and 1C were 68%, 2% and 30% respectively. No statistical difference was detected in stage distribution between the two groups. 90 patients (37.5%) underwent conservative surgery (either ovariectomy or cystectomy) while 150 (62.5%) received a radical approach. Five year disease free survival (DFS) rates in the conservative and radical surgery cohorts were 77% and 83% respectively (p=0.09).

Conclusion

In the present study conservative surgery did not affect the oncological outcome of stage I GCT patients and should therefore be considered the standard of care in patients desiring to retain their fertility.
ORAL 09 - OVARIAN AND CERVICAL CANCER

ESGO7-1363

PRETERM BIRTH AND CONIZATION PRIOR TO PREGNANCY: AN ANALYSIS OF THE NATIONAL INPATIENT QUALITY SURVEY DATA IN GERMANY; 2009-2014.

C. Dannecker1, J. Gallwas1, C. Hübener1, M. Rottmann2, S. Mahner1, S. wetzka1

1Ludwig Maximilian University Hospital of Munich, Obstetrics and Gynecology, Muenchen, Germany
2Ludwig Maximilian University Hospital of Munich.

Munich Cancer Registry MCR- Munich Tumour Centre TZM- Institute for Medical Information Processing- Biometry and Epidemiology, Muenchen, Germany

Aims

Conization for the treatment of cervical intraepithelial lesion has been linked to an increased risk of preterm delivery. Valid data from Germany are lacking. Our study aimed to investigate the association between conization and the risk of preterm birth in subsequent pregnancies, using data from a German population database.

Method

We performed a retrospective cohort study on data from the German nationwide performance measurement program in healthcare quality. Women with history of conization prior to pregnancy were compared to a control group of women without. Only primiparas with singleton pregnancies were included for analysis. Outcome measures are gestational age at birth, birth weight, neonatal morbidity and perinatal mortality. Data were analyzed using univariate and multivariate statistical methods.

Results

The database included a total of 4.002.503 deliveries between 2009 and 2014. 1.573.200 could be included for analysis. 14.337 women had a history of conization. This group were more likely to be (self-) employed, single, older, had a lower body mass index and a lower mean birth weight of the babies than in the control group [mean (SD), 3.240g (± 603g) vs. 3.307g (±545g), p < 0.0001]. The preterm birth rate was significantly higher after conization compared to the non-exposed cohort (12.2% vs. 7.5%; Chi² <0.0001). Conization was confirmed to be a significant risk factor for preterm delivery (odds ratio, OR 1.7; 95% CI: 1.65-1.83).

Conclusion

The data of this study are in accordance with the literature. Further analysis of the data should evaluate whether preterm delivery after conization affects the perinatal morbidity and mortality.
PROVE A PHASE II RANDOMIZED MULTICENTER STUDY OF PANITUMUMAB IN PLATINUM-SENSITIVE EPITHELIAL OVARIAN CANCER PATIENTS WITH KRAS WILD-TYPE

9Onkologische Tagesklinik und Ambulanz, Department of Gynecology- University Hospital, Tuebingen, Germany
10Department of Gynecology, University of Dresden, Dresden, Germany

Aims

For ovarian cancer (OC) patients with platinum-sensitive recurrence the addition of new biologic agents to chemotherapy may improve survival. Panitumumab is a fully human monoclonal antibody specific to the epidermal growth factor receptor (EGFR). The purpose of this trial was to investigate the therapeutic efficacy of panitumumab in the combination with carboplatin-based chemotherapy in relation to the respective standard combination in patients with a KRAS wildtype with platinum-sensitive recurrent ovarian cancer (NCT01388621).

Method

Only patients with platinum-sensitive epithelial ovarian/ fallopian/ peritoneal cancer, measurable disease or elevated CA125 and with KRAS wild type and no more than 2 prior treatments were registered for this study. Therapy included Carboplatin AUC4/Gemcitabine 1000 mg/m² or Carboplatin AUC5/PLD 40 mg/m² and randomized to panitumumab 6 mg/kg day 1 and day 15, every 3 or 4 weeks. Tumor assessment was performed at baseline and at every third cycle according to CT-scan and CA-125 criteria.

Results

In this multi-institutional phase II trial 102 patients were randomized and 96 enrolled for the final analysis. Progression-free survival in the intention-to-treat population (N=96) was 9.5 vs. 10.7 months (HR 0.829, 95%CI of 8.5-11.6 months vs 8.5-13.1 months) for the experimental vs. standard arm, p=0.45. Data of overall survival are not jet evaluable. The most common treatment related grade 3+ toxicities included hematologic toxicity (54%), skin reactions (18%) and gastrointestinal events (16%).

Conclusion

Addition of panitumumab to platinum-based chemotherapy for recurrent ovarian cancer does not influence efficacy and progression-free survival in platinum sensitive patients, while no new additional toxicity aspects for panitumumab were evaluated.
EFFECTIVENESS OF NATIONAL HUMAN PAPILLOMAVIRUS VACCINATION PROGRAM FOR JAPANESE YOUNG WOMEN

M. Yamaguchi1, R. Kudo1, S. Adachi1, M. Sekine1, A. Yagi2, Y. Tanaka2, Y. Ueda2, E. Miyagi3, T. Enomoto1

1Niigata University, Obstetrics and Gynecology, Niigata, Japan
2Osaka University, Obstetrics and Gynecology, Osaka, Japan
3Yokohama city University, Obstetrics and Gynecology, Yokohama, Japan

Aims

In Japan, human papillomavirus (HPV) vaccinations became public aid from 2010 and subsequently became routine for girls aged 12–16 years from April, 2013. However, after extensive news of adverse vaccine events and suspension of the governmental recommendation in June 2013, inoculation rate of HPV vaccine dramatically decreased. The present study was aimed to investigate the effectiveness of national human papillomavirus vaccination program for Japanese young women.

Method

We recruited 20-22 years old females who attended the public cervical cancer screening program from April 2014 to March 2017 in Niigata, Japan. HPV testing was performed using HCII® (Qiagen) and TM HPV kit® (MEBGEN) and questionnaire about HPV vaccination was conducted. A Chi-square test was used in this statistical analysis.

Results

HPV testing was performed to a total of 2196 registrants and 1972 women replied to questionnaire. A total of 1297 (65.8%) participants self-reported they were vaccinated, and 675 (34.2%) were unvaccinated. High risk HPV infection rate was 11.6% in vaccinated group and 15.9% in unvaccinated group, respectively. The prevalence of vaccine types 16 and 18 was significantly lower in vaccinated group (0.2%) than in unvaccinated group (1.8%; p = .0004 ). Similarly, the prevalence of HPV 31,33 and 45 which are cross-protected by HPV bivalent and quadrivalent vaccination was significantly lower in vaccinated group (0.3%) than in unvaccinated group (1.5%; p = .008 ).

Conclusion

Our study demonstrates evidence of high effectiveness of national HPV vaccination program in Japanese young women. National vaccination encouragement should resume as soon as possible.
ORAL 09 - OVARIAN AND CERVICAL CANCER

ESGO7-0333

CLINICAL ANALYSIS OF ENDOMETRIOID AND CLEAR CELL CARCINOMA OF THE OVARY WITH OR WITHOUT ENDOMETRIOSIS

S. Kim1, U. Ju1, W. Kang1
1Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Aims

We investigated the cases of endometriosis-associated ovarian cancers (EAOC) and analyzed outcome of endometrioid carcinoma (EC) and clear cell carcinoma (CCC) with or without endometriosis.

Method

Among 678 patients, received treatments for ovarian cancer from 2004 to 2015, 126 were identified to had EC (n=70) and CCC (n=56). They divided into two groups according to the presence of endometriosis or not (n=27 and n=99, respectively).

Results

38 patients (5.6%) had EAOC; 15 (39.5%) of EC, 12 (18.4%) of CCC, 7 (18.4%) of mucinous carcinoma, 3 (7.9%) of serous carcinoma, and one (2.6%) of endometrial stromal sarcoma. The frequency of coexistence of endometriosis was 21.4% (15/70) for EC and 21.4% (12/56) for CCC. FIGO stage were not significantly different between two groups of EC and CCC with or without endometriosis. 18 at I (66.7%), 7 at II (25.9%), and 2 at III (7.4%) vs. 69 at I (69.7%), 18 at II (18.2%), 10 at III (10.1%), and 2 at IV (2.0%). There was no difference in the rate of optimal cytoreduction and response to chemotherapy. During a median follow-up of 44 months (range, 14-156), 7 cases (25.9%) in group with endometriosis had a recurrence, while 36 (36.4%) in control group (p=0.038). The 5-year disease-free survival (DFS) and overall survival (OS) of patients with endometriosis vs. without endometriosis were 75% vs. 64% (p=0.030) and 86% vs. 80% (p=0.084), respectively.

Conclusion

EC and CCC with endometriosis had the lower recurrence rate and more improved 5-year DFS. However, the coexistence of endometriosis did not affect 5-year OS.

COMPARISON OF MRI, PET-CT, AND FROZEN BIOPSY IN THE EVALUATION OF LYMPH NODE STATUS BEFORE FERTILITY-SPRING RADICAL TRACHELECTOMY IN EARLY STAGE CERVICAL CANCER

G.W. Lee1, S.W. Lee1, J.Y. Park1, D.Y. Kim1, D.S. Suh1, J.H. Kim1, Y.M. Kim1, Y.T. Kim1, J.H. Nam1
1asun medical center, obstetrics and gynecology, Seoul, Republic of Korea

Aims

To compare the accuracy of magnetic resonance imaging (MRI), positron emission tomography/computed tomography(PET/CT) and frozen biopsy before fertility-sparing radical trachelectomy in early stage cervical cancer.

Method

This was a retrospective study including 73 young women with early stage cervical cancer who tried fertility-sparing laparoscopic or robotic radical trachelectomy. All patients underwent preoperative MRI and PET-CT. Comprehensive lymph node dissection was performed during surgery, and all retrieved lymph nodes were sent to frozen biopsy before proceeding radical trachelectomy. The diagnostic accuracy of MRI, PET-CT, and frozen biopsy was compared using McNemar test and logistic regression using generalized estimating equation. The final pathologic report on lymph nodes was the gold standard for diagnosis.

Results

A total number of retrieved lymph nodes was 1448, and mean some retrieved lymph nodes was 20 (range 2-61). Sixteen lymph node areas were positive in 11 patients (15.1%). There was no significant difference in sensitivity (27.27% versus 54.55%, P=0.18), specificity (80.36% versus 76.79%, P=0.41), accuracy (71.64% versus 73.13%, p=0.76) of MRI versus PET-CT. There was significant difference in sensitivity (100% vs. 27.27%, P=0.005), specificity (100% vs. 80.36%, P=0.001), accuracy (100% vs. 71.64%, P<0.001) of frozen biopsy versus MRI. There was significant difference in sensitivity (100% vs. 54.55%, P=0.025), specificity (100% vs. 76.79%, P<0.001), accuracy (100% vs. 73.13%, P<0.001) of frozen biopsy versus PET-CT.

Conclusion

Frozen biopsy of all retrieved lymph nodes during surgery is still the best way to evaluate lymph node status before fertility-sparing radical trachelectomy.
Aims

Several studies have identified L1CAM as a strong prognostic marker in endometrial cancer. To further underline the clinical usefulness of this biomarker, we here investigated L1CAM as a predictive marker for lymph node metastases and its prognostic impact in curettage specimens and preoperative plasma samples.

Method

Immunohistochemical staining of L1CAM was performed for 1134 curettage specimen from endometrial cancer patients. In addition L1CAM level in preoperative blood samples from 372 patients was determined using ELISA. Association between L1CAM level and clinicopathologic variables including lymph node status and survival was investigated.

Results

Expression of L1CAM in curettage specimen was significantly correlated to L1CAM level in corresponding hysterectomy specimen. Both in curettage specimen and preoperative plasma samples was L1CAM upregulation significantly associated with features of aggressive disease and poor outcome. L1CAM was an independent predictor of lymph node metastases, after correction for curettage histology, both in curettage specimen and plasma samples.

Conclusion

We demonstrate that preoperative evaluation of L1CAM levels, both in curettage or plasma samples, predicts lymph node metastases and adds valuable information on patient prognosis. Our results strongly support the usefulness of L1CAM as a biomarker in endometrial cancer.
Aims

To set up a simple test for circulating cell-free DNA (cfDNA) quantification in endometrial cancer (EC) and correlate it with the individual metabolic syndrome factor and tumor aggressiveness to help clinical diagnosis and prognosis.

Method

The blood of cancer patients was obtained before surgery and before the beginning of any treatment. Information about patients was obtained by reviewing their medical charts.

Blood samples were collected in vacutainer tubes and left at room temperature to allow to clot. The clot was removed by centrifuging at 1,000–2,000 x g for 10 minutes in a refrigerated centrifuge and stored at −80°C.

For measurement of cfDNA levels SYBR Gold Nucleic Acid Gel Stain we followed the protocol described by Goldshtein et al (Ann Clin Biochem. 2009 Nov;46(Pt 6):488-94).

Results

Our data show that cfDNA levels are higher in G2 (n=30) and G3 (n=17) compared with G1 (n=12) EC sera, but this increase does not depend on cancer stage. Moreover, a significant increase on cfDNA amount was detected in sera from patients with BMI>30 compared with those with BMI<30, even if not related with EC grading. Interestingly, we observed a further and significant increase of cfDNA in hypertensive patients with G2-G3, but not with G1 EC.

Conclusion

cfDNA levels are indicative of EC occurrence and aggressiveness and further increase in hypertensive patients with high grade EC. Our data indicate that assessment of cfDNA levels in blood sera with direct SYBR gold assay may help in prediction of EC development and aggressiveness.
Aims

POLE exonuclease domain-mutant (EDM) endometrial cancers (ECs) have an excellent clinical outcome. To reduce overtreatment, minimization of adjuvant treatment has been proposed in early-stage POLE-mutant EC. However, studies showing prognostic significance of these mutations failed to conclude its independence of adjuvant therapy. Therefore, we tested treatment sensitivities of POLE EDMs in a model system.

Method

Three somatic POLE exonuclease domain hotspot mutations were generated in mouse embryonic stem cells using CRISPR/Cas9. Spontaneous mutation frequencies and spectra were determined through Hprt assays. Cells were treated with ionizing radiation or chemotherapeutic agents including nucleoside analogs. IC50s were calculated and compared between isogenic wild type and POLE EDM cell lines.

Results

Similarly to POLE-mutant ECs, POLE EDMs resulted in a mutator phenotype in mouse embryonic stem cells (~8-30x higher mutation frequency compared to wild type). POLE EDM cells did not show increased sensitivity to ionizing radiation ($P = 0.8281$) or to chemotherapeutic agents (cisplatin, 5-FU, paclitaxel, doxorubicin, methotrexate and etoposide; $P=0.1091-0.9960$) compared to wild type cells. In contrast, POLE EDM cells displayed hypersensitivity to nucleoside analogs cytarabine and fludarabine (IC50 2.6 vs 6.5 μM, $P=0.0386$; IC50 18.0 vs 74.9 μM; $P=0.0002$, respectively).

Conclusion

Based on this study, hypersensitivity to currently used adjuvant treatments cannot explain the good prognosis of POLE-mutant (endometrial) cancers. These results support ongoing efforts to explore minimization of adjuvant therapy for early-stage POLE EDM ECs. Moreover, this study proposes nucleoside analogs as most effective chemotherapeutic agents for advanced-stage POLE-mutant cancers, which should be subject of further studies.
Aims

We aimed to clarify retrospectively, the post-pregnancy outcomes of young patients with endometrioid adenocarcinoma (EC) or atypical endometrial hyperplasia (AEH) who received fertility-preserving hormonal therapy using medroxyprogesterone acetate (MPA).

Method

We reviewed 248 patients with AEH (102), EC Grade1 (142), EC Grade2 (4) , who were determined to have neither myometrial invasion nor extrauterine metastasis. After 4 months oral administration of MPA (400-600mg/day), D&C was performed. An additional 2 months medication and D&C were repeated when positive residual disease. At intrauterine recurrence, we repeated MPA therapy for patients meeting the same eligibility for initial therapy. We analyzed the recurrence-free survival (RFS) rates in EC patients or AEH patients by Kaplan-Meier method.

Results

Median follow-up period was 60 months. In initial therapy, pathological CR rate was 97% in AEH, 90% in G1/G2. The pregnancy rate after MPA therapy was 34% in AEH, 34% in G1/G2. After delivery or abortion, 2 year-RFS rate was 91% in AEH, 65% in G1/G2, and 5 year-RFS rate was 65% in AEH, 38% in G1/G2 (p=0.0038, Log-rank test). RFS rate was similar between patients after abortion or patients after successful delivery (53% vs. 50%, p=0.49).

Conclusion

Post-pregnancy RFS rate was low especially in patients with EC. Careful surveillance for intra-uterine recurrence is needed even after successful pregnancies.
A COMPARATIVE STUDY OF TWO FOLLOW-UP STRATEGIES FOLLOWING TREATMENT OF ENDOMETRIAL CANCER BETWEEN AN ITALIAN AND A UK CENTRE

V. Ghirardi¹, N. Bizzarri¹, R.L. O'Donnell², S. Rundle³, I.C. Kotsopoulos⁴, P. Korompelis⁵, A. Kucukmetin⁶, A. Fisher⁷, C. Ang⁸, N. Rattanavelu⁹, H. Manderville⁹, K. Roberts⁹, S. Costantini², M. Valenzano Menada³, R. Naik¹

¹Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom
²IRCCS AOU San Martino – IST- University of Genoa, Academic Unit of Obstetrics and Gynecology- Department of Neurosciences- Rehabilitation- Ophthalmology- Genetics- Maternal and Child Health DiNOGMI, Genoa, Italy

Aims

To date there are no studies demonstrating survival advantage in endometrial cancer (EC) with intensity of follow-up (FU). The objective of this study was to compare PFS and OS in EC patients treated and followed-up in two European tertiary centers, each with markedly different FU protocols.

Method

This retrospective study included consecutive patients treated for EC 2005 to 2010, with 5-years of FU. FU in the Italian group (Genoa) included examination, vault cytology, CA125, CT and ultrasound scans at predefined intervals regardless of symptoms. In the UK group (Gateshead), FU included examination at decreasing time intervals with symptom-directed imaging.

Results

907 patients were surgically treated for EC 2005-2010. There were 61(10.9%) recurrences in the UK group and 24(8.0%) in the Italian group. In the UK group, 45(73.8%) recurrences were symptomatic with confirmation on examination in 14(22.9%) cases and radiologically in 31(50.8%). 16 cases were asymptomatic, of which 4(25.0%) were detected on examination and 12(75.0%) as an incidental finding on unrelated imaging. In the Italian group, 6(25.0%) cases were symptomatic. Of the 18(75.0%) asymptomatic cases, 2(11.1%) were detected following examination, and 7(38.9%) with pre-planned imaging. There was no survival advantage observed in the patients diagnosed using intensive FU in comparison to the less intense UK based FU.

Conclusion

This observational study suggests that early diagnosis of asymptomatic recurrence has no significant survival advantage. Structured FU interview and clinical assessment is likely to trigger appropriate and timely imaging. Initial evaluation suggests that there are significant health service costs associated with intensive FU.

DOES THE NODAL RE-STAGING SURGERY FOR HIGH RISK ENDOMETRIAL CANCER, ACCORDING TO THE RECOMMENDATIONS OF THE ESMO-ESGO-ESTRO GUIDELINES, CHANGE THE MANAGEMENT OF PATIENTS?

A. Maulard1, C. Beytout1, C. Chargari1, P. Pautier2, C. Genestie1, E. Bentivegna1, P. Morice1, S. Gouy1

1Gustave Roussy, Surgery, Villejuif, France
2Gustave Roussy, Radiotherapy, Villejuif, France
3Gustave Roussy, Oncology, Villejuif, France
4Gustave Roussy, Biology and Pathology, Villejuif, France

Aims

To evaluate in routine practice ESMO-ESGO-ESTRO guidelines which recommended a second staging surgery (SSS) to perform a para-aortic (+/- pelvic) lymphadenectomy in case of high risk endometrial cancer operated by only a radical hysterectomy.

Method

At Gustave Roussy, from 2010 to 2014, 55 patients had a hysterectomy with a diagnosis of high risk endometrial cancer.

Results

Median age and BMI were respectively 63 years (53-74) and 26 kg/m2 (23-30). Performance status was 0 (n=37), 1 (n=16), 2 (n=2). Twenty-four patients had a SSS with a number's median of para-aortic nodes of 18 (12-14). Six (25%) patients had at least one metastatic node and received radiotherapy with extension field in para-aortic area and adjuvant chemotherapy. We used systematically a laparoscopic approach (extraperitoneal approach in 87%). One patient required a conversion by laparotomy for a vascular injury. No major postoperative morbidity occurred. Twenty-one patients didn’t have a second staging surgery for the following reasons: age > 70 years (n=7), comorbidities (n=3), initial surgery’s delay (n=1), previous abdominal surgery (n=4), poor medical status (n=2), patient’s choice (n=1), combined reasons (n=10). Adjuvant treatment consisted on radiotherapy (n=44), brachytherapy (n=48) and chemotherapy (n=19). Among the 24 patients with a SSS, 23 (96%) received the complete adjuvant treatment whilst 8 patients (26%) of the 31 patients without SSS stopped the adjuvant treatment due to toxicity (P=.03).

Conclusion

Due to change of management, SSS via a laparoscopic approach should be considered in high risk endometrial cancer in light of age, comorbidities, BMI, medical status and previous abdominal surgery.

ESTROGEN RECEPTOR AND PROGESTERONE RECEPTOR DOUBLE NEGATIVITY PREDICTS POOR SURVIVALS IN PATIENTS WITH GRADE I AND II ENDOMETRIOD ENDOMETRIAL ADENOCARCINOMA

J. Guan1, L.Y. Xie2, Q. Zhu3, X.J. Chen2
1University of Oxford, Nuffield Department of Obstetrics and Gynecology, Oxford, United Kingdom
2Obstetrics and Gynecology Hospital of Fudan University, Department of Gynecology, Shanghai, China
3Obstetrics and Gynecology Hospital of Fudan University, Department of Pathology, Shanghai, China

Aims

A third of woman died for endometrial cancer were initially considered with low risk for relapse. This implies clinical classification as type I and type II is sub-optimal. Hence, more improved means are needed, to precisely identify high-risk patients from low-risk ones. Many studies associated the negativity of estrogen receptor (ER) and progesterone receptor (PR) with poor survival in endometrial carcinoma. However, their roles in low-risk endometrial cancer are unclear. This study was to investigate the prognostic value of double negative ER and PR (ER/PR loss) in low-grade endometriod endometrial adenocarcinoma (EEA).

Method

ER and PR expression were assessed by immunohistochemical staining on formalin-fixed paraffin-embedded tumor samples for 903 patients with grade I-II EEA. ER and PR negativity were determined if none of tumor cell nuclei was stained. The results were correlated with clinicopathologic parameters and survivals.

Results

Thirty-five of 903 patients were confirmed with ER/PR loss. They had deeper myometrial infiltration (P=0.006), severer FIGO stage (P=0.005), and higher rate for pelvic lymph node metastasis (P=0.016), vascular invasion (P=0.015) and relapse (P=0.001), when compared with other 868 of 903 patients who had positive ER and/or PR. In univariate analysis, ER/PR loss was associated with a shorter progression-free survival (PFS, P=0.0002) and overall survival (OS, P=0.0003). ER/PR loss also predicted poor PFS (HR=4.04, P=0.003) and OS (HR=5.56, P=0.016) in multivariate analysis.

Conclusion

In low-grade EEA, ER/PR loss seemed to correlate with a more aggressive subtype with poorer survivals. Implementing ER/PR evaluation into clinical algorithms may improve the risk stratification for tailored therapeutic strategy.

COMPARISON OF UTERINE LEIOMYOSARCOMA (LMS) AND LEIOMYOMA (LM) FINDINGS FOR CREATION OF A PREOPERATIVE LMS-RISK-SCORE

D. Trojnarska1, M. Köller2, C. Riechmann2, J. Krichbaum3, H. Lehnhoff1, A. Marcinek1, M. Franzef, M. Zygmunt1, G. Köhler1

1University Medicine Greifswald, Department of Obstetrics and Gynecology, Greifswald, Germany
2Center of Minimal Invasive Surgery, Department of Gynecologic Surgery, Sachsenhausen- Frankfurt/Main, Germany
3Velener Arbeitskreis Ambulantes Operieren, Münster, Germany
4University Medicine Greifswald, Institute for Community Medicine- Department Community Health, Greifswald, Germany

Aims

Are there any significant differences between LMS and LM clinical findings allowing the creation of a preoperative LMS-Risk-Score to prevent an inadequate LMS surgery?

Method

Matched data analysis of 235 LMS and 669 LM from the German Clinical Competence Centre for Genital Sarcomas and Mixed Tumours and cooperating departments was performed.

Results

There was a statistical significant difference (p < 0.01) in regard to the mean age of patients with LM vs. LMS (43.3 vs. 54 years) and in mean tumor diameter (5.2 vs. 10.1 cm), respectively. Further significant different findings are presented in table 1. Tamoxifen exposition, failure of prior pharmacological therapy of LM, and prior surgery of atypical smooth muscle tumor were higher in LMS group, but differences not reached significant levels. Tumor related symptoms without bleeding disturbances were slightly higher in LM. Despite these differences 60 % of the 235 LMS were operated under the diagnosis of LM and 66.8 % underwent an inadequate surgery.

Table 1. Significant (p < 0.01) different findings in LM and LMS

<table>
<thead>
<tr>
<th>Findings</th>

EXPRESSION OF miR-146a IN PRIMARY TUMOUR AND OMENTAL IMPLANTS IN OVARIAN CANCER PATIENTS AND ITS CORRELATION WITH CLINICOPATHOLOGICAL FEATURES, PROGNOSIS AND CHEMO-RESISTANCE

M. Wilczyński1, E. Żytko2, B. Szymańska3, M. Dzieniecka4, J. Danielska5

1Polish Mothers Health Center Research Institute, Department of Operative Gynecology-Endoscopy and Gynecologic Oncology, Łódź, Poland
2Polish Mother's Health Center Research Institute, Department of Gynecology and Oncological Gynecology, Łódź, Poland
3Medical University of Łódź, Central Scientific Laboratory CoreLab, Łódź, Poland
4Polish Mother’s Health Center Research Institute, Department of Pathology, Łódź, Poland
5Medical University of Łódź, Radiotherapy Department, Łódź, Poland

Aims

To study the miR-146a expression in primary tumour and omental implants of ovarian serous cancer, and to investigate the correlation with clinicopathological features, including chemosensitivity and survival.

Method

MiRNA-146a was evaluated in formalin-fixed, paraffin-embedded (FFPE) samples collected from 48 patients operated for advanced (FIGO III/IV stage) ovarian cancer. The reference group included 48 normal ovaries. Total RNA was extracted from FFPE tissue using Roche High Pure miRNA Isolation Kit. The yield and quality of RNA were measured using PicoDrop spectrophotometer. Reverse transcription to cDNA was carried out according to the miRCURY LNA Universal RT micro RNA PCR instruction. PCR amplification was performed using primer set for hsa-miR-146a-5p. U6 snRNA and SNORD48 were internal controls. Reactions were performed on a 7900HT Fast Real-Time PCR System. Relative expression was calculated according to the Cq method $2^{-\Delta\Delta Cq}$.

Results

MiR-146a expression in primary tumour was increased in comparison to normal ovaries (p=0.02) and implants (p=0.01). Negative correlation was found between miR-146a expression in primary tumours and serum levels of CA125 (R= -0.37, p=0.03) and ROMA index (R= -0.79, p=0.0007). Overall survival (OS) positively correlated with the miR-146a expression in the primary tumour (R= 0.38, p=0.01). Probability of survival was decreased in patients with lower miR-146a expression (HR=0.21, p=0.003) in the primary tumour. In multivariate analysis lower levels of miR-146a expression correlated with shorter progression-free survival (PFS) (p=0.04) in primary tumour and with platinum-resistance in implants (p=0.006).

Conclusion

MiR-146a expression could be a prognostic marker for chemosensitivity and survival in serous ovarian cancer.

ESGO7-0384

A panel of miRNAs, identified with global microarray, may provide prognostic information for patients with ovarian cancer

K.P. Prahm1

1Herlev Hospital, Molecular Unit: Dept. of Pathology, Copenhagen, Denmark

Aims

Ovarian cancer is the leading cause of gynecologic cancer deaths in the Western world. Prognosis of the disease is mainly related to stage at diagnosis, surgery and sensitivity to chemotherapy. The purpose of the current study was to identify miRNAs associated with prognosis and resistance to chemotherapy in patients with ovarian cancer.

Method

Patients who were surgically treated for epithelial ovarian cancer, diagnosed between September 2004 and January 2010 were enrolled in the study. MicroRNA expression profiles were identified from tumor tissue using microarray analysis. In the primary statistically analyses miRNA index predictors of survival and resistance to chemotherapy were developed with adaptive index models, adjusted for known prognostic variables.

Results

A total of 198 patients with epithelial ovarian cancer were included. Of these, 170 patients had received platinum-based chemotherapy as first-line treatment after primary surgery, and were eligible for analyses of resistance to chemotherapy. In the multivariate adaptive index model analyses combinations of three different miRNAs were identified to be significant and independent predictors of survival and time-to-progression. One miRNA were found to be significant for chemotherapy resistance.

Conclusion

In the current study combinations of either one or three miRNAs were identified as significant predictors of survival, time-to-progression and chemotherapy-resistance for patients with epithelial ovarian cancer. This approach could potentially give important information of prognosis and thereby support patient management towards a more individualized treatment.

¹Università Cattolica del Sacro Cuore, Gynecologic oncology, Roma, Italy
²Oncology Center Mansoura University, Surgical Oncology, Mansoura, Egypt
³University of Palermo, Gynecologic Oncology, palermo, Italy

Aims

To evaluate the surgical and pathological outcomes of patients underwent transperitoneal para-aortic lymphadenectomy (PAL) for gynecological cancer patients with minimally invasive approach.

Method

Between 2012 and 2016, 184 patients underwent robotic transperitoneal (R-PAL) (n=78) and laparoscopic transperitoneal (L-PAL) (n=106), 43 for cervical cancer (23.3%), 31 for endometrial cancer (16.8%) and 110 (59.7%) for ovarian cancer in Gemelli hospital in Rome. The patients were retrospectively evaluated and compared.

Results

78 patients underwent R-PAL were compared to 106 patients underwent L-PAL. The study showed no significant difference between the 2 groups in terms of age, BMI, and preoperative characteristics. In all series 24 (13%) patients had BMI > 32. The Median operative time for both groups was 237.5 minutes for R-PAL and 220 for L-PAL (p=0.446). Median blood loss was 100 in R-PAL and 80 in L-PAL (p=0.693). Only one patient was converted to open approach in the robotic group. The rate of intraoperative complications in the whole series was 2.7% with no significant difference between the 2 groups (P=0.652). The rate of the postoperative complications in the whole series was 16.8% with slightly higher rate in robotic group (p=0.045). In all series, the pathological results showed presence of lymph node metastasis in 18 (9.7%) patients, with no difference between the two groups.

Conclusion

The present study showed feasibility, safety of minimally invasive approach for PAL.

³Jules Bordet Institute, Pathology, Brussel, Belgium
⁴Jules Bordet Institute, Data Centre and Statistic, Brussel, Belgium

Aims

Cytoreductive surgery (CS) is limited by the vision of the surgeon. Furthermore, no tools exist for the detection of tumoral cells in post neoadjuvant chemotherapy (NAC) residual scars (RS).

The aims of this study are to evaluate the role of ICG-Fluorescence Imaging (FI) for the detection of peritoneal metastasis and tumoral cells in RS (post NAC).

Method

Patients admitted for primary or interval CS with stage III/IVa from September 2013 to August 2016 were elected for the study. Free ICG (0.25 mg/kg) was IV injected intraoperatively before CS. Fluorescence intensity and tumor to background ratio (TBR) was calculated for all peritoneal nodules (PN) and RS.

Results

Twenty patients including 17 seropapillar adenocarcinoma, and 3 others type of tumors were included. A total of 108 PN and 25 RS were imaged, resected and analysed by histopathology. Amongst PN, 73 were malignant (67.6%) and 35 benign (32.4%). The mean of the TBR (ex vivo) was 1.8 (SD 1.3) in malignant nodules and 1.0 (SD 0.79) in benign nodules (p = 0.007). With a TBR cut-off of 1.3, sensitivity and specificity are respectively 72.6% (53/73) and 45.7% (16/35). Amongst the 25 RS, the mean TBR (in vivo) was 2.06 (SD 1.15) in malignant (n=2) and 1.21 (SD 0.50) in benign nodules (n=23). The positive predictive value of ICG-FI to detect tumoral cells in scars was 57.1%.

Conclusion

ICG-FI is able to discriminate between benign and malignant PN, but not sufficient specific for the detection of tumoral cells in RS post NAC.

PRIMA-1MET INDUCES APOPTOSIS THROUGH ACCUMULATION OF INTRACELLULAR REACTIVE OXYGEN SPECIES IRRESPECTIVE OF P53 STATUS AND CHEMO-SENSITIVITY IN EPITHELIAL OVARIAN CANCER CELLS

N. Yoshikawa¹, Y. Shimizu¹, M. Yoshihara¹, K. Nakamura¹, S. Suzuki¹, H. Kajiyama¹, F. Kikkawa¹

¹Nagoya University Graduate School of Medicine, Obstetrics and Gynecology, Nagoya, Japan

Aims

PRIMA-1MET is a small molecule compound that restores wild-type p53 to mutant p53, and is recently confirmed to be safe at therapeutic plasma levels. The aims of this study were to identify the anti-tumour activity of PRIMA-1MET on epithelial ovarian cancer (EOC) cells and elucidate the underlying mechanism in vitro.

Method

We used nine EOC cell lines and their chronic cisplatin/paclitaxel-resistant cells and performed cell viability assay and cell apoptosis assay to evaluate the efficacy of PRIMA-1MET. Moreover, we assessed the functional role of reactive oxygen species (ROS) and their scavenger in the EOC cells.

Results

We examined the viability of the total 13 EOC cells after 48 h treatment with PRIMA-1MET. Measuring the half maximal inhibitory concentration (IC₅₀) of EOC cells revealed that the sensitivity was heterogeneous, and did not correlate with TP53 status. PRIMA-1MET induced apoptosis, PARP cleavage, and intracellular ROS accumulation in a p53-independent manner. The anti-tumour effects of PRIMA-1MET were completely rescued by a ROS scavenger, N-acetyl cysteine. Furthermore, PRIMA-1MET reduced the expression of antioxidant enzymes, PRX3 and GPX1, in a dose-dependent manner.

Conclusion

We demonstrated that PRIMA-1MET had an anti-tumour effect on EOC cells regardless of TP53 status and chemo-resistance. PRIMA-1MET is a promising therapeutic agent for chemo-resistant EOC patients and may contribute to a better prognosis in the future.

ESGO7-0499

GENOMIC LANDSCAPE OF BRAIN METASTASIS FROM OVARIAN/PERITONEAL CANCER

H.J. Kang¹, J.S. Park², S.Y. Hur³, Y.J. Choi³

¹College of Medicine - The Catholic University of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea
²Seoul St.Mary’s Hospital - The Catholic University of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea
³Seoul St. Mary’s Hospital - The Catholic university of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Brain metastasis from ovarian cancer is a rare disease entity which leads to dismal prognosis. However, the genomic alterations of primary ovarian/peritoneal cancer and the brain metastasis have not been fully elucidated.

Method

We performed whole-exome sequencing of three matched brain metastases and ovarian/peritoneal cancers.

Results

We detected increased number of genomic alterations from brain metastases when compared to ovarian/peritoneal cancers (range: 88-155 and 52-74, respectively). All the ovarian/peritoneal and brain tissues encompassed TP53 non-silent mutations and SEC16B non-silent mutations were harbored in two of the three cases. In addition, genetic alterations of ADGRB1, a tumor suppressor gene that is known to be related to glioblastomas, were detected only in brain metastases (two of the three cases).

Conclusion

Our data revealed that brain metastasis from ovarian/peritoneal cancer harbors a somatic mutation known to be associated with glioblastomas, suggesting that brain-specific genetic alterations may exist.

7 Sheba Medical Center, Gynecologic Oncology Department, Tel Hashomer, Israel
8 University Hospital 12 de Octubre, Medical Oncology, Madrid, Spain
9 Radboud University Medical Center, Medical Oncology, Nijmegen, The Netherlands
10 Groupe Hospitalier Diaconesses Croix Saint-Simon and Alliance Pour la Recherche en Cancérologie, Medical Oncology Service, Paris, France
11 Fios Genomics Ltd, Biostatistics Department, Edinburgh, United Kingdom
12 F Hoffmann-La Roche Ltd, Global Product Development/Medical Affairs, Basel, Switzerland
13 University Hospital Basel, Department of Gynecology and Gynecological Oncology, Basel, Switzerland

Aims

We compared prevalences of various genomic alterations in patients with epithelial ovarian cancer treated in two prospective clinical trials, ROSiA (single-arm: front-line bevacizumab-containing therapy [Oza 2016; NCT01239732]) and PENELOPE (placebo-controlled phase III: chemotherapy ± pertuzumab for low HER3 mRNA-expressing platinum-resistant disease [Kurzeder 2016; NCT01684878]), to explore genomic profiles predicting for platinum resistance.

Method

Pre-treatment tissue samples were analysed using FoundationOne® (Foundation Medicine). The distribution of mutational load was compared between trials using a bootstrapped Kolmogorov-Smirnov test. Relative prevalences of gene alterations in >5% of patients were compared using Fisher’s exact test. Benjamini-Hochberg false-discovery rate (FDR) adjustment for multiplicity was applied using a 10% threshold for statistical significance.

Results

Samples from 141 PENELOPE and 154 ROSiA patients were evaluable. The mean mutational load was 3.64/megabase and 4.48/megabase, respectively; the difference bordered on statistical significance (bootstrapped Kolmogorov-Smirnov test p=0.097). The figure shows mutational profiles by trial. There were marked differences between PENELOPE and ROSiA for alterations in BRCA1 (16/141 [11.3%] vs 34/154 [22.1%], respectively; odds ratio 0.45) and MYC (20/141 [14.2%] vs 38/154 [24.7%]; odds ratio 0.50); neither
remained statistically significant after multiplicity adjustment (both FDR p=0.21).

Conclusion

Apparent qualitative and quantitative inter-trial differences in mutational profile, particularly BRCA1 mutation, from diagnostic/archival samples may be attributable to prognosis and patient selection (poor-prognosis platinum resistant vs unselected newly diagnosed). No significant difference in mutational load was observed. Analyses by histological subtype and combined markers warrant exploration.
E-POSTER TALK SESSION 1

ESGO7-0530

SYMPTOMS RELEVANT TO SURVEILLANCE FOR OVARIAN CANCER

E. Pavlik1, R. Ore1

1University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To examine how frequently and confidently healthy women report symptoms during surveillance for ovarian cancer.

Method

A symptoms questionnaire was administered to 24,526 women over multiple visits accounting for 70,734 reports. A query of reported confidence was included as a confidence score (CS). Chi square, McNemars test, ANOVA and multivariate analyses were performed.

Results

17,623 women completed the symptoms questionnaire more than one time and >9500 women completed it more than one four times for >43,000 serially completed questionnaires. Frequency of reported symptoms is in Table 1. Reporting ovarian cancer symptoms was ~245 higher than ovarian cancer incidence. The positive predictive value (0.073%) for identifying ovarian cancer based on symptoms alone would predict one malignancy for 1368 cases taken to surgery due to reported symptoms. Confidence on the first questionnaire (63.3%) decreased to 74% when more than five questionnaires were completed. Age-related decreases in confidence were significant (p < 0.0001). Women reporting at least one symptom expressed more confidence (41,984/52,379 = 80.2%) than women reporting no symptoms (11,882/18,355 = 64.7%), p < 0.0001. Confidence was unrelated to history of hormone replacement therapy or abnormal ultrasound findings (p = 0.30 and 0.89).

ESGO7-0542

DEVELOPMENT OF AN ANTIBODY MEDIATED OPTICAL IMAGING METHODOLOGY IN MOUSE MODELS OF HIGH-GRADE SEROUS OVARIAN CARCINOMA

K. Bischof1, M. Popa2, I. Karlsen2, K. Kleinmanns2, S. Anandan2, B.T. Gjertsen3, L. Bjørge2, E. McCormack2

1Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway
2University of Bergen, CCBIO- Department of Clinical Science, Bergen, Norway
3Haukeland University Hospital, Department of Internal Medicine- Hematology Section, Bergen, Norway

Aims

Epithelial ovarian carcinoma remains the deadliest of all gynecological malignancies with high-grade serous ovarian carcinoma (HGSOC) being the most common subtype. Due to late stage diagnosis with peritoneal tumour spread, complete surgical debulking is often difficult to achieve. It is essential, that preclinical models are relevant and permit the analysis of tumour manifestations, treatment responses and the development of new treatment strategies.

Method

Through a series of immunophenotyping experiments, we screened a panel of biomarkers for the cell lines OV90 and CaOV3, and identified CD24 as a homogeneous biomarker of several HGSOC cell lines. Orthotopic xenograft models were subsequently generated by injecting stably transfected OV90 and CaOV3 cells into the ovarian bursa of immunodeficient mice. Further, we established patient derived xenografts (PDX) by orthotopical implantation of unprocessed cancer cells after immediate mechanical tumour dissociation. After conjugation of a specific monoclonal antibody directed against CD24 to the near-infrared dye Alexa680, we studied detection of primary tumour and metastasis by non-invasive optical imaging in parallel with the more established method of bioluminescence.

Results

We identify the cell surface receptor CD24 to be a suitable target for fluorochrome-conjugated antibodies in time-domain optical imaging of HGSOC and find this novel methodology to be comparable to bioluminescence.

Conclusion

We introduce a noninvasive fluorophore mediated optical imaging protocol for HGSOC that facilitates the study of orthotopic models without the need for genetic alteration of tumour cells. Exploration if this original technique is applicable in the established PDX models is ongoing.

10University Medical Center Groningen, Genetics, Groningen, The Netherlands
11Leiden University Medical Center, Gastroenterology & Hepatology, Leiden, The Netherlands
12University Medical Center Groningen, Gynaecologic Oncology, Groningen, The Netherlands

Aims

To describe clinical characteristics of ovarian cancer diagnosed in women with Lynch syndrome (LS) and the role of surveillance in the early detection of these cancers.

Method

All women with LS identified in the Dutch Lynch syndrome registry or from the cohort at our University Medical Center Groningen (UMCG) who developed ovarian cancer were included. Clinical data on age at diagnosis, mutation type, histological type, FIGO stage, treatment, follow-up and gynaecological surveillance were collected.

Results

In the Dutch LS registry, 46/785 women (6%) with ovarian cancer were identified and 7/80 (9%) from the UMCG. The mean age of 53 patients at ovarian cancer diagnosis was 46.1 years (range 20-75 years). MSH2 (32%) and MSH6 (28%) were the most frequent gene mutations. The most frequently reported histological type was endometrioid adenocarcinoma (40%) and most tumours (87%; n=46) were detected at an early stage (FIGO I/II). Forty-one of 53 (77%) patients were diagnosed with ovarian cancer before LS was known. In 12/53 (23%) women ovarian cancer developed after starting annual gynaecological surveillance. Three ovarian cancers were diagnosed during surveillance in asymptomatic women, (two FIGO stage 1A, one stage IC). Six ovarian cancers were detected together with a (pre)malignancy of the endometrial tissue, (four FIGO stage IA, one stage IB, one stage IIA)

Conclusion

Ovarian cancer in women with LS has a wide age-range of onset, is most often diagnosed at an early stage with an endometrioid type histology. The early stage at diagnosis could not be attributed to annual gynaecological surveillance.

ESGO7-0616

BORDERLINE OVARIAN TUMORS: A NATIONWIDE OVERVIEW OF INCIDENCE, SURVIVAL AND RISK OF SUBSEQUENT INVASIVE OVARIAN TUMORS

M. Schuurman1, M. Timmermans1, K. Van de Vijver2, T. van Gorp3, R. Kruitwagen2, M. van der Aa4, V. Lemmens5,6

1Comprehensive Cancer Organisation the Netherlands IKNL, Departement of Research, Utrecht, The Netherlands
2The Netherlands Cancer Institute, Divisions of Diagnostic Oncology and Molecular Pathology, Amsterdam, The Netherlands
3Maastricht University Medical Centre, Department of Obstetrics and Gynecology, Maastricht, The Netherlands
4Comprehensive Cancer Organisation the Netherlands IKNL, Research, Utrecht, The Netherlands
5Comprehensive Cancer Organisation the Netherlands IKNL, Department of Research, Utrecht, The Netherlands
6Erasmus MC, Department of Public Health, Rotterdam, The Netherlands

Aims

Population-based studies on borderline ovarian tumours (BOTs) are rare as data collection is mostly limited to invasive ovarian tumours. In this nationwide study, we provide an overview of trends in incidence and survival of BOTs and establish the risk of a subsequent invasive ovarian tumour.

Method

All patients diagnosed with BOTs between 1993 and 2015 (n=6,706) were selected from the Netherlands Cancer Registry (NCR). Age-adjusted incidence rates and relative survival ratios were calculated. Patients with a subsequent invasive ovarian tumour were identified by the NCR.

Results

Incidence of BOTs doubled between 1993 and 2011, after 2011 incidence declined (see Figure). Five-year relative survival increased from 91% in 1993-1997 to 98% in 2010-2015. The proportion of bilateral tumours decreased from 16% to 11% during the same time periods. Of all patients, 0.9% developed a subsequent invasive ovarian tumour during a median follow-up time of 8 years.

Conclusion

Incidence of BOTs increased over time, but declined since 2011. The decline might be due to changes in the classification of gynecological tumours. The risk of a subsequent invasive tumour is low. Survival is high and has improved since 1993. An earlier detection through improvements in ultrasound or improved distinction between BOTs and metastases of gastrointestinal tumors may have contributed to the increased survival. Further analyses are going on to gain more insight into those changes.
E-POSTER TALK SESSION 2

ESGO7-0663

SURGICAL MORBIDITY OF ROBOTIC-ASSISTED SENTINEL LYMPH NODE BIOPSY VS. SYSTEMATIC PELVIC LYMPHADENECTOMY FOR ENDOMETRIAL CANCER STAGING: A PROPENSITY-MATCHED ANALYSIS

J. Casarin\(^1\)\(^2\), F. Multinu\(^1\), A. Weaver\(^1\), L. Tortorella\(^1\), W. Cliby\(^1\), S.C. Dowdy\(^1\), J. Bakkum-Gamez\(^1\), A. Kumar\(^1\), C. Langstraat\(^1\), F. Ghezzi\(^2\), G. Glaser\(^1\), A. Mariani\(^1\)

\(^1\)Mayo Clinic, Gynecologic Oncology, Rochester, MN, USA
\(^2\)University of Insubria, Obstetrics and Gynecology, Varese, Italy

Aims

To compare perioperative surgical outcomes and treatment-related morbidity of patients undergoing robotic-assisted sentinel lymph node (SLN) biopsy vs. systematic pelvic lymphadenectomy (PLD) for apparent early stage Endometrial Cancer (EC) staging.

Method

Records of consecutive patients with FIGO stage I-III EC undergoing robotic-assisted staging during 01/01/2009-06/30/2016 were manually reviewed. Perioperative and 30-day surgical outcomes were compared between patients who underwent PLD vs. SLN as actual treatment for staging (i.e. patients who had SLN biopsy followed by pelvic lymphadenectomy were excluded). Inverse probability of treatment weighting (IPTW) derived from propensity scores was used to minimize the allocation bias when comparing outcomes between groups.

Results

423 patients were included in the analysis: 235 (55.6%) PLD and 188 (44.4%) SLN. IPTW analysis balanced for baseline characteristics (age, BMI, ASA score, Charlson comorbidity index, parity, prior C-section and prior abdominal surgery) showed no significant differences in intraoperative and postoperative complications, readmissions and reoperations between the groups. Women who received PLD and SLN had similar conversion to open surgery rates (1.5% vs 0.8%; p=0.48). Patients in SLN group had lower mean operative time (216.2 vs 138.1 minutes) and lower median blood loss (50 vs 100 mL) when compared to PLD (p<0.001). Table 1.
Table 1. Comparison of surgical outcomes in patients undergoing robotic-assisted pelvic lymphadenectomy (LND) vs. sentinel lymph node biopsy (SLN) for endometrial cancer staging from January 1, 2009 and June 30, 2016.

</tr>
<tr>
<td>EBL (mL), median (IQR)</td>
<td>100 (60-200)</td>
<td>50 (50-100)</td>
</tr>
</tbody>
</table>

†Comparisons between groups were evaluated using a logistic regression model for binary outcomes and a linear regression model for continuous outcomes. EBL was analyzed after applying a logarithmic transformation.

*EXCLUSION CRITERIA: FIGO Stage IV, synchronous cancer, neoadjuvant treatment performed, no lymph node assessment, para-aortic lymphadenectomy performed, SLN followed by pelvic lymphadenectomy.

Conclusion

The introduction of SLN biopsy reduces operative times and further improves short-term perioperative surgical outcomes of robotic-assisted staging for apparent early stage EC.

ESGO7-0935

OVARIAN PROTECTION AND FERTILITY PRESERVATION IN WOMEN WITH CANCER: A FRENCH REGISTRY ANALYSIS BETWEEN 2005 AND 2014.

M. Koskas¹, J. Phelippeau¹

¹Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France

Aims

The aim of the study was to describe the practices concerning ovarian protection and fertility preservation in young women treated for cancer over the last decade in France.

Method

The study population comprised women between 15 and 49 years old diagnosed with cancer between 2005 and 2014 abstracted from the Echantillon Généraliste des Bénéficiaires database, a 1/97th random sample of the French population covered by the national healthcare insurance system. To assess practices concerning ovarian protection, gonadotropin-releasing hormone (GnRH) agonists consumption and ovarian transposition were analyzed. For fertility preservation, GnRH agonists consumption, ovarian cryopreservation and oocyte cryopreservation within 6 months after cancer treatment were analyzed. Explanatory variables were analyzed using a multilevel model.

Results

2447 women were identified. Among the 553 patients exposed to ovarian failure, 74 (13%) had ovarian protection (67 received GnRH agonists and 7 underwent ovarian transposition). Among the 227 women exposed to fertility alteration, 53 (23%) had fertility preservation (37 received GnRH agonists and 16 had ovarian or oocyte cryopreservation). Factors associated with ovarian protection were the age under 40 years old, diagnosis of breast cancer and the type of health institution. Fertility preservation was more frequently performed in patients with breast cancer. The five years probability of pregnancy was 3.8% and 9.8% (p=0.26) for women with fertility preservation and without fertility preservation respectively.

Conclusion

Over the last decade, ovarian protection and fertility preservation concerned respectively 13% and 23% of French women treated for cancer (mainly breast cancer).

ESGO7-0963

THE TEN YEAR EXPERIENCE OF A REGIONAL SPECIALIST GYNAECOLOGY CANCER GENETICS CLINIC WITH LYNCH SYNDROME

R. Crawford¹, B. Newcombe¹, H. Bolton¹, S.F. Ngu¹, S. Freeman², H. Addley², M. Jimenez-Linan³, R. Armstrong⁴, M. Tischkowitz⁵

¹Cambridge University Hospital NHS Foundation Trust, Gynaecological Oncology, Cambridge, United Kingdom
²Cambridge University Hospital NHS Foundation Trust, Radiology, Cambridge, United Kingdom
³Cambridge University Hospital NHS Foundation Trust, Pathology, Cambridge, United Kingdom
⁴Cambridge University Hospital NHS Foundation Trust, Cancer Genetics, Cambridge, United Kingdom
⁵University of Cambridge, Clinical Cancer Genetics, Cambridge, United Kingdom

Aims

To review the outcomes from a single institution experience of a regional referral practice in Lynch Syndrome (LS)

Method

Service review. Surveillance was outpatient hysteroscopy, endometrial biopsy, CA 125 and TV ultrasound. Risk reducing surgery (RRS) was laparoscopic hysterectomy and bilateral salpingo-oophorectomy.

Results

Since 2007 60 patients have had RRS and a further 7 patients are undergoing surveillance. There are 18 MLH-1, 17 MSH-2, 7 MSH-6 and 2 PMS-2 mutation carriers having risk reducing surgery with the balance having strong family history. The frequency of surgery is increasing with more referrals. The mean age for RRS is 45 years (range 32-62 yrs). 21 patients opted for surveillance, mean time period 3 years, with the longest screen being 11 years. Forty patients chose RRS, 25 within 6 months of the specialist clinic, 9 within 12 months (1 cancer at surgery aged 54 years), 6 within 24 months (1 cancer at surgery aged 48 years). There has been one ovarian cancer (stage 1A endometrioid) discovered at the time of removing an abnormal ovary at time of colorectal cancer surgery aged 41 years which precipitated diagnosis of LS. Three patients have had endometrial cancer detected at RRS, one stage 2 requiring adjuvant radiotherapy. Prior cancer in carriers include bowel and breast cancer. There have been no deaths.

Conclusion

Centralised services provide excellent care for patients with cancer mutations

ESGO7-0968

RISK FACTORS FOR PARA-AORTIC LYMPH NODE METASTASIS IN ENDOMETRIAL CANCER

M.E. Sarı1, I. Yalçın1, H. Sahin1, M.M. Meydanlı1, T. Gungor1
1Zekai Tahir Burak Women’s Health Training and Research Hospital- Faculty of Medicine- University of Health Sciences, Gynecologic Oncology, Ankara, Turkey

Aims

The purpose of this study was to determine the risk factors for para-aortic LN metastasis in EC patients that underwent comprehensive surgical staging.

Method

A total of 641 women with EC (endometrioid, non-endometrioid, or mixed histology) who underwent comprehensive surgical staging including pelvic and para-aortic LN dissection between 2008 and 2016 were included in this retrospective study. Patient data were analyzed with respect to para-aortic LN involvement and predictive factors for para-aortic LN metastasis were investigated.

Results

Lymph node metastasis was detected in 90 (14%) patients; isolated pelvic LN metastasis in 28 (4.3 %), isolated para-aortic LN metastasis in 15 (2.3 %), and both pelvic and para-aortic LN metastasis in 47 (7.3 %) women, respectively. Univariate analysis revealed that the risk of para-aortic LN metastasis significantly increased in patients with non-endometrioid histology, >60 years of age, grade 3 tumor, deep myometrial invasion, lymphovascular space invasion (LVSI), primary tumor diameter (≥2 cm), cervical stromal invasion, adnexal involvement, serosal invasion, pelvic LN involvement, ≥2 positive pelvic LNs and positive peritoneal cytology (p<0.05). At the end of multivariate analysis, presence of LVSI (odds ratio [OR]: 4.8, 95% confidence interval [CI] 1.25 - 18.2, p= 0.022) and pelvic LN metastasis (OR: 18.8, 95% CI 5.7-61.6, p<0.001) remained as independent risk factors for para-aortic LN involvement in women with EC.

Conclusion

Presence of LVSI and pelvic LN involvement appear to be independent risk factors for para-aortic LN metastasis in patients with EC. LVSI may be considered as a routine pathological parameter during frozen section analysis in women with EC undergoing surgery.

IMPACT OF HORMONAL RECEPTOR STATUS AND Ki-67 EXPRESSION ON DISEASE FREE SURVIVAL IN PATIENTS AFFECTED BY HIGH-RISK ENDOMETRIAL CANCER

V. Di Donato1, V. Iacobelli1, M. Schiavi1, I. Pecorella1, I. Palaia1, C. Marchetti1, A. Musella1, F. Tomao1, M. Monti1, L. Muzzi1, L. Tramontano1, P. Benedetti Panici1

1Sapienza University Policlinico Umberto I, Obstetrics and Gynecology, Rome, Italy
2Sapienza University Policlinico Umberto I, Pathology, Rome, Italy

Aims

The aim of this study was to evaluate the immunohistochemical expression of Ki-67, estrogen (ERα) and progesterone (PR) receptors in high-risk endometrial cancer patients and to assess their prognostic impact.

Method

Immunohistochemical (IHC) expression of Ki-67, estrogen (ERα) and progesterone (PR) receptors was evaluated in primary untreated endometrial cancer. The correlation among IHC staining and risk factors of recurrence such as age, FIGO (Federation International of Gynecology and Obstetrics) stage, grading, depth of invasion, and metastatic spread was assessed.

Results

82 patients were available for the analysis. Mean age was 65.05 ± 10.48 years. The IHC assessment revealed a lack of ERα in 46.3%, of PR in 48.7%, and a high Ki-67 in 31.7%. Loss of ERα and PR was associated with a significant higher rate of advanced stage of disease, a higher frequency of G3 tumors and a myometrial invasion >50%. A strong Ki-67 expression correlated with a deeper myometrial invasion. Analysis of the inter-relationship between receptor immunonegativity revealed a relevant association of ERα immunolocalisation with PR and with a high Ki-67 expression. The present study also showed that loss of ERα (p = 0.003), advanced FIGO stage (p < 0.001) and high Ki-67 (p = 0.004) were independent prognostic factors of a shorter DFS. Importantly, loss of ERα, loss of PR and a high Ki-67 were correlated with a higher incidence of distant recurrence.

Conclusion

A systematic immunohistochemistry should be a key step in the therapeutic algorithm and could contribute to the identification of high-risk tumors.

REDEFINING THE PRE-MALIGNANT LANDSCAPE OF GYNAECOLOGIC CANCERS: GENOMIC ANALYSIS OF UTERINE LAVAGE FLUID DETECTS BOTH EARLY STAGE CANCERS AND PRECANCEROUS CELLS OF UNKNOWN POTENTIAL.

J. Martignetti1, N. Nair1, O. Camacho-Vanegas1, D. Rykunov1, M. Dashkoff1, S. Camacho1, C. Schumacher1, J. Irish2, T. Harkins3, E. Periera1, S. Kendall1, N. Nagarsheth2, T. Kalir2, R. Sebra1, B. Reva1, P. Dottino2

1Icahn School of Medicine at Mount Sinai, Genetics & Genomic Sciences, New York, USA
2Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology and Reproductive Sciences, New York, USA
3Swift Biosciences, - , Ann Arbor- MI, USA

Aims

The holy grail of cancer treatment remains detecting and eliminating cancers at their earliest. Endometrial cancer is the most common gynecologic malignancy and its incidence and associated mortality are increasing. Strikingly, there is no effective screening methodology. We hypothesized that ultra-deep, targeted gene sequencing of uterine lavage fluid could detect even microscopic endometrial cancer.

Method

Uterine lavage and paired blood samples were analyzed from 107 consecutive patients undergoing hysteroscopy and curettage for diagnostic evaluation. Cellular and cell-free DNA were isolated from each lavage fluid sample. Ultra-deep sequencing, coverage in excess of 5,000x, was performed using a targeted 12 gene endometrial cancer panel.

Results

Seven patients were diagnosed with endometrial cancer based on classic histopathology. Six were stage IA cancers and several were microscopic. Despite their microscopic size and demonstrating the extreme sensitivity of the molecular assay, all seven patients had significant cancer-associated gene mutations detected in their lavage fluid. Unexpectedly, nearly half of the study population without histopathologic evidence of cancer also possessed high levels of lavage fluid cancer driver-gene mutations. One returned 10 months later with stage IA cancer. Mutations in these women were age and menopausal status associated.

Conclusion

Given that a uterine lavage can be easily and quickly performed in a physician's office-based setting, our findings suggest the future possibility for screening women for the earliest stages of endometrial cancer. However, our findings further demonstrate the unprecedented opportunity and clinical necessity to gain additional insight into the genetic basis of endometrial cancer development and its possible interruption.

ESGO7-1129

GENETICS OF ENDOMETRIAL CANCER IS GREATER THAN PREVIOUSLY ESTIMATED IN THE OUR LOCAL POPULATION.

A. Benshushan¹, N. Gazit¹, Y. Goldberg², T. Peretz², A. Zik³
¹Hadassah-Hebrew University, Gynecology, Jerusalem, Israel
²Hadassah-Hebrew University, Genetics, Jerusalem, Israel
³Hadassah-Hebrew University, Oncology, Jerusalem, Israel

Aims

To expand the data base on the hereditary component of endometrial cancer (EC) in the local population.

Method

The study population included EC patients that visited the oncogenetic clinic in Hasassah Ein-Kerem hospital. The patients were either tested for 18 common germline mutations associated with Lynch syndrome and breast and ovarian cancer syndrome, or known carriers from previous genetic testing. DNA was extracted from blood samples provided by the patients after signing an informed consent form. The Genomic DNA was then analyzed using High Resolution Melting (HRM) method and the results were validated using Sanger sequencing.

Results

Out of a total of 166 endometrial cancer patients included in the study, 41 patients (25%) were found to be carriers of a pathogenic germline mutation (fivefold the expected); 25 patients (15%) were found to be Lynch carriers. 10 patient (6%) were found to be carrier of a BRCA mutation (7 BRCA1 and 3 BRCA2), and 6 carriers of the APC-K1307 mutation. Only 76% of the lynch carriers met The Bethesda criteria at time of EC diagnosis.

Conclusion

The results of this study suggest that the genetic component of EC is greater than previously estimated in the local population, both in lynch and none lynch carriers. Since the women included in the study are of high risk population, the prevalence of pathogenic mutation carriers in the general population cannot be estimated. More women with EC should be referred for genetic counselling in order to conduct further research.
HIGH GRADE SEROUS OVARIAN CARCINOMAS ORIGINATE IN THE FALLOPIAN TUBE

1Hopitaux Universitaires de Geneve, Department of Oncology, Geneva, Switzerland 2Dana-Farber Cancer Institute and Harvard Medical School, Department of Medical Oncology, Boston, USA 3Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Baltimore, USA 4Institute for Computational Medicine- Johns Hopkins University, Department of Biomedical Engineering, Baltimore, USA 5Johns Hopkins University School of Medicine, Sidney Kimmel Comprehensive Cancer Center, Baltimore, USA 6Personal Genome Diagnostics, Personal Genome Diagnostics, Baltimore, USA 7Brigham and Women’s hospital and Harvard Medical School, Department of Pathology, Boston, USA 8University of Pennsylvania Perelman School of Medicine, Department of Pathology, Philadelphia, USA 9Beth Israel Deaconess Medical Center, Department of Pathology, Boston, USA 10Faculty of Medicine- Geneva University Hospital, Division of Clinical Pathology, Geneva, USA 11Johns Hopkins University School of Medicine, Departments of Gynecology and Obstetrics and Pathology, Baltimore, USA 12Penn Ovarian Cancer Research Center- University of Pennsylvania Perelman School of Medicine, Department of Obstetrics and Gynecology, Philadelphia, USA

Aims

High-grade serous ovarian carcinoma (HGSOC) is the most frequent type of ovarian cancer and has a poor outcome. It has been proposed that fallopian tube cancers may be precursors of HGSOC but evolutionary evidence for this hypothesis has been limited. We aimed to provide insights into the origins of HGSOC.

Method

We performed whole-exome sequence and copy number analyses of laser-capture microdissected fallopian tube lesions (p53 signatures, serous tubal intraepithelial carcinomas (STICs), and fallopian tube carcinomas), ovarian cancers, and metastases from nine patients with HGSOC.

Results

The majority of tumor-specific sequence and structural alterations in ovarian cancers were present in STICs, including those affecting TP53, BRCA1, BRCA2 or PTEN genes. An evolutionary analysis revealed that p53 signatures and STICs were the precursors of ovarian carcinoma which in turn gave rise to metastatic lesions. In one patient we identified a second STIC as a metastasis in the fallopian tube opposite from the affected ovary. These analyses revealed a window of seven years between the development of a STIC and the initiation of ovarian carcinomas, with development of metastases following rapidly thereafter.

Conclusion

Our results provide insights into the etiology of ovarian cancer and have implications for the prevention, early detection and therapeutic intervention of this disease.

OSTEOMIMICISM INDUCED BY CDCA IS INTERFERED BY LITHOCHOLIC ACID IN BREAST CANCER

L. Absil1, F. Journé2, D. Nonclercq1
1UMONS, Department of Histology, Mons, Belgium
2UMONS, Department of Human Anatomy and Experimental Oncology, Mons, Belgium

Aims

We have investigated the involvement of farnesoid X receptor (FXR) in breast cancer cells to determine [1] a possible relationship between its expression and proliferation of cells; and [2] the role of FXR in osteomimetism of breast cancer.

Method

We evaluated [1] by immunofluorescence the FXR, the RUNX2 and some bone proteins (OPN, OC, BSP, OPG) expression; and [2] the cells proliferation by crystal violet staining in MCF-7 and MDA-MB-231 cell lines, after different treatments (chenodeoxycholic acid (CDCA), lithocholic acid, z-guggulsterone, ibandronate).

Results

We observed an activation of cell proliferation in MCF-7 but not in MDA-MB-231 after a CDCA treatment. This stimulating effect is interfered by lithocholic acid in MCF-7. Z-guggulsterone decreased cell proliferation in both cell lines. FXR expression increased after a CDCA treatment and decreased with ibandronate in both cell lines. CDCA induced an increase of RUNX2 and bone proteins expression and this expression is interfered by lithocholic acid (in both cell lines) and by z-guggulsterone in MDA-MB-231 cells.

Conclusion

Z-guggulsterone decreased bone proteins expression in MDA-MB-231 cells but not in MCF-7, caused by the ER implication in these cells. Lithocholic acid is a competitive inhibitor of FXR and indirectly of cells proliferation and bone proteins expression when it is used in combination with CDCA. Altogether, experimental data highly support a relationship between FXR, ER (in MCF-7) and RUNX2 expression, and the propensity of the tumor cells to develop osteomimetism, involving an increase of RUNX2 expression after CDCA treatment and a subsequent promotion of bone-related protein synthesis.

Correlation and Outcome Prediction of Biomarkers in Early, Estrogen Receptor-Positive and HER2-Negative Breast Cancer: Comparison of EndoPredict, uPA/PAI-1 and ki67

S. I. Anders¹, J. Ettl¹, E. Klein¹, A. Noske², M. Kiechle¹

¹Klinikum rechts der Isar Technische Universität München, Department of Gynecology and Obstetrics, Munich, Germany
²Klinikum rechts der Isar, Department for Pathology, Munich, Germany

Aims

Due to the molecular tumor heterogeneity of breast cancer, novel multigene assays have been developed helping to stratify patients according to their individual risk of distant recurrence. Especially for patients at intermediate risk a new dimension of risk estimation and therefore change in decision making has been achieved.

Method

321 patients with estrogen-receptor (ER)-positive and Her2-negative breast cancer at intermediate risk were included in this monocentric prospective study from 2011-2015. Classical clinic-pathological markers, ki-67, uPA/PAI-1 and EndoPredict (EP) were assessed for all patients. Concordance of these predictive markers and patient follow up, including the compliance to advised CTX, RTX and hormone therapy, was analysed.

Results

Overall survival, distant and local recurrence of all patients, as well as therapy compliance was assessed (min 21 months and max 5 year follow up).

Conclusion

Concordance of ki-67, PgR status and other pathology-based surrogates, uPA/PAI-1 and Epcin classification could be assessed. In this prospective comparison of EndoPredict, uPA/PAI-1, ki-67 and progesterone receptor we found, that EP is superior to all other biomarkers with respect to feasibility and decision impact. This leads to substantial avoidance of adjuvant chemotherapy in this patient collective.
ROLE OF PREOPERATIVE MRI IN GUIDING THE SURGICAL TREATMENT DECISION IN PATIENTS WITH INVASIVE BREAST CANCER

D. Atallah1, M. Moubarak2, W. Arab1, N. El Kassis1, G. Chahine3, M. Ghossain4, C. Salem4
1. Beirut, Lebanon
2. Saint Joseph University, Beirut, Lebanon
3. Oncology, Beirut, Lebanon
4. Radiology, Beirut, Lebanon

Aims

To illustrate the importance of preoperative MRI in the surgical treatment decision in patients with invasive breast cancer.

Method

We reviewed retrospectively the preoperative MRI (3 Tesla) of 169 patients operated at Hôtel-Dieu de France for invasive breast cancer. The sequences of 85 patients who underwent a radical treatment (mastectomy) were compared to those of 84 patients who benefited from conservative surgery. We estimated the tumor volume (TV) and breast volume (BV) on enhanced MRI and then we compared the tumor volume to breast volume ratio (TV/BV) in both groups.

Results

When compared to pathologic reports, the MRI seemed to slightly increase the estimation of tumor size. The mean of tumor to breast volume ratio was 9.5 % in the mastectomy group vs. 1.7% in the conservative treatment group (p = 0.000). Using a threshold of 4, a tumor to breast volume ratio less than 4 % seemed to favor the adoption of the conservative option in the surgical treatment decision in patients with invasive breast cancer (p = 0.000). MRI had also helped the assessment of multifocality and multicentricity of tumor which were noted respectively in 57.4 % and 54.4% % of cases treated with mastectomy vs. 15.5 % and 3.6% of cases treated conservatively (p = 0.000).

Conclusion

Our data suggest that preoperative MRI can aid the surgical treatment decision in patients with invasive breast cancer by assessing the tumor to breast volume ratio as well as by providing a full mapping of multifocal and multicentric lesions in the breast tissue.

ESGO7-0460

CLINICAL CHARACTERISTICS OF THE PATIENTS WHO EXPERIENCED EARLY RECURRENCE AFTER CURATIVE SURGERY FOR BREAST CANCER

J. Cha1, S. Kim2
1Yonsei University Wonju College of Medicine, Radiation Oncology, Wonju, Republic of Korea

Aims

To identify the patients with high risk of early recurrence who need to be evaluated during chemotherapy or radiotherapy after curative surgery.

Method

Seven hundred and seventy-four patients who underwent curative surgery and radiotherapy between January 2010 and December 2016 were reviewed retrospectively. Among them, recurrence was detected in two patients (0.3%) during the interval between the surgery and the completion of RT. Their tumor characteristics, treatment details, and follow up information were reviewed.

Results

</tr>
</tbody>
</table>

Suspicious mass was detected on simulation computer tomography (sCT) of patient 1. Total mastectomy was performed and it revealed 7.5cm-sized recurrence. She completed radiotherapy of total dose 54 Gy followed by 6 cycles of Cyclophosphamide/Methotrexate/Fluorouracil. Operation bed seroma was showed on sCT of patient 2 and she complained its growing. Wide excision revealed 3.1cm-sized metaplastic carcinoma. A month later multiple metastases developed in liver and bones.

Conclusion

In patients with risk factors such as negative hormone receptor and nodal metastasis, paying attention to sCT findings might be helpful to detect early recurrence. Considering rarity of the early recurrence, further study engaging large number of patients is required.

ENDOMETRIAL PATHOLOGY IN BREAST CANCER PATIENTS: PRELIMINARY DATA OF A MULTICENTRIC RETROSPECTIVE COHORT ANALYSIS

B. Chiofalo1, I. Mazzon2, E. Vizza3, S. Di Angelo Antonio1, D. Amadore1, G. Vocatura1, M. Grassi2, G. Corrado5, V. Palmara1, G. Cutillo1, S. Horvath2, A. S. Laganà1, L. Patrizi3, S. G. Vitale1, O. Triolo1

1 University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
2 Arbor Vitae Center- Clinica Nuova Villa Claudia, Endoscopic Gynecology, Rome, Italy
3 National Cancer Institute “Regina Elena”, Department of Experimental Clinical Oncology, Rome, Italy
4 University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy
5 Catholic University of the Sacred Heart, Department of Women’s and Children’s Health, Rome, Italy

Aims

Current literature showed that breast cancer patients using tamoxifen have an increased risk of endometrial pathology. To investigate the different incidence of histological alteration of endometrium and their possible correlation with the following adjuvant treatment: tamoxifen (TAM), non-steroidal aromatase inhibitors (AIs) or no treatment (NT).

Method

We reviewed retrospectively 970 breast cancer women who were referred to the Hysteroscopic Service of three Italian Centers (University of Messina, Gynecological Center “Nuova Villa Claudia” of Rome, “Regina Elena” National Cancer Institute of Rome) for vaginal bleeding or ultrasound indications.

Results

Hysteroscopic and histological findings in the TAM, AIs and NT groups, respectively, included: atrophic/physiological endometrium in 48, 52 and 33.3% of cases; endometrial polyp in 40.4, 38 and 49.1% of cases; submucous myoma in 4, 3 and 5.2% of cases; simple hyperplasia in 5, 3 and 7.1% of cases; complex hyperplasia in 0.3% in TAM patients and 0.4% in NT cases, no case in AIs group; dysplasia in 0.3% of TAM patients and 0.4% of NT patients, no case in AIs group; and endometrial cancer in 2, 4 and 4.1% of cases; one case (0.4%) of endometrial metastasis from the breast cancer was registered in the NT group (Table 1).

Conclusion

Our preliminary data analysis suggests that TAM is not likely to be associated with endometrial pathology in breast cancer patients. In conclusion, we suggest a gynecological follow-up for all breast cancer patients, regardless of the adjuvant treatment; in addition, we solicit future studies to confirm the TAM safety profile in breast cancer patients.
USE OF COMPLEMENTARY THERAPIES IN BREAST AND GYNAECOLOGICAL CANCER PATIENTS DURING SYSTEMIC THERAPY

L. Drozdoff¹, E. Klein¹, L. Gantner¹, M. Kiechle¹, D. Paepke¹
¹TU München, Frauenklinik Klinikum Rechts der Isar, München, Germany

Aims

Recent studies state that approximately 10 to 70% of breast and gynaecological cancer patients use complementary medicine (CAM) during systemic therapy. The aim of this study was to verify the number of CAM users at our certified cancer center.

Method

Between February and April 2017 a self-administered questionnaire was given to all breast and gynaecological cancer patients undergoing systemic cancer therapy at the certified cancer center of the Klinikum Rechts der Isar. Completed questionnaires (85%, n=202/238) were analyzed by age, cancer diagnosis, therapy status and CAM treatments.

Results

81% of the responding patients use complementary therapy methods. These include:

- 68% vitamins and minerals
- 38% phytotherapeutics
- 31% mistletoe treatment
- 37% homoeopathics
- 61% medicinal teas
- 2% others

CAM use is correlated with younger age (61 y vs. 66 y) and primary non metastatic cancer diagnosis (94%). No difference in breast cancer patients or patients with gynaecologic malignancy, as well as systemic therapy status could be analyzed.

Conclusion

Our data demonstrates high use of CAM by cancer patients undergoing systemic therapy. It is indispensable to implement counselling and evidence-based complementary treatments into clinical routine of cancer centers. A counselling service for integrative medicine concepts and outpatient program (ZIGG) was therefore implemented in our cancer center in 2005.

HIGHLY INCREASED CONCENTRATION OF ANTIBODIES AGAINST THE RED MEAT DERIVED SILIC ACID, Neu5Gc, IN WOMEN WITH BREAST CANCER UNDER CHEMOTHERAPY

P. Eleftheriou, I. Tantikis, P. Cazila, C. Andreadis, R. Iosifidou, O. Stefa, K. Chrysanthopoulos, G. Karagiannis, E. Constantinidou, C. Petrou, K. Varsamidis

1. Alexander Technological Educational Institute of Thessaloniki, Department of Medical Laboratory Studies, Thessaloniki, Greece
2. Theagenion anti-cancer Institute of Thessaloniki, Greece, Biochemical Laboratory, Thessaloniki, Greece
3. Theagenion anti-cancer Institute of Thessaloniki, Greece, 3rd Department of Oncology - Chemotherapy, Thessaloniki, Greece
4. Theagenion anti-cancer Institute of Thessaloniki, Greece, B Surgical Oncology department, Thessaloniki, Greece
5. Theagenion anti-cancer Institute of Thessaloniki, Greece, Department of Gynecology - Oncology, Thessaloniki, Greece
6. Theagenion anti-cancer Institute of Thessaloniki, Greece, Department of Gynecology-Oncology, Thessaloniki, Greece

Aims

N-glycolyneuraminic acid (Neu5Gc) is a sialic acid synthesized by animals, but not humans and birds. However, it can be incorporated in human cells and trigger immune response. Neu5Gc has been found on the surface of many cancer cells including breast cancer. Development of anti-Neu5Gc antibodies in cancer patients is thought to induce cancer progress by triggering inflammatory reaction. In the present study, anti-Neu5Gc antibodies were measured in 40 samples of healthy women and in 40 patients with breast cancer.

Method

Anti-Neu5Gc antibodies were measured using ELISA method. Different concentrations of human IgG (Sigma) were used to produce a standard curve for the expression of relative antibody concentrations in μg/ml.

Results

The patients with breast cancer exhibited a mean concentration of 89.6 μg/ml (median=57.4μg/ml, max.=378μg/ml), much higher than that healthy individuals (mean 6.6μg/ml, SD 6.7μg/ml, median=4.0μg/ml)(p<0.000). The average and maximum concentration of anti-Neu5Gc antibodies detected in women with breast cancer were much higher than that detected by our team in patients with lung cancer (average 20.6μg/ml–23.6μg/ml, depending on the type) and ovarian cancer (average 30.2μg/ml). Higher concentrations did not correlate with metastasis occurrence.

Conclusion

Highly increased concentrations of anti-Neu5Gc antibodies were found in patients with breast cancer. Future results may elucidate if it could be used as an indicator for the prognosis of the disease.

NO EVIDENCE OF HUMAN PAPILLOMAVIRUS (HPV) INFECTION ON BREAST CANCER IN INDIAN WOMEN

S. Hedau*
National Institute of Cancer Prevention and Research, Molecular Oncology, Noida, India

Aims

Two high-risk HPV types 16 and 18 associated with development of cervical carcinoma and also reported to be present in many other carcinomas. Presence of HPV has been reported in breast carcinoma which is the second most common cancer in India. The two early genes E6 and E7 of HPV type 16 have been shown to immortalize breast epithelial cells in vitro, but the role of HPV infection in breast carcinogenesis is highly controversial. To analyze prevalence of HPV infection in both breast tissues and blood from a large number of women with breast cancer from different regions.

Method

High-risk HPV 16 and 18 DNA was detected by two PCR methods - conventional PCR using consensus primers (MY09/11, or GP5+/GP6+) or HPV16 E6/E7 primers and (ii) highly sensitive Real-Time PCR. A total of 228 biopsies and corresponding 142 blood samples collected from 252 patients from four different regions of India with significant socio-cultural, ethnic and demographic variations were tested.

Results

All biopsies and blood samples of breast cancer patients tested by PCR methods did not show positivity for HPV DNA sequences in conventional PCRs either by MY09/11 or by GP5+/GP6+/HPV16 E6/E7 primers. Further testing of these samples by real time PCR also failed to detect HPV DNA sequences.

Conclusion

Lack of detection of HPV DNA either in the tumor or in the blood DNA of breast cancer patients by both conventional and real time PCR does not support a role of genital HPV in the pathogenesis of breast cancer in Indian women.

BREAST CANCER IN TUNISIAN YOUNG WOMEN

L. Naija1, B. Laamouri1, H. Henchiri1, S. Sakhri1, O. Jaidane1, M. Chemlali1, J. Ben Hassouna1, M. Hechiche1, K. Rahal1
1Salah Azaiez, Surgical Oncology, Tunis, Tunisia

Aims

Breast cancer occurrence in young women accounts for 9-10% in Tunisia. Tumor characteristics may be more aggressive.

The aim of our study was to describe characteristics in young Tunisian patients with breast carcinoma.

Method

This was a retrospective study about 348 young women aged less than 35 years treated for breast cancer at Salah Azaiez Institute from 2000 to 2008.

Results

The mean age was 31 years. A family history of breast cancer was reported in 28 patients (8%) and pregnancy was associated to breast cancer in 25 patients. The mean tumor size was 39mm. Tumor was bilateral in 2.3% cases. Stage T2 was frequent (39.6%) followed by T4 stage (24%). Patients were metastatic at diagnosis in 11.2% cases. Ductal breast carcinoma was the most common histological subtype (90.2%). Axillary lymph node involvement was found in 61.4% of cases and Hormone receptors were positive in 194 patients (61.4%). Surgery was performed in 90.2% of cases. Radiotherapy was delivered in 75% of cases and chemotherapy was administered in 330 patients (94.8%). Hormonotherapy by Tamoxifen was adjuvant in 176 patients and ovarian suppression was performed in 155. Overall survival and disease free survival at 5 years were 71.6% and 53.9%. Prognostic factors were TNM stage, tumour size, SBR grade, lymph node involvement and capsular rupture, surgery, radiotherapy, adjuvant chemotherapy, hormonotherapy and ovarian suppression.

Conclusion

Despite therapeutic advances, the survival rates remain worse in young women. Further investigations are needed to develop awareness campaigns to improve early detection.
Aims

Breast cancer represents a major public health problem in Tunisia. Few recent studies have exhaustively investigated the special features of Tunisian patients. The aim of this study was to identify the epidemiological, clinical, histological and therapeutic characteristics of breast cancer in Tunisia.

Method

It was a retrospective study of 730 patients with breast cancer diagnosed in 2012 and treated in Salah Azaiz Institute.

Results

Our series included 730 patients. Two percent were male. The median age was 50 years. The median clinical tumor size was 35 mm. The median radiological tumor size was 25 mm. Stage T2 was predominantly observed (41.6%). A clinical nodal involvement was present in 69.8% of cases. Metastatic localization was observed in 12.5% of patients. The infiltrating ductal carcinoma was the most common histological type. The median histological size was 25 mm. Hormone receptors were positive in 75.3% of cases. Receptors Her2 were overexpressed in 21% of cases. The most common molecular subtype was the Luminal B. The nodes were positive in 57.4% of cases. Surgery was performed in 89.7% of cases. Radiotherapy was performed in 76.1% of cases. Chemotherapy was administrated to 77.9% of patients. Hormonotherapy was administered to 89.4% of patients. Castration was performed for 61.2% of patients. The Herceptin was administered to 45.3% of cases.

Conclusion

The epidemiological characteristics of breast cancer in Tunisia are mainly the young age and the large tumor size at diagnosis.

SENTINEL LYMPH NODE BIOPSY IN BREAST CANCER AFTER NEOADJUVANT CHEMOTHERAPY

M. Hadidane, M. Slimane, H. Henchiri, S. Sakhri, B. Laamouri, H. Bouzaiene, J. Ben Hassouna, K. Rahal

1Salah Azaïz, Surgical Oncology, Tunis, Tunisia

Aims

Sentinel node biopsy (SNB) is largely recommended in breast cancer. However it is still debatable whether this procedure can accurately predict lymph node status after neoadjuvant chemotherapy (NAC). The aim of this study was to determine the detection rate and the false negative rate of SNB after NAC in advanced breast cancer.

Method

In this transversal monocentric study, 53 patients were enrolled in Salah Azaïz Institute from June 2012 to August 2016. After neoadjuvant chemotherapy for breast cancer, all patients had sentinel node biopsy.

Results

The median age was 48 years. The median clinical tumor size was 44.96 mm. Tumors were cN0 in 34 cases and cN1 in 19 cases. The most common molecular subtype was the luminal B in 23 cases. Lymphoscintigraphy was realized in 32 patients. Detection rate of this method was 83.3%. Patent blue was injected to 47 patients and the detection rate of this method was 95%. The detection rate of the combined method was 96%. The overall SNB detection was 94%. Axillary lymph node dissection was done to all patients. A complete pathologic response was obtained in 13.2% of cases. Immunohistochemical study was performed to the three SNB and was negative. Thus, false negative rate was 16%. Negative predictive value of this technique was 91%.

Conclusion

Detection and false negative rate of SNB were successively 94% and 16%, similarly to results of many prospective studies dealt with SNB in breast cancer after chemotherapy. Because SNB after chemotherapy is still not worldwide approved, more randomised studies are required.
MALE BREAST CANCER IN TUNISIA: EPIDEMIOLOGICAL AND CLINICAL FEATURES & PROGNOSIS FACTORS

O. Kaabia, G. Amine, A. Nawel, H. Feteni, B. Alraa

1CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia
2CHU Farhat Hached, General surgery, Sousse, Tunisia
3CHU Farhat Hached, Anesthesia and resuscitation, Sousse, Tunisia

Aims

This retrospective study has been realized to determine the epidemiological profile and clinico-pathological aspects of male breast cancer in the center of Tunisia and to analyze its therapeutic results and its prognostic factors.

Method

We analyzed all male breast cancers with a pathological proof of malignancy diagnosed in the departments of gynecology and obstetrics and general surgery of Farhat Hached hospital Sousse Tunisia, between 1997 and 2016. Survival was done with the Kaplan-Meier method.

Results

Forty four new cases of male breast cancer have been diagnosed. The average patient age was 54 years (extremes 28 and 92 years). According to the TNM classification, 6.8% were classified T1 and 43.1% T4; 18.2% were M1. Cancer was bilateral in 9%. 13.7% of the tumors were in-situ carcinomas and 86.4% ductal infiltrating carcinomas. Hormonal receptors were expressed in 45.5%. Triple negative cases represented 36.4%. Chemotherapy was indicated in 68.2% of the patients and loco regional radiation was performed in 86.4% of the cases. Hormonotherapy was prescribed in all cases of positive hormonal receptors. Overall survival rate at 5 years after diagnosis was 26% in all cases and about 55% in patients stage T1N0M0. After univariate analysis, the clinical stages T4, M1 and the pathological stage pN+ affected survival.

Conclusion

The male breast cancer in our area remains relatively less frequent than in women but its prognosis remains alarming even with gold standard treatments. To get better prognosis it is important to increase information among the population and general practitionners and to promote early detection.

INfiltrating Mucinous ADENOCARCINOMA of the BREAST: CLINical and PATHOLOGICAL Tumor CHARACTERISTICS & PRogNostic FACTORS

O. Kaabia, F. Hacheni, A. Brahimi, T. Yaacoubi, M. Mokni

1CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia
2CHU Farhat Hached, Anesthesiologia and Resuscitation, Sousse, Tunisia
3CHU Farhat Hached, Pathology, Sousse, Tunisia

Aims

The infiltrating mucinous adenocarcinoma (IMC) is a rare and challenging entity. The aim of our study is to evaluate epidemiologic, clinical and imaging characteristics of pure infiltrating mucinous adenocarcinoma (IMC) and its prognostic factors.

Method

We report a retrospective analysis including 36 female patients with pure IMC treated at the department of gynecology and obstetrics at Farhat Hached Hospital Sousse Tunisia between 2000 and 2016.

Results

The mean age was 53 years. The tumor was classified as T1 in 2 cases, T2 in 18 and T3 in 16 cases. Axillary nodes were staged as N0 in 3 patients, N1 in 12 and N2 in 11. Bone metastases were diagnosed in 2 patients. The sensitivity of mammography and sonography for pure IMC were 66% and 92%, respectively. Breast-conserving surgery was performed in 6. The mean histological tumor size was 42.5 mm. Patients were more likely to have low grade tumors (66%) and positive hormonal receptors (89%). Adjuvant chemotherapy was administered for 31 patients. After a mean follow-up of 70 months, 4 patients developed local recurrence and 5 distant metastases (bone). The overall survival at 5 years was 71% for all patients and 83% for non metastatic ones. On univariate analysis, clinical stage T, neoadjuvant chemotherapy and lymph node involvement were the most significant prognostic factors for overall survival.

Conclusion

Women presenting with breast symptoms should be examined carefully and evaluated with an appropriate diagnostic work-up because some patients with IMC may present radiologically benign-like lesions.
Ki-67 CAN BE USED AS A PREDICTIVE FACTOR FOR THE EFFECTIVENESS OF NEOADJUVANT CHEMOTHERAPY IN BREAST CANCER PATIENTS

N. Kozar¹, N. Čas Šikoshek¹, D. Arko¹, M. Ravnik¹, I. Takač¹
¹University Medical Centre Maribor, Clinic of Gynaecology and Perinatology, Maribor, Slovenia

Aims

Cell proliferation measurement is believed to be an important predictive factor for the success of neoadjuvant chemotherapy (NACT) in breast cancer, but its use is still controversial. The aim of the study was to determine the cut-off value of Ki-67 in breast cancer patients and evaluate its predictive potential.

Method

74 patients with locally advanced breast cancer undergoing NACT were analysed. Response to NACT was measured by pathological complete response (pCR) rate and neoadjuvant response index (NRI). All patients underwent centralized Ki-67 evaluation among other tumor characteristics. Optimal cut-off value of Ki-67 was determined using receiver operating characteristics curve while its predictive potential was confirmed using univariate and multivariate analyses.

Results

Ki-67 cut-off value of 50% was optimal for predicting both pCR rate and NRI. Patients with high Ki-67 (> 50%) achieved NRI 0.49 versus 0.32 in patients with Ki-67 < 50% (p < 0.01). Similar was shown for pCR rate (5.3% in Ki-67 > 50% group vs. 19.4% in Ki-67 < 50% group) yet pCR rate difference did not reach statistical significance (p = 0.06). Independent predictive value of Ki-67 cut-off value was confirmed using multivariate analysis.

Conclusion

Cell proliferation measured by Ki-67 is an important predictor of NACT response. Cut-off value of 50% could be used to identify patients with favorable NACT outcome and higher probability of achieving pCR.

LOW-DOSE METRONOMIC CHEMOTHERAPY WITH CYCLOPHOSHAMIDE AND METHOTREXATE IN METASTATIC BREAST CANCER PATIENTS

S. Krajnak1, M. Battista1, T. Elger1, K. Stewen1, A.S. Heimes1, A. Hasenburg1, M. Schmidt1

1University Medical Center of the Johannes Gutenberg University Mainz, Department of Gynaecology and Obstetrics, Mainz, Germany

Aims

Low-dose metronomic chemotherapy (LDMC) is increasingly used in metastatic breast cancer (MBC). In the current investigation we examined the therapeutic response of LDMC in MBC.

Method

In this retrospective analysis we focus on patients with MBC receiving LDMC with oral cyclophosphamide (CTX) (50mg daily) and methotrexate (MTX) (2.5mg every other day). Patients were treated between 2009 and 2015. Primary endpoint was disease control rate (DCR) ≥ 24 weeks after start of LDMC. DCR included complete remission (CR), partial remission (PR) and stable disease (SD). Secondary endpoints were duration of progression free survival (PFS) and rates of discontinuation due to progression and side effects.

Results

35 patients entered the study. 11 (31%) patients achieved DCR. 1 (3%) patient had CR, 6 (17%) PR and 4 (11%) showed SD, respectively. The patients had received a median of 2 (range: 1-8) lines of chemotherapy. DCR was 7/19 (37%) the first 2 lines. DCR was achieved in 8/24 (33%) hormone-positive patients and 3/11 (27%) hormone-negative patients. The median PFS was 12 (range: 6-86) weeks. 3 (9%) patients dropped out because of adverse events.

Conclusion

The DCR of 31% is in line with the results of previous phase-II-studies. This orally administered LDMC regimen has a favourable therapeutic index for advanced breast cancer patients without need for rapid response.

EXTENDED-FIELD RADIOTHERAPY WITH CONCURRENT CHEMOTHERAPY (EXTENDED-FIELD CCRT) FOR CERVICAL CANCER WITH PARA-AORTIC OR HIGH COMMON ILIAC LYMPH NODE INVOLVEMENT

M. Nishimura¹, M. Irahara¹, A. Abe¹
¹Tokushima University Hospital, Obstetrics and Gynecology, Tokushima, Japan

Aims

Lymph node metastasis in cervical cancer is a potentially important risk factor for recurrence. For cases of suspected para-aortic lymphadenopathy or high common iliac lymph node involvement, extended-field radiotherapy was applied. The present study aimed to retrospectively evaluate the efficacy of extended-field CCRT as primary treatment.

Method

Between January 2010 and December 2014, 26 patients with cervical cancer positive for para-aortic and/or high common iliac lymphadenopathy were treated with extended-field CCRT at our hospital.

Results

The median age was 56 years (range, 30-75), and the median size of the tumors was 55.5 mm (range, 27-106). The distribution of stage was as follows: Ib2, n=2; IIb, n=6; IIIa, n=2; IIIb, n=16, and MA, n=15. The 2- and 5-year OS rates were 86% and 52%, respectively. Eleven patients had a recurrence. Adjuvant therapy was administered to 12 patients (9 in MA), and TC therapy was administered monthly for 3 cycles after extended-field CCRT. Three patients had a recurrence (locoregional failure, n=2; distant recurrence, n=1). The other 14 patients were treated without adjuvant chemotherapy, of whom 8 had a recurrence (locoregional failure, n=4; distant recurrence, n=4). No significant differences were found in PFS or OS between the patients treated with and those treated without adjuvant chemotherapy (p=0.546 and p=0.895, respectively).

Conclusion

Extended-field CCRT appears effective as reported in previous studies. When followed by adjuvant chemotherapy, it decreased the incidence of distant recurrence. However, owing to the small number of cases in this study, the benefits of extended-field CCRT to PFS and OS could not be observed.

12Memorial Sloan Kettering Cancer Center, Gynecologic Medical Oncology Service, New York- NY, USA
13Arizona Oncology US Oncology Network- Gynecologic Oncology at University of Arizona and Creighton University, Gynecologic Oncology, Phoenix- AZ., USA

Aims

Prognostic biomarkers that identify high-risk patients may guide treatment decisions for patients with persistent, recurrent or metastatic cervical cancer (PRmCC). To identify such biomarkers, we evaluated the association between baseline inflammation-related serum protein levels and overall survival (OS) in 45 of the 50 AXAL-treated PRmCC patients participating in the phase 2 GOG/NRG-0265 trial (NCT01266460).

Method

The levels of inflammation-related analytes in PRmCC patients’ sera, collected prior to AXAL treatment, were measured using multiplex immunoassays. Linear regression and Kaplan-Meier analysis with log-rank test were used to evaluate the association of baseline levels of individual serum proteins with OS.

Results

Baseline levels of 4 serum proteins were significantly associated with OS (P < .01) and were significantly lower in patients surviving ≥12 months than in those surviving <12 months (P < .01). Unsupervised hierarchical clustering with complete linkage identified 2 patient clusters, distinguishable by low (cluster 1) or high (cluster 2) baseline levels of the 4 serum proteins. Survival analyses revealed that while the total patient population (n=50) exhibited a 12-month OS rate of 38%, cluster 1 (n=25) exhibited a rate of 56% and cluster 2 (n=20) exhibited a rate of 15%, suggesting that the baseline levels of these 4 serum proteins have prognostic value for OS (HR=0.23; 95% CI: 0.10-0.48; P<.001).

Conclusion

We have identified baseline levels of 4 distinct serum proteins as candidate prognostic biomarkers of clinical outcome in PRmCC patients. Cluster 1 criteria may identify PRmCC patients most likely to benefit from AXAL treatment.
KNOWLEDGE OF THE LEBANESE POPULATION TOWARDS HUMAN PAPILLOMAVIRUS AND ITS IMPLICATION IN CERVICAL CANCER

D. Atallah, M. Moubarak, N. El Kassis, G. Chahine, S. Abboud

1. Obstetrics and Gynecology, Beirut, Lebanon
2. Saint Joseph University, Obstetrics and Gynecology, Beirut, Lebanon
3. Saint Joseph University, Oncology, Beirut, Lebanon
4. Beirut, Lebanon

Aims

To evaluate the knowledge of Lebanese women concerning the Human Papillomavirus (HPV), its implication in cervical cancer as well as the screening methods and vaccination. To measure the pap smear and HPV vaccination uptake and to determine the factors influencing them in the same population.

Method

We have recruited randomly Lebanese women over 18 years old, residing in the greater Beirut area and with no medical history. 444 women were asked to fill out a questionnaire composed of 33 questions evaluating their knowledge about HPV and cervical cancer.

Results

14.4% had not heard of cervical cancer and 64.4% had not heard of HPV. Of those who did, 80.4% thought their information was lacking. Only 54.4% and 64.6% were aware of screening tests and vaccination for HPV respectively and over 50% could not correctly identify true facts about HPV, its diagnostic tests and vaccination. Only 37.6% had had a pap smear at least once in their lifetime whereas 9% did not know what a Pap smear was. Screening was significantly associated with cervical cancer awareness and regular visits to a gynecologist (p<0.001). Only 11.7% of participants aged between 18 to 26 years were vaccinated against HPV. Vaccination uptake was significantly associated with religion (p = 0.021), profession (p = 0.03) and regular visits to a gynecologist (p = 0.022).

Conclusion

Lebanese women are not well informed about HPV and cervical cancer. Screening by Pap smear and HPV vaccination uptakes are nonsatisfactory. Further interventions are required in order to improve these numbers.
SIZE OF THE SENTINEL NODE METASTASIS AND THE RISK OF NON-SENTINEL NODE METASTASIS IN CERVICAL CANCER

G. Baiocchi¹, H. Mantoan², L. Kumagai², L. Badiglian-Filho², C. Faloppa², L. De Brot¹, A.²

¹AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
², Brazil
³, Pathology,, Brazil

Aims

Correlate the size of metastatic sentinel node (SLN) with the risk of non-sentinel node (N-SLN) metastasis in cervical cancer.

Method

The study included 68 patients who met the FIGO staging criteria from IA2 to IB2, treated at AC Camargo Cancer Center from May 2014 to March 2017. The patients underwent SLN mapping using patent blue dye and systematic bilateral pelvic lymphadenectomy.

Results

Median SLN count was 2 (range, 1-8) and median total lymph node (LN) count 24 (range, 6-81). Bilateral pelvic detection was found in 41 (60.3%) cases. We found metastatic LN in 11/56 (19.6%) of patients. Of the 97 hemi-pelvises mapped, SLN was able to predict LN involvement in 96 (98.9%). Two patients had bilateral positive LNS. A total of 12 hemi-pelvises had LN metastasis, and in 11 the SLN was involved, resulting in a sensitivity of 91.7%, NPV of 98.8%. In 3 (6.4%) cases the SLN was positive only after immunohistochemistry – 6 macrometastasis, 2 micrometastasis and 1 ITC. The median positive SLN was 1 (range, 1-3) – 1 patient had 2 positive SLN and another had 3 positive SLN. Of 9 patients with positive SLN, 4 (66.6%) also had positive N-SLN. Of 6 patients with macrometastasis, 2 (33.3%) had positive N-SLN (1 contralateral positive N-SLN) – 1/7 (14.2%) hemipelvises. Of 3 patients with metastasis ≤2mm, 2 (66.6%) had positive N-SLN – 1/4 (25%) hemipelvises.

Conclusion

Macrometastasis (>2mm) of SLN in cervical cancer was not related to a higher risk of N-SLN metastasis compared to SLN metastasis of ≤2mm.
DETECTION OF LYMPH NODE METASTASIS IN CERVICAL CANCER USING THE SENTINEL NODE MAPPING ALGORITHM

G. Baiocchi¹, H. Mantoan², L. Kumagai², L. Badiglian-Filho¹, C. Faloppa², L. De Brot³, A. Camargo¹

¹AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
²Brazil
³Pathology, Brazil

Aims

Evaluate the sensitivity and negative predictive value (NPV) of sentinel node (SLN) procedure in cervical cancer, and test the SLN algorithm proposed by Memorial Sloan Kettering Cancer Center (MSKCC).

Method

The study included 68 patients, stages IA2 to IB2, treated at AC Camargo Cancer Center from May 2014 to March 2017. Following the SLN procedure with blue dye, a radical hysterectomy or trachelectomy that included parametrectomy and systematic bilateral pelvic lymphadenectomy was performed.

Results

Median SLN count was 2 (range, 1-8) and median total lymph node (LN) count 24 (range, 6-81). Fifty-six (82.4%) patients had at least 1 SLN detected. Bilateral pelvic detection was found in 41 (60.3%) cases. We found overall metastatic LN in 14/68 (20.5%) patients and in 11/56 (19.6%) of patients with SLN detected. There were 9 in 11 patients with LN metastasis with a positive SLN (one patient had positive node in hemipelvis where no SLN were found), with an overall sensitivity of 81.8% and NPV of 96.6%. Of the 97 sides mapped, SLN was able to predict LN involvement in 96 (98.9%) hemi-pelvises. A total of 12 hemi-pelvises had LN metastasis, and in 11 the SLN was involved, resulting in a sensitivity of 91.7%, NPV of 98.8%. In 3 (6.4%) cases the SLN was positive only after immunohistochemistry (2 micrometastasis and 1 ITC).

Conclusion

We found that SLN procedure is a safe and accurate technique that increases metastatic nodal detection rates by 6.4% after IHC. We found better performance of the SLN procedure when analyzing per side, however we still had one false negative even applying the MSKCC’s algorithm.

7Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8Centre hospitalier universitaire vaudois, Gynecology Department, Lausanne, Switzerland

Aims

To assess the post-operative morbidity of patients who have undergone a radical trachelectomy for early-stage cervical cancer and the oncologic outcomes.

Method

We retrospectively analyzed the data of two prospective trials on sentinel node biopsy for cervical cancer (SENTICOL I & II) between January 2005 and March 2012 from 8 French oncologic centers.

Results

A total of 61 patients have undergone a radical trachelectomy: 41 patients by laparoscopic-assisted vaginal way, 7 patients by total laparoscopic way, 11 patients by total vaginal way and 2 patients by laparotomy. The median age was 33 years (range = 22-68 years). 88.5 % of patients had a stage IB1 disease. There were 63.9% of epidermoid carcinoma and 34.4 % of adenocarcinoma. Eighteen patients (29.5%) had only a sentinel lymph node biopsy and 43 patients (70.5%) had an additional pelvic lymphadenectomy. The median follow-up was 46 months (range = 0-85 months). There were 12 cases of urinary infections (19.6%), 6 cases of dysuria (9.8%), 3 cases of urinary incontinence (4.9%), and one case of ureteral fistula (1.6%). The genito-femoral nerve was injured in 4 cases (6.5%) and the obturator nerve was injured in 5 cases (8.2%). There were 12 cases of limb lymphedema (19.7%) and 5 cases of pelvic lymphocyst (8.2%). During the follow-up, 3 patients (4.9%) had a local recurrence and two patients died: one from a breast cancer and one from a liver metastasis.

Conclusion

The radical trachelectomy is a safe alternative option for young patient with an early-stage cervical cancer to preserve their fertility.

7 Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8 Service de gynécologie, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Aims

The aim of this study was to assess the post-operative morbidity of patients who have undergone a radical hysterectomy (RH) for early-stage cervical cancer.

Method

We retrospectively analyzed the data of two prospective trials on sentinel node biopsy for cervical cancer (SENTICOL I & II). Patients underwent a radical hysterectomy for early-stage cervical cancer between January 2005 and March 2012 in 23 French oncologic centers.

Results

A total of 412 patients were enrolled and 284 had a radical hysterectomy. Data were complete for 232 patients: 115 by laparoscopic-assisted vaginal way, 80 patients by total laparoscopic way, 9 patients by total vaginal way, 22 patients by laparotomy and 6 patients by robot-assisted way. The median age was 44 years (range = 25-85 years). 89.6% of patients had a stage IB1 disease. 72.4% were epidermoid carcinoma and 24.6% adenocarcinoma. Eighty-one patients (35%) had only a sentinel lymph node biopsy and 151 patients (65%) had an additional pelvic lymphadenectomy. There were 45 cases of urinary infections (19.4%), 17 cases of dysuria (7.3%), 10 cases of urinary incontinence (4.3%), and 6 cases of ureteral or vesical fistula (2.6%). The genito-femoral nerve was injured in 25 cases (10.7%) and the obturator nerve was injured in 22 cases (9.5%). There were 38 cases of limb lymphedema (16.3%) and 14 cases of pelvic lymphocyst (6%).

Conclusion

These complications rates are similar with those found in the current literature. Urinary infections and limb lymphedema are the main complications of RH. The functional outcomes could be improved by applying nerve-sparing techniques.
FUNCTIONAL AND ONCOLOGIC OUTCOMES OF TRACHELECTOMY IN EARLY-STAGE CERVICAL CANCER: VAGINAL VERSUS LAPAROSCOPIC WAYS

V. BALAYA1,2, A.S. BATS1, D. QUERLEU3, E. LEBLANC4, P. MORICE5, H. MARRET6, E. DARAI7, P. MATHEVET8, F. LECURU1

1Hôpital Européen Georges Pompidou, Service de chirurgie cancérologique-gynécologique et du sein, Paris, France
2Faculté de Médecine Paris Descartes, URDIA EA 4465, Paris, France
3Institut Claudius Regaud, Département de Chirurgie, Toulouse, France
4Center Oscar Lambret, Département de Cancérologie Gynécologique, Lille, France
5Institut Gustave Roussy, Département de Chirurgie, Villejuif, France
6Centre Hospitalier Universitaire Bretonneau, Service de Chirurgie Pélvienne Gynécologique et Oncologique, Tours, France
7Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8Centre Hospitalier Universitaire Vaudois, Gynecology department, Lausanne, Switzerland

Aims

To compare the vaginal radical trachelectomy (VRT) and the laparoscopic-assisted vaginal radical trachelectomy (LAVRT) surgical approaches and to provide data on functional outcomes.

Method

We prospectively included patients who were elective to a radical trachelectomy for early-stage cervical cancer between March 2009 and March 2012 from 10 French oncologic centers.

Results

A total of 32 patients were included. Eleven patients had a VRT: 5 with a sentinel lymph node detection only and 6 with an additional pelvic lymphadenectomy. Twenty-one patients had a LAVRT: 13 with sentinel lymph node detection only and 8 with additional pelvic lymphadenectomy. The median age was 35 in the LAVRT group and 34 in the VRT group. The median follow-up was 43 months (range = 0–68 months). There were more urinary infection and dysuria in the VRT group than in LAVRT group respectively, 36.4% and 23.8% and, 9% and 4.8%. The genito-femoral nerve and the obturator nerve were more frequently injured in the VRT group (27.3% and 27.3%) than in the LAVRT group (4.8% and 4.8%). There were more limb lymphedema in the VRT group than in LAVRT group, respectively 54.5% and 23.8% and more lymphocele in the VRT group than in the LAVRT group, respectively 18.2% and 9.5%. There were two recurrences and one death in the LAVRT group and none in the VRT group.

Conclusion

The functional outcomes after a radical trachelectomy seem to be better with a laparoscopic-assisted vaginal approach for the early-stage cervical cancer with an aim of fertility-sparing. Bigger population is needed.

LINA LOOP MONOPOLAR DEVICE FOR CERVICAL AMPUTATION DURING LAPAROSCOPIC RADICAL TRACHELECTOMY

K. Beauchamp¹, E. Craig², V. Bahall², I. Harley², D. Brennan¹
¹Mater Misericordiae University Hospital, Gynaecology, Dublin, Ireland
²Belfast City Hospital, Gynaecology, Belfast, Ireland

Aims

Cervical cancer is the third most common gynaecological malignancy. Irish figures state that 52% of cases are under the age of 45. We present an intraoperative video and case series of 13 patients from two tertiary centres with early stage cervical cancer who underwent laparoscopic radical trachelectomy (LRT) and sentinel pelvic lymph node sampling. LRT involves excision of the cervix, upper 2cm of the vagina, parametrium and paracolpos and is a recognized fertility preserving procedure.

Method

The video demonstrates sentinel node biopsy using ICG, nerve-sparing radical trachelectomy and cervical amputation, performed using the Lina Loop monopolar device at the level of the internal os. The utero-vaginal anastomosis was performed using a V-Loc suture. The Lina Loop allows for an accurate and safe cervical amputation and clear interpretation of pathological margins, which is demonstrated in the video.

Results

13 women (9 nulliparous) were included in the case series with ages ranging between 25 to 39 years. All cases were FIGO stage 1B1. There were eight cases of squamous cell carcinoma, four cases of adenocarcinoma and one large cell neuroendocrine tumour. Two patients received neo-adjuvant chemotherapy. Post-operative margins were clear in all cases, two patients required adjuvant treatment. There was one death in the cohort.

Conclusion

The above cases were done using the Lina Loop monopolar device to amputate the cervix. This 5mm single use device provides a more accurate amputation of the cervix than standard monopolar devices, providing excellent haemostasis and clear, even margins for pathological assessment.
MESTASTATIC PARAORTIC LYMPH NODES IN LOCALLY ADVANCED CERVICAL CANCER: DO WE NEED TO BE MORE AGGRESSIVE IN THE TREATMENT?

V. Benito1, A. Lubrano2, S. Carballo3, O. Arenobia1, N. Medina1, M. Andujar2, M. Federico3, M. Moris4, F. Molano5

1Complejo hospitalario universitario insular-materno infantil, Gynecology Oncology, Las Palmas de Gran Canaria, Spain
2Complejo hospitalario universitario insular-materno infantil, Pathology, Las Palmas de Gran Canaria, Spain
3Hospital Universitario Dr. Negrín, Radiation Oncology, Las Palmas de Gran Canaria, Spain
4Hospital Universitario Dr. Negrín, Medical Oncology, Las Palmas de Gran Canaria, Spain
5Complejo hospitalario universitario insular-materno infantil, Medical Oncology, Las Palmas de Gran Canaria, Spain

Aims

To study risk factors in patients with LACC undergoing pretherapeutic laparoscopic paraaortic lymphadenectomy (LPL), as well as the progression-free and overall survival rates specifically in the subgroup of patients with metastatic paraaortic lymph nodes (PLN).

Method

Prospective study, conducted between 2009-2015, based on the review of data on demography, pathology, surgery, complications and disease-status of patients with LACC undergoing pretherapeutic LPL. All patients were treated with chemoradiotherapy and those with metastatic PLN received extended lumbo-aortic radiation therapy. Survival analysis was performed with the Kaplan-Meier method. Statistical significance was considered for p-values<0.05.

Results

The study included 139 patients. Their mean age was 49.2 years (SD10). The most frequent histologic type was SCC (77%) and the most frequent FIGO stage was IIB (48.2%). Metastatic PLN were identified in 18.7% of patients (26). The OS-rate after 28 months follow-up was 68.2 months (OR2.7; CI95%, 63-73.5). For N- patients, the mean survival time was 76.9 months (OR1.8; CI95%, 73.4-80.4) while for N+ patients; the mean survival time was 24.9 months (OR4.6; CI95% 15.9-33.9; p<0.0001). A logistic regression analysis revealed that the presence of metastatic PLN and tumor size were both independent risk factors for poor OS [(OR117.5; CI95% 11.6-990.2; p<0.0001) and (OR 21.5; CI95% 2-230.3; p=0.01)].

Conclusion

Women with LACC with metastatic PLN had a poor prognosis and low survival rate. We postulate that this finding could be accounted for by the presence of hidden systemic disease and high-recurrence rate following therapy. Efforts should be made to improve the available therapeutic schedules for this particular subgroup of patients.
MicroRNA PROFILING OF HUMAN PAPILLOMAVIRUS MEDIATED CERVICAL CANCER IN INDIAN WOMEN

M. Bharadwaj

National Institute of Cancer Prevention & Research, Molecular Genetics, Noida, India

Aims

Though persistent HPV infection is needed for development of cervical cancer but HPV infection alone is not sufficient but together with other genetic factors might be responsible for cervical carcinogenesis. There are two licensed prophylactic vaccines against HPV - 16 and -18; but they are prophylactic in nature. So, there is an urgent need to find novel molecular diagnostic markers and therapeutic targets for the treatment of cervical cancer.

Method

We investigated the role of miRNAs in HPV-mediated cervical pre-cancer and cancer cases in Indian population. We analysed the HPV infection and its genotypes both in cases and controls. Also, microRNA profiling was done in a subset of cervical pre-cancer (n = 20), cancer cases (n = 50) and normal samples (n = 30) by real-time quantitative PCR (qRT-PCR).

Results

The miRNA profiling revealed that in cervical pre-cancer, 100 miRNAs were significantly (p < 0.001) differentially expressed with 70 miRNAs upregulated and 30 miRNAs downregulated. In cervical cancer cases, 383 miRNA were found to be differentially expressed (p < 0.001), of which 350 miRNAs were upregulated and 33 miRNAs were downregulated. We also observed that 182 miRNAs were differentially expressed (p < 0.001) in HPV-16/18-positive (SiHa/HeLa) cell lines compared with HPV-negative (C33A) cell line. In addition, we identified the novel microRNAs such as miR-892b, miR-500, miR-888, miR-505 and miR-711 in cervical precancerous lesions and cervical cancer cases in Indian population.

Conclusion

Ultimately, the study demonstrates a crucial role of microRNAs in cervical cancer, which may serve as potential early diagnostic markers for cervical carcinogenesis.

CLINICAL AND PATHOLOGICAL FACTORS ASSOCIATED WITH RESIDUAL DISEASE IN Hysterectomy AFTER CONIZATION FOR MICROINVASIVE CERVICAL CANCER (STAGE IA1 AND IA2) TREATMENT.

C.A. Hartman¹, L. Andrade LA², J.C. Teixeira³, O. Rangel Neto¹, H.D.C. Machado¹, J. Braganca Bastos¹

¹Campinas State University, Gynecology and Obstetrics, Campinas, Brazil
²Campinas State University, Pathology Department, Campinas, Brazil
³Campinas State University, Statistics Department of ObGyn, Campinas, Brazil

Aims

Evaluate clinical and pathological factors associated with residual disease in hysterectomy after conization for microinvasive cervical cancer (stage IA1 and IA2) treatment.

Method

603 patients diagnosed and treated for squamous cervix microinvasive carcinoma, FIGO stage IA1 and IA2 (MIC), from 1975 to 2013 were included.

Results

CKC was performed in 333 patients (55.2%) and 270 (44.8%) LEEP. The analysis of surgical resection margins showed 489 (81.1%) free ectocervical margins and 331 (54.8%) endocervical margins. Cervical conization was definitive treatment in 170 (28.2%) patients, but in 433 (71.8%) women, a further hysterectomy was performed. Of these, 387 women with stage IA1 were treated with extra fascial hysterectomy and 46 women with stage IA2 disease or with LVSII were treated with radical hysterectomy with pelvic lymphadenectomy. Residual disease (CIN3 or MIC) was found in 179 (41.3%) hysterectomies specimens. Only one case of positive lymph nodes was detected, 32 women (5.3%) recurred during the follow up and two patients died due to the disease.

Multivariate analysis showed that conization margins involvement (OR=6.80, p<0.001) were significantly associated with residual disease. Absence of residual disease in hysterectomy specimens was associated with conization depth >19mm in woman >40yr (p=0.001) and >19.2 for all women (p<0.001) There was no significant difference in the presence of residual disease in hysterectomies, in women treated with both types of conization (p=0.204).

Conclusion

In Women, which fertility desire is a concern, the conservative treatment is a possible option. However, conization margins involvement and conization depth <19mm should be strongly avoided in exclusive conization treatment.

ESGO7-0091

PRETREATMENT NEUTROPHIL:LYMPHOCYTE RATIO IN PREDICTING THERAPEUTIC RESPONSE IN CERVICAL CARCINOMA TREATED WITH CONCURRENT CHEMORADIATION

D M Brazal

1 Jose R. Reyes Memorial Medical Center, Obstetrics and Gynecology- Section of Gynecologic Oncology, Manila, Philippines

Aims

Cancers have been linked with systemic inflammation. Neutrophil-to-lymphocyte ratio (NLR) has been investigated as prognostic markers for different cancers. The aim is to investigate the role of the pretreatment NLR and other factors in predicting response to treatment in cervical cancer patients treated with chemoradiation.

Method

This was a retrospective study with cervical cancer patients treated with chemoradiation at a single institution from January 2012 to December 2014. Primary end point was tumor response to treatment. Logistic regression analysis was used to identify prognostic factors to NLR and treatment response.

Results

A total of 150 subjects were included. The median NLR was 2.43, and patients were divided into high NLR and low NLR. Patients with low NLR had 100% complete response. Among patients with high NLR, 56% had complete response and 44% had incomplete response (p<0.01). Regression analysis showed that stage, tumor size and NLR are significant prognostic factors (p<0.01) with treatment response. The odds ratio for a complete response is decreased by a factor of 0.121 in high NLR, by 0.208 for >4cm tumors, and by 0.050 for stage III disease.

Conclusion

Pretreatment NLR may be used as parameter to predict therapeutic response to chemoradiation in cervical cancer. A low NLR is associated with good treatment response, and patients with advanced stage, larger tumor size and high NLR have lower chances of complete response to treatment.
COMPARISON OF INDOCYANINE GREEN VS RADIOCOLLOID AND/OR BLUE DYE FOR SENTINEL NODE MAPPING IN STAGE IB1 >2 CM–IIB CERVICAL CANCER: A RETROSPECTIVE EUROPEAN EXPERIENCE.

A. Buda1, C. Crivellaro2, G. Di Martino1, B. Bussi2, A. Papadia2, I. Zapardiel4, E. Vizza5, L. Locatelli6, M.L. Gasparri6, B. Diaz de la Noval4
1AO San Gerardo di Monza, Department of Obstetrics and Gynecology- University Milano-Bicocca, Monza, Italy
2University of Milano-Bicocca- Tecnomed Foundation, Nuclear Medicine, Monza, Italy
3Gynecologic Oncology Department, Department of Obstetrics and Gynecology- University of Bern, Bern, Switzerland
4Gynaecologic Oncology Unit, La Paz University Hospital- IdiPAZ, Madrid, Spain
5Gynecologic Oncologic Unit “Regina Elena” National Cancer Institute, Department of Oncological Surgery-, Rome, Italy

Aims

Compare the detection rate and bilateral mapping of sentinel lymph node (SLN) in women with cervical cancer (CC) with tumor > IB1 (>2cm) by using Indocyanine Green (ICG) versus Tc99m ± blue-dye (BD).

Method

Between 2008 and 2016, 95 women with stage IB1 (>2cm), or IB2, IIA and IIB cervical cancer at final pathology who underwent SLN mapping with Tc99m ± BD (n=47) or ICG (n=48) underwent radical hysterectomy with or without BSO were retrospectively reviewed from 4 European centers. Detection rate and bilateral mapping of ICG were compared with those obtained using the Tc99m radiotracer ± BD. A lymphadenectomy was performed, and false negative rate was assessed.

Results

Overall detection rate of SLN mapping was 91.5 and 100% for Tc99m ± BD and ICG respectively. Bilateral mapping rate for ICG resulted 91.7%, significantly higher with respect to 66% obtained with Tc99m + BD (p=0.025). False negative rate was 11.5% (3 false negative cases in ICG group only). Nine out the 23 SLN-positive patients (39,1%), were exclusively diagnosed as a result of ultrastaging, that allowed to identify micrometastasis or ITC only.

Conclusion

In advanced CC (stage IB1>2cm-IIB) the real-time fluorescence SLN mapping with ICG achieved higher detection rate and higher bilateral migration rate when compared to Tc99m radiotracer ± BD. SLN and ultrastaging could provide additional information on nodal staging also in advanced CC. In this setting, ICG is a promising tool for mapping, as it seems less affected by the higher stage of disease respect to the traditional methods.

MULTIPLE ALLELE SEQUENCE IN MICA INFLUENCE SUSCEPTIBILITY TO CERVICAL CANCER IN A KOREAN POPULATION

S.W. Byun1, J.S. Park2, T.C. Park3, J.H. Kim1, T.G. Kim2

1Uijeongbu St Mary’s hospital - Catholic University Medical College, obstetrics and gynecology, Uijeongbu-si- Gyeonggi-do, Republic of Korea
2Seoul St Mary’s hospital - Catholic University Medical College, obstetrics and gynecology, Seoul, Republic of Korea

Aims

We aimed to identify that variants of MICA(MHC class I chain-related gene A) can influence susceptibility to cervical cancer in a Korean population

Method

A case-control study was conducted on 124 cervical cancer patients and 200 controls in Korean women. The MICA 129 genotypes, MICA 129 alleles, STR allele, and sequencing alleles frequencies of the MICA gene were compared by PCR-SBT (polymerase chain reaction-sequence base typing) method.

Results

We identified protective effects of MICA-A5 (OR = 0.4, P= 2.4 x 10^-5) And MICA*027 (OR = 0.3, P=0.2 X 10^-2 ), MICA*008:01 increased the susceptibility to cervical cancer (OR = 1.6, P = 0.043) with the same association shown with MICA-A5.1 but, no association was observed between MICA-129 allele, genotypes and risk of cervical cancer.

In subgroup analysis, MICA * 008: 01 (OR = 2.6 corrected P = 0.045) and MICA * 027 (OR = 0.2, corrected P = 0.005) allele frequency were different in HPV 16 or 18 confirmed cervical cancer patients compared to HPV non-16,18 confirmed cervical cancer patients, the susceptibility was increased and corrected P value was validated.

In MICA * 002.01, there was a difference between the two groups at Stage IIA and below. And in stage IIA and above, Odd ratio was significantly increased in MICA * 002.01.

Conclusion

Our results revealed the susceptible and protective effect of MICA*008:01, MICA*027 in the pathogenesis of HPV 16 or 18 infected cervical cancer in Korean population

ESGO7-0586

POSTOPERATIVE COMPLICATIONS AND SURVIVAL AFTER PELVIC EXENTERATION: OUR EXPERIENCE ON 50 PATIENTS

M.E. Capilna¹, B. Moldovan², B. Szabo¹, S.C. Rusu¹, J. Becsi¹, N. Ioanid³

¹University of Medicine and Pharmacy, First Obstetrics and Gynecology Clinic, Targu Mures, Romania
²“Sf. Constantin” Hospital, Department of General Surgery, Brasov, Romania
³Regional Institute of Oncology, Second Department of General Surgery, Iasi, Romania

Aims

The pelvic exenteration became an ultimate, salvage therapy for patients with advanced or recurrent pelvic cancers. The aim of the study was to analyse our results regarding postoperative complications and survival after pelvic exenterations performed in a tertiary referral center.

Method

Between 2011 and January 2017, 50 patients underwent a pelvic exenteration. The indications were advanced or recurrent cervical (35 patients), vaginal (4), advanced or recurrent ovarian (7), advanced endometrial (2), recurrent vulva (1) or advanced bladder cancer (1).

Results

Out of the 50 exenterations, 25 were total, 17 anterior and 8 posterior. In respect to levator ani muscle, a supralevatorian exenteration was performed in 32 cases, an infralevatorian in 9 and an infralevatorian with vulvectomy in 9. A Bricker non-continent ileal or sigmoid urinary conduit was performed in 41 out of 42 anterior and total exenterations, and a continent orthotopic Budapest pouch in one. Four patients (8%) developed grade V Dindo-Clavien complications (perioperative deaths), 3 patients grade IVa (6%), and 12 (24%) grade IIIb. Among the 50 patients, at this moment, 28 are alive; 20 are dead because of the disease, one is dead of non-oncologic cause and one is lost to follow-up.

Conclusion

Pelvic exenteration for recurrent or advanced pelvic malignancies can be associated with long-term survival and even cure without high perioperative mortality in properly selected patients. However, postoperative complications are common and can be lethal.
ROBOTIC VERSUS LAPAROSCOPIC RADICAL HYSTERECTOMY FOR EARLY CERVICAL CANCER: A CASE MATCHED CONTROL STUDY

V. Gallotta1, C. Conte1, A. Federico1, K. Gaballa2, L. Pedone Anchora1, V. Chiantera3, G. Vizzielli4, B. Costantini1, F. Cosentino4, S. Gueli Allelti1, A. Fagotti1, G. Scambia1, M.G. Ferrandina1
1Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome, Italy
2Oncology Center Mansoura University, Surgical Oncology, Mansoura, Egypt
3Università di Palermo, Gynecologic Oncology, Palermo, Italy
4Fondazione di Ricerca e Cura “Giovanni Paolo II”, Gynecologic Oncology, Campobasso, Italy

Aims

To evaluate the surgical, pathological and oncological outcomes of robotic radical hysterectomy (RRH) versus laparoscopic radical hysterectomy (LRH) in patients with early-stage cervical cancer (ECC).

Method

Between 2010 and 2016, 204 patients underwent RRH (n=70) and LRH (n=134) were retrospectively evaluated and compared.

Results

No statistically significant difference were found between the two approaches with regard to clinical characteristics. Median operative time was longer in RRH (245.5 vs 210 min, p: 0.008) compared to LRH; no difference in terms of EBL, intraoperative complications and rate of conversion to open approach were revealed between the two groups. In all series, 15 patients experienced major postoperative complications, with no difference between the two groups. Pathological characteristics did not differ significantly between the two groups, as well as no significant differences were found in pathological FIGO stage, histology and tumor grade. Pathological results revealed 19 (9.3%) patients with parametrial invasion and 29 (14.2%) patients with lymph nodes metastasis. 96 (47%) patients underwent adjuvant therapy. With a median follow up of 30 months no differences in DFS (p: 0.866) and OS (p: 0.723) were found between the two groups. In all series 22 patients experienced relapse of disease and 5 died of disease.

Conclusion

The present study showed feasibility, safety of minimally invasive approach for ECC with no relevant differences in surgical and clinical outcomes between RRH and LRH.

CERVICAL CANCER PATIENTS BECOME MALNOURISHED DURING TREATMENT WITH CONCOMITANT CHEMO-RADIOThERAPY

M. Sanchez- Lopez1, A.D. Castro-Eguiluz1, R. Jimenez-Lima2, V. Casique-Perez4, U. Velazquez-Morales4, L. Flores1

1Instituto Nacional de Cancerología- Universidad Nacional Autónoma de México- Mexico City- Mexico
Clinical Research, Mexico City, Mexico
2Instituto Nacional de Cancerología- Consejo Nacional de Ciencia y Tecnología- Mexico City- Mexico
Clinical Research, Mexico City, Mexico
3Instituto Nacional de Cancerología- Universidad Autónoma de México- Mexico City- Mexico
Clinical Research, Mexico City, Mexico
4Instituto Nacional de Cancerología- Universidad Autónoma de Tlaxcala, Clinical Research, Mexico City, Mexico

Aims

To evaluate the magnitude of malnutrition in cervical cancer patients that received cisplatin based chemotherapy concomitant with radiotherapy

Method

55 patients with locally advanced cervical cancer were included in this longitudinal, prospective, observational study, at the National Cancer Institute in Mexico. Nutritional evaluation was performed using objective and subjective tools, including anthropometric, biochemical and dietary data, during and after patients received treatment and standardized dietary recommendations. Percentage change and trajectory analysis were calculated, comparing the initial and final evaluations

Results

By the end of treatment, 96.3% patients lost weight (p=0.001); of these, 78.2% had severe weight loss (>5.1% weight loss); 62% patients presented anemia and all of them had lymphopenia. All patients consumed less than 95% energy required; carbohydrate intake increased, while protein and fat intakes decreased during treatment.

At the initial nutritional evaluation, 8 patients were undernourished, during treatment 31 patients, and by the third evaluation 45 patients were undernourished, showing a clinical and statistical significance (p<0.001). The percentage change between the initial and third evaluation was 462%. In other words, the number of undernourished patients increased 4 times in a period of 9 weeks. By the end of treatment only 2 patients (3.6%) presented an adequate nutritional status (p=0.001).

Conclusion

Malnutrition in cervical cancer patients undergoing chemo-radiotherapy, is clinically and statistically significant. Since nutritional status has been proven determinant in the quality of life, response to treatment and survival of patients, it is of utmost importance to take individualized nutritional measures to prevent malnutrition.
CHEMORADIOThERAPY WITH CISPLATIN VS GEMCITABINE IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER WITH COMORBIDITIES. RETROSPECTIVE ANALYSIS OF PATIENTS TREATED AT THE NATIONAL CANCER INSTITUTE

L. Cetina-Pérez1, L. Lugo-Alferez2, M. Cuba1, R. Jimenez-Lima1, A.D. Castro-Eguilez3

1Instituto Nacional de Cancerología- Mexico City- Mexico, Clinical Research- Medical Oncology, Mexico City, Mexico
2Instituto Nacional de Cancerología- Universidad Autónoma de Mexico- Mexico City- Mexico, Clinical Research, Mexico City, Mexico
3Instituto Nacional de Cancerología- Consejo Nacional de Ciencia y Tecnología- Mexico City- Mexico, Clinical Research, Mexico City, Mexico

Aims

Cervical cancer is third most frequent cancer in worldwide. In Mexico it represents 49% of new cancer cases in women. Standard treatment consists of chemoradiotherapy with cisplatin, which could cause impair renal function, neuropathy and ototoxicity. Currently, two emerging problems are being presented: the increase in the geriatric population and the chronic noncommunicable diseases. These variables impose an increased risk of adverse effects in patients with cervical cancer and comorbidities, which may limit them to receive standard treatment.

Objective: To Evaluate the activity and Toxicity of cisplatin vs gemcitabine chemoradiotherapy in locally advanced cervical cancer

Method

A retrospective review was conducted of 212 patients with cervical cancer diagnosis (stage FIGO IB2-IVA) and fragility data (Diabetes Mellitus type 2, systemic arterial hypertension or geriatric patients) treated with cisplatin vs gemcitabine chemoradiotherapy.

Results

Significantly more acute hematologic and gastrointestinal toxicity was present in cisplatin group. Changes in creatinine clearance, pretreatment, posttreatment, and one year after treatment were analyzed; creatinine clearance declined at one year in cisplatin group (p= 0.0001). No difference was found in terms of response rates, overall survival (OS) and disease-free survival (SLE) between the two groups. The 5-year OS was 77.2% for gemcitabine group and 86.4% for cisplatin group (p= 0.15). The 5-year SLE for the gemcitabine group was 76.8% vs 84% for the cisplatin group (p= 0.827).

Conclusion

Response and survival rates of gemcitabine group were similar to those of cisplatin, but in cisplatin group, renal function was significantly deteriorated at one year after the end of treatment, compared with gemcitabine.
SAFETY AND EFFICACY OF A QUADRIVALENT HPV (qHPV) VACCINE IN CHINESE WOMEN: RESULTS OF BASE STUDY WITH 30-MONTH FOLLOW-UP

W. Chen¹, Y. Zhao², X. Xie³, J. Liu⁴, X. Liao⁵, Q. Shou⁶, M. Zheng⁷, A.J. Saah⁸, L. Wei⁹, Y. Qiao⁹

⁸Peking University People’s Hospital, Department of Obstetrics and Gynecology-, Beijing, China
⁹National Cancer Center/Cancer Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Epidemiology, Beijing, China

Aims

To assess safety and efficacy of a quadrivalent HPV (types 6, 11, 16, 18) L1 virus-like particle vaccine (qHPV vaccine, Gardasil®) in women of mainland China.

Method

A randomized, double-blind, placebo-controlled, multicenter trial was conducted among 3006 women subjects aged 20-45 years who were randomized (1:1) to receive 3 doses of vaccine/placebo at Day 1, Month 2 and 6, and followed up for 30 months (base study). The co-primary efficacy endpoints of base study were combined incidence of HPV 6/11/16/18-related 6-month persistent infection (PI) and genital disease endpoints in two age groups (20-45 and 20-26 years). Efficacy against 6-month and 12-month PI was also analyzed. Safety measurements included adverse events (AEs) within 15 days after each vaccination, deaths, vaccination-related serious AEs (SAEs), and pregnancy outcomes. (ClinicalTrials.gov registry: NCT00834106)

Results

The co-primary efficacies were 76.8% (95.6% CI: 44.8, 91.7) in women aged 20-45 years (N=3006) and 82.3% (95% CI: 38.3, 96.7) in women aged 20-26 years (N=1840). The base study met the co-primary efficacy objectives. The efficacies against HPV6/11/16/18 6- and 12-month PI were 75.9% (95% CI: 43.5, 91.1) and 94.3% (95% CI: 63.8, 99.9), respectively. Injection-site AEs were more frequent in the vaccine group (37.6% vs. 27.8%, p<0.001), while similar incidences of systemic AEs were observed (50.4% vs. 48.7%). One SAE was reported from each group. No safety issues were identified regarding the pregnancy outcomes.

Conclusion

The qHPV vaccine is generally well-tolerated and highly efficacious against HPV6/11/16/18-related PI and genital disease among Chinese women aged 20-45 and 20-26 years.

WHO’S TALKING ABOUT GYNAECOLOGICAL ONCOLOGY ON TWITTER

M. Cheung1, R. McVey1, D. Brennan1, W. Boyd1, T. Walsh2, R. Arnett3, E. Clarke3

1Mater Misericordiae University Hospital, Gynaecology, Dublin, Ireland
2Royal College of Surgeons, Quality Enhancement Office, Dublin, Ireland
3Royal College of Surgeons, Foundation Year Medicine and Physiotherapy, Dublin, Ireland

Aims

Patients and physicians live in an information era dominated by the Internet and social media. Patients have unparalleled access to medical information from all sources. Much of present-day patient education occurs online through social media platforms like Twitter.

The aim of this study was to gain a better understanding of what online conversations about gynaecological cancers are taking place and what sources most commonly provide information to the general public.

Method

Over an 80 day period, individual tweets containing hashtags relating to women’s cancer were collected via the Twitter API. Data collection was limited to 14 terms relating to women’s cancers, sourced from the CDC web site.

Results

Of the 200 most linked websites on Twitter, 14% were social media (e.g. www.youtube.com), 13% were general news (e.g. www.telegraph.co.uk), 12% were medical/science news (e.g. www.medicalnewstoday.com), 12% were charity/advocacy websites (e.g. www.jostrust.org.uk), 11% were commercial websites (e.g. www.amazon.co.uk) and 8% were academic journals (e.g. oncology.jamanetwork.com).

Conclusion

The dissemination of good quality information by Healthcare professionals to patients has always presented challenges. Social media presents further challenges, as any users may broadcast or promote content without regulation. Also, social media organizations need to generate revenue and depend on advertising and other commercial entities. Our results demonstrate that only 20% of Twitter conversations that specifically tag gynaecological cancers contain links to web sites associated with credible medical or scientific professional sources. Analysis and deeper understanding of social media content allows healthcare professionals to enter this global social conversation and to leverage it for the benefit of patients.

⁶First Faculty of Medicine- Charles University in Prague and General University Hospital in Prague, Department of Surgery, Prague, Czech Republic
⁷Bata Hospital in Zlin, Department of Gynaecology and Obstetrics, Zlin, Czech Republic

Aims

Pelvic exenteration (PE) offers a chance of 40–60% for long-term survival to selected patients with recurrent pelvic malignancies and no other curative alternative. Traditionally, the involvement of large vessels, nerves, and pelvic bones are considered contraindications. The aim of the paper is to present the outcome of the procedures performed with curative intent that go beyond the traditional limits of PE.

Method

Extended pelvic resections (EPR) were defined as procedures that included the resection of large pelvic nerves, external and common iliac vessels, and pelvic bones.

Results

EPR were performed in 20 patients with the recurrence of gynecological malignant tumours between 2011–2017. The spectrum of procedures comprised nerve resections in 18, bone resection in 5, and large vessel resection in 6 patients. No patient died of complications, but postoperative complications occurred in 12 patients, 9 of which required re-operation. Bone resection was not associated with any specific morbidity. Two cases of vascular resection required femoro-femoral artery bypass. Resection of large nerves caused functional loss and loss of sensation corresponding to individual nerve injury. Within the median follow-up of 18 months, 6 patients died of disease progression, 1 died of another cause, 2 are alive with disease, and 11 are without evidence of disease.

Conclusion

EPR is associated with specific short- and long-term morbidity; it is, however, feasible. The involvement of large vessels, nerves and bones do not represent an absolute contraindication for surgery in selected cases with pelvic recurrence.
A NEED FOR ADJUVANT RADIOTHERAPY IN HIGH-RISK STAGE IB LYMPH-NODE-NEGATIVE PATIENTS WITH CERVICAL CANCER AFTER PROPER SURGICAL TREATMENT? THE SEDLIS CRITERIA REVISITED AFTER 30 YEARS.

D. Cibula¹, L. Dostalek¹, M. Zikan¹, M. Fischerova¹, R. Kocian¹, A. Germanova¹, F. Fruhauf¹, L. Dusek², J. Slama¹
¹First Faculty of Medicine- Charles University in Prague and General University Hospital in Prague, Department of Obstetrics and Gynaecology, Prague, Czech Republic
²Faculty of Medicine- Masaryk University, Institute for Biostatistics and Analysis, Brno, Czech Republic

Aims

The role of adjuvant radiotherapy (RT) in LN negative patients with high-risk stage IB cervical cancer is not uniformly accepted. It is advocated based on GOG RCT, which was initiated in 1989. The aim of the current study was to assess the oncological outcome of a similar cohort of patients treated recently by surgery without adjuvant radiotherapy.

Method

Data from patients who were treated by radical surgery in a single institution and who fulfilled the inclusion criteria for original GOG RCT were reviewed. None of the patients received adjuvant treatment.

Results

136 patients were included in the final analysis. Distribution of histological types and tumor size groups did not differ significantly from the GOG trial. The 2-year recurrence rate (RR) reached 7% in our study, while in the GOG trial the figures were 12% and 21% in groups with and without RT. The corresponding figure for 5-year RR was 13% in our study, but 15% and 28% in the GOG trial. The isolated pelvic RR was 4% in our trial, and 14% and 21% in the GOG trial. Only the adenosquamous histological type and the presence of micrometastases in LN were significant prognostic factors in univariate analysis in our study.

Conclusion

Excellent oncological outcome, especially pelvic control, was achieved by tailored radical surgery in high-risk IB cervical cancer patients without adjuvant RT. The substantially better outcome than in the GOG trial can be attributable to more accurate pre-operative or pathologic LN staging, improvement in surgical standards, or both.

EFFECT OF TRACHELECTOMY ON QUALITY OF LIFE, AND ONCOLOGICAL OUTCOMES IN PATIENTS WITH EARLY STAGE CERVICAL CANCER

N.U. Dogan¹, G. di Favero², T. Pfiffer³, X. Le², C. Köhler²
¹Akdeniz University School of Medicine, Ob&Gyn, Antalya, Turkey
²Asklepios Klinikum Altona, Gynecologic Oncology, Hamburg, Germany
³Asklepios Klinikum Harburg, Gynecology, Hamburg, Germany

Aims

to follow up patients undergoing laparoscopic assisted vaginal trachelectomy by objective questionnaires in order to evaluate changes in bladder, bowel and sexual functions and compare these with patients undergoing vaginal assisted laparoscopic radical hysterectomy (RH).

Method

51 patients were included prospectively. Control group consisted of patients undergoing RH. German pelvic symptom questionare was used preoperatively and re-evaluated 6 months after surgery.

Results

Mean age of patients was 38.6 years. 26 patients underwent trachelectomy, 25 patients underwent RH. In preoperative testing median scores of all four items were comparable between patients with trachelectomy and RH. In six month control all four items and pelvic scores were comparable in two groups. When difference between changes in scores preoperatively and six months postoperatively were evaluated, all scores were also comparable but there is a tendency for higher scores in bladder function of patients undergoing RH. Regarding urinary morbidity 4 out of 26 patients (15%) undergoing trachelectomy experienced urinary problems while 40% of patients undergoing RH had urinary problems in 6 month control. Urinary morbidity in early postoperative period was more prevalent in patients with RH. However, urinary morbidity was not pronounced as higher scores in questionnaires in 6 months control. Regarding the oncological outcomes, two patients experienced early relapses.

Conclusion

Radical trachelectomy is a reasonable option for fertility preservation in young patients. Urinary morbidity is acceptable. Urinary, sexual, pelvic prolapse and bowel symptoms are not augmented after 6 months which all are important aspect long term effects of radical oncologic surgeries.

PROMISING SURVIVAL RESULTS FOR DOSE-INTENSE NEOADJUVANT WEEKLY CHEMOTHERAPY, CONCURRENT CHEMORADIATION, HDR BRACHYTHERAPY AND PELVIC SIDE WALL BOOSTS IN PATIENTS WITH CERVICAL CANCER

L. Eastlake¹, R. Moyoed², S. Dubey³, G. Hughes³, A. Talaat¹, D. Yiannakis¹, ²

¹Plymouth Hospitals NHS Trust, Oncology, Plymouth, United Kingdom
²University of Plymouth, School of Computing - Electronics and Mathematics, Plymouth, United Kingdom
³Plymouth Hospitals NHS Trust, Gynaecology, Plymouth, United Kingdom
⁴Lancashire Teaching Hospital NHS Trust, Oncology, Preston, United Kingdom

Aims

To audit our survival results for cervical cancer patients treated with radical radiotherapy.

Method

Retrospective review of 32 patients from Derriford Hospital (Plymouth, UK) treated March 2012-April 2015. Median follow-up 29.6 months (data locked November 2016).

Patients received pelvic external beam radiotherapy[EBRT] with concurrent chemotherapy, HDR brachytherapy and pelvic side wall boosts[PSWB]. Stage IIIB+ disease offered neoadjuvant dose-intense weekly chemotherapy.

Results

Median age: 54 years (range25-83). Histology: 18 squamous, 8 adenocarcinoma and 6 adenosquamous. TNM staging: IB=1, IIB=17, IIIB=10 and IVB=4 patients. PET staging in 31 patients; median SUV of 12 (range0-59). Median EBRT dose to pelvis 50.4Gy/28 fractions[#]; 2 patients received 45Gy/25#. 12/32 received PSWB; median dose of 3.6Gy/2# (range3.34-5Gy/2-3#). Fourteen received neoadjuvant chemotherapy; median of 6 cycles (range2-6). 29/32 received concurrent chemotherapy, median 5 cycles (range3-6). Median duration of EBRT brachytherapy was 45 days (range38-86, IQR44-50); median duration of EBRT/brachytherapy/PSWB was 49 days (range38-86, IQR45-55), 6 patients relapsed; 3 within the radiotherapy field. Median time (months) from diagnosis to relapse was 12.5 (range6-17). Four patients died. 2 year actuarial overall survival [OS] was 92% (95%CI 76-100) and 3 year OS 88% (95%CI 76-100). Actuarial relapse-free survival at 2 years 81% (95%CI 68-96) and at 3 years 76%. 10/32 patients experienced grade 3+ toxicities. Nil exploratory analyses were significant.

Conclusion

Our survival data are promising, giving credence to current hypotheses being explored in clinical trials of definitive chemoradiotherapy in cervical cancer (e.g. minimum 5 cycles of concurrent chemotherapy, total treatment time <50 days, adequate brachytherapy dosage (ICRU 89), and use of neoadjuvant/adjuvant chemotherapy).
INTRAOPERATIVE AND POSTOPERATIVE MORBIDITY IN SENTINEL LYMPH NODE BIOPSY VS PELVIC LYMPHADENECTOMY IN EARLY-STAGE CERVICAL CANCER

S. Escura1, A. Rodríguez-Trujillo1, B. Gil-Ibáñez1, P. Fusté1, M. Del Pino1, J. Pahisa1, M. Munmany1, I. Nicolás1, A. Glickman1, A. Torné1

1Hospital Clinic, ICGON, Barcelona, Spain

Aims

To compare the morbidity associated to lymph node staging in patients with early-stage cervical cancer undergoing sentinel lymph node biopsy (SLNB) vs. bilateral pelvic lymphadenectomy (LDN).

Method

Retrospective cohort study in patients with FIGO IA1-IB1/IIA1 cervical cancer. From February 2001 until May 2011 lymph node staging was performed by SLNB and LDN and between June 2011 and October 2016 by only SLNB, being LDN performed when SLNB was unilaterally or non-detected. When SLNB was intraoperatively positive, para-aortic lymphadenectomy was performed in order to plan the radiation field. Otherwise, radical surgical treatment was performed. Intraoperative and early postoperative complications following Clavien-Dindo classification were assessed.

Results

We recruited 134 patients. Fifty-four patients were included in the SLNB group and 80 in the LDN group. The median age of the whole cohort was 43 years (range 22-76). Ninety patients (67.2%) presented tumors ≤ 2cm. Most of the patients had FIGO stage IB1 (121/134, 90.3%) and squamous cell carcinoma (91/134, 67.9%). No differences regarding type of surgery (trachelectomy vs. histerectomy) and rate of para-aortic lymphadenectomy was observed between both groups.

In the SLNB group we observed 1 (1.8%) intraoperative complication (urinary tract lesion). In the LDN group, we observed 4 (5%) intraoperative complications (2 urinary tract lesion, 1 vascular lesion and 1 intestinal lesion). We observed a lower rate of Clavien-Dindo ≥ II complications in SLNB group compared with LDN group (5.5% vs. 11.2%). All these differences were not statistically significant.

Conclusion

SLNB seems to be associated with less intraoperative and early postoperative morbidity compared with LDN.
A PHASE III STUDY OF ORAL ONDANSETRON VERSUS TRANSDERMAL GRANISETRON FOR WOMEN WITH GYNECOLOGIC CANCERS RECEIVING PELVIC CHEMORADIATION

M. Frumovitz, A. Jhingran, M. Munsell, P. Eifel, A. Klopp, R. Coleman, L. Ramondetta

1University of Texas MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA
2University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA
3University of Texas MD Anderson Cancer Center, Biostatistics, Houston, USA

Aims

Pelvic radiation with cisplatin is highly emetogenic and late onset (days 4-7) nausea and vomiting occurs in > 25% of these women. The objective of this study was to measure response rates to anti-emetic therapies of granisetron administered via a transdermal patch (TG) compared to orally administered ondansetron (OO) in women with cervical, endometrial or vaginal cancer undergoing chemoradiation therapy.

Method

Eligible patients were assigned either granisetron formulated in a transdermal patch replaced every 7 days or 8 mg of ondansetron orally thrice daily starting with cisplatin administration and continued for 72 hours after chemotherapy infusion using outcome adaptive randomization. The primary endpoint was complete response to anti-emetic therapy on days 4-7 of chemoradiation therapy. Data on compliance/ease of administration, amount of nausea and vomiting, and effect of nausea and vomiting on quality of life were collected.

Results

Seventy-five women were randomized. The majority of patients were receiving chemoradiation for cervical cancer (83%) followed by endometrial (14%) and vaginal cancers (3%). TG achieved a success rate of 49.8% (90% CI 37.5-62.1%) and OO achieved a success rate of 39.7% (90% CI 26.6%-53.5%). The posterior probability that TG achieved a higher success rate in controlling late onset nausea and vomiting compared to OO was 82%. There was no difference between the 2 groups in the compliance or in the effect of nausea and vomiting on quality of life.

Conclusion

Transdermal granisetron is better than oral ondansetron in controlling late onset nausea and vomiting from pelvic radiation with weekly cisplatinum in women with gynecologic malignancies.
CERVICAL CANCER STAGING IN THE NORDIC COUNTRIES - SURVEY FROM THE NORDIC SOCIETY OF GYNECOLOGICAL ONCOLOGY (NSGO)

1Aarhus University Hospital, Dept. of Obstetrics and Gynecology, 8200, Denmark
2Haukeland University Hospital, Dept. of Gynecologic Oncology, Bergen, Norway
3Kuopio University Hospital, Dept. of Gynecology, Kuopio, Finland
4Helsinki University Hospital, Dept. of Gynecology and Obstetrics, Helsinki, Finland
5Linköping University Hospital, Dept. of Oncology, Linköping, Sweden
6Landspitali University Hospital, Dept. of Obstetrics and Gynecology, Reykjavik, Iceland
7Copenhagen University Hospital, Dept. of Oncology, Copenhagen, Denmark
8Haukeland University Hospital, Dept. of Radiology, Bergen, Norway
9Odense University Hospital, Dept. of Obstetrics and Gynecology, Odense, Denmark

Aims

In the Nordic countries much resources are spent on pretreatment imaging like ultrasound, MRI, PET-CT or CT, and sentinel node for cervical cancer patients. The NSGO surgical group performed this survey to collect information about the use of these modalities, handling of the information gained, and how the information is integrated into the treatment algorithm.

Method

We conducted a questionnaire-based survey from 1 January to 31 March 2017. The NSGO surgical group elaborated a questionnaire in the fall 2016. In the five Nordic countries, all 22 Gynecological Oncology Centers were invited to participate. (Denmark 5, Finland 5, Iceland 1, Norway 4, and Sweden 7).

Results

The questionnaires were returned by 19 (86%) centers. The median number of cases treated in each center was 32 (15-120). All, except one center that only used PET-CT, used a combination of imaging for treatment planning. Eighteen (94%) centers used MRI and 15 (79%) centers used PET-CT. The clinicians knew the imaging results before FIGO clinical staging in 14 (74%) centers. The result of the imaging had an influence on the clinical staging in more than half of the centers, 11 (58%). Sentinel node was a routine procedure in three (16%) centers and was used in protocol in five (28%) centers.

Conclusion

The majority of the Nordic Gynecological Oncology Centers report a FIGO clinical stage influenced by pretreatment imaging. Therefore, the NSGO surgical group plans to elaborate a proposal for future amendments of the staging guideline and streamlining the reporting of the stage to increase transparency of results.

ESGO7-0039

COST UTILITY ANALYSES DEMONSTRATING SUPPORT FOR INDICATION SPECIFIC PRICING FOR THE TARGETED THERAPY BEVACIZUMAB

J. Geisler1, R. Navarro2, K. Manahan1
1CTCA, Newnan, USA
2University of Florida, Pharmacy, Gainesville, USA

Aims

Medications in the U.S. are approved because of safety and efficacy not price. The object of this study was to see what potential prices would look like if indication specific pricing existed for bevacizumab in cervical and colon cancer using various willingness to pay (WTP) thresholds ($50,000 – 150,000/QALY).

Method

Information from two phase III studies was examined with pharmacoeconomic techniques, specifically Markov analysis and deterministic sensitivity analysis.

Results

The per cycle cost of bevacizumab for both indications is currently $10830 for a standard 100 kg patient ($72.03/10mg, Medicare Average Sales Price (ASP)+6%). If a WTP of $50,000/QALY was used, the cost of bevacizumab should be lowered to $29.15/10mg for cervical cancer and $11.80/10mg for colon cancer. If instead a WTP of $100,000/QALY was the target, the cost would be decreased to $63.38/10mg for cervical cancer and $30.22/10mg for colon cancer. Alternatively, if a WTP $150,000/QALY was chosen, the price would be increased to $97.63/10mg for cervical cancer and still decreased to $48.78/10mg for colon cancer. This would be a 36% increase in cost per dose for a cervical cancer indication and a 32% decrease in cost per dose for an indication of colon cancer.

Conclusion

Indication specific pricing would change prices for bevacizumab when used for cervical cancer and colon cancer depending on the WTP target.

PROGNOSTIC VALUE OF THE CONUT - SCORE IN PATIENTS WITH CERVICAL CANCER

L. Gensthaler, R. Schwameis, C. Grimm, S. Polterauer, A. Reinthaller, S. Aust

1Medical University of Vienna, Gynecology and oncologic Gynecology, vienna, Austria

Aims

The pretreatment Controlling Nutritional Status (CONUT) Score was established as a screening tool for early detection of poor nutritional status. However, it is an independent prognostic marker in oncologic patients, the prognostic value in patients with cervical cancer is still unknown.

Method

The pretreatment CONUT – Score of 429 patients with cervical cancer was calculated. Patients were classified as either as „low risk or „high – risk“ depending on their score. The Patients’ prognosis was calculated by uni- and multivariated analysis.

Results

371 patients (86.3%) had a low risk, 59 (13.7%) patients a high risk CONUT Score. In univariate analysis, patients in the high risk group were associated with a shorter overall survival (p=0.024). Thus, those results couldn’t be verified in the multivariate analysis (HR 1.3 [0.8-2.3], p=0.33). There was a significant association between the CONUT – Score and tumor stage (OR 3.4 [1.8-6.2], p<0.001) and tumor Grading (OR 6.6 [0.9-49.1], p=0.04) There was no significant result regarding the patients’ age or the histological subtype.

Conclusion

The overall survival of patients with cervical cancer and a CONUT – Score > 2 was significantly shorter. A CONUT Score >2 was associated with severe malnutrition. The benefit of nutritional intervention in patients with pretherapeutic malnutrition should be investigated in further studies.

SMALL CELL NEUROENDOCRINE TUMORS OF THE CERVIX (SCNEC). DO TUMOR CHARACTERISTICS AND ORDER OF MULTIMODALITY THERAPY INFLUENCE OUTCOMES IN EARLY STAGE DISEASE?

1Oslo University Hospital- The Norwegian Radium Hospital, Department of Gynecologic Oncology, Oslo, Norway
2Oslo University Hospital- The Norwegian Radium Hospital, Department of Oncology, Oslo, Norway
3Oslo and Akershus University College of Applied Sciences, Department of Public Health, Oslo, Norway
4Oslo University Hospital- The Norwegian Radium Hospital, Department of Pathology, Oslo, Norway

Aims

To report our experience in the management of women with SCNEC. To explore favorable tumor and treatment characteristics related to survival.

Method

All cases with SCNEC treated at our institution from 01/1978-12/2015 were identified. Demographic, pathologic, treatment and survival-data were collected. Appropriate statistical methods were applied.

Results

64 women met inclusion criteria. 22 (34%) presented as early stage (ES) (I-IIA), 41% (9/22) had lymph node metastasis (LNM). 20/22 (91%) ES cases underwent initial radical surgery accompanied by platinum-based neoadjuvant chemotherapy (NACT) in 10/20 (50%), adjuvant chemotherapy (AdCT) in 6 (30%) and adjuvant radiotherapy in 4 (20%). NACT versus surgery as initial therapy did not influence overall survival (OS) (p=0.72). There was no association between ≤3NACT<3 cycles and recurrence free survival (RFS) (p=0.61) or OS (p=0.55). Tumor size ≤ 4cm< did not influence RFS (p=0.31) or OS (p=0.08). Early versus advanced stage (AS) was not associated with RFS (p=0.073), it was however associated with OS (p=0.002). Presence of LNM negatively influenced RFS (p= 0.015) and OS (p=008). With a median follow up of 23.3 months (range 0.4+315.7) 1 patient is currently without evidence of disease. Median time to recurrence was 28.1 months in ES and 13.5 months in AS. The 5-year OS was 49.4% for ES and 18.1% for AS.

Conclusion

SCNEC is an aggressive disease. LNM and AS were negatively associated with survival. NACT versus AdCT did not influence survival. Targeted therapies being investigated for small cell lung cancer should also be tested for patients with SCNEC.

ESGO7-0774

RECURRENT FREE SURVIVAL AFTER SENTINEL LYMPH NODE BIOPSY IN PATIENTS WITH EARLY-STAGE CERVICAL CANCER

B. Gil-Ibáñez1, A. Rodríguez-trullijo1, S. Escura1, P. Fuste1, E. Mension1, M. Del Pino1, J. Pahisa1, M. Munmany1, I. Nicolas1, A. Glickman1, A. Torne1

1Hospital CLINIC, Gynecology Oncology Unit, barcelona, Spain

Aims

To compare recurrence free survival (RFS) in women with early-stage cervical cancer who were primarily treated by radical surgery and pelvic bilateral lymphadenectomy (LDN) versus sentinel lymph node biopsy only (SLNB).

Method

From 02/2001 until 05/2011, patients with FIGO stage IA1-IB1/IIA1 cervical carcinoma underwent SLN biopsy followed by complete pelvic LDN as part of their primary treatment in University Hospital Clinic (Barcelona, Spain). Between 06/2011 and 10/2016, patients underwent radical surgery after SLNB. Patients underwent complete preoperative staging workup and were treated by radical hysterectomy or radical tachelectomy. Patients in whom SLN were detected unilaterally or not detected underwent a complete lymphadenectomy of the failed mapped side. SLN were evaluated by pathologic ultrataging. Intraoperative and postoperative as well as follow up data were prospectively recorded. SPSS 20.0 was used for statistical analysis.

Results

80 patients underwent radical surgery plus LDN and 54 patients underwent surgery with SLNB. No differences regarding age at diagnosis, size of the tumor (≤ 2cm vs > 2cm), FIGO stage, histology type and type of surgery were seen between both groups. Median follow up time was 60.6 months (0.13-190.3). Detection rate of the sentinel node group was 96% and it was bilaterally detected in 47 patients (87%). 121 patients were node negative patients, 73 LDN- and 45 SLNB-. No statistically significant differences were seen in term of RFS between both groups with negative nodes.

Conclusion

Patients with SLNB negative at the time of primary surgery seem to have the same RFS than patients with LDN negative nodes.
CERVICAL CANCER

ESGO7-0330

LAPAROSCOPIC PELVIC EXENTERATION FOR RECURRENT OR COMPLICATED PELVIC TUMORS: ANALYSIS OF TECHNIQUE AND POSTOPERATIVE OUTCOMES
S. Baydo¹, A. Vinnytska², D. Golub³, S. Pryndyuk³, A. Goman¹
¹LISOD – Israeli Oncological Hospital, surgery, Kyiv, Ukraine
²LISOD – Israeli Oncological Hospital, gynecology, Kyiv, Ukraine
³LISOD – Israeli Oncological Hospital, urology, Kyiv, Ukraine

Aims

Pelvic exenteration is an ultra-radical surgical procedure with both palliative and curative intent in management of pelvic tumors. It remains one of the most difficult with high postoperative morbidity (31-90%). We want to represent our experience in performing laparoscopic pelvic exenteration (LPE).

Method

In 2012-2017 we performed 16 LPE (9 total, 4 anterior and 3 posterior). Indications were central pelvic recurrence of cervical (9), colorectal (6) and bladder cancer (1) after combined chemo-radiotherapy and surgery, complicated with different fistulas. Five ports technique was used in all cases. Dissection was performed with harmonic scissors and bipolar. Colorectal reconstruction: terminal colostomy (7) or anastomosis (5). For urinary diversion an ileal-loop conduit (the Bricker technique) was used. Uretero-ileostomy and stenting were performed intracorporally (2) and extracorporally (11).

Results

Average age 44.2(31-66) years. Average operative time 392(295-520) minutes. Estimated blood loss 295(95-500) ml. Mean length of hospital stay 8.9(5-14) days. The number of lymph nodes harvested 16 (5-34). Postoperative complications grade IIIB-IV (Clavien-Dindo, 2004) occurred in 6 patients (37,5%): anastomotic leak (4) with 2 relaparoscopy; small intestine perforation (1) with relaparoscopy and suturing; arterial thrombosis with multiple organ failure and death (1). Grade I-IIIA complications: gastroparesis (3), seroma (2), lymphocyst (2), positional fibular neuritis (1). After 1 year 10 out of 15 patients (66,7%) were alive, after 2 years: 4 out of 12 (33,3%).

Conclusion

Laparoscopic pelvic exenteration is technically feasible and can be offered to carefully selected patients with locally advanced pelvic tumors. Potential postoperative advantages of laparoscopic approach are faster recovery and relatively low morbidity.
CERVICAL CANCER

ESGO7-1277

IMPACT OF PLATELET, LEUCOCYTE AND HEMOGLOBIN VALUES ON THE PROGNOSIS OF LOCALLY ADVANCED CERVICAL CANCER

A. Maulard¹, A. Alwohaibi², M. Faron¹, E. Bentivegna¹, A. Leary², P. Pautier², C. Genestie³, P. Morice¹, C. Chargari⁴, S. Gouy¹

¹Gustave Roussy, Surgery, Villejuif, France
²Gustave Roussy, Oncology, Villejuif, France
³Gustave Roussy, Pathology, Villejuif, France
⁴Gustave Roussy, Radiotherapy, Villejuif, France

Aims

To evaluate the prognosis value of pretreatment leucocyte, platelet and hemoglobin disorders in locally advanced cervical cancer (LACC).

Method

We conducted a prospective study of 240 patients treated from 2007 to 2015 at Gustave Roussy for LACC with negative PET imaging of the PA area and undergoing laparoscopic PA lymphadenectomy. Patients with a poor prognosis histologic subtype or peritoneal carcinomatosis were excluded. All patients were treated by chemo-radiation and brachytherapy. All patients had preoperative blood cell count and clinical follow-up.

Results

Patients had clinical International Federation of Gynecology and Obstetrics stages IB2 (n =79), IIA (n=10), IIB (n=124), III (n=18), or IVA (n=9). One hundred ninety-one patients had squamous carcinoma, 43 had adenocarcinoma/adenosquamous lesions and 6 clear cells carcinoma. Twenty-two patients (9%) had nodal involvement (false-negative PET imaging). median follow-up was : 53 months [48-59]. We identified three cut-off whose impact disease free survival at 36 months: 114 g/L for hemoglobin (81% [75-89] vs 62% [52-74], p < 0.001); 11.7x10⁹/L for leucocyte (48% [32-73] vs 79% [73-85], p < 0.001); 308x10⁹/L for platelet (65% [54-77] vs 79% [73-87], p = 0.005) for patients above and under the cut-off respectively.

Conclusion

Leucocyte, platelet and hemoglobin are significant prognostics factors for relapse in locally advanced cervical cancer. Those biomarkers could help identifying patients with higher risk of relapse and requiring new strategies as neo-adjuvant and adjuvant chemotherapy.

MANAGEMENT OF VERTEBRAL METASTASIS IN PATIENTS WITH UTERINE CERVICAL CANCER

M. Kocaer1, V. Gülseren1, İ.A. Özdemir2, Ö. Güngördük2, E.M. Mart1, M. Sancı4, K. Güngördük2

1Tepeçik Education and Research Hospital, Obstetrics and Gynecology, İzmir, Turkey
2Bakırköy Dr Sadi Konuk Education and Research Hospital, Gynecologic Oncology, İstanbul, Turkey
3Muğla Sıtkı Koçman University- Education and Research Hospital, Obstetrics and Gynecology, Muğla, Turkey
4Tepeçik Education and Research Hospital, Gynecologic Oncology, İzmir, Turkey
5Muğla Sıtkı Koçman University- Education and Research Hospital, Gynecologic Oncology, Muğla, Turkey

Aims

We sought to identify risk factors and management options for uterine cervical cancer (UCC) patients with a vertebral metastasis (VM) treated over the course of 23 years.

Method

Among 844 UCC patients, 18 were diagnosed with a VM. Thirty-six control patients with UCC but without recurrence were matched to these 18 in terms of stage and histological tumor type using a dependent random sampling method. A logistic regression analysis was employed to identify factors prognostic of VM; the results are presented as odds ratios with 95% confidence intervals (CIs).

Results

The mean survival time after VM treatment commenced was 12.1 ± 2.7 months (95% CI=5.3–12.6 months) in patients who received chemotherapy (CT) and 15.0 ± 2.3 (95% CI=9.7–14.2) months in those treated via chemoradiotherapy (CRT) (P=0.566). In patients who underwent CT, the 1- and 2-year survival rates after recurrence were 19.2% and 0%, respectively. However, these figures were 50% and 8.3% in those treated via CRT. Both lymphovascular space invasion (LVSI) and mean corpuscular volume were risk factors for VM. Cox’s regression analysis showed that these prognostic factors had no effect on survival duration after recurrence.

Conclusion

We found that patients with LVSI were at high risk for isolated VM and that the survival times after CT and CRT were similar.
DO PATIENTS AND PHYSICIANS ACCEPT LESS RADICAL PROCEDURES OFFERING LOWER MORBIDITY IF THEY ARE ASSOCIATED WITH HIGHER ONCOLOGICAL RISK?

K. Gungorduk1, R. Kocian2, D. Basaran3, T. Turan4, A. Ozdemir5, D. Cibula2

1Muğla Sıtkı Koçman University Education and Research Hospital, Department of Gynecologic Oncology, Muğla, Turkey
2First Faculty of Medicine Charles University, Gynecologic Oncology Center Department of Obstetrics and Gynecology, Prague, Czech Republic
3Etlik Zübeyde Hanım Education and Research Hospital, Department of Gynecologic Oncology, Ankara, Turkey

Aims

This prospective survey study aimed to evaluate the opinions of women who underwent radical surgery for cervical cancer (CC) and physicians who treat CC about the acceptability of increased oncological risk after less radical procedures in the surgical treatment of CC.

Method

Patients (n=182) and physicians (n=101) were asked whether they would accept any additional oncological risks, which can be attributable to the omission of parametrectomy (radical hysterectomy/trachelectomy vs. simple hysterectomy/trachelectomy) and omission of PLND (systematic resection vs. sentinel lymph node (SLN)) sampling, if these less radical procedures offered diminished postoperative morbidity.

Results

Although more than half of the patients (52.2%) reported morbidity related to the previous treatment, the majority of them would not accept less radical surgical treatment if it was associated with any increased risk of recurrence (50–55 % No risk and 17–24% risk < 0.1%). Physicians tend to accept a significantly higher risk than patients in the Czech Republic but not in Turkey (Table 1). Risk acceptance was not significantly modified by the type of the procedure. Patients with higher education levels, advanced stage disease, adverse events related to previous cancer treatment, and patients that received adjuvant therapy were significantly more likely to accept an increased oncological risk. Physicians’ risk acceptance increased only with age (Table 2).

Table 1. Comparison of risk acceptance between patients and physicians

The answers to the risk acceptance questions are treated as continuous variables.
Conclusion

Patients, even if they suffer from morbidity related to previous treatment of CC, do not want to choose between oncological safety and better QoL. Physicians tend to accept the higher oncological risk associated with less radical surgical procedures, but attitudes differ regionally.

ASSISTED MOLECULAR STAGING GUIDED BY ONE-STEP NUCLEIC ACID AMPLIFICATION (OSNA) IN ADVANCED CERVICAL CANCER: A PROSPECTIVE STUDY

I. jaffré1, G. selmes2, O. kerdraon3, P. jezequel4, J.M. classe1, J.S. FRENEL5

1Institut cancerologie de l’ouest, surgery, nantes, France
2Institut cancerologie de l’ouest, surgery, nantes, France
3Institut cancerologie de l’ouest, pathology, nantes, France
4Institut cancerologie de l’ouest, biology, nantes, France
5Institut cancerologie de l’ouest, oncology, nantes, France

Aims

Radiochemotherapy is the standard treatment for locally advanced cervical cancer. Para-aortic (PA) lymph nodes metastases remain a poor prognostic factor. Recently, a multicentric prospective study has reported the same survival rate for patients with PA nodal metastases ≤ 5 mm treated by an extended radiation field and patients pN0. Detecting occult metastases in PA lymph nodes may have an impact on survival.

We aimed to compare prospectively the accuracy of OSNA with both standard Hematoxylin and Eosin (H&E) analysis and intensive histopathology for the detection of lymph node metastases of cervical cancer.

Method

A total of 127 lymph nodes from 10 patients with stage FIGO ≥ IIb cervical cancer were assessed. Among them, 68 were also assessed by OSNA. Half of each lymph node was analyzed initially by H&E followed by an intensive histologic workup: 5 levels of H&E and immunohistochemistry analyses. The other half was analyzed using OSNA.

The OSNA method is based on the detection of CK19 mRNA as a marker for cervical cancer. The positivity of the CK19 was investigated on the prior cervical biopsy. A cut off value of 250mRNA copies/µL was used.

Results

The concordance rate was 79%. 14 cases were discordant: 12 OSNA-positive/histology negative (11 micrometastasis) and 2 OSNA-negative/histology positive (2 macrometastasis). OSNA was more sensitive for detecting micrometastasis compared with H&E and resulted in an upstaging of 5 of 10 patients.

Conclusion

OSNA appeared to be a promising molecular tool for the detection of lymph nodes metastasis and may lead to an interesting upstaging.
CLINICAL SIGNIFICANCE OF ATYPICAL GLANDULAR CELLS IN CERVICAL PAP SMEARS: AN ANALYSIS OF 329 CASES AT A SINGLE INSTITUTION
T.K. Jang¹, S.W. Lee¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹, J.Y. Park¹
¹Asan Medical center- University of Ulsan College of Medicine- Seoul- Korea, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims
To determine the rate of clinically significant histopathologic lesions by analyzing patients identified as atypical glandular cells (AGC) in Papanicolaou (pap) test

Method
Data were collected from histopathologic results of women identified as AGC in the pap test from 1999 to 2008. There were 503 cases reported as AGC, 329 women with AGC who underwent histopathologic evaluation including colposcopy directed biopsy, loop electrical excision procedure, endocervical curettage and endometrial biopsy were analyzed to correlate with AGC on pap test.

Results
Among 329 women with AGC who underwent histologic follow up, clinically significant histologic results including pre-cancerous lesions and cancer lesions were diagnosed in 58 women with AGC (17.6%). Of the 58 patients, 23 (7%) were diagnosed with pre-cancerous lesions including cervical intraepithelial neoplasia (CIN) 2-3 and endometrial hyperplasia (EH), and 35 (10.6%) were diagnosed with cancer including cervical/endometrial carcinoma. Cervical carcinoma in situ (CIS)/invasive carcinoma and endometrial carcinoma were identified in 5.5%, 2.7%, and 2.1% of cases, respectively

Conclusion
AGC results on pap test indicated clinically significant lesions in approximately 15% of our cases. These results support that women with AGC should require the need for histologic confirmation of the uterine cervix and endometrium including colposcopy directed biopsy, endocervical curettage and endometrial sampling.

MUTATIONAL ANALYSIS OF KRAS AND ITS CLINICAL IMPLICATIONS IN CERVICAL CANCER PATIENTS

W. Jiang¹, L. Xiang¹, X. Pei¹, T. He¹, H. Yang¹
¹Fudan university Shanghai Cancer Center, Gynecologic oncology, Shanghai, China

Aims

The predictive and prognostic role of KRAS mutations in cervical cancer remains inconclusive. The aim of this study was to explore the clinicopathological and prognostic relevance of KRAS mutations in invasive cervical cancers (ICC).

Method

Reverse transcription polymerase chain reaction (PCR) and Sanger sequencing were employed to detect KRAS mutations in 876 ICC patients. Quantitative real-time PCR was used to detect human papillomavirus (HPV) 16 and HPV 18.

Results

Non-synonymous mutations of KRAS were identified in 30 (3.4%) patients. These mutations were more common in non-squamous carcinoma than in squamous cell carcinoma (8.2% vs 2.2%, respectively, p<0.001) and were associated with HPV18 infection (p=0.003). The prevalence of mutations was highest (19.2%) in the uncommon histological subtypes followed by adenocarcinoma (7.3%) and adenosquamous carcinoma (5.8%). During the median follow-up of 55 months, compared to patients with wild-type KRAS, a greater percentage of patients with mutant KRAS relapsed (20.0% vs 42.9%, respectively, p=0.007; Fisher’s exact test). The 3-year relapse-free survival (RFS) was poorer in patients with mutant KRAS than in patients without KRAS mutations (57.1% vs 81.9%, respectively, p=0.001). Furthermore, the multivariate analysis showed that the presence of a KRAS mutation was an independent predictor for disease recurrence (HR=2.064, 95% CI: 1.125–3.787, p=0.019).

Conclusion

KRAS mutations were predominant in non-squamous cell carcinomas of the cervix and were associated with HPV 18 infection. A combination of KRAS mutation detection and HPV genotyping would be useful in identifying patients with poor prognosis for further interventions.

ESGO7-0323

OUTCOME OF WOMEN WITH HIGH-GRADE CERVICAL INTRAEPITHELIAL NEOPLASIA (CIN 2/3) AFTER RECEIVING LOOP ELECTROSURGICAL EXCISION PROCEDURE (LEEP)

U. JU¹, W. KANG¹, S. KIM¹
¹Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Aims

The aims are to present the long-term outcome after loop electrosurgical excision procedure (LEEP) for high-grade cervical intraepithelial neoplasia (CIN2/3) and to identify the rate and risk of treatment failure.

Method

We reviewed retrospectively 1105 cases, confirmed to CIN2/3 after LEEP at our center from 2000 to 2009. Patients were followed with cervical cytology and HPV test. If the results were abnormal, patients received cervical biopsy. The CIN2 or worse was considered as treatment failure.

Results

During a mean follow-up of 94.6 months (range, 60-144), 100 cases (9.0%) had treatment failure; 6.1% in the first 2 years, 1.8% between 2 and 5 years, and 1.1% beyond 5 years. Excision margin involvement and positive result of immediate endocervical cytology after LEEP were significant risk factors for treatment failure (HR=4.280; 95% CI, 2.579-7.105; p<0.001 and 6.696; 2.832-15.833; p<0.001, respectively). Especially, positive endocervical margin had higher risk compared to positive ectocervical margin (5.743; 3.655-9.742; p<0.01 vs. 3.725; 2.627-6.835; p<0.01). Persistent or recurrent infection with HPV-16 (2.417; 1.527-4.484; p<0.01), HPV-18 (3.518; 1.941-6.715; p<0.01) or HPV-58 (1.460; 1.143-2.815; p=0.03) was associated with treatment failure in positive margin group. Persistent or recurrent infection with HPV-16 (3.742; 2.590-6.743; p<0.01), HPV-18 (4.155; 2.610-8.594; p<0.01), or HPV-31 (1.385; 1.092-2.475; p=0.03) was associated in negative margin group.

Conclusion

LEEP is effective, however, treatment failure can appear for a long time. Excision margin involvement and positive endocervical cytology after LEEP are strong predictors for treatment failure. Persistence or recurrence of HPV-16/18 increase the probability of treatment failure regardless of excision margin involvement.
IMIQIMOD AS A VALUABLE OPTION FOR YOUNG WOMEN WITH HIGH GRADE SQUAMOUS EPITHELIAL LESION (HSIL): A RETROSPECTIVE STUDY

D.W. Jung¹, J.H. Kim¹, K. Dae-Yeon¹, S. Dae-Shik¹, K. Jong-Hyeok¹, N. Joo-Hyun¹, K. Young Tak¹, K. Yong Man¹

¹ASAN Medical center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

In young women, it is not easy to decide on excisional therapy for cervical intraepithelial neoplasia (CIN). We aimed to evaluate how effective topical imiquimod is in the treatment of high-grade CIN in young women.

Method

Patients with high-grade CIN were allocated to this study. They required a once-a-week hospital visit for 8 weeks for the application of imiquimod to the cervix by a specialist. If the lesion got worse, we decided to convert to excisional therapy.

Results

A total of 55 patients with a median age of 30 years (range, 22–42 years). Twenty-nine patients (52.7%) had cervical intraepithelial neoplasm 3 (CIN)3, and 24 (43.6%) had CIN2 on initial biopsy. Two patients had high-grade squamous intraepithelial lesion (HSIL) on their PAP without punch biopsy. Fifty-two patients (94.5%) finished the 8-week imiquimod therapy and two patients were treated with additional imiquimod therapy. One patient stopped treatment because of pregnancy. On the last examination, 32 patients (59.2%) had negative intraepithelial lesions, 7 (12.7%) had atypical squamous cells of undetermined significance, and 4 (7%) had LSIL. Three patients (5.6%) had ASC-H. Two of them underwent loop electrosurgical excision procedure (LEEP). The results were CIN3. Eight patients (14.8%) had persistent HSIL: 5 patients underwent LEEP, resulting in CIN 3 except two patients with superficially invasive squamous cell carcinoma.

Conclusion

This study showed that topical imiquimod therapy was effective for the treatment of high-grade CIN, with a regression rate of 79.6%, and HPV eradication rate of 33.3%. To confirm its efficacy, a phase II study with larger cohort would be needed.

RISK FACTORS OF DIAGNOSTIC DISCREPANCY BETWEEN COLPOSOCRALLY DIRECTED BIOPSIES AND LOOP ELECTROSURGICAL PROCEDURE CONIZATION OF THE UTERINE CERVIX

Y. Jung1, S.J. Lee1, Y.S. Lee1, E.K. Park1
1College of Medicine- The Catholic University of Korea, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

This study aimed to determine the factor of pathologic discrepancy between colposcopically directed punch biopsies and LEEP conization.

Method

A total of 1,200 patients with conization were identified in our center between 2004 and 2016, 667 patients of whom underwent all of cervical cytology, HPV test, punch biopsy, and conization were included in retrospective study. We analyzed patient's age, menopausal status, number of delivery, abortion times, visualization of the entire transformation zone, number of punch biopsies and duration of between punch and conization.

Results

Logistic regression analysis of the final diagnosis showed that reproductive age and HPV type were associated with cancer diagnosis, while ASC-H, HSIL and HPV type 16 affected the diagnosis of CIN2. The overall concordance rate of histopathology between the punch biopsy and LEEP conization was 43.3%. The rates of detecting a more severe lesion by LEEP conization than gained by biopsy (biopsy underestimation) were 23.1%. The rates of a less severe lesion detected by LEEP conization than gained by biopsy (biopsy overestimation) were 33.6%. Logistic regression analysis of discrepancy has demonstrated that less than 1 time of vaginal delivery, HSIL, number of punch biopsies and HPV type were factors of biopsy underestimation. Punch biopsies number is a unique factor of biopsy overestimation.

Conclusion

Patients with ASC-H, HSIL and HPV type 16 may undergo conization immediately without punch biopsy by the colposcopic findings. Number of 3 or 5 punch biopsies affected both biopsy underestimation and overestimation. We suggest that colposcopically directed 3-5 punch biopsies may be used to determine conization.
MEDICOBIOLOGICAL PROPERTIES OF PHOTOLON IN A EXPERIMENTAL MODEL

I. Kasenka1, E. Alexandrova1, T. Litvinova2, D. Tserkovsky3, A. Vasileuski4
1NN Alexandrov National Cancer Center, Gynaecological cancer group, Minsk, Belarus
2Belarusian State Medical University, Department of Oncology, Minsk, Belarus
3NN Alexandrov National Cancer Center, Laboratory of Photodynamic Therapy and. Hyperthermia with Chemotherapy Group, Minsk, Belarus
4NN Alexandrov National Cancer Center, Isotopic laboratory with unsealed sources complex, Minsk, Belarus

Aims

Evaluating the dynamics of Photolon sensitizer accumulation in HeLa tumor cells and it's photodynamic activity by the criteria of cytostatic and cytotoxic effects.

Method

The in vitro studies were performed on a monolayer culture of HeLa tumor cells. The cellular culture was grown in the nutritious Medium 199 with addition of 10% blood serum of cow fetuses and canamicin 50 mg/ml. On the third day after the cell culture sowing in the nutritious medium, chlorin e6 conjugated with polyvinyl pyrrolidone (Photolon ®) solution was added. The photoradiation of the HeLa cells tumor was performed with a laser of 667 nm wavelength at a dose of 5 J/cm².

Results

Photolon accumulation in tumor cells was found to be lasting for 2 hours. No further significant change in its cell level was noted. For this reason, a 3-hour incubation time was selected for studying dark cytotoxicity and photodynamic activity of Photolon. Cell incubation with Photolon for 3 hours with 25 or 50 mg/ml end concentration of the photosensitizer resulted in dose-dependent inhibition of HeLa culture growth, and with a concentration higher than 100 mg/ml it led to intensive cell death. IC50 of Photolon cytostatic effect index was 43.60 ±3.67 mg/ml, and LC50 cytotoxic effect index was 152.63±3.67 mg/ml.

Conclusion

Photolon accumulation in tumor cells occurs in the course of 2 hours, with no further significant change in its level. Photoradiation of HeLa tumor cells at dose of 5 J/cm² after the incubation with the photosensitizer for 3 hours produces strong cytotoxic and cytostatic effects.
BIM OF APOPTOTIC MARKER PREDICTS FAVORABLE SURVIVAL OUTCOME IN CERVICAL CANCER

B. Kim1, H. Cho2, J.Y. Chung3, J.H. Kim2, S. Hewitt3
1International St. Mary’s Hospital- Catholic Kwandong University, Obstetrics and Gynecology, Incheon, Republic of Korea
2Gangnam Severance Hospital, Obstetrics and Gynecology, Seoul, Republic of Korea
3National Institutes of Health, Experimental Pathology Laboratory, MD, USA

Aims

Bcl-2 interacting mediator (BIM) is a pro-apoptotic protein belonging to the BCL 2 protein family. BIM elicits cell death by binding to prosurvival BCL-2 proteins. Even though association of BIM expression and cell death has been investigated, clinical survival significance for BIM is not investigated in cervical cancer. Prognostic significance of BIM was investigated by immunohistochemical analysis in cervical cancer.

Method

The study subjects included cervical intraepithelial neoplasia (CIN, n = 275) and invasive cervical cancer (n = 164). Immunohistochemistry (IHC) was performed to identify BIM protein expression. IHC scoring was performed using automated digital image analysis and the association of BIM with prognostic factors was investigated.

Results

BIM expression was higher in cervical cancer than normal cervix (p<0.001). Well and moderate differentiation showed higher expression of BIM than poor differentiation (p=0.001). Squamous cell type revealed high expression of BIM compared to non-squamous cell type (0.008). BIM expression was highly observed in radiation sensitive cervical cancer compared to radiation resistant cancer (P=0.049). High expression of BIM showed better 5-year disease-free survival and overall survival rate (p=0.049 and 0.030, respectively) than low expression group. In multivariate analysis, BIM was shown as an independent risk factor with hazard ratio of 0.22 (p=0.006) for disease-free survival and hazard ratio of 0.46 (p=0.046) for overall survival in cervical cancer.

Conclusion

BIM is associated with favorable prognostic marker to predict disease-free and overall survival in cervical cancer. High expression of BIM, apoptotic marker of tumor, might be significant survival factor in cervical cancer.

SENTINEL LYMPH NODES MAPPING WITH INDOCYANINE GREEN IN CERVICAL CANCER STAGE IAI – IIB : A SINGLE CENTER EXPERIENCE

J.H. Kim¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹Asan medical center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To determine the validity of sentinel lymph nodes(SLN) mapping using Indocyanine green(ICG) in cervical cancer.

Method

We have performed a retrospective study of cervical cancer patients with SLN mapping from 2015 to 2017 at the Asan Medical Center. Hundred-three patients were included. After using ICG to detect SLN during surgery, we removed SLN following standard radical surgery and bilateral pelvic lymphadenectomy.

Results

The most common surgery was a laparoscopic radical hysterectomy(44.7%). Stage IB1 was most common (61.2%). The median tumor size was 2.4cm. At least One SLN was detected in all cases. Eighty-eight patients (85.4%) had bilateral pelvic SLN. Side specific detection rate was 92.7%. Twenty-seven patients had nodal metastasis after lymphadenectomy on final H&E. On a side-specific basis, the sensitivity of SLN was 71.43%, specificity was 100% and Native predictive value(NPV) was 93.98%. In the case of tumor size less than 2 cm and negative lymph node metastasis at imaging test, sensitivity was 100%, specificity was 100%, and NPV was 100% as side-specific. The size over 4cm, lymphovascular space invasion, parametrium(PM) invasion and previous LEEP history were the risk factors affecting false negative detection of SLN.

Conclusion

It may be possible to perform SLN Biopsy alone in an early stage in which the size is less than 2 cm and the lymph node metastasis is not suspected in the imaging test. However, if tumor size is large and vagina extension is suspected, and if any suspicion of PM invasion, we should be cautious in doing the SLN biopsy alone.

ESG07-0783

INFLUENCE OF AGE ON HISTOLOGIC OUTCOME OF CERVICAL INTRAEPITHELIAL NEOPLASIA: RESULTS FROM A LARGE COHORT, SYSTEMATIC REVIEW AND META-ANALYSIS

C. Bekos¹, C. Grimm², E. Joura², R. Horvat³, A. Reinthaller², S. Polterauer²

¹AKH Wien, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria
²Medical University Vienna, Department of Obstetrics and Gynecology- Division of General Gynecology and Gynecologic Oncology, Vienna, Austria
³Medical University Vienna, Department of Pathology, Vienna, Austria

Aims

Age is one of the crucial factors influencing the natural history of cervical intraepithelial neoplasia (CIN). Aim of this study was to investigate the histologic outcome of CIN during observational management in young women.

Method

This analysis included 783 women presenting with CIN at our outpatient clinic between 2006 and 2010. At least one colposcopically guided biopsy (CGB) for histologic diagnosis had to be obtained and observational management for at least three months was mandatory. The histologic findings of initial and follow-up visits were collected and rates of persistence, progression and regression were assessed. Uni- and multivariate analyses were performed. In addition, a systematic review of the literature and meta-analysis of published data was performed.

Results

In our cohort CIN I, II, and III was diagnosed by CGB in 42.5%, 26.6% and 30.9%, respectively. Younger patients had higher rates of regression (p<0.001) and complete remission (<0.001) and lower rates of CIN progression (p=0.003). Among women aged <25, 25<30, 30<35, 35<40, and >40 years, regression rates were 44.7%, 33.7%, 30.9%, 27.3%, and 24.9%, respectively. Pooled analysis of published data showed similar results. Multivariable analysis showed that with each five years of age, the odds for regression reduced by 15% (p<0.001) independently of CIN grade, and presence of HPV high-risk infection.

Conclusion

Patient's age has a considerable influence on the natural history of CIN – independent of CIN grade and HPV high-risk infection. Observational management should be considered for selected young patients with CIN. Results of this analysis can be useful for patient counselling.

NOMOGRAM-BASED PREDICTION OF CERVICAL DYSPLASIA PERSISTENCE / RECURRENTNESS

G. Bogani1, A. Ditto1, F. Martinelli2, M. Signorelli1, V. Chiappa1, U. Leone Roberti Maggiore1, E. Tagliabue1, L. Domenica1, F. Raspagliesi1

1National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To identify predictors of cervical dysplasia persistence/recurrence among women undergoing primary conization.

Method

Data of consecutive women undergoing LASER CO2 conization were retrospectively evaluated. The risk of developing cervical dysplasia persistence/recurrence was assessed with Kaplan-Meier and Cox hazard models. Additionally, two nomograms were built to estimate probability of cervical dysplasia persistence/recurrence: the first based on baseline and operative parameters and the second focusing on type-specific HPV detected. The performance of the above nomograms was assessed using concordance index (c-index).

Results

Overall, 2680 patients were included. After a mean (SD) follow-up of 47.7 (±20.7) months, 149 (5.5%) patients required secondary conization. Via multivariate analysis, HIV infection (HR: 8.22 (95%CI: 3.81, 17.7); p<0.001), positive margins (HR: 10.1 (95%CI: 5.73, 17.8); p<0.001) and persistence of HPV (HR: 11.4 (95%CI: 7.94, 16.49); p<0.001) correlated with CIN2+ persistence/recurrence. The importance of those variables was corroborated by our first nomogram (Figure). The second nomogram suggested the impact of type-specific HPV infection in predicting cervical dysplasia recurrence. HPV16, 33, 35 and 45 were the most common HPV types associated with cervical dysplasia persistence/recurrence. The c-index was 0.73 for both nomograms, thus suggesting the reproducibility of our models.

Conclusion

No other nomogram estimated the risk of developing cervical dysplasia persistence/recurrence is still published. We developed the first two nomograms predicting this risk. Although the large sample size and the high performance of our nomograms, external validation of our data is needed. Once validated our data might be useful to plan a tailored postoperative surveillance of women having conization.

ESGO7-1097

RISK OVARIAN MALIGNANCY ALGORITHM (ROMA) VALIDITY ASSESSMENT IN IRANIAN WOMEN WITH AN OVARIAN MASS

Z. Bouzari1, R. Hadiseh2, Y. Shahla1, M. Merat3
1. Cellular and Molecular Biology Research Center, Babol University of Medical Sciences- Babol- Iran, Babol, Iran
2. Cellular and Molecular Biology Research Center, Babol university o f medical sciences, Babol, Iran
3. ...., Business Management- Islamic Azad University of Babol- Babol- Iran., Babol, Iran

Aims

Ovarian cancer is the most common type and lethal of gynecological malignancy. Distinguish between benign and malignant ovarian masses is very important to refer patients to centers with experience in the surgical. The aim of this study was to investigate the validity of the risk ovarian malignancy algorithm (ROMA) in ovarian mass.

Method

One-hundred patients who had been diagnosed with ovarian masses were assessed for the tumor markers CA125, and the ROMA. The sensitivity and specificity of each parameter were calculated using receiver operating characteristic curves according to the area under the curve (AUC) for each method.

Results

The median CA125, and ROMA serum levels had different significant between benign and malignant tumors in the overall assessment (P<0.001). The areas under the curve (AUC) were 0.83(CA125), and 0.92 (ROMA) for benign vs malignant tumors in whole patients. The ROC curves were compared using a pairwise comparison method, and no differences were detected between the CA125, and ROMA. At specificity 75 percent, sensitivity was 64.7 for CA125, 82.4 ROMA generally

Conclusion

The results based on the area under the curve markers of CA125 and ROMA show that ROMA had the best accuracy of AUC-ROC than CA125 in all patients and each group pre- and post-menopausal patients.
Aims

BRCA1/2 mutation carriers are at increased risk of developing ovarian carcinoma arising from precursor lesions in the tubal epithelium (p53 signature/STIL/STIC lesions). Risk-reducing salpingo-oophorectomy (RRSO) is still recommended between the age of 35-40 years. We aimed to analyse the presence of preinvasive lesions in BRCA1/2 mutation carriers undergoing RRSO and associated clinical predictors.

Method

Retrospective study of BRCA1/2 mutation carriers undergoing RRSO at the Vall d’Hebron Hospital over a seven year-period. Data was collected on women’s age at RRSO, parity, personal history of breast cancer, CA125 levels, TVUS results and final histology. All tubes/ovaries were assessed using the SEE-Fim protocol.

Results

Out of 133 women undergoing RRSO, 73 (55%) had a BRCA1 mutation and 60 (45%) BRCA2. The median age was 46 years (range 35-70) and CA125 levels 10,8 U/mL (2,6-48). Twenty-five women were nulliparous (19%) and eighty (60%) had a personal history of breast cancer. Four women had a simple cyst on TVUS. Final histology confirmed p53 signature/STIL lesions in 10 women (7.5%) and one was diagnosed with invasive carcinoma. Multivariate analyses showed a positive correlation between age over 50 years [OR 4.46 (95%CI 1.12-17.6); p=0.033] and abnormal TVUS [OR 13.03 (95%CI 1.39-121); p=0.024] with the presence of preinvasive lesions.

Conclusion

About 8% of BRCA1/2 mutation carriers will have a preinvasive lesion at the time of RRSO and this risk significantly increased in women over 50 years. This suggests that the identification of new markers that predict the development of precursor lesions may help us in the future to defer RRSO when possible. Thus, efforts and future research should be devoted in this direction.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0200

PRIMARY HPV-BASED SELF-SAMPLING SCREENING WITH THE COBAS® HPV TEST FOR UNDERSERVED GREEK WOMEN. PRELIMINARY RESULTS OF THE GRECOSELF STUDY

1 Aristotle University of Thessaloniki- Hippokratio General Hospital, 4th Department of Obstetrics and Gynecology, Thessaloniki, Greece
2 Aristotle University of Thessaloniki- Hippokratio General Hospital, 2nd Department of Obstetrics and Gynecology, Thessaloniki, Greece
3 Centre for Research & Technology - Hellas, Institute of Applied Biosciences, Thessaloniki, Greece
4 Hippokratio General Hospital, Department of Neonatology, Thessaloniki, Greece
5 PEDY, 25th Martiou, Thessaloniki, Greece
6 Hippokratio General Hospital, Laboratory of Cytology, Thessaloniki, Greece
7 Hippokratio General Hospital, Department of Histopathology, Thessaloniki, Greece

Aims

To assess the performance of self-sampling HPV-based screening in underserved Greek women, in comparison to historical real-life cytology-based screening results, and the acceptability of the Roche® self-collection cervicovaginal specimen device.

Method

Women (sample size n=12,700) 25-60 years old, residing in rural Greek areas, are contacted by midwives, via public announcement, and are provided, after written informed consent, with a self-sampling kit (Roche®). After sampling each woman fills in a questionnaire designed to assess cervical cancer screening participation and outcome history during the last 10 years, and the acceptance of the self-sampling procedure. Samples are tested using the cobas® HPV Test, Roche®, which detects HPVs 16 and 18 separately, and HPVs 31,33,35,39,45,51,52,56,58,59,66 and 68 as a pooled result. HPV-positive women are referred for colposcopy. In case of Cervical Intraepithelial Neoplasia (CIN) grade 1 or 2 or worse (CIN2+) they are referred to follow up or appropriate treatment respectively.

Results

Between May 2016 and April 2017 7,143 samples were collected, 6,456 were tested, of which 489 (7.6%) were HPV-positive, 249 colposcopies were performed and CIN 1, 2 and 3 was detected in 21, 12, and 10 cases respectively. There was a case of vaginal intraepithelial neoplasia and a case of cervical adenocarcinoma. The prevalence of high-grade disease or cancer among HPV-positive women examined was 9.6%.

Conclusion

The preliminary report of the GRECOSELF study shows that HPV-testing with individual HPV16/18 genotyping on self-collected cervicovaginal samples is a feasible and effective cervical cancer prevention method for Greek women residing in rural distant areas.

EVALUATE A REAL TIME MID-IR SPECTROSCOPIC METHOD BASED ON ATR-FTIR AS AN ADDITIONAL METHOD TO 'FROZEN SECTION' IN GYNEONCOLOGY PROCEDURE – A PRELIMINARY STUDY

I. Bruchim1, G. Haran2, D. Malonek3, A. Blecher4, R. Reens Carmel1, H. Ben-Amram3, S. Midler3, G.M. Groisman4, M. HALLAK1, D. Ben-Zion1
1Hillel Yaffe medical center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
2Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
3Academic Center Ruppin, School of Engineering, Emek-Hefer, Israel
4Hillel Yaffe Medical Center, Department of Pathology, Hadera, Israel

Aims

The sensitivity of the 'frozen section' test is in the range of 75% to 100% and the specificity is 80% to 100%. Increasing those measures is needed to improve the clinical decision-making process. ATR-FTIR spectroscopy is a rapid and sensitive technique that measures changes in molecular structures. Hence, it has the potential to differentiate between malignant and benign tumors. The objective of the current study was to explore the potential of mid-IR ATR-FTIR technique in improving the accuracy of pathology evaluation during surgical procedure.

Method

18 samples extracted from suspected tumors were tested using an ATR-FTIR system. Absorption spectrum were measured and analyzed. 'Frozen section' and histopathological results of these samples were used to develop a discriminant model using multivariate classification methods.

Results

Preliminary results of our study suggest that measured spectra of malignant and benign tumors differ from each other (Figure 1). The model demonstrated that the ATR-FTIR technique was able to correctly differentiate between malignant and benign tumors with 100% sensitivity and 93% specificity.

Conclusion

The ATR-FTIR technique was able to discriminate between malignant and benign tumors. Thus, it has the potential to be used as an additional or alternative technique to the 'frozen section' test during the clinical decision-making process. Further study is needed to support this finding.
Aims

Response rates to treatment of vulval intraepithelial neoplasia (VIN) with imiquimod and cidofovir are approximately 57% and 61% respectively. Treatment is associated with significant side effects and, if ineffective, risk of malignant progression. Treatment response is not predicted by clinical factors. Identification of a biomarker that could predict response is an attractive prospect. This work investigated HPV DNA methylation as a potential predictive biomarker in this setting.

Method

DNA from 167 cases of VIN 3 from the RT3 VIN clinical trial was assessed. HPV positive cases were identified using Greiner PapilloCheck and HPV 16 type-specific PCR. HPV DNA methylation status was assessed in three viral regions: E2, L1/L2, and the promoter, using pyrosequencing.

Results

Methylation of the HPV E2 region was associated with response to treatment. For cidofovir (n=30), median E2 methylation was significantly higher in patients who responded (p < 0.0001); E2 methylation >4% predicted response with 88.2% sensitivity and 84.6% specificity. For imiquimod (n=33), median E2 methylation was lower in patients who responded to treatment (p = 0.03 (not significant after Bonferroni correction)); E2 methylation <4% predicted response with 70.6% sensitivity and 62.5% specificity.

Conclusion

These data indicate that cidofovir and imiquimod may be effective in two biologically defined groups. HPV E2 DNA methylation demonstrated potential as a predictive biomarker for the treatment of VIN with cidofovir and may warrant investigation in a biomarker-guided clinical trial.
HPV GENOTYPE IS IMPORTANT IN PREDICTING DISEASE PROGRESSION IN WOMEN WITH ATYPICAL SQUAMOUS CELL OF UNDETERMINED SIGNIFICANCE (ASC-US) CYTOLOGY.

W. Kang, U.C. Ju, S.M. Kim

Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Our aim was to estimate the risk of disease incidence in women with atypical squamous cell of undetermined significance (ASC-US) without histology-proven cervical intraepithelial neoplasia grade 2 or worse (CIN2+) by human papillomavirus (HPV) genotype.

Method

Between January 2002 and September 2010, incidence of CIN2+ in 2,880 women including 2,172 with ASC-US and histology-proven negative and 708 with ASC-US with histology-proven CIN1 was investigated. Baseline HR-HPV status was determined by the hybrid capture II assay (HC2) and HR-HPV genotype by the HPV DNA chip test (HDC). Cumulative incidence and hazard ratios were estimated to explore differences between index data and associations with CIN2+.

Results

Of the 2,880 women, the HC2 was positive in 1,509 women (52.4%) and the HDC was positive in 1,563 women (54.3%). The overall agreement between the HDC and HC2 was 97.4%. One hundred ninety (6.6%) patients developed CIN2+. The 5-year cumulative incidence rate of CIN2+ in HPV-16, HPV-31, HPV-52, and HPV-58 were 16.7%, 15.1%, 12.6%, and 12.9%, respectively. On multivariate analysis, being positive in HPV-16 (hazards ratio [HR] = 2.431; 95% CI, 1.789-3.332; P < 0.01), HPV-31 (HR = 2.335; 95% CI, 1.373-3.971; P < 0.01), HPV-52 (HR = 1.592; 95% CI, 1.031-2.458; P = 0.03), and HPV-58 (HR = 1.650; 95% CI, 1.132-2.407; P < 0.01) were significantly associated with developing CIN2+ compared to being negative for that type.

Conclusion

Among women with ASC-US, HPV-16, HPV-31, HPV-52, or HPV-58 positive women may need intensified follow-up as they have the highest risk of becoming CIN2+.
HARMONISATION OF BIOBANKING STANDARDS IN ENDOMETRIAL CANCER RESEARCH (HASTEN): SURGICAL AND PATIENT DATA COLLECTION, STANDARD OPERATIVE PROCEDURE FOR TISSUE AND FLUID COLLECTION, PROCESSING AND STORAGE

M. Adishesh¹, A. Fyson¹, B. Decruze², J. Kirwan², H. Werner³, D. Hapangama¹
¹Institute of Translational Medicine, Women's Health Research, Liverpool, United Kingdom
²Liverpool Women’s Hospital, Gynaecology, Liverpool, United Kingdom
³Haukeland university hospital, Obstetrics and Gynaecology, Bergen, Norway

Aims

Endometrial cancer (EC) is the most common gynaecological cancer. Incidence of EC is predicted to escalate by a further 50 -100% by 2025 with a parallel increase in associated mortality. Variations in the collection, processing and storage of bio-specimens can affect the internal and external validity and thus the generalisability of the scientific data. We aimed to harmonise the collection of bio-specimens and the associated essential clinical data relevant to EC and to develop standard operative procedures for the collection, processing and storage of EC-biospecimens.

Method

We designed EC research tools, which were evaluated and revised through three consensus rounds – to obtain local/regional, national and European consensus. Modified final tools were disseminated to a group of multi-disciplinary panel members (n=40) representing all stakeholders in EC research, and a modified Delphi technique was used to generate consensus.

Results

We devised three research tools: patient data collection tool, surgical data collection tool, biospecimen tool and a standard operating procedure. The final consensus demonstrated unanimous agreement with the minimal surgical and patient data collection tools. A high level of agreement was also observed for the standard tool.

Conclusion

We here present the final versions of the forms, which are freely available and easily accessible to all EC researchers. We believe that these tools will facilitate rapid progression in EC research; both in future collaborations and in large-scale multi-centre studies, in integrating data from various studies and finally, in uncomplicated clinical translation of new scientific discoveries for the benefit of EC patients.

REGIONAL RECURRENCE RATES OF STAGE I ENDOMETRIAL CARCINOMA PATIENTS TREATED WITH ADJUVANT BRACHYTHERAPY

1Ege University Faculty of Medicine, Radiation Oncology, IZMIR, Turkey
2Ege University Faculty of Medicine, Radiation Oncology, IZMIR, Turkey
3Onkomer Radiotherapy Center, Radiation Oncology, Izmir, Turkey
4Tepecik Education and Research Hospital, Obstetrics and Gynecology- Division of Gynecological Oncology, Izmir, Turkey
5Ege University Faculty of Medicine, Obstetrics and Gynecology- Division of Gynecological Oncology, IZMIR, Turkey
6Tepecik Education and Research Hospital, Internal Medicine- Department of Medical Oncology, Izmir, Turkey

Aims

After the publication of PORTEC 2 in 2010, there had been an increasing use of brachytherapy in stage I medium risk and HIR (high intermediate risk) patients. Our aim is to investigate the relapse patterns in stage I endometrial carcinoma patients treated with adjuvant brachytherapy.

Method

189 patients who underwent brachytherapy between January 2011 and December 2015 were retrospectively reviewed. Brachytherapy was performed with Iridium 192 source as 3x 700 cGy in 5 mm periphery of vagina.

Results

All cases were endometrioid type endometrial adenocarcinoma. Stage and grade distribution is as follows IA G3 (1.1%), IB G2 (72.5%), IB G3 (1.6%), IC G1 (5.8%) and IC G2 (19%). Within a median of 32 months (range: 12-72 m) of follow-up there was no local recurrence. Five patients had regional (pelvic/paraaortic) recurrence. Operation could not be performed due to the unresectability of the recurrent tumor, besides morbidity and mortality risks of the surgery therefore chemotherapy and/or radiotherapy was administered as salvage treatment. 3-year DFS was 96%. In univariate analysis, LVI (p: 0.06), high grade tumor histopathology (p: 0.008), tumor size ≥ 5 cm (p: 0.01) and the number of dissected median pelvic lymph nodes ≤ 15 (p: 0.05) were found to be negative prognostic factors for 3-year DFS.

Conclusion

In stage I endometrial cancer patients brachytherapy is a preferred adjuvant treatment method and provides high local control rates. However in case of regional recurrence cure rates are low. Determination of further molecular prognostic factors is required to better understand the tumor biology.
Aims

To validate and evaluate feasibility of Memorial Sloan Kettering Cancer Center –Sentinel Lymph Node Algorithm (MSK-SLN algorithm) to detect lymph node metastasis (LNM) in clinical early stages endometrial cancer by using near-infrared fluorescent imaging and indocyanine green (NIR/ICG) integrated laparoscopic system.

Method

Clinically early stages endometrial cancer patients were included in this prospective study. ICG was injected to the uterine cervix and NIR/ICG integrated laparoscopic system was used during the operations. SLN and/or suspicious lymph nodes were resected. Side specific lymphadenectomy were done when mapping was not achieved. Systematic lymphadenectomy was completed following SLN algorithm steps. External validation was performed by evaluating histopathologic results of SLN algorithm steps. Comparison of SLN algorithm steps and systematic lymphadenectomy histopathologic results were used for internal validation.

Results

Seventy-one eligible patients were analyzed. There were 8 (11.2%) patients with LNM. One of them was isolated para-aortic node metastasis. SLN algorithm was able to detect all pelvic metastases. Negative predictive value, sensitivity and falsenegative rate were 98.4%, 87.5% and 1.5%, respectively. There was non-SLN involvement in addition to SLN metastasis in approximately half of the patients with pelvic LNM.

Conclusion

All pelvic node metastases could be detected by SLN algorithm using NIR/ICG integrated laparoscopic system. SLN algorithm may be incapable to diagnose isolated para-aortic metastasis. Using the whole algorithm, instead of removing only mapped nodes, increases detection rate and decreases false negative rate. SLN algorithm for clinical early stage uterine cancer can be used more prevalently with laparoscopic systems.

TRANSVAGINAL ULTRASOUND-GUIDED MYOMETRIAL INJECTION OF RADIONUCLIDE (TUMIR) FOR SENTINEL NODE DETECTION IN ENDOMETRIAL CANCER

M. Ángeles 1, M. Del Pino 1, P. Paredes 1, J. Pahisa 1, P. Fusté 1, S. Martínez 1, F. Migliorelli 1, S. Escura 1, N. Carreras 1, A. Tomé 1

1Hospital Clinic of Barcelona, Gynecology, Barcelona, Spain

Aims

to determine accuracy of TUMIR for sentinel lymph node (SLN) detection in endometrial cancer (EC).

Method

during 2005-2017, 132 patients with high-risk EC were prospectively recruited. Twenty-four hours before surgery, 5-8 ml of 99mTc-nanocolloid (92-148 MBq) were injected into two spots (anterior and posterior myometrium) using an ultrasound-guided transvaginal puncture. SLN was localized preoperatively by lymphoscintigraphy and intraoperatively with gamma probe. After SLN biopsy, patients underwent pelvic and paraaortic lymphadenectomy. Performance of technique for detection of SLN and accuracy to predict Lymph Node (LN) status were analysed.

Results

TUMIR was achieved in all patients without serious adverse effects. SLN was identified in 96/132 (72.7%) patients. Drainage location is shown in Table 1. In 88/96 (91.7%) patients, SLN was resected during surgery, with a final detection rate of 66.7%. After lymphadenectomy, LN were positive in 12/88 (13.6%) patients, with paraaortic involvement in 5/88 (5.7%) cases. From 88 patients with SLN resected, 145 SLN were obtained. Table 2 shows histological diagnosis of SLN and corresponding lymphadenectomy. Sensibility and negative predictive value of TUMIR to diagnose LN metastasis were 84.2% (IC95%: 62.4-94.5) and 97.7% (IC95%: 93.4-99.2), respectively.

Conclusion

TUMIR has good accuracy for detecting SLN in high-risk EC.
THE VALUE OF SENTINEL LYMPH NODE BIOPSY IN INTERMEDIATE AND HIGH RISK ENDOMETRIOID ENDOMETRIAL CANCER

O. Aristegi Guridi¹, A. Bombin Arregui¹, O. Vazquez Maiz¹, R. Ruiz Sautua¹, M. Gorostidi Pulgar¹, I. Jaunarena Marin¹,
D. Del Valle Peña¹, J. Aguerre Gogorza¹, K. Goiri Little¹, A. Lekuona Artola¹
¹OSI Donostialdea, H.U. Donostia, Donostia, Spain

Aims

To analyze the biopsy of sentinel lymph node (SLN) in intermediate and high risk endometrioid endometrial cancer (EC) as a method to detect nodal disease and to compare it with systematic pelvic and aortic lymphadenectomy.

Method

A series of 49 consecutive cases with diagnosis of intermediate or high risk endometrioid EC following the ESMO criteria.

We inject the indocyanine green tracer in the uterine fundus transcelvicaly and in cervix (3-9h) to cover aortic and pelvic lymphatic drainage after creation of pneumeperitoneum. Then, we identify and biopsy the fluorescent SLN with a laparoscopic optical (NIR/ICG system KARL STORZ®). Finally, we complete the aortic and pelvic lymphadenectomy.

The anatomophatological study is benefited by ultra standing of the SLN, using fine sections and the inmunohistochecmistry.

Results

The overall detection rate of SLN was 95.9%, 89.8% in pelvic area and 63.3% in aortic area. In 3 cases the detection was exclusively aortic and in 16 exclusively pelvic.

We found 5 cases with metastatic lymph nodes, 4 of them the SLN was positive, nevertheless the other case was a false negative.

In the other 44 cases lymphadenectomy was negative, 38 of them with SLN negative, but we found micro-disease in 6 cases (12.2%).

Conclusion

Lymph node involvement in endometrioid EC is low, even in intermediate or high risk cases. Systematic lymphadenectomy in these patients may involve overtreatment. The SLN technique reduces the number of systematic lymphadenectomies. Moreover it permits an exhaustive histological. To minimize the rate of false negatives with a standardized technique is a challenge for the future.

WHY DID WE REFRAIN FROM ROBOT-ASSISTED LAPAROSCOPIC SURGERY IN ENDOMETRIAL CANCER PATIENTS?

G. Aune1, S. Tingulstad1, B. Hagen1

1St Olavs Hospital - Trondheim University Hospital, Department of Laboratory Medicine- Children's and Women's Health, Trondheim, Norway

Aims

To study why women with primary endometrial cancer underwent open laparotomy rather than robot-assisted laparoscopic surgery in the era of robotic surgery, and evaluate the surgical treatment.

Method

A retrospective study, including all women undergoing surgery for endometrial cancer from November 2012 through December 2015 at St.Olavs Hospital, a referral teaching hospital in Norway. Data were extracted from patient records.

Results

239 cases were identified. 137 (57%) underwent robot-assisted laparoscopic operation and 102 (43%) underwent open laparotomy. Suspected advanced disease was the most common reason for laparotomy (31%), followed by concomitant ovarian tumor (21%), large uterus (17%), and comorbidity (14%). Less frequent causes were previous pelvic/abdominal cancer (2%), planned concomitant gastrointestinal surgery (2%), lack of robotic capacity (2%), and previous abdominal surgery (1%). Six cases planned for robot-assisted surgery were converted to open operation, due to anesthesia complications or surgical challenges.

There was no difference in BMI or age between the laparotomy and robot-assisted laparoscopy group (median BMI 30 and 27, respectively, p=0.21, median age 67 years in both groups, p=0.32). The laparotomy group had more advanced stage disease (p=0.002). Lymph nodes were removed in 72% of laparotomy cases, and 93% of robotic cases (p=0.001). Number of nodes removed was significantly higher in the laparotomy group (median 12 vs 6 lymph nodes, p<0.001). The lymph node metastatic rate was 18% in the laparotomy group, compared to 12% in the robotic group (p=0.059).

Conclusion

Advanced stage disease was the main reason for laparotomy instead of robot-assisted laparoscopic operation.
ENDOMETRIAL CANCER

SIZE OF THE SENTINEL NODE METASTASIS AND THE RISK OF NON-SENTINEL NODE METASTASIS IN ENDOMETRIAL CANCER

G. Baiocchi¹, H. Mantoan¹, L. Kumagai¹, L. Badiglian-Filho¹, C. Faloppa¹, L. De Brot², A. da Costa³

¹AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
²AC Camargo Cancer Center, Pathology, Sao Paulo, Brazil
³AC Camargo Cancer Center, Sao Paulo, Brazil

Aims

Correlate the size of metastatic sentinel node (SLN) with the risk of non-sentinel node (N-SLN) metastasis in endometrial cancer.

Method

We analyzed a series of 195 patients treated at AC Camargo Cancer Center from January 2013 to April 2017 that had SLN mapping with cervical injection of only blue dye (n=184) or indocyanine green (n=11). Eight-six (44.1%) patients had high-risk tumors (endometrioid grade 3, serous, clear cell, carcinosarcomas, deep myometrial invasion or lymphovascular space invasion). The SLNs were examined by immunohistochemistry when the hematoxylin-eosin was negative.

Results

The overall SLN detection rate was 85.6%, and bilateral of 60%. Median SLN detected was 2 per patient (range, 1-8). In low risk cases, there were only 2 (1.8%) patients with positive SLN – both with micrometastasis detected by immunohistochemistry (IHC). For high-risk group, there were 22 (25.6%) positive SLN cases. Five (5.8%) ITC, 7 (8.1%) micrometastasis, and 10 (11.6%) macrometastasis. 9/22 (40.9%) SLN metastasis was found only by IHC. Of the 24 patients with positive SLN, the median number of positive SLN was 1.5 (range, 1-8). Six (6/24, 25%) had positive N-SLN, with a median of 7 (range, 3-23) positive N-SLN. Regarding the size of SLN metastasis, presence of N-SLN were found in any (0/5) patient with ITC, 11% (1/9) with micrometastasis and in 50% (5/10) of patients with macrometastasis.

Conclusion

Our data suggest that size of metastasis in SLN correlates with the risk of N-SLN metastasis. Any patient with ITC in SLN had other metastatic lymph node.
Aims

To determine the detection rate, sensitivity and predictive negative value of SLN for low and high-risk endometrial cancer (endometrioid grade 3, serous, clear cell, carcinosarcomas, deep myometrial invasion or lymphovascular space invasion).

Method

We analyzed a series of 195 patients treated at AC Camargo Cancer Center from January 2013 to April 2017 that had SLN mapping with cervical injection of blue dye (n=184) or indocyanine green (n=11). Eight-six (44.1%) patients had high-risk and 109(55.9%) low-risk tumors.

Results

Sixty-two (31.8%) patients had pelvic lymph node dissection (LND), 65 (33.3%) pelvic+para-aortic LND, and 68(34.9%) had only SLN. The overall SLN detection rate was 85.6%, and bilateral of 60%. Median SLN detected was 2 per patient (range,1-8). In low risk cases, there were only 2 (1.8%) patients with positive SLN – both with micrometastasis detected by immunohistochemistry (IHC). For high-risk group, there were 22(25.6%) positive SLN cases. Five (5.8%) ITC, 7 (8.1%) micrometastasis, and 10 (11.6%) macrometastasis. 9/22(40.9%) SLN metastasis was found only by IHC. Only 2 patients had false negative SLN, with ipsilateral pelvic non-sentinel positive nodes. Of 164 patients with endometrioid histology, 17(11.3%) had positive SLN, and 8(47.1%) cases were found only after IHQ. We found an overall sensitivity was 92.3%, negative predictive value 98.6%, and false negative rate 7.6% (2/26).

Conclusion

Our data suggest SLN mapping as a safe and accurate technique for endometrial staging that increases metastatic nodal detection rates by 5.6% after IHC. In endometrioid tumors, 4.8% patients had nodal metastasis detected after IHC that clearly impacts the indication of adjuvant chemotherapy.
DOES SENTINEL NODE MAPPING IMPACT THE PREVALENCE OF ISOLATED PARA-AORTIC NODAL METASTASES IN ENDOMETRIAL CANCER?

G. Baiocchi1, H. Mantoan2, L. Kumaga2, L. Badiglian-Filho2, C. Faloppa2, L. De Broty3, A. Da Costa4

1, AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
2, Brazil
3, Pathology, Brazil
4, Sao Paulo, Brazil

Aims

To determine the impact of sentinel node (SLN) mapping in staging high-risk endometrial cancer (grade 3 endometrioid, serous, clear cell, carcinosarcomas, deep myometrial invasion, or angiolympathic invasion).

Method

Eighty-three patients that had SLN mapping with blue dye cervical injection (SLN group) and pelvic ± para-aortic lymph node (LN) dissection from June 2007 to June 2015, were compared to 142 patients that received pelvic + para-aortic lymph node dissection (LND group) from June 2007 to June 2015. Patients with adnexal, peritoneal or suspicious LN metastasis were excluded.

Results

SLN group patients had more minimally invasive surgeries (71.1% vs. 3.5% years; p<0.001), and more presence of angiolympathic invasion (42.1% vs. 14.8%; p<0.001). There was no difference between SLN and LND groups regarding deep myometrial invasion (55.4% vs. 63.4%; p=0.23), and presence of non-endometrioid histologies (34.9% vs. 29.6%). The overall detection rate for SLN group was 86.7% and bilateral in 61.4% of cases. Eight in 19 (41%) positive SLN were detected only after immunohistochemistry. SLN group had more pelvic LN (PLN) metastasis detected compared to LND group (25.3% vs. 12.7%; p=0.016). However no difference were found regarding para-aortic LN (PALN) metastasis between SLN and LND groups (8.6% vs. 5.6%; p=0.38). In LND group, 5 (3.5%) patients had PALN without PLN. Conversely, in SLN group, 1 (1.2%) patient had isolated PALN. Although included in the SLN group, this patient had no SLN detected.

Conclusion

Our data suggest that SLN mapping identified more PLN metastasis compared to only LN dissection. Furthermore, we found no isolated PALN metastasis when SLN was detected.

CONTRIBUTION OF MAGNETIC RESONANCE IMAGING FOR PRE-OPERATIVE ASSESSMENT OF MYOMETRIAL AND CERVICAL INVASION AND PELVIC LYMPH NODE IN ENDOMETRIAL CARCINOMA

I. Ben Safta1, O. Jaidane1, H. Mansouri1, S. Gadria1, J. Ben Hassouna1, K. Rahal1
1Institut Salah azeiz of oncology, surgical oncology, TUNIS, Tunisia

Aims

To evaluate the accuracy of preoperative magnetic resonance imaging (MRI) to detect deep myometrial invasion, cervical extension and pelvic lymph node metastasis in patients with endometrial cancer.

Method

We retrospectively reviewed 42 cases of women with endometrial cancer, who underwent preoperative MRI assessment and surgical staging between January 2000 and December 2015. The MRI findings were then compared with the post-operative histopathological findings that served as reference standards.

Results

The sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of MRI for differentiation between superficial myometrial invasion and deep myometrial invasion were 86.6%, 40.9%, 50% and 81% respectively. The sensitivity, specificity, PPV and NPV for cervical invasion were 60%, 96.2%, 90% and 91.25% for cervical invasion and 70%, 84.37%, 58.3 and 90% for pelvic lymph node metastasis, respectively. There were significant correlation between preoperative FIGO-MRI staging and FIGO-histological staging (p=0.047).

Conclusion

In patients with endometrial cancer, a preoperative MRI contributes to accurate staging, allowing planning for the scale of surgery and preoperative counseling.
FDG PET/CT AS PROGNOSTIC TOOL IN THE PREOPERATIVE STAGING OF ENDOMETRIAL CANCER

A. Bergamini, P. Mapelli, F. Fallanca, D. Ferrari, E. Incerti, F. Pella, P.M.V. Rancolta, E.G. Rossi, M. Picchio

1 San Raffaele Hospital, Obstetric and Gynecology, Milan, Italy
2 IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy
3 IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy
4 IRCCS San Raffaele Scientific Institute, Department of Obstetrics and Gynecology, Milan, Italy
5 Vita-Salute San Raffaele University, University Centre of Statistics in the Biomedical Sciences, Milan, Italy
6 IRCCS San Raffaele Scientific Institute, IRCCS San Raffaele Scientific Institute, Milan, Italy

Aims

To investigate the prognostic role of FDG PET/CT in the preoperative assessment of patients with endometrial carcinoma (EC)

Method

18F-FDG PET/CT was performed in 57 patients for EC preoperative staging. Maximum and mean standardized uptake values (SUVmax, mean), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of primary tumours, at different thresholds of 40%, 50%, 60% were compared with histopathological features. The diagnostic performance of PET-parameters in discriminating low-risk disease from high-risk disease have been assessed

Results

Categorized TLG40-50-60 were related to FIGO stage I versus FIGO Stage II-III-IV (P=0.003); the optimal cut-off values for risk stratification were 83.69, 61.81 and 41.32, respectively, with correspondent sensitivity and specificity of 60.00% and 71.43%. Categorized SUVmax, SUVmean40-50-60 and MTV40-50-60 were not related to FIGO Stage. Categorized SUVmax and SUVmean40-50-60 could discriminate between endometrioid vs non endometrioid subtype with 14.35, 8.55, 9.8 and 10.9 threshold (P=0.01) for SUVmax and SUVmean50-60, P=0.0237 for SUVmean40). Correspondent sensitivity was 64.86% and 62.16% for SUVmax and SUVmean50-60 and 62.16% for SUVmean40; specificity was 70.00%. The mean OS rate was 79.77% ±3.34 and the mean DFS rate was 77.89±3.73. Tumour type was the only variable significantly associated with OS and TLG50 was the only variable significantly associated with DFS; specifically, TLG50>77.58 cc is associated with a higher risk of relapse according to logrank test

Conclusion

TLG40-50-60 of primary EC can predict FIGO staging; TLG40-50 can predict pathological staging. These parameters, being able to discriminating between low and high risk disease, may be useful in the preoperative assessment of EC

LONG-TERM COMPLICATIONS OF LYMPH NODE DISSECTION IN ENDOMETRIAL CANCER SURGERY

L. Volpi1, G. Sozzi1, V. Capozzi1, V. Coni1, M. Pugliese1, C. Carrera1, A. Cianciolo1, G. Gambino1, M. Di Serio1, R. Berretta1

1Azienda Ospedaliero Universitaria, OB Gyn unit, Parma, Italy

Aims

To investigated the incidence and the potential causes of lymphadenectomy’s complications in primary surgery for endometrial cancer.

Method

Observational study in a tertiary care centre between January 2007 and March 2014. All women who underwent to pelvic and/or paraaortic lymphadenectomy for endometrial cancer were analyzed. Each patients were compared by age, comorbidity, cancer stage, BMI, surgical approach, number of resected pelvic and/or para-aortic lymph nodes and use of intraoperative devices.

Results

Of the 428 patients tested, 238 underwent to pelvic lymphadenectomy (55,6%), 36 (15,1%) of those underwent both pelvic and para-aortic lymphadenectomy. Among the 238 patients, a total of 38 (16%) developed lower-limb-lymphedema, while 10 of 238 (4,2%) lymphocele, 1 of 238 developed neurological complication due to nerve injury, none vessel injury.

The number of resected lymph nodes was found to be higher in patients with lymphedema and lymphoceles. To detect the independent developmental risk factors for lymphatic complications, we performed multivariate analysis with logistic regression for four variables (stage disease, intraoperative-haemostatic-devices, abdominal drains and number of dissected lymph nodes). Among these, we found a significant difference for only number of dissected lymph nodes.

Conclusion

lymphadenectomy continues to be an important part of the surgical staging for endometrial cancer as it can identify important prognostic information that may alter treatment decisions. Currently, it has been introduced the sentinel-lymph-node-mapping (SLNM) in endometrial cancer staging. This procedure upholds the effectiveness of standard lymphadenectomy allowing identifying node positive patients, minimizing the risk of lymphadenectomy-related morbidity.

TUMOR SIZE: AN INDEPENDENT PREDICTOR OF LOCAL RECURRENCE IN LOW RISK ENDOMETRIAL CANCER

G. Sozzi\(^1\), S. Uccella\(^1\), L. Volpi\(^1\), V. Capozzi\(^1\), V. Cenci\(^1\), M. Di Serio\(^1\), G. Gambino\(^1\), C. Carrera\(^1\), A. Cianciolo\(^1\), M. Petrillo\(^2\), M. Pugliese\(^1\), F. Ghezzi\(^3\), R. Berretta\(^1\)

\(^1\)Azienda Ospedaliero Universitaria, OB Gyn Unit, Parma, Italy
\(^2\)OB Gyn Unit, Department of Obstetrics and Gynecology- Catholic University of the Sacred Heart- Largo A. Gemelli- 8- 00168 Rome- Italy,
\(^3\)Department of Obstetrics and Gynecology- Catholic University of the Sacred Heart- Largo A. Gemelli- 8- 00168 Rome- Italy, Italy

Aims

The purpose of this study was to analyze the correlation between tumor size (TS) and recurrence, in particular local recurrence, in patients with endometrial cancer (EC), stratified according to the new ESMO-ESGO-ESTRO classification.

Method

Data of patients with histologically proven EC who received primary surgical treatment from November 1999 to November 2014, were retrospectively retrieved from two institutions. Optimal TS cut-off was calculated using a Receiver Operating Characteristic (ROC) curve. Site of recurrence as a function of TS and group of risk was calculated using the Chi-Square test. Local recurrence-free survival (LRFS) and overall survival (OS) were calculated by Kaplan- Meier method.

Results

Data of 363 patients were analyzed. Among them 166 (45.7%) had low risk EC, 61 (16.8%) had intermediate risk EC, 37 (10.2%) had high-intermediate risk EC and 99 (27.3%) had high risk EC. A total of 47 women had (12.9%) recurrence: 13 of them had local relapse and 34 had relapse at any other site. TS >25 mm emerged as the optimal threshold for a higher rate of local recurrence (p=0.046, HR=4.699, \(p_{HR}=0.032\)) and a lower 2-years LRFS (94% vs 100%, \(p_{OS}=0.029\)) only in patients with low risk EC. There was no statistically significant correlation between TS < or >25 mm and recurrence in the other risk groups.

Conclusion

Tumor size seems to be an independent prognostic factor of local recurrence in women with low-risk EC and could be a valuable additional criterion to personalize the treatment approach to these patients.
IDENTIFICATION OF MICRO-RNA EXPRESSION PROFILES RELATED TO RECURRENCE IN WOMEN WITH ESMO LOW RISK ENDOMETRIAL CANCER

G. Canlorbe1, T. Cyril2
1Pitié-Salpêtrière University Hospital- Assistance Publique des Hôpitaux de Paris, Department of Surgery and Oncological Gynaecology- , Paris, France
2Creteil Intercommunal Hospital- Université Paris Est- Paris XII, Department of Obstetrics and Gynaecology, Créteil-, France

Aims

Introduction: Actual European pathological classification of early-stage endometrial cancer (EC) may show insufficient accuracy to precisely stratify recurrence risk, leading to potential over or under treatment. Micro-RNAs are post-transcriptional regulators involved in carcinogenic mechanisms, with some micro-RNA patterns of expression associated with EC characteristics and prognosis. We previously demonstrated that downregulation of micro-RNA-184 was associated with lymph node involvement in low-risk EC (LREC).

Objectives: The aim of this study was to evaluate whether micro-RNA signature in tumor tissues from LREC women can be correlated with the occurrence of recurrences.

Method

Methods: MicroRNA expression was assessed by chip analysis and qRT-PCR in 7 formalin-fixed paraffin-embedded (FFPE) LREC primary tumors from women whose follow up showed recurrences (R+) and in 14 FFPE LREC primary tumors from women whose follow up did not show any recurrence (R-), matched for grade and age. Various statistical analyses, including enrichment analysis and a minimum p-value approach, were performed.

Results

Results: The expression levels of micro-RNAs-184, -497-5p, and -196b-3p were significantly lower in R+ compared to R- women. Women with a micro-RNA-184 fold change < 0.083 were more likely to show recurrence (n=6; 66%) compared to those with a micro-RNA-184 fold change > 0.083 (n=1; 8%), p = 0.016. Women with a micro-RNA-196 fold change < 0.56 were more likely to show recurrence (n=5; 100%) compared to those with a micro-RNA-196 fold change > 0.56 (n=2; 13%), p=0.001.

Conclusion

Conclusion: These findings confirm the great interest of micro-RNA-184 as a prognostic tool to improve the management of LREC women.

FROZEN SECTION REVEALING THE ABSENCE OF LYMPHATIC TISSUE DURING SENTINEL LYMPH NODE BIOPSY IN ENDOMETRIAL CANCER STAGING.

J. Casarin, F. Multinu, A. Weaver, M. McGree, L. Tortorella, W. Cliby, S.C. Dowdy, F. Ghezzi, A. Mariani, G. Glaser

1Mayo Clinic, Gynecologic Oncology, Rochester, MN, USA
2University of Insubria, Obstetrics and Gynecology, Varese, Italy

Aims

To assess the role of frozen section (FS) to identify the absence of lymphatic tissue (“empty node” (EN)) during sentinel lymph node (SLN) biopsies for apparent early stage endometrial cancer (eEC) to avoid potential understaging in patients at high-risk of metastasis.

Method

All eEC patients undergoing SLN removal using cervical injection with Indocyanine Green from 06/01/2014 to 06/30/2016 were analyzed. FS was used to examine all SLNs removed. EN was defined as SLN specimen without evidence of lymphatic tissue. The association of tumor and patient’s characteristics with EN was evaluated. Trend analysis to compare the rate of EN over calendar quarters was performed using Cochrane-Armitage test.

Results

ENs were easily identified in 24/300 (8%) patients (23 cases unilateral and 1 case bilateral). No association between age, stage, histology, BMI, prior abdominopelvic surgery and presence of EN was observed. Rate of EN revealed at FS did not change over time (p=0.68 for trend) (Table1).

Table 1. Consecutive patients who underwent sentinel lymph node (SLN) biopsies with at least unilateral SLN removal for endometrial cancer staging using cervical injection of Indocyanine Green (ICG) at Mayo Clinic from June 1, 2014 to June 30, 2016.

*Cochrane-Armitage test for trend (after stratification by quarters from 2014Q1 to 2016Q4).

Conclusion

The presence of EN during SLN biopsies is not a rare event. The easy identification of absence of lymphatic tissue at FS is useful to reveal intraoperative EN and avoid the need of reoperation for appropriate staging in patients undergoing SLN biopsy at high-risk of lymph node metastasis. Individual institutions should examine their own EN rates and determine if this would assist them in their SLN practices for eEC.

THE PREGNANCY OUTCOME AFTER FERTILITY-SPARING TREATMENT OF EARLY ENDOMETRIAL CANCER

S.H. Chae1, J.H. Suh1, S.H. Shim1, S.J. Lee1, J.Y. Lee1, S.N. Kim1, S.B. Kang1

1Konkuk university medical center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Incidence of endometrial cancer has been increasing among young women since 2000. It is difficult to make a decision between fertility sparing treatment and hysterectomy for early stage endometrial cancer patients in reproductive age. The aim of this study is to evaluate the fertility and pregnancy outcome of early stage endometrial cancer patients in reproductive age.

Method

Retrospective single center study was done from 1998 to 2017. Endometrial cancer patients with presumed FIGO stage 1 & 2 with grade 1 & 2 were included. Exclusion criteria were patients with age over 45, presumed FIGO stage over 3 and any stages with FIGO grade 3. Pregnant group and non-pregnant group of early stage endometrial cancer patients after fertility sparing treatment were compared.

Results

Total 117 endometrial cancer patients were enrolled in the study. Among 117 endometrial cancer patients, 48 patients wanted to be pregnant and 20 of them were successfully pregnant (41.6%). The number of endometrial curettage was not different between two groups. However, 18 patients (18%) had not got remission within 6 month and hysterectomy was done in these patients. The age factor was different between pregnant and non-pregnant endometrial cancer patients (34±3.9 vs 36±2.7, P ≤ .05). Moreover, basophil count was different between two groups (0.34±0.91 vs 0.69±0.43, P ≤ .05).

Conclusion

The pregnancy outcome was good after fertility sparing treatment in early stage endometrial cancer patients. Endometrial curettage does not affect the pregnancy outcome. Further study of large group should be done.
PAX2 and BCL-2 EXPRESSION AS A PROGNOSTIC FACTOR IN ENDOMETRIAL ENDOMETRIOID ADENOCARCINOMA GRADE 1

M. Kırşavoğlu¹, A. Çorakçı¹, Y. Doğan¹
¹Kocaeli University Faculty of Medicine, Gynecology and Obstetrics, Kocaeli, Turkey

Aims

Our aim is to detect the influence of bcl2 and PAX2 expression on the prognosis of endometrial endometrioid adenocarcinoma grade 1.

Method

All endometrial endometrioid adenocarcinoma grade 1 patients detected in Kocaeli University Medical Faculty Hospital between 2009-2012 were analysed. Fiftyseven endometrium carcinoma patients were included in the study and control group was composed of 34 patients reported as benign hyperplasia. Immunoreactivity was scored half quantitavely based on bcl2 and PAX2 staining. Staining intensity of gland epiteliom was scored from 0 to 3. The extensity of the stain was evaluated also, if the tissue did not stain 0 score was given, 1-33% staining was scored as 1, 34-66% staining was scored as 2, 67-100% staining was scored as 3. Total scores were between 0 and 6. Immunohistochemical staining scores of the patients and control group were compared by MannWhitney U test. Bcl2 and PAX2 were compared with other prognostic factors including myometrial invasion, tumor size lymphovascular invasion and MELF (microcytic elongated fragmented pattern) using Mann Whitney U and Kruskal Wallis tests.

Results

Mean age of the patients was 58±8.5 (38-80). Bcl2 and PAX2 expression decreases significantly in endometrium carcinoma (p<0.01) but is not associated with myometrial invasion, tumor size and lymphovascular invasion (Tables). Bcl2 and PAX2 scores were higher in microcytic elongated fragmented pattern (p=0.05 and p=0.007 respectively).

*LVSI lymphovascular invasion. **MELF: microcytic elongated fragmented pattern

Conclusion
Immunohistochemical evaluation of transcription factors can be useful for establishing prognosis and identification of patients that need adjuvant treatment. Bcl-2 and PAX2 can differentiate carcinoma from normal tissue but further studies are needed.

ENDOMETRIAL CANCER

ESGO7-0937

GENE PROMOTER METHYLATION IN THE DEVELOPMENT FROM NORMAL ENDOMETRIAL CANCER AND ITS RELATION TO K-RAS GENE MUTATION

K. Cornel1, K. Wouters2, K. van de Vijver3, A. van der Wurff4, M. van Engeland5, R. Kruitwagen1, H. Pijneng5

1Maastricht University Medical Center +, Gynaecology & Obstetrics, Maastricht, The Netherlands
2Maastricht University Medical Center +, Pathology, Maastricht, The Netherlands
3Netherlands Cancer Institute, Diagnostic Oncology and Molecular Pathology, Amsterdam, The Netherlands
4Elisabeth Tweesteden Ziekenhuis, Pathology, Tilburg, The Netherlands
5Radboud University Medical Center, Obstetrics and Gynecology, Nijmegen, The Netherlands

Aims

Up to 60% of untreated atypical hyperplastic endometrium will develop into endometrial carcinoma (EC), and for those who underwent a hysterectomy a coexisting EC is found in up to 20%. Gene promoter methylation might be related to the EC development. The aim of this study is to determine changes in gene methylation profiles and K-Ras mutation in normal, atypical hyperplastic endometrium and EC.

Method

A retrospective study was conducted of patients diagnosed with hyperplasia based on endometrial sampling between 1996 and 2011. After hysterectomy promoter methylation was performed for APC, hMLH1, O6-MGMT, P14, P16, RASSF1, RUNX3, SFRP1, CD01 and ER are related to final histological diagnosis. For each case K-Ras mutations were analysed.

Results

A total of 98 cases were analysed. For P16, promoter methylation was significantly increased from 10% in normal endometrium (n=1) and 7.7% in atypical hyperplasia (n=2) to 38% in EC (n=13). hMLH1 methylation gradually increased from 27.3% (n=3) in normal to 36.4% (n=12) in atypical hyperplasia to 38.0% (n=1) in EC. For O6-MGMT methylation it shows 8.3% (n=1), 18.2% (n=6) and 31.4% (n=16) respectively. K-Ras mutation was only observed in 12.1% (n=4) of atypical hyperplasia, and 19.6% (n=10) in EC. No relation between K-Ras mutations and gene promoter methylation was seen.

Conclusion

hMLH1 and O6-MGMT promoter methylation are early events and already seen in atypical endometrial hyperplasia, whereas P16 promoter methylation occurs later and is especially seen in EC. K-Ras mutations are more frequently seen in EC than in atypical hyperplasia.
Aims

Diagnostic potential of the serum levels of HE4 and MMP2 in patients with endometrial cancer and benign endometrial diseases. To assess the relationship between the serum levels of HE4 and MMP2 and the typical prognostic factors in endometrial cancer patients.

Method

Included in the study was a group of 112 patients presenting with bleeding abnormalities at the Pomeranian Medical University in years 2012-2016. Serum HE4 concentrations were measured using the Elecsys ECLIA assay from Roche. MMP2 concentrations were quantified in the serum using multiplex immunoassays (Luminex Corporation, Austin, TX, USA).

Results

The diagnostic potential of HE4 and MMP 2 in differentiation of high (FIGO III i IV) vs. low (FIGO I and II) clinical stage of tumor and prediction of cellular differentiation grade (G1 vs. G3) on the basis of the analysis of the area under the curve is respectively 0.86 and 0.82 for HE4 and 0.82 and 0.74 for MMP2. The HE4 marker was significantly more specific than MMP2 in every study group and amounted to: 93% vs. 86% in all patients included in the analysis, 94% vs. 84% in pre-menopausal patients, and 84% vs. 79% in post-menopausal patients.

Conclusion

HE4 and MMP2 are characterized by high specificity and may be useful as biomarkers in the diagnostics of endometrial cancer. When determined preoperatively, HE4 is correlated with the prognostic factors of endometrial cancer and may be helpful in the planning of individual treatment of endometrial cancer patients.
A CASE OF EXTRA-UTERINE SPREAD IN NONINVASIVE SEROUS PAPILLARY ENDOMETRIAL CARCINOMA ARISING FROM A POLYP

M. Puljiz1, D. Danolic1, I. Alvir1, I. Mamic1, D. Tomic2, L. Susnjara1, K. Cindric4, V. Stepanic2, M. Peric-Balja3

1University Hospital for Tumors - University Hospital Centre Sestre Milosrdnice, Department of Gynecologic Oncology, Zagreb, Croatia
2General Hospital Scheibbs, Department of Gynecology and Obstetrics, Scheibbs, Austria
3University Hospital for Tumors - University Hospital Centre Sestre Milosrdnice, Department of Clinical Pathology, Zagreb, Croatia
4Clinical Hospital Centre Split, Department of Gynecology and Obstetrics, Split, Croatia
5Clinical Hospital Merkur, Department of Gynecology and Obstetrics, Zagreb, Croatia

Aims

To report a case of noninvasive serous papillary endometrial carcinoma with para-aortic lymph node metastases.

Method

A 61 years-old nulliparous woman, with history of breast carcinoma, was admitted to our department for postmenopausal bleeding. Transvaginal ultrasonography was performed and an endometrial thickness of 6 mm was found. She underwent hysteroscopy that showed small endometrial polyp arising from the anterior uterine wall. The endometrial polyp was resected and pathological examination revealed noninvasive serous papillary carcinoma arising from the polyp. The immunohistochemical staining analysis showed negative estrogen and progesterone receptors and strong p53 overexpression. She underwent hysterectomy, bilateral salpingo-oophorectomy, omentectomy and pelvic and para-aortic lymphadenectomy.

Results

The pathological finding revealed atrophic endometrium without lymphovascular space invasion and no omental or pelvic lymph node metastasis. Residual tumor was not found in the endometrium. Para-aortic lymph node metastases were present in 3 of 17 lymph nodes. Six cycles of adjuvant chemotherapy with carboplatin and paclitaxel were given. Patient is receiving radiation therapy.

Conclusion

The present case emphasizes the aggressive behavior of uterine serous papillary carcinoma, along with the need for complete surgical staging including para-aortic lymphadenectomy. Extra-uterine disease spread may frequently occur even with noninvasive disease. The performance of pelvic lymphadenectomy alone represents an incomplete surgical effort resulting in failure to identify patients who may benefit from adjuvant therapy.

⁴Leiden University Medical Center, Human Genetics, Leiden, The Netherlands
⁵Gustave Roussy Cancer Center, Medical Oncology, Villejuif, France
⁶Gustave Roussy Cancer Center, Genetics, Villejuif, France

Aims
High grade endometrial cancer (EC) has a poor prognosis. By assessing the incidence and molecular basis of homologous recombination deficiency (HRD) in EC, we aimed to determine whether EC patients may benefit from treatments that target homologous recombination deficiency.

Method
Fresh tumour tissue of 28 ECs was prospectively collected in the LUMC between 2015-2017 (16 endometrioid (EEC) and 12 non-endometriod endometrial cancers (NEEC). For functional analysis, the ability of replicating tumour cells to form RAD51-foci after ionizing radiation was used as a functional read out for HR-proficiency. Molecular analysis was done by copy number aberration analysis (CNA, genomic instability score, GIS) and sequencing of known HR-genes (BRCA1, BRCA2, ATM, PALB2, BRIP1, RAD51D, RAD51C, BARD1, CHEK2). Immunohistochemical staining was performed to determine p53-status and mismatch-repair deficiency (MMRd).

Results
Functional HR-analysis showed impairment of HR in 39% (n=11) of the 28 ECs. HRD was more frequently observed in NEECs (9/12, 75%) compared to EEC (2/16, 13%, p<0.01). 3 (27%) HRD cases were MMRd and 7 (64%) cases displayed a p53-mutant staining pattern. GIS derived from aCGH data showed concordant outcomes with RAD51-assay in 82%. In three HRD-EC we identified gene mutations that might explain the phenotype (two BRCA1, one BRIP1). TCGA-data showed a BRCA-like profile in 42% (81/192) of NEEC and 8% (33/404) of EEC.

Conclusion
A significant proportion of EC, mainly NEEC, are defective for homologous recombination. Assessment of HR efficacy in EC might allow identification of patients that could benefit from treatments targeting HRD.
Aims

Obesity is strongly associated with endometrial cancer (EC). The levonorgestrel intrauterine system (LNG-IUS) reduces the risk of EC and its precursor lesion, atypical hyperplasia (AH). We assessed the feasibility, acceptability and endometrial impact of the LNG-IUS for primary prevention of EC in obese women.

Method

Morbidly obese women (BMI>40kg/m²) with histologically normal endometrium were recruited to a clinical trial of the LNG-IUS for endometrial protection. Sequential blood and endometrial samples were obtained before and after LNG-IUS insertion. Quality of life and menstrual function questionnaires were completed. Endometrial samples underwent histological assessment and biomarkers of endometrial proliferation (Ki-67, pAKT) and hormone receptor status (ER, PR, AR) quantified by immunohistochemistry. Circulating biomarkers of insulin resistance and reproductive function were measured. Follow up for six months after LNG-IUS insertion will be completed in August 2017.

Results

In total, 25 women received an LNG-IUS. Their median age and BMI were 54 years (IQR 52, 57) and 46.7kg/m² (IQR 43.6, 50.8) respectively. Three women were ineligible due to EC/AH on their baseline biopsy. The LNG-IUS had a positive overall effect on bleeding patterns and quality of life. The LNG-IUS was associated with morphological, Ki-67 and PR expression changes in the endometrium but circulating biomarkers of proliferation and reproductive function were unchanged.

Conclusion

The incidence of occult endometrial neoplasia was high in morbidly obese women screened for participation (9%). The LNG-IUS was well tolerated and all completed patients chose to keep it for ongoing endometrial protection. Use of the LNG-IUS for this indication appears feasible.

SURVIVIN, BCL-2, BAD, BAX AND CASPASE-9 GENE EXPRESSIONS AFTER METFORMIN AND MEDROXYPROGESTERONE ACETATE TREATMENT ON ENDOMETRIAL HYPERPLASIA

E. Şahin1, M. Eraslan Şahin1, M. Dolanbay1, B. Özçelik1, H. Akgün2, Ç. Saatçioi
1Erciyes University, Obstetrics and Gynecology, Kayseri, Turkey
2Erciyes University, Pathology, Kayseri, Turkey
3Erciyes University, Genetics, Kayseri, Turkey

Aims

The aim of study is to determine Survivin, Bcl-2, Bad, Bax and Caspase-9 gene expressions after metformin (M) and medroxyprogesterone acetate (MPA) treatment on endometrial hyperplasia rat model.

Method

Three groups created (E, E+P, E+M). We have applied 4mg/kg 17β Estradiol hemihydrates (E) for 20 days after oophorectomy operation to all groups. In the tenth day of E treatment 50 mg/kg metformin added for E+M group and 1mg/day MPA for E+Progesterone (P) group. Only 4mg/kg 17β estradiol hemihydrates was used for 20 days in group E. Hysterectomies were performed at 20. day of treatment. RNA isolation was performed from tissues for genetic analysis. cDNA was obtained using the reverse transcriptase enzyme. Real time PCR used for detected Survivin, Bcl-2, Caspase-9, Bad and Bax gene mRNA expressions. Endometrial histopathological samples were stained with hematoxylin eosin.

Results

Metformin and progesterone have significant and similar effect on endometrial hyperplasia. Survivin, Bcl-2, Caspase-9, Bad and Bax gene expressions were not statistical significant between the groups (p>0.05). Bcl-2/Bax ratio was significantly decreased in MPA and M group compared to the control group (E) (p: 0.020).

Conclusion

We conclude that metformin and progesterone have significant and similar effect on endometrial hyperplasia. These agents stimulate the apoptotic pathway of the endometrial cells and prevent the tissue from endometrial cancer.
Aims

The aim of the study was to evaluate the effectiveness of combined surgery and brachytherapy for the local recurrences of endometrial cancer after primary surgery.

Method

41 patients with microscopy proven local recurrences of endometrial cancer were treated in years 2010-2015. The treatment of recurrences consisted of adjuvant irradiation of the pelvis (mean dose 46Gy) plus intracavitary brachytherapy HDR with dose 20-25 Gy at 0.5 cm below the surface of the mucosa. Follow-up ranged from 12-60 months (median 18 months). Survival curve was calculated with Kaplan-Meier method. The log-rank test was used to evaluate the influence of the following prognostic factors on survival: clinical stage (Ia, Ib), histological type, grading, time from the completion of primary treatment to the diagnosis of recurrence, and localisation of the relapsing tumor.

Results

The probability of survival of 3 and 5 years was 0.33 and 0.21 respectively. Both analyses prognostic factors – time to the diagnosis and localisation of the recurrence had a statistically significant influence of survival. The risk of death from the disease was significantly higher with extravaginal spread of the tumor and time delay of less than 1 year after completion of primary treatment (p<0.05).

Conclusion

The results of treatment confirmed a very serious prognosis in this particular group of patients, with the use of presently available methods of treatment. Better methods of early detection of relapses and more effective treatment may contribute to the better survival of these high risk patients.
Aims

Aim of this study was to rate the misdiagnosis between preoperative endometrial biopsy, intra-operative frozen section and final pathology in endometrial cancers. Secondary objective was to evaluate whether the failure in preoperative recognition of non-endometrioid endometrial cancers (NE-EC) impacts the surgical planning and the oncological outcomes.

Method

A multicenter retrospective study was conducted in patients with histological diagnosis of endometrial cancer who underwent surgical staging between 2011 and 2016. The concordance rate and the Kappa Cohen coefficient were calculated to assess the correlation between endometrial biopsy or frozen section and final pathology concerning the histological type.

Results

295 patients were enrolled, 226 were endometrioid carcinomas and 61 non-endometrioid at final pathology. The concordance rate between pre-operative and final pathology for NE-EC and the Kappa Cohen coefficient were 83.33% and 0.6203 (IC 95% 0.5004-0.7402), respectively. 24 out of 61 (39.34%) NE-EC were preoperatively misdiagnosed. The frozen section was performed in 86 patients (29.15%). The concordance rate between frozen section and final pathology for NE-EC was 80% and the Kappa Cohen coefficient was 0.391 (IC 95% 0.267-0.456). In patients with non-corresponding and corresponding histology, the surgical procedures were similar, and the 5-year overall survival and the disease free survival were not statistically different, (73% vs. 63.8%; p=0.9) and (32% vs. 65%; p=0.18) respectively.

Conclusion

Pre-operative and intra-operative histotype assessment do not reliably forecast final pathology in endometrial cancers and therefore may not be the optimal determinant for surgical and therapeutic planning. In our study, the failure to identify preoperatively NE-EC did not affect oncological outcomes.
ENDOMETRIAL CANCER

CLINICAL SIGNIFICANCE OF CLASSIFICATION BETWEEN G1 AND G2, IN UTERINE BODY ENDOMETRIOID ADENOCARCINOMA

S. Furukawa¹, H. Iwase¹, Y. Endo¹, T. Tazo¹, H. Sato¹, T. Takada¹, M. Arai¹, T. Onda¹
¹Kitasato University School of Medicine, Obstetrics and Gynecology, Sagamihara, Japan

Aims

Although uterine body endometrioid adenocarcinoma (EMA) is usually classified into three grades by the degree of differentiation; high (G1), intermediate (G2), and low (G3), recommended management for G2 is the same as G1 in both Japanese and ESGO Guidelines. The aim of this study is to evaluate the necessity to distinguish G2 from G1 in EMA.

Method

We retrospectively reviewed medical records of 365 patients with EMA (G1: 281, G2: 84) treated at our hospital from 2005 to 2013. Clinicopathological features and prognosis were analyzed.

Results

Median age of G1/G2 patients was 55/59 years-old, and stage distribution was 235/15/30/1 and 55/10/17/2 in stage I/II/III/IV (FIGO 2008), respectively. G2 patients had higher risk for recurrence (high risk in Japanese Guideline or high/advanced/metastatic in ESGO Guideline) (34.5% vs. 16.4%, p=0.0006), and thus underwent adjuvant treatment more frequently (58.3% vs. 35.9%, p=0.0004) compared to G1. The median follow-up period of all patients was 61 months. Overall survival (OS) in G2 was significantly worse than G1 (p=0.0086, 5Y-OS: 89.9% vs. 97.1%). Among the pathological risk factors, significant differences in frequency between G2 and G1 were observed in deep muscular invasion (>1/2), lymphovascular space invasion, cervical involvement, and lymph node metastasis. On multivariate analysis, positive peritoneal cytology and to be high-risk for recurrence were the only independent predictors of unfavorable OS.

Conclusion

Although G2 had poor prognosis compared to G1, the grade itself may not be the cause of worse prognosis. We could not find the reason to distinguish G2 from G1 in management.
ENDOMETRIAL CANCER

ACCURACY OF 2D AND 3D ULTRASOUND IMAGING IN THE ANATOMICAL EVALUATION OF TUMOR INVASION IN ENDOMETRIAL CANCER

L. Fusco1, V. Facelli2, L. Ottino3, L. Mariani3, G. De Rosa4, G. Menato3, A. Ferrero3

1ASO Mauriziano, Gynecology Obstetrics, Torino, Italy
2ASO Mauriziano, Gynecology and Obstetrics, Torino, Italy
3ASO Mauriziano, Gynecology and Obstetrics, Torino, Italy
4ASO Mauriziano, ASO Mauriziano, Torino, Italy

Aims

Prognosis in early stages endometrial cancer depends on histological type and grading, depth of myometrial invasion, cervical involvement and lymph-node metastases. Prognostic factors are acquired by surgical staging with hysterectomy and bilateral salpingo-oophorectomy. Pelvic and para-aortic lymphadenectomy are recommended for patients at risk for lymphatic dissemination on the basis of intraoperative findings, in particular the depth of myometrial invasion. Performing a lymphadenectomy has specific risks such as lymphedema, lymphocele or urinary complications. Thus the need of performing lymphadenectomy only when strictly necessary.

To evaluate if the use of a standardized diagnostic protocol adopting 2D and 3D ultrasound imaging could improve the accuracy of intraoperative frozen section of the uterine sampling detecting the depth of myometrial invasion

Method

2D ultrasound and frozen section performance was prospectively evaluated on 50 consecutive patients diagnosed with endometrial cancer (tumor dimension, depth of myometrial invasion and tumor free margin) Then 2D - 3D US examination performed by a gynecologic oncologist with expertise in ultrasounds was applied in a protocol designed to guide the anatomopathologist to the best cut on frozen section. This procedure aimed to improve the sensitivity and specificity of the pre and intraoperative examination

Results

A preoperative standardised protocol adopting 2D-3D US giving accurate information on anatomical localization of the tumour to anatomopathologist results in improving the performance of the intraoperative frozen section (sensitivity from 67% to 100%, specificity 93% to 100%, PPV from 83% to 100%, VPN from 83% to 100%).

Conclusion

This leads to a better management of patients with endometrial cancer.
ENDOMETRIAL CANCER

ESGO7-1297

ENDOMETRIAL CANCER: IS THERE A BETTER WAY TO EVALUATE MYOMETRIAL INVASION WITH TVUS 2D?
L. Fusco1, L. Ottino1, V. Liberale1, L. Mariani1, A. Ferrero1, G. Menato1, N. Biglia1
1ASO Mauriziano, Gynecology Obstetrics, Torino, Italy

Aims

To compare the diagnostic performance of four different TVUS 2D methods to study the myometrial invasion in endometrial cancer.

Method

This prospective single Institution study was performed on 42 endometrial cancer patients between Jan/2015 and Dec/2016. Myometrial invasion (<50% vs > or = 50%) was estimated in each patient, using four TVUS 2D different methods: IETA d/D, subjective assessment, endometrial thickness (considered positive if > or = 18 mm) and myometrial-endometrial junction (considered positive if interrupted or not defined). The concordance between the TVUS 2D and pathological findings has been calculated and reported as sensitivity, specificity, PPV, NPV and k Cohen’s.

Results

Median age was 66 years, 38 patients had EC, 4 had NEC; 13/42 patients had myometrial invasion > or = 50% at histopathology. The results are shown in Table 1.

Table 1: sensitivity, specificity, PPV, NPV and k Cohen’s of four different TVUS 2D methods

<table>
<thead>
<tr>
<th>Method</th>

<td>57% (0.31-0.83)</td>
<td>88% (0.73-1)</td>
<td>0.46 (0.19-0.72)</td>
</tr>
</tbody>
</table>

Conclusion

The evaluation of the myometrial-endometrial junction interruption has shown the best diagnostic performance and could be an interesting modality to foresee the depth of myometrial invasion. The study is ongoing to increase the sample size and to substantiate this preliminary observation.
ENDOMETRIAL CANCER

ESGO7-0189

ENDOMETRIAL CARCINOMA IN A SINGLE HORN OF A BICORNUATE UTERUS: A CASE REPORT

K. M. Gaballa¹, C. Cicero², V. Gallotta², G. Zannoni³, G. Scambia²

¹Oncology Center Mansoura University, Surgical oncology, Mansoura, Egypt
²Largo Agostino Gemelli, Gynecologic Oncology, Rome, Italy
³Largo Agostino Gemelli, Human Pathology, Rome, Italy

Aims

In the presence of bicornuate uterus, a bilateral endometrial biopsy should be performed in order to reduce the risk of delayed or missed diagnosis.

The possibility of existence of a separate uterine cavity should always be considered when endometrial cancer is clinically suspected but pathology fails to confirm the diagnosis.

Method

we discuss the diagnosis and the management of endometrial carcinoma in a single horn of bicornuate uterus in a 64 years old woman as a case report

Results

The gross examination of the uterus revealed a bicornuate uterus with a greater horn of 12x9x8 cm and a smaller horn of 10x3 cm (Figure 2). The cavity of the greater horn showed a neoplastic growth of 10 cm with infiltration of about 1.8 cm of the myometrium from whole thickness of thickness of 1.9 cm. while the other horn was free of tumor tissue

The microscopic examination of the uterus revealed G2 endometrioid adenocarcinoma of the endometrium of the greater horn with infiltration of more than 50% of the myometrium.

Conclusion

The management of a case of bicornuate unicollis uterus with endometrial carcinoma in only one horn is the same as patients with endometrial cancer in single uterus and depends mainly on stage and histological grade of the tumor.

The possibility of existence of a separate uterine cavity should always be considered when endometrial cancer is clinically suspected but pathology fails to confirm the diagnosis. This points out the importance of a careful physical examination and radiographic evaluation in such cases.
FERTILITY-PRESERVING MANAGEMENT OF EARLY STAGE ENDOMETRIAL CANCER: ONCOLOGICAL AND REPRODUCTIVE OUTCOME

P. Gatsingha1, R.P. Namuduri2, Y.K. Lim2, I. Aggarwal2, W.L. Wong2, K.L.P. Yarr2

1Duke-NUS Medical School, School of medicine, Singapore, Singapore
2KK Women and Children’s Hospital, Gynaecological Oncology, Singapore, Singapore

Aims

Assess efficacy of progestins as fertility-sparing treatment of early endometrial cancer and to evaluate the oncological and reproductive outcome in a South East Asian population.

Method

This is a retrospective cohort study in a large tertiary institution in Singapore. We identified women below 40 years, with clinically presumed stage IA grade 1 and selected grade 2 endometrial cancer (The two patients were keen to try fertility preservation treatment and were adequately counseled) who were offered progestin therapy for fertility-sparing management at our center between 2010 and 2015. We retrieved their medical record and ran analyses for association of patient characteristics with treatment outcome.

Results

Forty-three patients with grade 1 tumors and two patients with grade 2 tumors were identified. Fourteen were either lost to follow up, sought treatment elsewhere, or requested for definitive treatment. Thirty-one were included in the analysis. Twenty-one (67%) achieved complete remission at median time of 5 months (2-25). Nine patients (29%) did not respond to treatment and underwent hysterectomy (median time: 9 months). Both patients with grade 2 tumors achieved remission. The overall probability of remission increases steeply for the first 9 months, then plateaus and gradually increases after 15 months. Three patients had subsequent pregnancies. Ten patients (45%) patients recurred at a median time of 17 months (6-64) after remission. Morbidly high BMI was associated with increased recurrence risk (p<0.05).

Conclusion

With aggressive monitoring, high dose progestin appears to be a safe therapy for early endometrial adenocarcinoma in women 40 years old or younger wishing to preserve fertility.
MOLECULAR AND CLINICOPATHOLOGICAL CLASSIFICATION OF HIGH RISK ENDOMETRIAL CANCER (EC) TREATED WITH CONCURRENT CHEMORADIATION THERAPY (CCT)

5Instituto Regional de Enfermedades Neoplásicas del Sur IREN SUR, Medical Oncology, Arequipa, Peru
6Institut Català d’Oncologia-Hospital Duran i Reynals. IDIBELL, Medical Oncology, L’Hospitalet de Llobregat-Barcelona, Spain
7Institut Català d’Oncologia. IDIBELL. CIBERESP, Unit of Biomarkers and Susceptibility- Cancer Prevention and Control Program, L’Hospitalet de Llobregat-Barcelona, Spain
8Institut Català d’Oncologia. IDIBELL, Clinical investigation Unit, L’Hospitalet de Llobregat-Barcelona, Spain
9Institut Català d’Oncologia-Hospital Duran i Reynals. IDIBELL, Radiation Oncology, L’Hospitalet de Llobregat-Barcelona, Spain

Aims

To evaluate the outcome of high risk EC treated with CCT and its correlation with a surrogated molecular classification.

Method

Forty-nine patients (pts) treated from 2011 to 2016 were included in a prospective database. Pts were treated with cisplatin with pelvic external beam radiotherapy (RT), plus brachytherapy; followed by paclitaxel and carboplatin. The molecular classification into the 4 TCGA groups (POLE mut, MSI, CN-low, CN-high/serous-like) was performed in 38 pts using a surrogate classification: POLE mutations (detected by Sanger), and immunohistochemistry for p53 and MMR (as surrogate markers for TP53 mutations and MSI).

Results

Pts median age was 67yo; Endometrioid pathology in 59%, serous 20%; up to 73% grade 3; and FIGO Stage III in 82%. With a median follow-up of 39 months, 30% of pts experienced metastatic relapse. 3-year overall survival (OS) was 80%, and 3-year progression free survival was 74%.

Pts were molecularly classified as: 0% POLE mut, 13% CN-low, 37% MSI and 50% CN-high. CN-low present an 3-y OS of 100%, MSI of 82% and CN-high of 67%. No statistically significant differences were found (low number of events and pts). It is remarkable the survival difference between endometrioid and serous tumors in the CN-high group (86% vs 50%, respectively).

Conclusion

CCT followed by CT is an effective adjuvant therapy in high risk EC pts with an acceptable toxicity. Molecular prognostic classification has shown a big proportion of patients in MSI and CN-high groups, with known worse prognosis. Morphologic differentiation between endometrioid and serous carcinomas in CN-high hold prognostic implications.

ROBOT-ASSISTED MANAGEMENT OF APPARENT EARLY-STAGE ENDOMETRIAL CANCER: THE BELGIAN EXPERIENCE
J. Pinckers¹, C. Ver Eecke², K. Tran³, P. Van Trappen⁴, F. Peeters⁵, E. Despierre⁵, I. Vergote², F. Goffin¹
¹Hôpital de la Citadelle, Department of Obstetrics and Gynecology, Liege, Belgium
²University Hospitals Leuven, Department of Obstetrics and Gynecology, Leuven, Belgium
³Onze-Lieve-Vrouweziekenhuis, Department of Obstetrics and Gynecology, Aalst, Belgium
⁴AZ Sint-Jan Hospital, Department of Obstetrics and, Bruges, Belgium
⁵AZ Klina, Department of Obstetrics and Gynecology, Brasschaat, Belgium

Aims

We report the Belgian experience of endometrial cancer management with robotic-assisted laparoscopy.

Method

A retrospective, multicenter, descriptive study including patients with presumed early stage endometrial cancer surgically treated by robot-assisted laparoscopy between 2007 and 2016. All patients were treated according to local policies and had a total hysterectomy with bilateral salpingo-oophorectomy with or without lymph node dissection. Operative and postoperative variables were measured to assess the feasibility and safety of the procedure. Follow-up data and oncological outcomes were collected.

Results

Four hundred sixty-five patients were included. The median age was 68 years and the median BMI was 30 kg/m². Histology types were endometrioid (78%), serous (11%), carcinosarcoma (3%), mixed (6%) and mucinous (1%). Nodal staging was performed in 274 patients (58%). The median nodal counts were 21 for pelvic and 10 for para-aortic areas. The median estimated blood loss was 75 ml. Median operative times were 170 min (skin to skin) and 122 min (console time). We report 3 conversions to laparotomy (0.6%). Sixteen % of the patients developed at least one post-operative complication graded according to Clavien (Clavien I-II: 17%, Clavien III: 4.7%, Clavien IV-V: 0.8%). There was one perioperative death (necrotizing fasciitis). The median hospital stay was 3 days. After a median follow-up of 21 months, the disease-free survival was 88.8%.

Conclusion

This large series supports the feasibility and safety of robotic surgery in apparent early stage endometrial cancer patients. The low complication and conversion rates associated with the favorable oncological outcomes support its use in this indication.
Aims

A third of woman died for endometrial cancer were initially considered with low risk for relapse. This implies clinical classification as type I and type II is sub-optimal. Hence, more improved means are needed, to precisely identify high-risk patients from low-risk ones. Many studies associated the negativity of estrogen receptor (ER) and progesterone receptor (PR) with poor survival in endometrial carcinoma. However, their roles in low-risk endometrial cancer are unclear. This study was to investigate the prognostic value of double negative ER and PR (ER/PR loss) in low-grade endometriod endometrial adenocarcinoma (EEA).

Method

ER and PR expression were assessed by immunohistochemical staining on formalin-fixed paraffin-embedded tumor samples for 903 patients with grade I-II EEA. ER and PR negativity were determined if none of tumor cell nuclei was stained. The results were correlated with clinicopathologic parameters and survivals.

Results

Thirty-five of 903 patients were confirmed with ER/PR loss. They had deeper myometrial infiltration ($P=0.006$), severer FIGO stage ($P=0.005$), and higher rate for pelvic lymph node metastasis ($P=0.016$), vascular invasion ($P=0.015$) and relapse ($P=0.001$), when compared with other 868 of 903 patients who had positive ER and/or PR. In univariate analysis, ER/PR loss was associated with a shorter progression-free survival (PFS, $P=0.0002$) and overall survival (OS, $P=0.0003$). ER/PR loss also predicted poor PFS (HR=4.04, $P=0.003$) and OS (HR=5.56, $P=0.016$) in multivariate analysis.

Conclusion

In low-grade EEA, ER/PR loss seemed to correlate with a more aggressive subtype with poorer survivals. Implementing ER/PR evaluation into clinical algorithms may improve the risk stratification for tailored therapeutic strategy.
Aims

There is a host immune response to the tumor cells by tumor infiltrating lymphocytes (TILs). These cells infiltrate many solid tumors like in melanoma or lung cancer, with different prognosis impact and development of new therapies. The aim of this study was to describe the TILs in endometrial cancer (EC) from a quantitative and functional point of view.

Method

We studied a prospective cohort of patients with endometrial cancer. All FIGO stage and histological type were included. Tumoral and normal endometrium was sampled from surgical hysterectomy, prior to any treatment. A peripheral blood was also obtained for each patient and mononuclear cells were extracted (PBMC). All samples were analyzed in flow cytometry.

Results

The CD45+ cells infiltrate significantly higher tumor tissue than in normal endometrium (p=0.0195). The tumor immune microenvironment presents more Treg cells (p=0.002), but less Natural Killer (NK) cells (p<0.001) than normal endometrium. In comparison to PBMC from the same patients, TILS have a different activation profile with higher PD1, TIM3 and OX40 surface expression.

Conclusion

Our study highlights more TILs in EC than in normal endometrial tissue. In term of functional activity, the immune response of TILs against tumor cells appears to decrease. An inversion of the TILs function, by immunotherapy, could be a new treatment for EC.
ENDOMETRIAL CANCER

ENDOTHELIAL PROGENITOR CELLS (EPCs) AND CIRCULATING ENDOTHELIAL CELLS (CECs) IN PERIPHERAL BLOOD OF WOMEN WITH ENDOMETRIAL CANCER

A. Czekański¹,², M. Paprocka², A. Kantor³, A. Bielawska-Pohl⁴, P. Lepka¹,², M. Jedryka¹,²

¹Lower Silesian Cancer Center, Oncological Gynaecology, Wrocław, Poland
²Wroclaw Medical University, Oncology, Wrocław, Poland
³Polish Academy of Sciences, Institute of Immunology and Experimental Therapy, Wrocław, Poland

Aims

To analyze the number of endothelial progenitor cells (EPCs) and circulating endothelial cells (CECs) – as potential new markers of neoangiogenesis – in peripheral blood from endometrial carcinoma patients regarding the stage and grade of the malignancy.

Method

We studied 30 patients with endometrial cancer compared to control group of 28 women with non malignant diseases. The blood samples were taken perioperatively and labeled with monoclonal antibodies: anti CD31, anti CD45 for CECs and anti CD34, anti VEGFR2/KDR for EPCs. After incubation with fluorescent CytoCount beads all samples were calculated by flow cytometry. Analysis was supported by CellQuest software with the use of debris gates.

Results

The CECs numbers (CD31⁺, CD45⁻) were similar in both groups but EPCs numbers (CD34⁺, VEGFR2/KDR⁺) in the peripheral blood of women with endometrial carcinoma were significantly augmented as compared with those of control healthy women (Fig. 1). When patients were divided, according the grading, into G1 and G2 groups it appeared that augmented EPC numbers may be demonstrated only in G1 stage patients (Fig.2). When patients were divided, according to the stage into FIGO I and FIGO II groups difference in EPC number was found in patients with FIGO I (Fig.3).

Conclusion

We demonstrated that the general number of EPCs is significantly increased in peripheral blood from women with endometrial cancer what may be related with tumor neoangiogenesis. However we could not show such result referring to CECs and the correlation with tumor stage and grade. Further studies could clarify the subject.
PELVIC LYMPHADENECTOMY IN THE MANAGEMENT OF ENDOMETRIAL CANCER: A SERVICE REVIEW OF WALES’ LARGEST TERTIARY CENTRE

R. Jones1, M. Awad1, F. Drews1, E. Rzyska2, R. Howells1, K. Lim1, A. Sharma2
1University Hospital of Wales, Gynaecological Oncology, Cardiff, United Kingdom
2University Hospital of Wales, Obstetrics & Gynaecology, Cardiff, United Kingdom

Aims

The 2015 Cochrane review which concluded the role of Pelvic lymphadenectomy (PLA) in intermediate & high risk early stage endometrial cancer (EC) is unclear means PLA in the management of endometrial cancer remains controversial. Standard practice includes external beam radiotherapy (EBRT) +/- brachytherapy (BT) in these cases. The South East Wales Gynaecological Oncology Centre (SEWGOC) guidelines include PLA for high risk EC, avoiding EBRT if nodes negative. Our aim was to undertake a service evaluation of PLA in high risk EC patients and whether EBRT was avoided in node negative patients.

Method

We conducted a retrospective review of patients referred to the SEWGOC whose treatment included surgery from 01/04/2013-31/03/2015 with SEWGOC guidelines on patient selection for PLA as the standard.

Results

292 patients had surgery for EC, 123 had PLA indicated, 113 underwent PLA. 2 year disease free survival was 76% with 2 year mortality 15%.

Post-operatively 77 patients had ≤ stage 2 disease and 36 ≥ stage 3 disease. Following PLA, 16 patients were up-staged & 9 were down-staged altering their management accordingly.

After PLA, 68 patients were intermediate/high risk of recurrence; 7 received EBRT & BT, 59 BT alone & 2 were not fit for adjuvant therapy. In the follow-up period there were no recurrences in the EBRT & BT group, 6 in the BT group & 1 in the patients who were unfit for adjuvant treatment group.

Conclusion

Adherence to the local SEWGOC guidelines is high and 90% of patients avoided EBRT as a result of having PLA.

6Aalborg University Hospital, Institute of Pathology, Aalborg, Denmark
7Aalborg University, Department of Health Science and Technology, Aalborg, Denmark
8Aalborg University Hospital, Department of Cardiology and Epidemiology/Biostatistics, Aalborg, Denmark

Aims

To estimate the risk of venous thromboembolism (VTE) in uterine cancer considering possible risk factors. We aim to clarify if minimally invasive surgery (MIS) is correlated with a lower risk of VTE compared to open surgery which thromboprophylactic recommendations are mainly based on.

Method

In a registry based nationwide cohort study data on patients with uterine cancer was retrieved from the nationwide Danish Gynaecological Cancer Database (DGCD). Data on VTE was extracted from the Danish National Patient Register. The National Population Register and the National Causes of Death Register hold information on vital status, date of birth and death including cause of death.

Time to VTE was examined with cox proportional hazard models.

Results

We identified 7,067 patients with uterine cancer in DGCD diagnosed in the period 2005-2014.

Focusing on patients undergoing surgical treatment for uterine cancer (n=6330) we found a 30-day VTE incidence of 0.49% with open surgery (23/4651) and 0.48% (8/1679) with MIS (P=0.918). In a multivariable cox regression model we identified advanced disease and previous VTE as significant predictors of 30-day VTE risk. The 30-day hazard ratio for VTE following MIS did not show any significant difference compared to open surgery (HR 0.92, CI 0.41-2.05, P= 0.833).

Conclusion

The 30-day incidence of venous thromboembolism after surgery for uterine cancer was low overall (0.49%) and there was no difference in hazard ratios between MIS and open surgery.

SURGICAL OUTCOME OF FLUORESCENT IMAGE GUIDED SENTINEL LYMPH NODE (SLN) DISSECTION WITH INDOCYANINE GREEN (ICG) IN ENDOMETRIAL CANCER PATIENTS

S.W. Kim¹, Y.N. Kim¹, Y.J. Lee¹, S.H. Park¹, Y.S. Chung¹, K.J. Eoh¹, J.Y. Lee¹, E.J. Nam¹, S. Kim¹, Y.T. Kim¹
¹Yonsei University College of Medicine, Women's Cancer Center- Yonsei Cancer Center, Seoul, Republic of Korea

Aims

The purpose of this study was to review the current performance of sentinel lymph node biopsy (SLNB) in terms of success rate, bilateral detection rate, location, and number of nodes per level. Through subgroup analyses of node positive patients, the clinical pre-operative risk factors that warrant full lymphadenectomy are outlined.

Method

We performed a retrospective review of 112 endometrial cancer patients who underwent laparoscopic or robotic lymphadenectomy after fluorescent SLNB with ICG from May 2014 to March 2017.

Results

SLN detection rate was 94.6% (106/112 patients) and bilateral detection rate was 74.6% (88/112 patients). The median number of harvested SLN was 5 (ranging from 1 to 24) and harvested total lymph node was 20 (ranging from 1 to 94). SLN metastasis was found in 6.25% (7/112 patients). Out of seven patients who were positive for SLN metastasis (3 with SLN only, 4 with both SLN and non-SLN metastasis), one patient 0.94% (1/106) had isolated non-SLN metastasis in para-aortic lymph node. This patient had serous carcinoma, r/o carcinosarcoma with >5cm tumor size and suspicious para-aortic lymph node on PET-CT. There was no pelvic non-SLN metastasis. Percentage of metastatic node of all harvested node was 1.86% (12/645) for SLN and 0.73% (16/2220) of non-SLN. Sensitivity for SLN detection was 87.5% and negative predictive value was 99.1%.

Conclusion

SLN detection with ICG was feasible and useful for its high specificity and negative predictive value. However, in high risk endometrial cancer patients, full lymphadenectomy should be done.
ENDOMETRIAL CANCER

ESG07-1212

THE MSKCC NOMOGRAM IS MORE ACCURATE IN THE PREDICTION OF OVERALL SURVIVAL IN A GERMAN ENDOMETRIAL CANCER PATIENT POPULATION THAN THE FIGO STAGING SYSTEM.

A. Huss¹, A. Hasenburg², M. Oehler³, M. Klar¹

¹University Clinic of Freiburg, Obstetrics and Gynecology, Freiburg, Germany
²University Clinic of Mainz, Obstetrics and Gynaecology, Mainz, Germany
³University of Adelaide, Gynaecological Oncology, Adelaide, Australia

Aims

Nomograms have shown better discrimination and calibration values to predict overall survival (OS) compared to conventional staging systems for a number of tumours. We tested the Memorial Sloan Kettering Cancer Center (MSKCC) nomogram for the prediction of OS in endometrial cancer (EC) patients in our patient cancer population.

Method

493 (322 type I and 171 type II) EC patients who received primary surgical treatment at the Universitaetsfrauenklinik Freiburg between 1991 and 2011 were included and a dataset of 50 covariates was created. Cox regression analyses were performed to identify independent predictors of survival. Predicted survival was calculated using the nomogram calculator on https://www.mskcc.org/nomograms. Receiver operating characteristic (ROC) curves were created for the FIGO 1988, FIGO 2009 staging classification and for the MSKCC 1, 3 and 5 year-survival prediction models. The calculated area under the curve (AUC) values of predicted versus actual OS were compared.

Results

After a mean follow-up time of 100 months, 232 patients were reported dead (47 %). Independent predictors of survival in our population of EC patients were FIGO stage (1988 and 2009), positive cytology and positive resection margins (p < .01). The AUC values of the ROC curves were 0.66 (FIGO 1988), 0.64 (FIGO 2009), 0.79 (predicted 1-year OS), 0.79 (predicted 3-year OS) and 0.8 (predicted 5-year OS).

Conclusion

In this external validation, the FIGO classification showed a moderate and the MSKCC models showed a good accuracy in predicting OS in endometrial cancer patients. The MSKCC nomogram may be useful for a better patient stratification in clinical trials.
L1CAM AS RISK FACTOR FOR RECURRENCE IN STAGE I ENDOMETRIAL CANCER PATIENTS

J. Klat1, A. Mladenka1, O. Simetka1, J. Dvorackova2

1University hospital Ostrava, Ob/Gyn, Ostrava, Czech Republic
2University Hospital Ostrava, Dept. of Pathology, Ostrava, Czech Republic

Aims

Endometrial cancer is the most common gynecologic cancer in developed countries and the second most common gynecologic cancer worldwide. From clinical and epidemiological studies, a dualistic classification of endometrial cancers was proposed, namely type I and type II tumors, which have different patterns of molecular alterations that underlie their pathogenesis and clinical outcome. In general, prognosis of early-stage type I endometrial cancer is excellent, with a 10-year overall survival rate exceeding 80%. L1 cell adhesion molecule (L1CAM) expression has been implicated as risk factor for disease recurrence and risk of death in endometrial cancer type I.

Method

We conducted a retrospective single center study to determine expression of L1CAM by immunohistochemistry in 273 FIGO stage I endometrial cancer patients. All tumor specimens were endometroid adenocarcinoma.

Results

Total number of 273 patients with endometroid adenocarcinomas were included in the study. 84 women (30.8%) were rated as L1CAM-positive and 189 women (69.2%) were related a L1CAM-negative. Of these L1CAM-positive cancer patients 11.9% recurred during follow-up compared with 4.23% L1CAM-negative cancers (p-value = 0.03632).

Conclusion

L1CAM has been shown to be strong prognostic factor in FIGO stage I endometrial adenocarcinoma for disease recurrence.
NOVEL ALGORITHM FOR DIAGNOSIS OF ENDOMETRIAL CANCER

T. Knific¹, J. Osredkar², Š. Smrkolj³, I. Tonin³, K. Vouk⁴, A. Blejec⁴, S. Frković Grazio⁵, T. Lanišnik Rižner¹

⁵Department of Pathology, Division of Obstetrics and Gynecology, University Medical Centre, Ljubljana, Slovenia

Aims

To evaluate the diagnostic and prognostic potential of preoperative serum levels of CA-125 and HE4 in endometrial cancer patients and control group of patients.

Method

Prospective case-control study of 133 women that underwent surgical treatment at the University Medical Centre Ljubljana (64 endometrial cancer patients, 69 control patients with prolapsed uterus or myoma). Serum levels of CA-125 and HE4 were determined with electrochemiluminescent specific assays.

Results

Concentrations of CA-125 and HE4 were significantly increased in case compared to control groups with p values of 2.67×10⁻⁴ and 1.36×10⁻⁷, respectively. With logistic regression analysis we built a diagnostic model that combines CA-125, HE4 and BMI with an AUC of 0.804, sensitivity of 66.7% and specificity of 84.6%. Serum levels of HE4 significantly differed when patients were stratified according to presence/absence of deep myometrial invasion (p = 3.39×10⁻⁴). The median values of HE4 were higher in patients with lymphovascular invasion (p = 0.06) but this difference was not significant.

Conclusion

A model including preoperative levels of CA-125, HE4 and BMI has good diagnostic characteristics, while serum levels of HE4 have prognostic potential to stratify patients according to myometrial and lymphovascular invasion.
Aims

Since 66.8% of patients with leiomyosarcoma (LMS) receive an inadequate surgery, the development of a preoperative LMS-risk-score is an imperative.

Method

We calculated the LMS-risk in presumed LM by a logistic regression model for a binary response variable based on clinical findings from 670 LM and 231 LMS from the German Clinical Competence Centre for Genital Sarcomas and Mixed Tumours and cooperating departments.

Results

Table 1. LMS-risk-points calculated by a logistic regression model

ESGO7-0600

EVALUATION AND SELECTION OF QUALITY INDICATORS FOR THE MANAGEMENT OF ENDOMETRIAL CANCER

M. Koskas¹, L. Chenoz², J. Phelippeau¹
¹Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France

Aims

To evaluate 36 quality indicators (QI) for monitoring the quality of care of uterine cancer to be implemented in the EFFECT (EFFectiveness of Endometrial Cancer Treatment) project.

Method

The 36 QI were evaluated in the first ten patients diagnosed with endometrial cancer and managed in fourteen French hospitals in 2011. To assess the status of each QI, a questionnaire detailing the 36 QI was sent to each hospital, and the information was cross-checked with information from the multidisciplinary staff meeting, surgical and pathological reports. The QI were evaluated in terms of measurability and improvability. The remaining QI were evaluated with a multiple correspondence analysis (MCA) to highlight the interrelationships between qualitative variables describing a population.

Results

Thirteen of the 14 institutions responded to the survey for a total of 130 patients. Twenty-five of the 36 QI affected less than 80% of the patients. Thirteen QI were found not to be improvable because they reached >95% of the theoretical target. Finally, five QI concerning more than 80% of the patients were found to be improvable. The MCA finally identified three dimensions—outcome, safety and perioperative management—that included the five QI.

Conclusion

In the present study, five of the 36 QI suggested by the EFFECT project appear to be sufficient to report on the quality of endometrial cancer management. Further studies are needed to correlate the information provided by those five questions and the relevant outcomes reflecting quality of care in endometrial cancer.

ESGO7-0935

OVARIAN PROTECTION AND FERTILITY PRESERVATION IN WOMEN WITH CANCER: A FRENCH REGISTRY ANALYSIS BETWEEN 2005 AND 2014.

M. Koskas\textsuperscript{1}, J. Phelippeau\textsuperscript{1}
\textsuperscript{1}Hôpital Bichat-Claude Bernard, Gynecology, PARIS, France

Aims

The aim of the study was to describe the practices concerning ovarian protection and fertility preservation in young women treated for cancer over the last decade in France.

Method

The study population comprised women between 15 and 49 years old diagnosed with cancer between 2005 and 2014 abstracted from the Echantillon Généraliste des Bénéficiaires database, a 1/97th random sample of the French population covered by the national healthcare insurance system. To assess practices concerning ovarian protection, gonadotropin-releasing hormone (GnRH) agonists consumption and ovarian transposition were analyzed. For fertility preservation, GnRH agonists consumption, ovarian cryopreservation and oocyte cryopreservation within 6 months after cancer treatment were analyzed. Explanatory variables were analyzed using a multilevel model.

Results

2447 women were identified. Among the 553 patients exposed to ovarian failure, 74 (13%) had ovarian protection (67 received GnRH agonists and 7 underwent ovarian transposition). Among the 227 women exposed to fertility alteration, 53 (23%) had fertility preservation (37 received GnRH agonists and 16 had ovarian or oocyte cryopreservation). Factors associated with ovarian protection were the age under 40 years old, diagnosis of breast cancer and the type of health institution. Fertility preservation was more frequently performed in patients with breast cancer. The five years probability of pregnancy was 3.8\% and 9.8\% (p=0.26) for women with fertility preservation and without fertility preservation respectively.

Conclusion

Over the last decade, ovarian protection and fertility preservation concerned respectively 13\% and 23\% of French women treated for cancer (mainly breast cancer).

LAPAROSCOPIC SURGERY FOR LOW, INTERMEDIATE AND HIGH-RISK ENDOMETRIAL CANCER: A RETROSPECTIVE ANALYSIS OF LONG-TERM OUTCOMES

M.A. VARDAR1, U. KUCUKGOZ GULEC1, A.B. GUZEL1, D. GUMURDULU3, G. SEYDAOGLU2, G. KHATIB1

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
2Cukurova University School of Medicine, Pathology, Adana, Turkey
3Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

The aim of the present study was to compare the long-term outcomes of laparoscopic and laparotomic surgeries and to evaluate the results according to low, intermediate, and high-risk groups of endometrial cancer.

Method

Data of endometrial cancers were collected retrospectively from a single gynecologic oncology department between the January 2005 and January 2016. Patients were divided into 2 groups as laparotomic surgery (group 1, n=515) and laparoscopic surgery (group 2, n=286) groups. Patients’ demographics, clinical characteristics such as stage, grade, histopathologic type, lymphovascular space invasion (LVSI), myometrial invasion, lymph node involvement, and risk groups, peri- and post-operative outcomes, and survival outcomes were compared between the groups.

Results

The demographic characteristics of both groups were similar except age. Shorter hospital stay and fewer complications were observed in group 2. The overall survival (OS) was similar in the low and intermediate risk groups but higher in the high-risk patients for laparoscopy compared to laparotomy. The covariate analysis revealed that the death and recurrence risks were approximately twice higher in the laparotomy group than in the laparoscopy group (OR: 1.9, 95%CI: 1.2-3.1 for overall survival; OR: 2, 95%CI: 1.2-3.3 for disease-free survival). Age, stage, histopathological type, and operation type were determined as independent prognostic factors in the multivariate analysis for both of DFS and OS.

Conclusion

The results of our study support the well known positive aspects of laparoscopy as well as safe and effective use in cases of intermediate and high risk endometrial cancer.

ESGO7-0218

IS IT REALLY UTERINE GRADE 3 ENDOMETRIOID ADENOCARCINOMA AND CARCINOSARCOMA CLINICALLY SIMILAR?

U. Kucukgoz Gulec, S. Paydas, A.B. Guzel, G. Khatib, D. Gumurdulu, M.A. Vardar

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
2Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
3Cukurova University School of Medicine, Pathology, Adana, Turkey

Aims

Was to compare the clinical characteristics and outcomes of the cases with uterine high grade (grade 3) endometrioid adenocarcinoma (HGEAC) and uterine carcinosarcoma (CS).

Method

A total of 141 patients recruited from the Gynecologic Oncology Unit of Cukurova University, Faculty of Medicine were included in this study; 61 cases with uterine HGEAC (group 1) and 80 cases with CS (group 2) followed between January 1996-2016. Clinical and pathological characteristics including age, stage, initial symptom, operation type, myometrial invasion, lymphovascular invasion, lymph node invasion, adjuvant therapy and survival were compared between the groups.

Results

There are no statistically significant differences between the groups according to age, nulliparity, menopausal status, medical history of patients, family history of cancer, complication rate. PPALND was performed 85% of the group 2 and 67% of the group 1 (p<0.001). Stage, myometrial invasion degree, lymph node metastasis were similar between the groups. Lymphovascular space invasion was more present in group 1 than group 2 (p=0.032). But positive cytology was more common in group 2 (p=0.008). Adjuvant RT was given more in group 1 (p=0.001) and KT was applied more in group 2 than 1 (p=0.008). There is no difference between the group according to DFS (p=0.316) but OS was found better in group 1 (p=0.02).

Conclusion

Patients in both groups had similar stage. KT was used more frequently in patients with carcinosarcoma, RT was used more in patients with HGEAC for the main adjuvant therapy modality. The survival was found better in patients with HGEAC.

CLINICAL AND PROGNOSTIC EFFECTS OF OBESITY ON ENDOMETRIAL CANCER

A.B. GUZEL1, U. KUCUKGOZ GULEC1, M. SUÇU2, G. KHATIB1, M.A. VARDAR2

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey

Aims

To determine the association of body mass index (BMI) on operative outcomes, clinicopathologic characteristics and prognosis in endometrial cancer.

Method

Three hundred ninety two patients with endometrial carcinoma who were operated and followed up in our clinic were evaluated according to the BMI groups. Patients' demographics, clinical characteristics such as stage, grade, histopathologic type, lymphovascular space invasion (LVSI), myometrial invasion, lymph node involvement, and risk groups, peri- and post-operative outcomes, and survival outcomes were compared according to BMI stratifications.

Results

BMI groups were <30 (n= 104, 26.5%), 30–34 (n=85, 21.7%), 35–39 (n=96, 24.5%), and≥40 (n=107, 27.3%). Laparotomy was performed to 186 cases, and laparoscopy to 206 cases. The medians of age, comorbidity status, surgical type (laparotomy or laparoscopy) were not different among the groups (p=0.057, 0.065, 0.263, respectively). The medians of operation time (p=0.224), postoperative hospitalization time (p=0.212), estimated blood loss (p=0.077), drop in hb level (p=0.387) were similar. High BMI increased intra- and postoperative complication rates (p= 0.049). Stage (p= 0.481), grade (p=0.756), myometrial invasion (p=0.190), risk groups (low, moderate and high; p=0.638), nodal involvement (p=0.334) and histologic type (p= 0.919) were not differed according to groups of BMI. Median of overall survival and disease free survival were found similar (p=0.551, 0.534, respectively).

Conclusion

We demonstrated that BMI did not alter the patient's clinicopathologic characteristics and did not affect the prognosis negatively but increased the operative complications.
PROGRAMMED DEATH-1 (PD-1), PROGRAMMED DEATH-LIGAND 1 (PD-L1) EXPRESSION IN UTERINE CARCINOSARCOMAS

U. Kucukgoz Gulec¹, E. Bagir², S. Paydas³, G. Seydaoglu⁴, A.B. Guzel¹, M.A. Vardar¹
¹Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
²Cukurova University School of Medicine, Pathology, Adana, Turkey
³Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
⁴Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

Programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) are new targets in cancer immunotherapy. PD-1 protein is an immune checkpoint expressed in many tumors. The aim of this study is to evaluate the clinical and prognostic importance of PD-1 and/or PD-L1 in uterine carcinosarcomas (UCS).

Method

Formalin fixed, paraffin-embedded tissue samples from 59 cases with UCS were analyzed in this study. Immunohistochemical staining was performed to detect the PD-1 and PD-L1 expressions in tumor tissue and microenvironment, separately.

Results

PD-1 expression in tumor tissue and microenvironment was detected in 15 (25 %) and 18 (30 %) cases, respectively. PD-L1 expression in tumor tissue and microenvironment was detected in 15 (25 %) and 12 cases (20 %), respectively. It has been found that expression of PD-L1 in tumor was associated with longer survival although PD-1 expressions were not found to be related with survival. Median survival in cases with and without PD-L1 expression were 38 and 15 months, respectively (p=0.019). Lymphovascular space invasion (LVSI) (p=0.014), myometrial invasion (p=0.008) and PD-L1 expression were found prognostic factors. Cox regression analysis showed that expression of PD-L1 was found to be an independent risk factor for prognosis (OR 3.9; 95 % CI 1.4–11.0).

Conclusion

Targeting PD-1 and/or PD-L1 meaningful due to the 25 % expression of each in UCS, and we found an important association between PD-L1 expression and prognosis in UCS. Programmed death pathway is involved in UCS development/biology and larger studies will be more informative for targeted treatment and/or checkpoint blocking therapies.

PROGRAMMED DEATH-1 (PD-1), PROGRAMMED DEATH-LIGAND 1 (PD-L1) EXPRESSION IN TYPE 2 ENDOMETRIAL CANCER

U. Kucukguz Gulec1, E. Bagir2, S. Paydas3, G. Seydaoglu4, A.B. Guzel1, M.A. Vardar1

1Cukurova University School of Medicine, Obstetrics and Gynecology, Adana, Turkey
2Cukurova University School of Medicine, Pathology, Adana, Turkey
3Cukurova University School of Medicine, Medical Oncology, Adana, Turkey
4Cukurova University School of Medicine, Biostatistics, Adana, Turkey

Aims

Programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) are new targets in cancer immunotherapy. PD-1 protein is an immune checkpoint expressed in many tumors. The aim of this study is to evaluate the clinical and prognostic importance of PD-1 and/or PD-L1 in type 2 endometrial cancer.

Method

Formalin fixed, paraffin-embedded tissue samples from 67 cases with type 2 endometrial cancer were analyzed in this study. Serous adenocancer (n=21, 31%), clear cell (n=14, 21%) and mixed type adenocancer (n=32, 48%) were consisted the study cohort. Immunohistochemical staining was performed to detect the PD-1 and PD-L1 expressions in tumor tissue and microenvironment, separately.

Results

PD-1 expression in tumor tissue and microenvironment was detected in 26 (39 %) and 34 (51 %) cases, respectively. PD-L1 expression in tumor tissue and microenvironment was detected in 11 (16 %) and 19 cases (28 %), respectively. It has been found that expression of PD-1 and PD-L1 in tumor was associated with shorter survival although PD-1 and PD-L1 in microenvironment expressions were not found to be related with survival. Median survival in cases with and without PD-1 expression were 48 and 21 months, respectively (p=0.004). Median survival in cases with and without PD-L1 expression were 48 and 15 months, respectively (p=0.0001).

Conclusion

This study demonstrated an important association between PD-1 and PD-L1 expression and prognosis in type 2 endometrial cancers. Larger studies will be more informative for targeted treatment and/or checkpoint blocking therapies in type 2 endometrial cancer.

ESGO7-0860

IMPACT OF GYNECOLOGIC SCREENING IN LYNCH SYNDROME
M. Gosset1, L. Rossi2, C. Cornou2, C. Ngo2, M. Delomenie2, C. Nos2, F. Lecun2, A.S. Bats2
1Hôpital Européen Georges Pompidou, Chirurgie Gynécologique Cancérologique et du Sein, Paris, France
2Hôpital Européen Georges Pompidou, Chirurgie Cancérologique Gynécologique et du Sein, Paris, France

Aims

Lifetime risk of developing endometrial cancer in Lynch syndrome is higher than in the general population and gynecologic screen appears interesting, although unproven until now. The aim of our study was to determine the diagnostic value of gynecologic screening for the diagnostic of endometrial cancer in patients with Lynch syndrome.

Method

We conducted a prospective study in patients with Lynch syndrome and identified mutation from 1998 to 2016 at the European Georges-Pompidou Hospital in Paris. All patients had an annual screening including clinical examination, pelvic ultrasound, endometrial biopsy, and hysteroscopy. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each test and of the global screening strategy were described.

Results

One hundred and ninety one patients, with 620 surveillance visits, were included in the study. The median age of patients was 51 years. Identified mutation were MLH1 (49.4%), MSH2 (48.4%), MSH6 (23.17%), and PMS2 (4.7%). Sensitivity, specificity, PPV, and NPV of pelvic ultrasound were respectively 84.6%, 92.8%, 40.7%, and 99.0%. For endometrial biopsy, they were respectively 89.5%, 99.8%, 94.4%, and 99.5%, and for hysteroscopy, they were 84.6%, 99.7%, 88.9% and 98.8% in all cases. Sensitivity of the global screening strategy was 100%. Five cases of endometrial cancers (ECs) were diagnosed through the screening. One case of EC was associated with an ovarian cancer (endometrioid carcinoma), which was detected by pelvic ultrasound.

Conclusion

A screening strategy including pelvic ultrasound, endometrial biopsy, and hysteroscopy appears efficient for the diagnosis of gynecologic cancers in Lynch syndrome.
REDEFINING THE PRE-MALIGNANT LANDSCAPE OF GYNAECOLOGIC CANCERS: GENOMIC ANALYSIS OF UTERINE LAVAGE FLUID DETECTS BOTH EARLY STAGE CANCERS AND PRECANCEROUS CELLS OF UNKNOWN POTENTIAL.

J. Martignetti1, N. Nair2, O. Camacho-Vanegas1, D. Rykunov1, M. Dashkoff1, S. Camacho1, C. Schumacher3, J. Irish1, T. Harkins1, E. Periera1, S. Kendall1, N. Nagarsheth2, T. Kall2, R. Sebra1, B. Reva1, P. Dottino2

1Icahn School of Medicine at Mount Sinai, Genetics & Genomic Sciences, New York, USA
2Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology and Reproductive Sciences, New York, USA
3Swift Biosciences, - Ann Arbor- MI, USA

Aims

The holy grail of cancer treatment remains detecting and eliminating cancers at their earliest. Endometrial cancer is the most common gynecologic malignancy and its incidence and associated mortality are increasing. Strikingly, there is no effective screening methodology. We hypothesized that ultra-deep, targeted gene sequencing of uterine lavage fluid could detect even microscopic endometrial cancer.

Method

Uterine lavage and paired blood samples were analyzed from 107 consecutive patients undergoing hysteroscopy and curettage for diagnostic evaluation. Cellular and cell-free DNA were isolated from each lavage fluid sample. Ultra-deep sequencing, coverage in excess of 5,000x, was performed using a targeted 12 gene endometrial cancer panel.

Results

Seven patients were diagnosed with endometrial cancer based on classic histopathology. Six were stage IA cancers and several were microscopic. Despite their microscopic size and demonstrating the extreme sensitivity of the molecular assay, all seven patients had significant cancer-associated gene mutations detected in their lavage fluid. Unexpectedly, nearly half of the study population without histopathologic evidence of cancer also possessed high levels of lavage fluid cancer driver-gene mutations. One returned 10 months later with stage IA cancer. Mutations in these women were age and menopausal status associated.

Conclusion

Given that a uterine lavage can be easily and quickly performed in a physician's office-based setting, our findings suggest the future possibility for screening women for the earliest stages of endometrial cancer. However, our findings further demonstrate the unprecedented opportunity and clinical necessity to gain additional insight into the genetic basis of endometrial cancer development and its possible interruption.

COMBINING CA-125 AND COMPUTED TOMOGRAPHY IMPROVES SELECTION OF ADVANCED STAGE ENDOMETRIAL CARCINOMA

B. Israel1, C. Reijnen1, N.N.C. Visser2, J. Kasius1, J.J. Hermans3, L.F.A.G. Massuger1, J.M.A. Pijnenborg1

1RadboudUMC, Obstetrics & Gynaecology, Nijmegen, The Netherlands
2RadboudUMC, Pathology, Nijmegen, The Netherlands
3RadboudUMC, Radiology and Nuclear Medicine, Nijmegen, The Netherlands

Aims

To investigate the predictive value of preoperative CA-125 and computed tomography (CT) for advanced FIGO stage in the work-up for endometrial carcinoma (EC).

Method

The Pipelle Prospective ENDometrial carcinoma (PIPENDO) study cohort comprised all consecutive patients treated for endometrial carcinoma at nine hospitals in the Netherlands between September 2011 and December 2013. Patient characteristics, preoperative CA-125 and CT-scan results, histology, and follow-up data were collected. CT-scan results were classified as: suspected or unsuspected for extra-uterine disease, or inconclusive. Serum levels of CA-125 > 35 Ku/L were considered as elevated. Primary outcome was advanced FIGO III-IV stage, determined for low-(grade 1-2), and high (grade 3) tumor grade.

Results

A total of 432 EC patients were included: 25.9% with high-grade, and 74.1% with low-grade EC. Overall, 29.0% of the patients had an elevated CA-125, and 14.1% of the patients were suspected for extra-uterine disease based on CT-scan. Elevated CA-125 had a positive predictive value for advanced stage in of 8.8% in low-grade EC, compared to 47.5% in high-grade EC. Abnormal CT-scan had a positive predictive value for advanced stage of 30.0% in low grade EC, compared to 53.3% in high grade EC. Combined elevated CA-125 and abnormal CT-scan resulted in a positive predictive value of 28.6% in low-grade EC and 66.7% in high grade EC.

Conclusion

Combining Ca-125 and CT-scan increases the positive predictive value for advanced FIGO stage in high-grade EC.

RISK FACTORS FOR PARA-AORTIC LYMPH NODE METASTASIS IN ENDOMETRIAL CANCER
M.E. Sarı¹, I. Yalcın¹, H. Sahin¹, M.M. Meydanlı¹, T. Gungor¹
¹Zekai Tahir Burak Women's Health Training and Research Hospital- Faculty of Medicine- University of Health Sciences, Gynecologic Oncology, Ankara, Turkey

Aims

The purpose of this study was to determine the risk factors for para-aortic LN metastasis in EC patients that underwent comprehensive surgical staging.

Method

A total of 641 women with EC (endometrioid, non-endometrioid, or mixed histology) who underwent comprehensive surgical staging including pelvic and para-aortic LN dissection between 2008 and 2016 were included in this retrospective study. Patient data were analyzed with respect to para-aortic LN involvement and predictive factors for para-aortic LN metastasis were investigated.

Results

Lymph node metastasis was detected in 90 (14%) patients; isolated pelvic LN metastasis in 28 (4.3 %), isolated para-aortic LN metastasis in 15 (2.3 %), and both pelvic and para-aortic LN metastasis in 47 (7.3 %) women, respectively. Univariate analysis revealed that the risk of para-aortic LN metastasis significantly increased in patients with non-endometrioid histology, >60 years of age, grade 3 tumor, deep myometrial invasion, lymphovascular space invasion (LVSI), primary tumor diameter (≥2 cm), cervical stromal invasion, adnexal involvement, serosal invasion, pelvic LN involvement, ≥2 positive pelvic LNs and positive peritoneal cytology (p<0.05). At the end of multivariate analysis, presence of LVSI (odds ratio [OR]: 4.8, 95% confidence interval [CI] 1.25 - 18.2, p= 0.022) and pelvic LN metastasis (OR: 18.8, 95% CI 5.7-61.6, p<0.001) remained as independent risk factors for para-aortic LN involvement in women with EC.

Conclusion

Presence of LVSI and pelvic LN involvement appear to be independent risk factors for para-aortic LN metastasis in patients with EC. LVSI may be considered as a routine pathological parameter during frozen section analysis in women with EC undergoing surgery.
Univariate and multivariate analysis of women with endometrial cancer with regard to para-aortic LN metastasis

PREOPERATIVE IMAGING MARKERS AND PDZ-BINDING KINASE TISSUE EXPRESSION PREDICT LOW-RISK DISEASE IN ENDOMETRIAL HYPERPLASIAS AND LOW GRADE CANCERS

A. Berg¹, I.L. Tangen¹, K. Woie², L. Bjorge², H.M.J. Werner², I.S. Haldorsen³, C. Krakstad¹

¹University of Bergen, Departement of Clinical Science, Bergen, Norway
²Haukeland University Hospital, Department of Gynecology and Obstetrics, Bergen, Norway
³University of Bergen, Departement of Clinical Medicine, Bergen, Norway

Aims

Distinguishing complex atypical hyperplasia (CAH) from grade 1 endometrioid endometrial cancer (EECG1) has clinical value, particularly in patients who wish to preserve their fertility or in patients with increased risk of perioperative complications due to obesity or co-morbidities. Surgical overtreatment of patients with CAH seems to exist, and this study search to identify imaging and tissue biomarkers to individualize treatment strategies.

Method

Clinicopathological data was available for 277 patients with CAH and EECG1. Preoperative histological diagnosis and radiological evaluation were compared with final histological diagnosis. Imaging characteristics by preoperative magnetic resonance imaging (MRI) and fluorodeoxyglucose positron emission tomography/computer tomography (FDG-PET/CT) were compared with tumor DNA oligonucleotide microarray data, immunohistochemistry findings and clinicopathological annotations.

Results

MRI assessed tumor volume was higher in EECG1 than in CAH (p=0.004) whereas apparent diffusion coefficient value was lower in EECG1 (p=0.005). EECG1 had increased metabolism with higher maximum and mean standard uptake values than CAH (p≤0.002). Unsupervised clustering of EECG1 and CAH revealed differentially expressed genes within the clusters, and identified PDZ-binding kinase (PBK) as a potential marker for selecting endometrial lesions with less aggressive biological behavior.

Conclusion

Both PBK expression and preoperative imaging markers at MRI and PET/CT are promising biomarkers that may aid in the differentiation between suspected EECG1 and CAH preoperatively. These biomarkers should be explored in larger patient series to define the potential role of these markers to accurately identify CAH patients having low risk of concomitant cancer or cancer progression, where conservative treatment might be the preferred treatment.
LYMPHATIC MAPPING AND SENTINEL-LYMPH-NODE BIOPSY IN ENDOMETRIAL CANCER: A PROSPECTIVE STUDY

B. Díaz de la Noval1, M.D. Diestro Tejeda1, J. Zapardiel1, J. Siegrist Ridueto1, J. de Santiago García2, A. Hernández Gutiérrez1

1La Paz University Hospital, Gynaecology Oncology, Madrid, Spain
2MD Anderson Cancer Center, Gynaecology Oncology, Madrid, Spain

Aims

We aimed to assess if the detection rate and diagnostic accuracy by ultrastaging can improve the surgical staging.

Method

A prospective study of incident cases with clinical early-stage EC scheduled for laparoscopic staging surgery at La Paz University Hospital. Patients underwent preoperative SLN mapping with an intracervical injection of radiotracer-Tc-99m the day before surgery and intraoperative dye during surgery.

Results

From February 2012 to February 2017, 143 patients were enrolled. Overall detection rate for the dual technique was 94.4% (n=135), bilaterally of 86.6%. 431 SLNs were obtained, mean of 3.2 SLNs per patient, usually in an iliac and obturator location (77%). Diagnostic rates were sensitivity 100%, specificity 95.16%, and NPV 100%.

Twenty-eight (6.5%) metastatic nodes: 8 (1.9%) macrometastases, 17 (4%) micrometastases, 3 (0.7%) ITC. Node metastases were identified in 25 (18.5%) patients, 20 (80%) were confined to SLNs, 65% of which had low tumor burden. In 13 cases (65%) the SLN was the only affected. Diagnostic rates (per patient) of SLN mapping to detect metastases after SLN-ultrastaging were sensitivity 50%, specificity 88.24%, NPV 90.91% and false-negative rate of 7.5%.

Mean follow-up of 55 months, 84.4% disease-free survival, and 93.3% overall survival. 28.6% of relapses had metastatic SLNs (p = 0.03); 65% of the patients with macrometastatic-SLN relapsed (p=0.001). Mean time to relapse of 14.8 months.

Conclusion

Though multicentre studies are underway, the high NPV of the SLN-technique accurately predicts nodal status, which could be considered as an alternative standard for staging early-stage endometrial cancer.
FERTILITY / PREGNANCY

FERTILITY AND SURVIVAL OUTCOME IN A LARGE COHORT OF BORDERLINE OVARIAN TUMORS: A SINGLE CENTER EXPERIENCE

M. Delle Marchette1,2, L. Ceppi1,2, M. Lamanna1,2, S. Magni1,2, F. Dell’Orto1,2, F. Galli3, A. Buda2, F. Sina1,2, D. Giuliani2, T. Grassi1,2, R. Milani1,2, C.M. Bonazzi2, R. Fruscio1,2

1University of Milano-Bicocca, Department of Medicine and Surgery, Piazza dell’Ateneo Nuovo 1- 20126 Milan, Italy
2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33- 20900 Monza, Italy
3IRCCS - Istituto di Ricerche Farmacologiche “Mario Negri”, Laboratory of Methodology for Clinical Research - Department of Oncology, Via La Masa 19- 20156 Milan, Italy

Aims

Borderline ovarian tumors have excellent oncologic outcome and fertility sparing treatment in young women is indicated. However, pregnancy rate success is affected by multiple gonadal surgeries for relapse and it may be influenced by type of surgery (oophorectomy v. cystectomy). We investigated the effect of surgical fertility-sparing approach on fertility and survival.

Method

borderline ovarian tumor patients treated at San Gerardo Hospital, Monza between 1978 and 2013 were considered. The effect of type of surgery on recurrence and death was analyzed. A Cox model was used to investigate the association between clinical variables and time to first post-surgical pregnancy, as well as the association between time to first recurrence

Results

Among a larger cohort, 252 patients had desire of pregnancy and were included in the analysis: 121 patients underwent oophorectomy, 131 cystectomy, with comparable clinicopathological characteristics. Median follow-up time from date of diagnosis was 13.5 years.

Results of the Cox model investigating factors potentially associated with recurrence showed: Advanced stage disease as significantly associated with the risk of recurrence (p<0.001), with bilateral cysts patients with higher risk of recurrence (HR= 2.20, IC95%= 1.41-3.44). The inverse weighted probability Cox model showed no effect of type of ovarian surgery on first recurrence (HR0.95; p=0.83), and on fertility (HR0.96; p=0.79). No detrimental effect on pregnancy rates was associated with histology, stage, laterality of the tumor or with a relapsing disease.

Conclusion

Type of surgery was observed not affecting recurrence risk and pregnancy success rate. These reassuring data can aid clinicians and patients tailoring the best treatment strategies

REPRODUCTIVE OUTCOMES AFTER GESTATIONAL TROPHOBLASTIC NEOPLASIA: A COMPARISON BETWEEN SINGLE-AGENT AND MULTIAGENT CHEMOTHERAPY. RETROSPECTIVE ANALYSIS FROM THE MITO-9 GROUP

P. Cioffi1, A. Bergamini1, A. Gadducci2, G. Cormio3, V. Giorgione1, M. Petrone1, E. Rabaiotti1, F. Pella1, M. Candiani1, G. Mangili1
1IRCCS San Raffaele Hospital, Gynaecology and Obstetrics, Milan, Italy
2University of Pisa, Gynaecology and Obstetrics, Pisa, Italy
3University of Bari, Gynaecology and Obstetrics, Bari, Italy

Aims

Gestational trophoblastic neoplasia (GTN) affects young women and is treated by chemotherapy. Possible concerns are the risk of infertility, early menopause, and teratogenic effects. Present study’s aim is to analyze menstrual and reproductive outcomes of women treated with single-agent versus multi-agent chemotherapy for GTN.

Method

One-hundred fifty-one patients were treated. Patients older than 45 years, with placental site/epithelioid trophoblastic tumor, undergoing hysterectomy by patient choice or hCG follow-up coinciding with analysis were excluded. Seventy-five patients were divided into subgroups according to FIGO score: patients scoring <7, receiving single-agent chemotherapy (group A, n=42); patients scoring ≥7, receiving combination treatment (group B, n=33). Patients’ outcomes were compared by univariate and multivariate analyses.

Results

Temporary amenorrhea occurred in 33% of A patients and 66.7% of B (p=0.01). Premature menopause occurred in 3 B patients (0% vs 9%, p=0.02).

Ten B patients underwent salvage hysterectomy.

Pregnancy desire did not differ between the two groups (p=0.555). In A, 57.1% became pregnant; in B, 36.4% did (p=0.060). Instead, pregnancy rate was 52.2% among high-risk patients not undergoing hysterectomy (57.1% vs 52.2%, p=0.449).

There was no difference in miscarriage (p=0.479) and premature birth (p=0.615) rates.

In a multivariate analysis including age, FIGO score, chemotherapy type, Assisted Reproductive Technologies, previous pregnancies and pregnancy desire, only age (p=0.006) and pregnancy desire (p=0.002) were independent factors.

Conclusion

Excluding the risk of premature menopause, a rare side-effect of combined treatments, single-agent and multi-agent chemotherapy can be safely administered to patients with childbearing desire. High-risk patients have worse reproductive outcomes because they undergo hysterectomy more frequently than low-risk patients.
Epidemiology of malignancies diagnosed in pregnancy in Czech Republic

M. Halaska¹, M. Hruda², T. Pichlik¹, H. Robova², L. Rob²

¹3rd Medical Faculty- Charles University and Faculty hospital Kralovske Vinohrady, Dept. of OB/GYN, Prague, Czech Republic
²3rd Medical Faculty Charles University and Faculty hospital Kralovske Vinohrady, Dept. of OB/GYN, Prague, Czech Republic

Aims

Malignancy diagnosed during pregnancy represents a rare diagnosis, but the incidence of such a disease has sharply increased in recent decades. The reason for this tendency is the increased age of women becoming pregnant. Today, 21.9% of women in the EU are older than 35 years at delivery. Exact data on the incidence of malignant disease is sparse and in most cases inaccurate. However, there is a clear trend in coincidence of malignancy and pregnancy and there are some obvious differences between countries and races. Only a few reports are available that used a linkage of national oncological and birth registries to detect patients diagnosed with cancer during pregnancy. The aim of the work was to evaluate the incidence of malignancies diagnosed in pregnancy in Czech Republic.

Method

The desired data were obtained by linking the National oncological register with Birth and abortion register between 1996-2010.

Results

Malignant diseases in pregnancy occur approximately in 20-40 / 100,000 pregnant women. The most common diagnoses in Czech Republic include cervical cancer (5.5 / 100,000), breast cancer (2.58 / 100,000), melanoma (3.05 / 100,000) and haematological malignancies (2.78 / 100,000) and they account for 60-75% of all malignancies detected during pregnancy.

Conclusion

20-40 pregnancies per 100,000 pregnant women is complicated by malignant disease, most often cervical cancer, breast cancer, melanoma and hematologic malignancies.

This work was supported by the Charles University research program PROGRES Q 28 (Oncology).
ONCOLOGIC AND OBSTETRIC OUTCOME AFTER VAGINAL SIMPLE TRACHELECTOMY OR LEEP FOR CERVICAL CANCER

F. Demirkiran1, I. Kahrmanoglu1, H. Turan1, T. Bese1, M. Arvas1
1Istanbul University Cerrahpasa School of Medicine, Obstetrics and Gynecology, ISTANBUL, Turkey

Aims

The purpose of our study is to evaluate oncologic and obstetric outcomes after vaginal simple trachelectomy or the loop electrosurgical excisional procedure (LEEP) for cervical cancer.

Method

The medical records of patients who underwent vaginal simple trachelectomy or LEEP with or without pelvic lymphadnectomy were retrospectively reviewed.

Results

The summary of the patients were presented in Table 1. The median age of patients was 31.1 years, and the median follow-up time was 22.2 months. There was no recurrence during follow-up and none died after treatment. A total of 7 patients attempted conceive after surgery, and 4 pregnancies were achieved in 4 women. Hence, the the pregnancy rate among patients who attempted to onceive was 57.1%. Two babies were delivered by cesarean section at 24 and 37 weeks. Two cases of miscarriage occured in the second trimester.

Conclusion

Our data indicate that LEEP and vaginal simple trachelectomy in stage IA1-IB1 cervical cancer are effective procedures in patients who wish to preserve fertility. However, miscarriage was frequently observed. Thus, future studies should focus on prevention of complications during pregnancy.
TAILORED THERAPY FOR FERTILE WOMEN WITH ENDOMETRIAL CANCER: THE DUTCH EXPERIENCE

M. van Gent¹, M. Kagie², T. Bosse³, B. Trimbos⁴, C. de Kroon⁴

¹Center of Gynaecological Cancer Amsterdam, Antoni van Leeuwenhoek, Amsterdam, The Netherlands
²Haaglanden Medical Center, Gynaecology, The Hague, The Netherlands
³Leiden University Medical Center, Pathology, Leiden, The Netherlands
⁴Leiden University Medical Center, Gynaecology-K6-P, Leiden, The Netherlands

Aims

To evaluate the oncological and obstetrical outcomes after the introduction of a nationwide protocol for tailoring therapy in young women with endometrial cancer (EC) with the wish to preserve fertility.

Method

Patients with low-grade, stage I endometrioid EC were treated with progesterones. Staging was done by physical examination, ultrasound and contrast enhanced MRI. Strict follow-up rules were defined. Complete response (CR) was defined as two subsequent endometrial biopsies with normal histo-pathological findings.

Results

33 patients were treated since the introduction of the protocol. Mean age: 33 yr. Mean BMI: 28 kg/m². The majority (n = 23, 70 %) was treated with medroxyprogesterone 200 mg/day. Mean follow-up: 44 months (median 33 months). CR was obtained in 61% (20/33). Mean time to CR was 8 months (median 7.5 months). Recurrence rate was 65% (13/20). Mean time to recurrence after end of therapy was 13.4 months (median 11 months). CR after re-treatment for recurrence was 67 % (6/9). Recurrence after second course: 50 % (3/6). Mean time to recurrence: 23.3 months (median 15 months). 17 pregnancies resulted in 7 deliveries and 2 current third trimester pregnancies in 7 patients. Five out of 15 patients undergoing hysterectomy had no residual disease, 10 had grade 1 disease (9 stage 1A, 1 stage III). One patient suffered from ovarian recurrence after hysterectomy with USO (18 months after hysterectomy).

Conclusion

The results confirm previous findings in literature on efficacy and safety of fertility preserving therapy in endometrial cancer. Women should be informed about recurrence rates after complete response.

CAN TUMOR MARKERS HE4 AND CA125 BE USEFUL IN DIFFERENTIATION INTRA-PELVIC FROM EXTRA-PELVIC ENDOMETRIOSIS?

N. Abdalla¹, R. Piorkowski¹, A. Timorek¹, P. Stanirowski¹, K. Cendrowski¹, W. Sawicki¹
¹Medical University of Warsaw, Chair and Department of Obstetrics- Gynecology and Oncology, Warsaw, Poland

Aims

The aim of the study was to compare the serum level of tumor markers HE4 and CA125 between group of patients with intra-pelvic endometriosis (IPE) and group of patients with features of extra-pelvic endometriosis (EPE).

Method

A total of 67 patients were included in the retrospective study. The serum level of HE4 and CA125 was measured for each patient before surgical intervention. The final diagnosis of endometriosis was established according to histological examination of endometriosis foci. Patients were divided into two groups according to anatomic localization of endometriosis. The first group included patients with only features of intra-pelvic endometriosis. The second group include patients with features of extra-pelvic endometriosis with or without intra-pelvic endometriosis. U Mann-Whitney test was used in statistical analysis.

Results

The age range was 20-59, with a mean of 36.1 years, standard deviation (SD) = 8.7 years. A total of 52 (77.61%) patients had only intrapelvic endometriosis while 15 (23.39%) had extra-pelvic endometriosis. The mean of serum level of HE4 in IPE and EPE group was 48.21 (SD 14.29) pmol/L and 47.41 (SD 10.81) pmol/L, respectively. The mean of serum level of CA125 in IPE and EPE groups was 64.14 (SD 63.51) U/ml and 62.75 (SD 41.64) U/ml, respectively. The serum level of HE4 and CA125 didn’t differ significantly between IPE and EPE groups (p level 0.875 and 0.718, respectively).

Conclusion

Both tumor markers HE4 and CA125 were not useful for differentiation the main localization of endometriosis whether intra-pelvic or extra-pelvic.
Aims

In 1983, 1993, and 2002 results of studies identifying patient perceptions and individual ranking of chemotherapy side effects (CSE) were reported. We aimed to update this survey and evaluate changes in patient perceptions a further decade later.

Method

Patients with breast (BC) and ovarian cancer (OC) planned for chemotherapy were recruited in this prospective study. At week 12 +/- 3 weeks after chemotherapy initiation patients were asked to identify from 72 cards displaying potential physical and non-physical CSE the ten most burdensome and ranking them finally to top five by severity. Results are reported for the entire group and in comparison to published data. Additionally, socio-demographic and clinical characteristics were evaluated.

Results

In total, 126 patients (85 BC and 41 OC) were interviewed. The most severe CSE reported was “difficulty sleeping” compared to “vomiting” in 1983, “nausea” in 1993, and “affects my family/partner” in 2002 (table 1). “Loss of hair” remained a top concern over all studies. The most severe CSE in BC patients was “loss of hair” in contrast to “difficulty sleeping” in OC patients.

Conclusion

Conclusions

Patient perceptions of CSE have changed markedly compared with previous studies. Especially taxane related CSE are reported more frequently. However, “loss of hair” has remained an unsolved problem over decades. Ranking the most severe CSE by cancer type demonstrated clinically relevant differences.
Aims

Fibrinogen plays an important pathophysiological role in tumor cell progression and development of metastases in different types of cancer. The aim of the present study was to evaluate the value of pre-treatment fibrinogen plasma levels as a prognostic biomarker in patients with uterine leiomyosarcoma (ULMS).

Method

Data of women with ULMS were extracted from a multi-center database. Pre-treatment fibrinogen plasma levels were measured. The association between fibrinogen plasma levels and clinico-pathological parameters was investigated and univariate and multivariable survival analyses were performed.

Results

A total of 70 patients with ULMS was included into this analysis. Mean (SD) pre-therapeutic fibrinogen plasma level was 480.2 (172.3) mg/dL. Patients with advanced tumor stage had higher fibrinogen levels (p=0.02). Five-year overall survival (OS) rates in ULMS patients with increased fibrinogen levels were 25.0% compared to 52.9% in ULMS patients with normal fibrinogen. Univariate survival analyses revealed that elevated fibrinogen plasma levels (p<0.003), advanced tumor stage (p<0.001) and high histological grade (p=0.004) were associated with unfavorable OS. In multivariable analysis, only histological grade (p=0.07) was independently associated with survival.

Conclusion

Elevated fibrinogen plasma levels were associated with advanced disease and unfavorable prognosis in women with ULMS in univariate survival analysis. After validation in future studies fibrinogen might be a useful biomarker for tumor stage and prognosis in ULMS patients.
IS SURGICAL TUMOR FRAGMENTATION AN INDEPENDENT PROGNOSIS FACTOR IN THE OVERALL SURVIVAL OF UTERINE SARCOMAS?
V. Benito1, A. Lubrano1, S. Carballo1, O. Arencibia1, N. Medina1, M. Andújar2, M. Mori3, M. Federico4, F. Molano5

1Complejo hospitalario universitario insular-materno-infantil, gynecology oncology, las palmas de gran canaria, Spain
2Complejo hospitalario universitario insular-materno-infantil, pathology, las palmas de gran canaria, Spain
3Hospital universitario Dr. Negrín, Medical Oncology, Las Palmas de Gran Canaria, Spain
4Hospital universitario Dr. Negrín, Radiation Oncology, Las Palmas de Gran Canaria, Spain
5Complejo hospitalario universitario insular-materno-infantil, Medical Oncology, las palmas de gran canaria, Spain

Aims
To evaluate clinicopathologic data and prognostic factors for patients with uterine sarcomas (US), with special emphasis on uterine fragmentation during surgery.

Method
Retrospective analysis of all consecutive patients with US treated between 1990-2016. During this period 1,863 patients with uterine malignancies were diagnosed, of which 1,681 were excluded for endometrial carcinoma and 85 for carcinosarcomas, so finally the study sample included 97 patients (5.2% incidence). Survival-rates were analysed using the Kaplan-Meier method.

Results
The distribution by histological-type was: 46.4% leiomyosarcoma; 23.7% high-grade ESS; 17.5% low-grade ESS; 11.3% adenosarcomas and 1% liposarcoma. Median age was 52 years (25-90) and 49.5% were premenopausal. The most frequent preoperative diagnosis was uterine fibroids in 49.5%. Tumor surgical rupture occurred in 25.9% of cases. FIGO stages I-II and III-IV were identified in 74% and 26% of patients, respectively. Median tumor size was 8 cm (2-40). EFS rates after 2, 5, and 10-years were 71%, 57%, and 53% respectively, with a median time of 63 months (95%CI, 35.5-90.4). OS rates after 2, 5, and 10-years were 66%, 53%, and 38% respectively, with a median time of 19 months (95%CI, 1-43.7). Multivariate analysis showed that stage; histological type and surgical tumor rupture were independent prognostic factors [(OR7.9; CI95% 1.6-38.2; p=0.01); (OR5.3; CI95% 2.1-13; p<0.0001) and (OR2.6; CI95% 1.1-6.5; p=0.03)].

Conclusion
US are rare but aggressive tumors whose prognosis is strongly influenced by FIGO-stage, histological-type and tumor surgical rupture. Efforts should be made to avoid any type of uterine fragmentation during surgery since it seriously compromises the prognosis of this pathology.

INCIDENCE AND SURVIVAL OF GYNECOLOGIC CARCINOSARCOMAS IN ISRAEL

A. Blecher1, Y. Brudner1, G. Haran1, B.G. Silverman2, M. Hallak1, I. Bruchim1
1Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hedera, Israel
2Israel Ministry of Health, Israel National Cancer Registry, Ramat Gan, Israel

Aims

Gynecologic carcinosarcoma is a rare and aggressive tumor. Following latest immunohistochemically studies the carcinosarcomas are considered subtypes of carcinomas but seem to have a distinct natural history and presumably worse prognosis. The aim of this study is to report the incidence and outcome of gynecologic carcinosarcomas in Israel.

Method

Records of gynecologic carcinosarcomas diagnosed between 1980-2014 were extracted from the Israeli National Cancer Registry and classified according to ICD-03. Age-standardized incidence rates (ASRs), 1&5 year and overall survival rates were calculated according to anatomical site, population group, stage and grade at diagnosis.

Results

935 new gynecologic carcinosarcomas were diagnosed in Israel between 1980-2014. During the last 15 years there was a substantial increase in ASR from 8 to 11 per million females with a significantly higher incidence in Jewish compared to Arabic population (13 vs 4 per million females respectively). Incidence was highest in women 55-75 years old and extremely low in women younger than 30 years old. The most common anatomical site was uterus (83%) followed by ovary (11%). The survival rates increased significantly between 1985-1990 and 2010-2014 but were lower than the survival rates for sarcomas. There was no significant difference in survival rates between the populations.

Conclusion

Gynecologic carcinosarcomas seem to have a distinct behaviour in regard to incidence, age at presentation and survival rates compared to gynecological sarcomas. This is to our best knowledge the first study evaluating this rare histologic subtype in Israeli population and provides important information for clinical practice and further research.
MISCELLANEOUS INCIDENCE AND SURVIVAL OF GYNECOLOGIC SARCOMAS IN ISRAEL

Y. Brudner1, G. Haran1, A. Blecher1, B.G. Silverman2,3, M. Hallak1, I. Bruchim1
1Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
2Israel Ministry of Health, Israel National Cancer Registry, Ramat Gan, Israel
3Tel Aviv University, Seckler School of Medicine, Tel Aviv, Israel

Aims

Survival after gynecologic sarcomas is known to be poor, although limited data are available on the subject. A recent British report showed a substantial survival increase, explained perhaps by improved therapies. The aim of this study is to report the incidence and outcome of gynecologic sarcomas in Israel.

Method

Records of gynecologic sarcomas diagnosed between 1980-2014 were extracted from the National Israeli Cancer Registry and classified according to ICD-03. Age-standardized incidence rates (ASRs), 1&5 year and overall survival rates were calculated according to anatomical site, morphology subtype, population group, stage and grade at diagnosis.

Results

1271 new gynecologic sarcomas were diagnosed in Israel during 1980-2014, with incidence increasing between 1980-2010 years up to ASR of 15.7 per million females in 2010. ASR was significantly lower in the Arab compared to Jewish population (7.7 vs. 16.4 per million females in 2010 respectively), with a more substantial increase during the years. Incidence was highest in women 40-65 years old. The most common histologic diagnosis was leiomyosarcoma (47%) and most common anatomical site was uterus (89%). The observed survival rates were comparable to previous reports in literature, with no difference between the Jewish and Arabic populations.

Conclusion

Although the incidence of gynecologic sarcomas in the Israeli population is higher than in European populations, the distribution of histologic types and anatomic sites is similar. We found no significant difference in survival rates between Arabic and Jewish population through the years. These results provide important information regarding gynecologic sarcoma incidence and survival in Israel.
Aims

To review the outcomes of different urinary diversion techniques following post radiotherapy pelvic exenteration for recurrent/persistent gynaecological cancers.

Method

The current study pertains to those patients undergoing urinary diversion following pelvic exenteration between August 1993 to December 2013. These diversions were performed by a urological consultant. Data regarding age, type of cancer, previous treatment, time and site of recurrence, surgical details and complications as well as follow-up and long term sequelae were collected.

Results

There were a total of 86 patients who underwent pelvic exenteration between the study dates. Of these 60 underwent a urinary diversion procedure (69.7%). 31 had cervical cancer (51.7%), 12 vaginal cancer (20%), 9 endometrial cancer (15%) and 8 were vulval cancer (13.3%). Of these 60 cases 13 (21.6%) had a Mitrofanoff continent urinary diversions, 45 (75%) had an ileal conduit, 1 (1.7%) had a transverse colonic conduit and 1 (1.7%) had a Mainz-Sigma II procedure. Common early complications included UTI and stenosis of the Mitrofanoff. Later complications included revision of Mitrofanoff (5), and stones requiring percutaneous removal (1). There was one anastomotic leak [from an ileal conduit], treated conservatively. 41 (68%) patients have since died of disease [median time to death after exenteration being 18 months (3 months to 13 years)], and 18 (30%) are alive with 1 lost to follow up. Median follow up was 10 years (7 months to 20 years).

Conclusion

In our cohort of 60 patients undergoing pelvic exenteration over a 20-year period, there was a very acceptable rate of complications related to urinary diversion.

ROBOT-ASSISTED SURGERY IN ELDERLY AND VERY ELDERLY WOMEN AFFECTED BY GYNECOLOGICAL MALIGNANCIES: OUR SINGLE INSTITUTION EXPERIENCE ABOUT INTRAOPERATIVE AND POSTOPERATIVE OUTCOMES

V. Gallotta1, M. D’Indinosante2, A. Federico2, A. Biscione1, C. Conte1, S. Pelligra1, G. Vizzielli1, B. Costantini1, M.T. Giudice1, V. Chiantera3, A. Fagotti1, G. Scambia1, M.G. Ferrandina2

1Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome, Italy
2Università Cattolica del Sacro Cuore, Gynecologic Oncology, Roma, Italy
3Università Cattolica del Sacro Cuore, Gynecologic Oncology, Palermo, Italy

Aims

To assess the role of robotic surgery for the management of elderly patients with gynecological malignancies.

Method

Between December 2015 and March 2017, 112 patients underwent robotic-assisted laparoscopic surgery procedure for gynecological malignancies were retrospectively evaluated. 41 patients age> 75 years (very elderly group) were compared with 71 patients age from 65 to 74 years (elderly group). Demographic, operative and perioperative outcomes were analyzed retrospectively.

Results

The mean age was 68 years (range, 65-74 years) in the elderly group and 77.0 years (range, 75-87 years) in the very elderly group. There were no differences between two groups in body mass index, preoperative comorbidities and ASA (p 0.247).

Patients underwent surgery for different gynecologic oncological disease: 12 (11%) cervical cancer, 2 (1%) ovarian cancer, 98 (88%) endometrial cancer.

The types of surgical procedures performed were: 112(100%) radical hysterectomies with bilateral salpingo-oophorectomy, 44 (39%) pelvic lymphadenectomy, 11 (10%) aortic lymphadenectomy, 5 (4.5%) total omentectomy, and 2 (1.8%) pelvectomy. No difference were revealed between the two groups in terms of estimated blood loss, median operative time, median hospital stay and conversion rate. Rate of pulmonary failure was higher in elderly group (4% vs 0%). There were no between-group differences in postoperative infectious morbidity, cardiovascular complications, reoperation and intensive care unit admission.

Conclusion

The perioperative complication rate of robotic-assisted surgery are comparable in very elderly women and elderly women. This study support the feasibility and the role of robotic surgery in elderly and very elderly patients affected by gynecological cancers.
INCISSIONAL NEGATIVE PRESSURE WOUND THERAPY IN ONCOLOGICAL PATIENTS.
M.T. Climent1, C. Molinet Coll2, M.D. Martí Cardona1, M. Barahona Orpinell1, J. Rovira Montané1, M.J. Pla Farnós1, J. Ponce Sebastià1
1Bellvitge University Hospital, Gynecology, Barcelona, Spain
2Hospital Sant Joan de Déu, Gynecology, Barcelona, Spain

Aims

This study evaluates the efficacy of negative – pressure therapy in prevention of complicaciones in the surgical site in surgical oncologic patients.

Method

All major oncologic procedure performed with a laparotomy incision performed in two years. We performed a retrospective descriptive cohort study. We evaluated two cohorts, patients undergoing surgery in 2014 and cohort in 2016. The goals of the statitical analyses were to assess the wound complications and days of hospitalization were distributed differently between the incisional negative pressure wound therapy group (INPWT) and the NON-INPWT group.

Results

We included 147 patients. Of the total of patients, 39.6% of the patients used this dispositive. (mean of days to use it was 3 days). The total complication rate in our sample was 21.1%.

Rates of surgical complications in patients treated with INPWT was 2.7% compared with patients which no use INPWT was 18.4% (p=0.000) Performing a stratified analysis of complications; Infection (p=0.001), seroma (p=0.005), dehiscence (p=0.001) and were observed significant differences with a lower incidence of complications in INPWT group, an exception hematoma which no significant difference was found.(p=0.063).

Evaluating the hospital stay, we obtain a decrease in two days of admission, with statistically significant differences. (p=0.048)

Conclusion

Prophylactic use of closed-wound negative pressure therapy may decrease wound complications in oncological patients.
Cost utility analysis of methotrexate versus actinomycin-D in low risk gestational trophoblastic neoplasia

J. Geisler, K. Manahan
1CTCA, Gyn Oncology, Newnan, USA
2CTCA, Gyn Oncology, USA

Aims

To determine the most cost effective first line regimen for women with low risk gestational trophoblastic neoplasia (GTN) (WHO risk score 0-4 and no choriocarcinoma).

Method

Markov decision model (1000 patients) was used to analyze published data GOG 174. Arm 1 was weekly methotrexate at 30 mg/m2 weekly while arm 2 was actinomycin-D 1.25mg/m2 biweekly. Costs were based on average sale price (ASP) +6%. Utility values were determined by rating scale.

Results

The mean cost of therapy for methotrexate arm was $11,970/quality adjusted cure (95%CI $11,149-$12,791). The mean cost of the actinomycin-D arm was $26,865/quality adjusted cure ($26,780-$26,950). Weekly methotrexate dominated actinomycin-D as first line therapy.

Conclusion

First line therapy of low risk GTN should be weekly methotrexate.
ONCOLOGICAL OUTCOME OF SURGICAL TREATMENT IN PATIENTS WITH RECURRENT UTERINE CANCER—A MULTICENTER RETROSPECTIVE COHORT STUDY

11 La Paz University Hospital, Gynecologic Oncology Unit, Madrid, Spain

Aims

To assess survival impact of salvage surgery in recurrent cervical or endometrial cancer and to determine prognostic variables for improved oncological outcome

Method

Retrospective multicenter analysis of medical records of 518 patients with cervical (N=288) or endometrial cancer (N=230) who underwent surgical treatment for disease recurrence and who had available at least one year follow-up

Results

Median survival reached 57 and 112 months after surgical treatment of recurrence in patients with cervical and endometrial cancer (p=0.036). Histological subtype had significant impact on overall survival, with the best outcome in endometrial-endometroid cancer (120 months) followed by cervical squamous-cell carcinoma, cervical adenocarcinoma or other types of endometrial cancer (81 vs. 35 vs. 35 months; p<0.001). Site of recurrence did not significantly influence survival in cervical cancer (81, 45, 35, and 45 months for vagina, pelvis, lymph nodes, abdomen) nor in endometrial cancer (56, 48, 120, 112 months for vagina, pelvis, lymph nodes, abdomen). Stage at the first diagnosis, tumor grade, lymph node status at recurrence, PFI after first diagnosis, free resection margins were associated with improved OS on univariate analysis. On multivariate analysis, stage at first diagnosis and resection margins were significant independent predictive parameters of improved oncological outcome

Conclusion

Long-term survival can be achieved after surgical treatment in selected patients with recurrent cervical and endometrial cancer. Excellent results can be obtained, especially in patients with endometrial cancer, even if site of recurrence is in lymph nodes or in abdomen. Achieving free resection margins is the most significant prognostic factor in both types of cancer

VASCULAR INJURIES DURING PELVIC AND PARAORTAL LYMPH NODE DISSECTION – LAPAROSCOPIC MANAGEMENT

S. Baydo\(^1\), A. Vinnytska\(^2\), D. Golub\(^2\)

\(^1\)LISOD – Israeli Oncological Hospital, surgery, Kyiv, Ukraine
\(^2\)LISOD – Israeli Oncological Hospital, gynecology, Kyiv, Ukraine

Aims

Major vessels injury during laparoscopic surgery is rare but very dramatic complication. Almost always it required conversion to laparotomy for completion of hemostasis. We represent our experience in performing laparoscopic hemostasis after vascular injuries during pelvic (PLND) and paraaortal (PALND) lymph node dissection.

Method

In 2010-2017 we performed 267 PLND and 396 PALND. Among them 581 single-region dissection: 226 PLND and 355 PALND, while 41 - both regions. Indications: cervical – 130(20,9%), endometrial – 122(19,6%), ovarian – 15(2,4%), colorectal – 343(55,1%), other malignancies – 12(1,9%). We obtained 7 major vascular injuries (1,1%): 2 – aorta, 2 - vena cava inferior, 2 – v.iliaca, 1 – a.iliaca. All vascular injuries occurred in patients with history of chemoradiotherapy, and there weren’t any in primary treated patients. In all cases we performed laparoscopic hemostasis. To achieve hemostasis we used next steps: 1) pressure of vascular wound; 2) round dissection of vessel and applying of vascular clamps for injuries longer than 2mm; 3) suturing the vascular damage (prolene 5/0).

Results

Size of vascular damage: up to 2mm in 5, 5 and 8mm in 2 cases of vena cava injury. Average time from injury to completion of hemostasis - 17min (11-34). The estimated blood loss – 150ml (45-700). There was no need for transfusion. Median hospital stay in case of vascular injury was 4,9 days versus main group (4,5). No thrombotic complications and death occurred.

Conclusion

Vascular injury of major vessels during lymphadenectomy is rare but very serious complication that can be successfully treated laparoscopically by experienced surgeon.
CHARACTERISTICS OF OVARIAN CANCER IN WOMEN WITH LYNCH SYNDROME

11 Leiden University Medical Center, Gastroenterology & Hepatology, Leiden, The Netherlands
12 University Medical Center Groningen, Gynaecologic Oncology, Groningen, The Netherlands

Aims

To describe clinical characteristics of ovarian cancer diagnosed in women with Lynch syndrome (LS) and the role of surveillance in the early detection of these cancers.

Method

All women with LS identified in the Dutch Lynch syndrome registry or from the cohort at our University Medical Center Groningen (UMCG) who developed ovarian cancer were included. Clinical data on age at diagnosis, mutation type, histological type, FIGO stage, treatment, follow-up and gynaecological surveillance were collected.

Results

In the Dutch LS registry, 46/785 women (6%) with ovarian cancer were identified and 7/80 (9%) from the UMCG. The mean age of 53 patients at ovarian cancer diagnosis was 46.1 years (range 20-75 years). MSH2 (32%) and MSH6 (28%) were the most frequent gene mutations. The most frequently reported histological type was endometrioid adenocarcinoma (40%) and most tumours (87%; n=46) were detected at an early stage (FIGO I/II). Forty-one of 53 (77%) patients were diagnosed with ovarian cancer before LS was known. In 12/53 (23%) women ovarian cancer developed after starting annual gynaecological surveillance. Three ovarian cancers were diagnosed during surveillance in asymptomatic women, (two FIGO stage 1A, one stage IIC). Six ovarian cancers were detected together with a (pre)malignancy of the endometrial tissue, (four FIGO stage IA, one stage IB, one stage IIA)

Conclusion

Ovarian cancer in women with LS has a wide age-range of onset, is most often diagnosed at an early stage with an endometrioid type histology. The early stage at diagnosis could not be attributed to annual gynaecological surveillance.
GESTATIONAL TROPHOBLASTIC DISEASE: ALTERNATIVE TREATMENT OPTIONS?

M. Huang1, A. Pinto2, R.P. Castillo3, B. Slomovitz3

1University of Miami, Gynecologic Oncology, Miami, USA
2University of Miami, Pathology, Miami, USA
3University of Miami, Radiology, Miami, USA

Aims

Gestational trophoblastic neoplasia (GTN) usually has high cure rates. However, in patients presenting with advanced disease, only 60-70% achieve complete remission with current chemotherapies. We present a case of choriocarcinoma and introduce a novel treatment option.

Method

Case X medical records were reviewed and treatment history summarized. Molecular genomic testing was performed to identify potential targetable pathways.

Results

Ms X is a 26 y.o presenting with stage IV choriocarcinoma with a WHO score of 18 initiating treatment with multi-agent EMA-CO every 2 weeks. Patient developed brain metastasis on treatment, received gamma knife therapy and changed to EMA-EP regimen. Treatment was complicated by grade 3 thrombocytopenia requiring treatment delays resulting in rising beta HCG levels (Table 1). Molecular testing demonstrated PD-L1 IHC positive, 2+ (90%), TP53 exon 7, G245S mutation, Her2/Neu IHC positive 3+ (30%), TOP2A IHC positive 1+ (90%) and RRM1 IHC negative 2+ (10%). Based on results, treatment with PD1 inhibitor was given with normalization of BHCG following two cycles and near complete response.

Conclusion

Targeted therapy with PD-1 receptor blockade may be a more efficacious and tolerable treatment option than current standard multi-agent chemotherapies. Prospective clinical trials should explore this therapy.

9Universitätsklinik Göttingen, gynecology and obstetrics, Göttingen, Germany
10Leopoldina-Krankenhaus, gynecology and obstetrics, Schweinfurt, Germany
11Hochtaunus-Kliniken, gynecology and obstetrics, Bad Homburg, Germany
12Uni.-Klinikum Carl Gustav Carus, gynecology and obstetrics, Dresden, Germany
13Klinikum der Universität München, gynecology, München, Germany
14Universitätsklinik der Johannes Gutenberg-Universität Mainz, obstetrics and women’s health, Mainz, Germany
15Universitätsklinik der Johannes Gutenberg-Universität Mainz, radiooncology and radiation therapy, Mainz, Germany

Aims

The aim of this register is to prospectively collect data of patients with gynecological sarcomas to describe their course of disease, diagnostics and therapies.

Method

An electronic case report was designed to register clinical data from patients in Germany such as disease, surgery, therapy and success of therapy after informed consent.

Results

Within 20 months 170 patients from 87 sites have been included into the study. 152 of the patients are evaluable. Patients were between 24 and 87 years old (mean 56 years), 106 of them with primary diagnosis and 46 with recurrent disease. There were 74 leiomyosarcomas, 33 endometrial stromal sarcomas (high grade 11, low grade 22), 6 undifferentiated uterine sarcomas, 9 adenosarcomas and 23 others (e.g. rhabdomyosarcoma among others). 15 patients presented with distant metastases at primary diagnosis. Vaginal bleeding was the most common symptom for diagnosis followed by stomach pain. 18 patients showed no symptoms at the time of initial diagnosis. 49 women had myoma diagnosed in advance to the initial diagnosis of sarcoma. In 88 patients with primary diagnosis (43 leiomyosarcomas, 22 endometrial stromal sarcomas, 3 undifferentiated uterine sarcomas, 6 adenosarcomas and 14 others) surgery has been performed - in 13 cases (14.8%) with morcellation. Morcellation was conducted in 8 leiomyosarcomas, 4 endometrial stromal sarcomas and 1 STUMP.

Conclusion

Due to a first analysis of the patients’ data there has been insight into characteristics of gynecological sarcoma patients and their treatment. Morcellation was performed in a non-neglectable number of patients with sarcoma. Further follow up is ongoing.
LATERALLY EXTENDED ENDOPELVIC RESECTION FOR THE PELVIC SIDE WALL TUMORS: EXPERIENCE FROM A PROSPECTIVE COHORT STUDY

L. Maria1, K. Se Ik1, H.S. Kim1, K. Jae Weon1
1Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims
To evaluate the efficacy and safety of laterally extended endopelvic resection (LEER) for removing the pelvic side wall tumors in a prospective cohort study.

Method
We enrolled patient with primary (n=12) and recurrent (n=10) diseases between March 2014 and April 2017. All patients showed tumor invasion to the pelvic side wall by gynecologic examination and preoperative imaging studies. We evaluated the feasibility of LEER by using the learning curve related with surgical outcomes. Furthermore, we investigated survival after LEER, and relevant complications.

Results
Among a total of 22 patients, 16 (72.9%), 3 (13.6%), 1 (4.5%), 1 (4.5%) and 1 (4.5%) showed cervical cancer, ovarian cancer, endometrial stromal sarcoma, Müllerian adenosarcoma and malignant melanoma. Among all patients, 16 patients (72.7%) showed negative resection margin and 18 (81.8%) preserved at least one pelvic organ after LEER. Perioperative outcomes improved as our experience of LEER increased in recurrent diseases despite no change in primary diseases. After LEER, grade 2 or 3 neuropathy, hydronephrosis, infected lymphocele, grade 3 lymphedema developed in 7 (35%), 1 (5%), 4 (20%), 2 (10%) and 2 (10%) patients without no treatment-related death. In locally advanced cervical cancer, LEER showed similar survival outcomes to primary chemoradiation, and response to neoadjuvant chemotherapy was related with better survival.

Conclusion
LEER may require a training period for improving surgical outcomes. It can be considered to be feasible and safe for patients with the pelvic side wall tumors if no effective alternative to control local tumors (No. NCT02986568).
The clinicopathological study of 21 cases with uterine smooth muscle tumors of uncertain malignant potential: centralized review can purify the diagnosis.

1Etlik Zubeyde Hanım Research and Training Hospital, Gynecologic Oncology, Ankara, Turkey
2Hacettepe University Faculty of Medicine, Department of Clinical Pathology, Ankara, Turkey
3Hacettepe University Faculty of Medicine, Department Obstetrics and Gynecology, Ankara, Turkey
4Etlik Zubeyde Hanım Research and Training Hospital, Department of Clinical Pathology, Ankara, Turkey

Aims

To investigate the clinicopathological features and factors associated with recurrence in patients with uterine smooth muscle tumor of uncertain malignant potential (STUMP).

Method

Forty-six cases diagnosed between 2000 and 2014 from two tertiary centers underwent blind slide review. Initial diagnosis included smooth muscle tumors with equivocal diagnosis, STUMPs and cases that were named as leiomyosarcomas (LMS) or low grade LMS despite not fulfilling the Stanford criteria. (Figure-1)

Results

In total, 21 patients with a final diagnosis of STUMP were available. 15/22 of (68.1%) patients with an initial diagnosis of STUMP, 4/18 (22.2%) of cases with an equivocal smooth muscle tumor diagnosis and 2/6 of (33.3%) cases with an initial diagnosis of LMS were interpreted as STUMP after slide review (Table 1). The mean age at diagnosis was 43 years (range: 20-64 years). The mean follow-up time was 65.9 months (range 10-154 months). Four (19.0%) patients developed recurrent disease. Recurrent tumors were LMS in 3 (75%) patients. One (4.8%) patient with recurrence succumbed to disease (Table 2). There was no difference in patients’ age (p=1.0) or type of initial surgery (uterus conserving versus hysterectomy) (p=0.57) between patients who recurred and did not recur.

Copyright © 2017 by IGCS and ESGO. Unauthorized reproduction of this article is prohibited.
Conclusion

Most cases with uterine STUMPs have favorable oncological outcomes, however; some may have a more aggressive clinical course associated with recurrence and death. Uterine mesenchymal tumors other than ordinary myomas and overt sarcomas deserve a second opinion in centers with experience because the real diagnosis may vary significantly.
ENDOARTERIAL CHEMOTHERAPY AND TRANS-ARTERIAL CHEMOEMBOLIZATION IN GYN CANCER PATIENTS WITH PELVIC RELAPSES IN PREVIOUSLY IRRADIATED ZONES.

J. Kreynina, L. Shevchenko, N. Khoronenko, M. Kaskulova

1. Russian scientific center of roentgenradiology, Brachytherapy, Moscow, Russia
2. Russian scientific center of roentgenradiology, Endovascular Technologies, Moscow, Russia

Aims

Pelvic relapse is a fatal outcome for majority of GYN cancer patients, with severe complications of tumor progression, low life quality, ≤10-20% significant response to conventional therapy. Endovascular chemotherapy can overcome tissue and vessel changes for tumors in previously irradiated zones.

Method

8 pelvic relapsed patients after 40-84Gy irradiation were included, 4 (50%) - with cervical, 1 (12.5%) – uterine, 2 (25%) – vulvar, 1 (12.5%) - ovarian cancer recurrences, localised centrally in 2 (25%) pts, lateral or centro-lateral with pelvic wall involvement – in 6 (75%). All relapses were symptomatic, with severe pain in 6 (75%), bleeding – in 4 (50%), severe lymphedema in low extremities – 3 (37.5%). Endoarterial prolonged infusions of Cisplatin 75-100mg/m2 were performed in all 8 (100%) pts., twice - in 6 (75%) pts with 18–21 day intermission, chemoembolization (Hepasphere®) with Carboplatinum AUC3-4 – in 2 (25%).

Results

Clinical response RECIST 2.0 was achieved in 7 (87.5 %) pts., no complete response, PR >50% – in 3 (37.5%) pts, 25–45% of tumor volume reduction – in 4 (50%) pts. Local progression with bladder and rectal fistulas was diagnosed in 1 (12.5 %). Salvage surgery was performed successfully in 2 (25%) pts in 6-10 weeks, interstitial brachytherapy or hypofractioned IMRT – in 5 (62.5%) pts in 2–6 weeks after endovascular procedures.

Conclusion

Endoarterial chemotherapy and trans-arterial chemoembolization are the perspective ways to improve overall results and life quality for GYN cancer patients with loco-regional relapses in previously irradiated zones, opening new treatment options for salvage therapy.
IMPLEMENTATION OF AN ENHANCED RECOVERY PROGRAM IN GYNAECOLOGIC SURGERY: PRELIMINARY RESULTS FOR ONCOLOGICAL INDICATIONS.

1 Institut Paoli Calmettes, Département de Chirurgie Oncologique 2, Marseille, France
2 Institut Paoli Calmettes, Département d’Anesthésie Réanimation, Marseille, France
3 Institut Paoli Calmettes, Département Biostatistique, Marseille, France

Aims

Enhanced Recovery Program (ERP) is a multimodal approach of perioperative patient’s clinical pathways that results in a faster recovery after surgery and decreased length of stay (LOS).

The objective of this study is to evaluate the results of the implementation of ERP in gyn oncological indications on LOS, morbidity and readmissions.

Method

A prospective observational study was performed at Paoli-Calmettes Institute Cancer Center (Marseille, FRANCE) between December 2015 and June 2016. All the patients referred for hysterectomy and/or pelvic or para-aortic lymphadenectomy for gynaecological cancer were managed with a standardized ERP. Our results were compared to a control group including 100 patients, previously managed in our center between April 2015 and November 2015, without ERP.

Results

A total of 100 patients were included. 87% of the procedures were performed by conventional or robotic assisted laparoscopy. The readmission rate was 6% and the total complication rate was 25% (2% intraoperative, 3% major (grade III, IV) and 20% minor (grade I, II) according to Clavien Dindo classification). After ERP implementation, median length of stay of our cohort was significantly reduced (3.15 days vs. 3.89 days; p=0.002), particularly for laparoscopic approaches (2.67 days vs 3.33 days; p=0.0005). The percentage of patients discharged before 2 days increased (45% vs. 24%; p=0.002) without increasing major complications rates.

Conclusion

ERP in gynaecological surgery is safe and feasible. We demonstrate the interest of patient centered clinical pathway to standardize outcomes and reduce length of stay in respect with patients’ safety, particularly in gyn oncological indications.

THE RESULTS OF TREATMENT WITH HIGH-DOSE CHEMOTHERAPY AND PERIPHERAL BLOOD STEM CELL SUPPORT FOR GESTATIONAL TROPHOBLASTIC NEOPLASIA

M. Frijstein¹, C. Lok¹, D. Short², K. Singh³, R. Fisher³, B. Hancock³, J. Tidy³, N. Sarwar³, M. Winter³, P. Savage³, M. Seckl²

¹Center of Gynaecologic Oncology Amsterdam, Department of Gynaecology, Amsterdam, The Netherlands
²Charing Cross Hospital, Department of Medical Oncology, London, United Kingdom
³Weston Park Hospital, Trophoblastic Disease Centre, Sheffield, United Kingdom

Aims

Most women with gestational trophoblastic neoplasia (GTN) are cured, but a small number become refractory to all standard chemotherapy regimens. The value of high-dose chemotherapy (HDC) with peripheral blood stem cell support (PBSCS) and the optimal number of courses (1 or 2) for refractory choriocarcinomas and poor prognosis PSTT/ETTs is unclear.

Method

Databases of two referral centers for GTN were searched. All patients treated with HDC between 1994 and 2015 were eligible for the study. Patient files were analyzed and tissue samples were retrieved for genetic evaluation. In total 32 patients were identified.

Results

The majority of the patients were initially high-risk according to their FIGO score and had multiple lines of chemotherapy and surgery. Twenty-two patients were treated with 1 course HDC and 10 patients with 2 courses. An hCG response occurred in 44% (14/32), and overall, 41% (13/32) of the patients remained disease free after HDC. Thirty-two percent of the patients treated with 1 course HDC survived compared to 60% of the patients treated with 2 courses, (p=0.244).

Conclusion

HDC with PBSCS appears to be active in salvaging selected patients with poor prognosis PSTT/ETTs and drug resistant choriocarcinomas. Whilst two courses of HDC seem more beneficial for survival, this may be explained by tumour stage, clinical performance status and toleration of the first course of treatment. HDC should only be given in centers with adequate experience, both in treatment of patients with GTN and in administration of HDC.
Aims

Are there any significant differences between LMS and LM clinical findings allowing the creation of a preoperative LMS-Risk-Score to prevent an inadequate LMS surgery?

Method

Matched data analysis of 235 LMS and 669 LM from the German Clinical Competence Centre for Genital Sarcomas and Mixed Tumours and cooperating departments was performed.

Results

There was a statistical significant difference (p < 0.01) in regard to the mean age of patients with LM vs. LMS (43.3 vs. 54 years) and in mean tumor diameter (5.2 vs. 10.1 cm), respectively. Further significant different findings are presented in table 1. Tamoxifen exposition, failure of prior pharmacological therapy of LM, and prior surgery of atypical smooth muscle tumor were higher in LMS group, but differences not reached significant levels. Tumor related symptoms without bleeding disturbances were slightly higher in LM. Despite these differences 60 % of the 235 LMS were operated under the diagnosis of LM and 66.8 % underwent an inadequate surgery.

Table 1. Significant (p < 0.01) different findings in LM and LMS

<table>
<thead>
<tr>
<th>Findings</th>
<th>LM %</th>
<th>LMS %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Postmenopause</td>

A SINGLE INSTITUTION QUALITY ASSURANCE PROGRAM FOR PRIMARY DEBULKING SURGERY IN ADVANCED OVARIAN/TUBAL/PRIMARY PERITONEAL CANCER

E. Araya¹, M. Sundset¹, S. Tingulstad¹, M. Ravlo¹, N. Nordskår¹, J. Kippervik¹, A.K. Engebretsen¹, G. Aune¹, B. Hagen¹
¹St. Olavs University Hospital, Dept of Obstetrics and Gynecology- Section of Gynecologic Oncology, Trondheim, Norway

Aims

To report initial results following the implementation of prospective registration of surgical procedures and completeness, postoperative complications and postoperative mortality, as part of a single institution quality assurance program in advanced ovarian/tubal/primary peritoneal cancer.

Method

Prospective data from 01.01.2014 to 31.12.2016. Details on surgical procedures categorized into surgical complexity scores (SCS). 3 surgical outcome categories: no gross residual tumor (NGR), gross residual tumor ≤ 1 cm (GR-1) and gross residual tumor > 1 cm (bulky) (GR-B). 30 days postoperative complications according to the Clavien Dindo Classification (CD) and 30 days' postoperative mortality. Finally, rate of chemotherapy omission and time to initiation of chemotherapy was registered together with recurrences for the calculation of progression-free survival.

Results

Among 153 patients diagnosed, 103 (70%) had stages 3 or 4 of whom 96 underwent primary debulking surgery (PDS). A trend of increasing surgical complexity was observed. The NGR rate was 46 %, 57 % and 73 % in 2014, 2015 and 2016, respectively. Corresponding rates for GR-1 were 18 %, 20 % and 18 %; and for GR-B 36 %, 23 % and 9 %. Corresponding rates of clinically significant complications (CD III-IV) were 29 %, 20 % and 33 %. The rate of postoperative mortality (CD V) for the whole period was 5 %. Median PFS was 16.5 months increasing from 9.9 months for patients with GR-B to 24.0 months for patients with NGR.

Conclusion

Implementation of prospective registration of surgery may improve the surgical outcome in advanced ovarian cancer.
TP53 DOMAINS’ MUTATIONS ALTER GLYCOLYSIS IN EPITHELIAL OVARIAN CARCINOMA: EX-VIVO AND IN VITRO STUDY

D. Atallah¹, S. Antoun², M. Moubarak³, N. El Kassis³, G. Chahine⁴, G. Hilal⁴
¹ Obstetrics and Gynecology, Beirut, Lebanon
² Cancer and metabolism laboratory, Beirut, Lebanon
³ Beirut, Lebanon
⁴ Oncology, Beirut, Lebanon

Aims

To investigate the effect of TP53 different domain mutations on its transcriptional activity, its ability to induce apoptosis and to regulate glucose consumption and lactate production in epithelial ovarian cancer.

Method

30 ovarian cancer biopsies were characterized. Immunohistochemistry for p53 expression and PCR for exons 2 till 11 were performed, followed by the Single Strand Conformation Polymorphism (SSCP) technique and sequencing. The transcriptional activity of p53 was studied by a qPCR for its target genes p21 and MDM2. Viability and Annexin V tests were performed to study the ability of mutant p53 to induce apoptosis. The expression of the glycolytic enzymes regulated by p53 was quantified by qPCR. SK-OV-3 cell line was transfected by different p53 mutated plasmids, and the same experiments performed on the biopsies were done on transfected cells.

Results

The immunohistochemistry and qPCR showed an approximately 2 folds increase in p53 expression between wild type and mutated cases. The expression of p21 and MDM2 decreased only in DNA binding domain mutated cases and transfected cells, which indicates a decreased transcriptional activity with this type of mutation. The highest increase in apoptosis induction was clear in Sk-Ov-3 cells transfected with WT p53, and p53 proline rich domain mutations decreased the protein’s apoptotic function. Glucose consumption and lactate production increased by mutated cells compared to wild type.

Conclusion

Mutant p53 is overexpressed in ovarian cancer cells. DNA binding domain mutations modify the protein’s transcriptional activity, whereas proline rich domain mutations decrease the protein’s apoptotic activity. Glycolysis is affected differently in both types.

MHC I DOWN-REGULATION AND PD-L1 EXPRESSION ARE MUTUALLY EXCLUSIVE IN SEROUS OVARIAN CANCER

S. Aust¹, A. Reinthaller², A. Katharina³, L. Kerner³, S. Dekar³, C. Grimm¹, D. Pils³

¹Medical University of Vienna.
²Department for Gynecology and Gynecologic Oncology- Gynecologic Cancer Unit- Comprehensive Cancer Centre, Vienna, Austria
³Medical University of Vienna, Center for Medical Statistics- Informatics- and Intelligent Systems & Dept. of Surgery, Vienna, Austria

Aims

The importance of the tumor immune microenvironment in epithelial ovarian cancer (EOC) has been demonstrated and evokes high expectations for tumor specific immunotherapy. Currently, promising activity of antibodies targeting programmed cell death receptor ligand 1 (PD-L1) across multiple malignancies raise expectations on their role also in EOC. Our aim was to determine the clinical role of PD-L1 as mechanism to escape immune recognition in EOC.

Method

We analyzed PD-L1 expression of primary ovarian and peritoneal tumor tissues together with several other parameters (whole transcriptomes of isolated tumor cells, local and systemic immune cells, systemic cytokines and metabolites) and compared PD-L1 expression between primary tumor and tumor recurrences.

Results

All expressed major histocompatibility complex (MHC) I genes were negatively correlated to PD-L1 abundances on tumor tissues, indicating two mutually exclusive immune-evasion mechanisms in EOC: either down-regulation of T-cell mediated immunity by PD-L1 expression or silencing of self-antigen presentation by down-regulation of the MHC I complex. In our cohort, low PD-L1 expression is associated with unfavorable outcome. Differences in immune cell populations, cytokines, and metabolites suggest the existence of concurrent pathways for progression of this disease. Furthermore, recurrences showed significantly increased PD-L1 expression compared to the primary tumors, supporting trials of checkpoint inhibition in the recurrent setting.

Conclusion

This data shows that targeting immune-escape mechanisms is complex and various pathways have to be considered simultaneously. As data obtained within different cancer types might not apply for all tumor entities we still need to define criteria to guide patient selection for PD-L1 therapy in EOC.
THE IMPORTANCE OF DNA PLOIDY MEASUREMENT IN FOLLOW UP OF PATIENT WITH MALIGNANT EPITHELIAL OVARIAN TUMORS

S. Babloyan¹, G. Beglaryan², P. Karakitsos³

¹Yerevan State Medical University, Erebouni Medical Center, Yerevan, Armenia
²Yerevan State Medical University, OBGYN N1, Yerevan, Armenia
³National University of Athens, Department of Cytolpathology- University Hospital Atticon, Athens, Greece

Aims

The aim of our study was to evaluate the importance of different of DNA ploidy parameters in analysis of survival rate in patients with malignant epithelial ovarian cancer.

Material: Our study was carried out on 105 patients with malignant common epithelial tumors of the ovary in the age ranged from 22 to 70 years (Mean value 45,2, SD=18,35 years)

Method

DNA ploidy measurement in cytological and histological material of tumors was performed. To determine the prognostic significance of various ploidy parameters one-dimensional and multivariate statistical Cox analysis were performed.

Results

Analysis of hyperploidy index (DH) showed that patients with a degree of hyperploidy corresponding to >3% have a roughly 7-fold greater risk of fatal outcome (Hazard ratio-7.20, p <0.001, CI- 2.99-17.32) in comparison to patients with degree of hyperploidy below <3%. Analyzing the results of the ploidy balance (PB) shows, that patients with a ploidy balance <70% have a roughly 5 times higher risk of unfavorable prognosis (Hazard ratio-5.16) compared to patients with a balance of ploidy corresponded to > 70%. The result demonstrate that degree of ploidy parameters and aneuploidy in malignant epithelial tumor has important prognostic value.

Conclusion

Cox statistical analysis showed the measurement importance of different ploidy parameters in the overall survival of patients with malignant epithelial ovarian tumors (p <0.001). According to the one-dimensional and multivariate statistical analysis degree of aneuploidy (DA), degree of hyperploidy (DH) and ploidy balance (PB) are important indicators for the general survival rate of patients with malignant epithelial tumours of ovaries (p <0.001).

3Lecturer of clinical oncology- Ain Shams faculty of medicine, clinical oncology, cairo, Egypt
4Assistant professor of clinical oncology- Kasr Alini faculty of medicine, clinical oncology, cairo, Egypt
5Lecturer of clinical oncology- kasr alini faculty of medicine, clinical oncology, cairo, Egypt
6Lecturer of clinical oncology- Zagazig faculty of medicine, clinical oncology, cairo, Egypt
7Lecturer of clinical oncology- Suez canal faculty of medicine, clinical oncology, eskandera, Egypt
8Lecturer of clinical oncology- national cancer institute, clinical oncology, cairo, Egypt
9King Faisal Specialist Hospital- oncology research data analyst, oncology, riyadh, Saudi Arabia

Aims

To report clinical characteristics and long-term outcomes of adult-type OGCTs at our center and to determine prognostic factors affecting relapse and survival

Method

From 1988 to 2014, we retrospectively reviewed patients with adult-type OGCTs. Baseline characteristics, pathological findings and outcomes were analyzed

Results

61 patients with adult-type OGCTs were identified with median age of 49 years. Median follow-up was 5.0 years. 74% of patients had FIGO stage I, 7% had stage II, 5% had stage III and unknown in 14%. Most common presenting symptoms included abdominal pain (43%) and vaginal bleeding (43%). Majority of patients (37 patients, 60.7%) were treated with TAH and BSO. 5 (8%) patients received adjuvant chemotherapy. Sixteen patients (26%) relapsed with a median time to relapse of 5.5 years. Half of recurrence (8 patients) occurred after 5 years of diagnosis. Five-year overall survival and disease-free survival were 93% and 84%, respectively. Factors associated with high risk of recurrence were ascites (p=0.000) and elevated preoperative CA 125 (0.048). Overall survival was significantly influenced by menopausal status (premenopausal 100% vs. postmenopausal 84%; p=0.02), preoperative CA 125 (normal 100% vs. elevated 64%; p=0.005), Ascites (present 33% vs. absent 100%; p=0.000), and age (<55 years 100% vs. ≥ 55 years 77%; p=0.002)

Conclusion

This confirms a good outcome of patients with OGCTs. They require long-time follow-up because recurrence can occur many years after primary therapy. Presence of ascites and elevated preoperative CA 125 were associated with higher risk of recurrence and poor prognosis. Outcome seems not to be affected by fertility-sparing surgery

EXPRESSION PATTERN OF p53, BAX PROTEIN AND CANCER STEM CELL MARKERS CD133 AND NOTCH IN OVARIAN CANCERS

J. Bar1, A. Lis-Nawara1, L. Hirnle2, M. Jelen3
1Wrocław Medical University, Immunopathology and Molecular Biology, Wroclaw, Poland
2Wrocław Medical University, First Department of Gynecology, Wroclaw, Poland
3Wrocław Medical University, Department of Pathomorphology and Clinical Oncology, Wroclaw, Poland

Aims

Biological heterogeneity of ovarian carcinoma is well documented. Up to now several biological parameters have been analyzed to describe the biological behavior of ovarian carcinoma cells. The aim of the study was to evaluate the expression of stem cells proteins (CD133, Notch1) and p53, Bax protein in ovarian carcinomas in order to establish the biological behavior of ovarian carcinoma.

Method

Stem cells proteins (CD133, Notch1) and p53, Bax proteins expression was analyzed on 104 malignant ovarian tumors using immunohistochemistry (IHC).

Results

P53 protein was found in 39% of ovarian carcinomas and was observed more frequently in advanced stage of disease (FIGO III/IV) (P = 0.04), and poorly differentiated tumors (G3) (P = 0.01). Nuclear accumulation of p53 protein dominated in serous ovarian carcinomas (P = 0.02). Bax protein expression occurred in 42% of ovarian carcinomas and was associated with low stage of disease (FIGO I/II) (P = 0.03). CD133 and Notch expression was observed in 38.0% and 33.0% of ovarian carcinomas respectively. The association between poorly differentiated tumor and Notch1 expression (P = .002) was found. CD133 molecule did not correlate with clinicopathological parameters of ovarian carcinomas. Positive correlation between CD133 and Notch 1 was revealed in ovarian carcinomas (P = 0.02). CD133+/Notch1+ immunophenotype dominated in poorly (G3) differentiated ovarian carcinomas.

Conclusion

Our results suggest that parallel expression of CD133 and Notch1 molecules on tumor cells identified subgroup of ovarian carcinomas with high morphological malignancy. Co-expression of CD133 and Notch1 might be associated with redifferentiation of tumor cells.
Aims

To evaluate the benefit of hormonal therapy (HT) in advanced ovarian cancer (AOC).

Method

We reviewed the data of patients with AOC who underwent HT between 2009 and 2016. Primary endpoint was clinical benefit (CB). Secondary endpoints were overall survival (OS), progression-free survival (PFS) and toxicity. Descriptive analysis of the main demographic and clinical characteristics was performed. PFS and OS were evaluated using the Kaplan-Meier method.

Results

We identified 47 patients. Median age was 61 years. Serous carcinoma was the main histologic subtype (70%). Clinical stages at presentation were FIGO IIIB (13%), IIIC (55%) and IV (21%). Hormone receptor expression (HRE) was positive in most of the tested patients. Previous to HT, 36% were treated with one regimen of chemotherapy (CT) and 60% with ≥2 regimens. HT was initiated in 34% due to disease progression and the remaining as maintenance therapy. The majority had ECOG ≤1 (70%). Letrozole was the most commonly used (77%), followed by tamoxifen (17%) and megestrol (6%). No relevant toxicity was reported. PFS was 6 months (CI 95% 2.1-9.9) and OS was 22 months (CI 95% 13.0-31.0). Based on imaging response criteria, one patient had complete response, 70% had stable disease and 19% progressed on the first evaluation. Overall CB was 72%.

Conclusion

CB was superior to the reported in the literature, probably related to its maintenance use between CT treatments. More prospective studies are needed to determine the real advantage of HT in AOC vs clinical surveillance in the maintenance setting, as well as its correlation with HRE.

ESGO7-0436

COMPARISON OF SYMPTOMS AND QUALITY OF LIFE IN RECURRENT OVARIAN CANCER BY RURAL/URBAN RESIDENCE: ANCILLARY ANALYSIS OF GOG-0259

S.M. Belcher¹, S.M. Sereika¹, M.K. Mattos², T.L. Hagan³, H.S. Donovan¹
¹University of Pittsburgh School of Nursing, Health and Community Systems, Pittsburgh, USA
²University of Virginia School of Nursing, Acute and Specialty Care, Charlottesville, USA
³Massachusetts General Hospital, Harvard Medical School, Boston, USA

Aims

Women with recurrent ovarian cancer (OC) experience a wide range of cancer- and treatment-related symptoms that negatively impact their quality of life (QOL). Research demonstrates that geographic differences in access to high-quality care are associated with healthcare disparities. Our objectives were to evaluate whether rural (versus urban) residence is associated with worse symptoms and poorer QOL in a nationwide sample of women with recurrent OC.

Method

Baseline GOG-0259 data were analyzed. We mapped zip codes to Rural Urban Continuum Code approximations and compared sociodemographic and clinical variables between rural and urban groups using two-sample t and chi-square tests. We used multivariate analysis of covariance to test for associations between residence and symptoms and QOL (FACT-O), controlling for known personal, social, and health risk factors.

Results

Rural (n=75, 15.1%) and urban (n=422, 84.9%) women differed by marital status (83% vs. 70% married), number of concurrent symptoms (16 vs. 14), and overall QOL (107.5 vs. 111) (p<.05). In omnibus multivariate analyses, geographical residence was not associated with either symptoms or QOL. Higher anxiety and lower optimism were associated with worse symptoms. Higher social support, lower depressive symptoms, lower anxiety, and fewer comorbidities were associated with better QOL.

Conclusion

Despite differences in symptoms and QOL by rural/urban residence in bivariate relationships, multi-variate analyses suggest that social and psychological factors may be more important predictors of these outcomes. Future large sample studies should evaluate the interactions between place of residence and social/psychological factors in influencing symptoms and QOL among women with OC.
OPEN VERSUS MINIMALLY INVASIVE SURGERY FOR THE TREATMENT OF GRANULOSA CELL TUMORS OF THE OVARY: RESULTS FROM THE MITO 9 STUDY

Aims

To compare oncological outcomes between laparoscopic and open surgery in the treatment of stage I granulosa cell tumors of the ovary (GCT).

Method

Data from 240 patients with stage I GCT were retrospectively collected among MITO centers (Multicenter Italian Trials in Ovarian cancer and gynecologic malignancies) and analyzed.

Results

19 patients were affected by juvenile GCT (7.5%), 222 (92.5%) by adult type GCT. Stage 1A, 1B and 1C were 68%, 2% and 30% respectively. 138 patients (57.5%) underwent open surgery while 102 (42.5%) laparoscopic surgery. No differences in residual tumor or postoperative complications were detected between the two groups. Five year disease free survival (DFS) rates in the laparoscopic and open-surgery cohorts were 84% and 80% respectively (p=0.3). Median DFS were 228 ± 29 months and 161± 18 months, respectively.

Conclusion

In the present study laparoscopy did not affect the oncological outcome of patients affected by GCT, with comparable postoperative outcomes.

TP53 MUTATIONAL ANALYSIS IN OVARIAN CANCER
A. Berger1, I. Tsibulak1, S. Abdel Azim2, G. Shivalingaiah2, S.S. Wenzel2, I. Gaugg1, M. Fleischer1, A. Zeimet1, H. Fieg1, J. Zschocke1, C. Marth1
1Med. Universität Innsbruck, Department für Gynäkologie und Geburtshilfe, INNSBRUCK, Austria
2Med. Universität Innsbruck, Devision für Humangenetik, INNSBRUCK, Austria

Aims

p53 is the most frequently mutated gene in cancer. There are conflicting results in literature regarding TP53 mutations and survival in ovarian cancer (OC) patients. Therefore we analyzed the TP53 mutational status in a well-defined patient-cohort.

Method

Samples from 199 ovarian cancer patients diagnosed at our Department between 1989 and 2014 were analysed. After DNA extraction the TP53 mutational status was determined by Next generation sequencing using the TruSight Cancer Sequencing Panel. Results were correlated with clinicopathologic features using the chi-square test. Survival probabilities were calculated according to the Kaplan Meier method and the multivariate Cox regression model.

Results

TP53 mutations were detected in 59% (118/199) and unclassified TP53 variants (UVs) in 15% (29/199) of ovarian carcinomas. TP53 mutant tumours were significantly associated with adverse tumour grade and high-grade serous OC (HGSOC; p<0.001). Patients with TP53 mutant OC showed a significantly impaired overall survival (OS; 3.4 vs 8.2 years; p=0.004) as did the subgroup of 127 HGSOC patients (3.3 vs. 5.8 years; p=0.005). Interestingly all the TP53 UVs identified in this study were also associated with poor OS in the whole cohort (p=0.001) and the subgroup of HGSOC patients (p=0.002).

In the multivariate analysis the TP53 mutational status was confirmed as a prognostic marker in all OC patients (p=0.019) and the subgroup of HGSOC patients (p=0.001).

Conclusion

We demonstrated that the TP53 mutational status is an independent marker for poor OS in HGSOC. TP53 UVs identified within this study showed the same prognostic relevance as the verified mutations.
CIRCULATING MIRNA LANDSCAPE IDENTIFIES MIR-1246 AS PROMISING DIAGNOSTIC BIOMARKER IN HIGH-GRADE SEROUS OVARIAN CARCINOMA: A VALIDATION ACROSS TWO INDEPENDENT COHORTS

1ASST Spedali Civili di Brescia- Istituto di Medicina Molecolare “A.Nocivelli”, Obstetrics and Gynecology, Brescia, Italy
2University of Padova, Department of Biology, Padova, Italy
3IRCCS “Mario Negri” Institute for Pharmacological Research, Department of Oncology, Milan, Italy
4University of Bologna, Department of Experimental- Diagnostic and Specialty Medicine-DIMES, Bologna, Italy
5Catholic University of the Sacred Heart, Department of Obstetrics and Gynecology, Rome, Italy
6University of Brescia, Clinical and Experimental Sciences, Brescia, Italy
7ASST Spedali Civili di Brescia, Obstetrics and Gynecology, Brescia, Italy
8University of Ferrara, Department of Morphology- Surgery and Experimental Medicine, Ferrara, Italy

Aims

High-grade serous ovarian carcinoma (HGSOC) is the most lethal gynecologic neoplasm, with five-year survival rate below 30%. Early disease detection is of utmost importance to improve HGSOC cure rate. The focus of this study was the detection of the levels of circulating miRNAs in tissues and sera from patients with HGSOC as a first step in the evaluation process of their role as diagnostic biomarkers.

Method

Sera from 168 HGSOC patients and 65 healthy controls were gathered together from two independent collections and stratified into a training set, for miRNA marker identification, and a validation set, for data validation. An innovative statistical approach for microarray data normalization was developed to identify differentially expressed miRNAs. Signature validation in both the training and validation sets was performed by quantitative Real Time PCR (RT-qPCR) and droplet digital PCR (ddPCR).

Results

In both the training and validation sets, miR-1246, miR-595 and miR-2278 emerged significantly over expressed in the sera of HGSOC patients compared to healthy controls. Receiver Operating Characteristic curve analysis revealed miR-1246 as the best diagnostic biomarker, with a sensitivity of 87%, a specificity of 77% and an accuracy of 84%.

Conclusion

This study is the first step in the identification of circulating miRNAs with diagnostic relevance for HGSOC. According to its specificity and sensitivity, circulating miR-1246 levels are worthy to be further investigated as potential diagnostic biomarker for HGSOC.
DEVELOPMENT OF AN ANTIBODY MEDIATED OPTICAL IMAGING METHODOLOGY IN MOUSE MODELS OF HIGH-GRADE SEROUS OVARIAN CARCINOMA

K. Bischof, M. Popa, I. Karlsen, K. Kleinmanns, S. Anandan, B.T. Gjertsen, L. Bjørge, E. McCormack

1Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway
2University of Bergen, CCBIO- Department of Clinical Science, Bergen, Norway
3Haukeland University Hospital, Department of Internal Medicine- Hematology Section, Bergen, Norway

Aims

Epithelial ovarian carcinoma remains the deadliest of all gynecological malignancies with high-grade serous ovarian carcinoma (HGSOC) being the most common subtype. Due to late stage diagnosis with peritoneal tumour spread, complete surgical debulking is often difficult to achieve. It is essential, that preclinical models are relevant and permit the analysis of tumour manifestations, treatment responses and the development of new treatment strategies.

Method

Through a series of immunophenotyping experiments, we screened a panel of biomarkers for the cell lines OV90 and CaOV3, and identified CD24 as a homogeneous biomarker of several HGSOC cell lines. Orthotopic xenograft models were subsequently generated by injecting stably transfected OV90 and CaOV3 cells into the ovarian bursa of immunodeficient mice. Further, we established patient derived xenografts (PDX) by orthotopical implantation of unprocessed cancer cells after immediate mechanical tumour dissociation. After conjugation of a specific monoclonal antibody directed against CD24 to the near-infrared dye Alexa680, we studied detection of primary tumour and metastasis by non-invasive optical imaging in parallel with the more established method of bioluminescence.

Results

We identify the cell surface receptor CD24 to be a suitable target for fluorochrome-conjugated antibodies in time-domain optical imaging of HGSOC and find this novel methodology to be comparable to bioluminescence.

Conclusion

We introduce a noninvasive fluorophore mediated optical imaging protocol for HGSOC that facilitates the study of orthotopic models without the need for genetic alteration of tumour cells. Exploration if this original technique is applicable in the established PDX models is ongoing.

HIGH LEVELS OF FOLLICLE STIMULATING HORMONE DURING AGING IS ASSOCIATED WITH CHRONIC OVARIAN STRESS AND MALIGNANT TRANSFORMATION

A. Barua1, L. Rosen2, S. Sharma3, P. Gattuso4, P. Bitterman4

1Rush University Medical Center, Cell & Molecular Medicine, Chicago, USA
2University of Chicago, Pathology, Chicago, USA
3Rush University Medical Center, Obstetrics & Gynecology, Chicago, USA
4Rush University Medical Center, Pathology, Chicago, USA

Aims

The lack of information on the molecular etiology of ovarian cancer (OVCA) makes it a lethal malignancy. Longstanding unresolved stress and persistent high levels of circulating follicle stimulating hormone (FSH) are characteristic features in the postmenopausal ovary. The goal of this study was to examine whether chronic unresolved stress is associated with malignant development and if high levels of FSH is associated with ovarian chronic stress in postmenopausal women.

Method

Ovarian tissues from healthy per- and post-menopausal subjects, BRCA1+ subjects and patients with early and late stage OVCA were examined for the expression of markers of chronic stress including glucose regulator protein 78 (GRP78, a maker of endoplasmic reticular stress), OGG1 (a marker of DNA-damage repair mechanism) and FSH receptor (FSHR) using immunohistochemistry, proteomics and gene expression studies. Changes in the intensity of expression of markers by ovarian surface epithelium (OSE) and inclusion cysts as well as malignant cells were determined and compared among normal and different pathological groups.

Results

Compared with OSE, the intensity of GRP78, OGG1 and FSHR expression was significantly higher in ovarian malignant cells. Similarly, inclusion cysts (potential premalignant lesions) in postmenopausal ovaries and fimbrial epithelium of the fallopian tube in BRCA1+ showed significantly higher intensities than the OSE. The expression of these markers were positively associated with FSHR expression.

Conclusion

The results of this study suggest that increased expression of FSHR is associated with ovarian chronic stress in postmenopausal subjects, and may be involved in malignant transformation in the ovary. Support: NIHR01 CA210370-01

ESGO7-0880

SPLENECTOMY IN CYTOREDUCTIVE SURGERY FOR ADVANCED OVARIAN CANCER: HIGHER INVOLVEMENT RATE THAN EXPECTED?

N. Bizzarri¹, P. Korompelis¹, V. Ghirardi¹, R.L. O'Donnell¹, S. Rundle¹, I.C. Kotsopoulos¹, A. Kucukmetin², C. Ang¹, A. Fisher¹, N. Ratnavelu¹, C.W. Helm², R. Naik¹
¹Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom
²Royal Cornwall Hospitals Trust, Gynaecological Oncology, Truro, United Kingdom

Aims

Complete surgical resection (CSR) to no macroscopic residual disease (RD) is the most important prognostic factor in advanced ovarian cancer (AOC). To achieve CSR it is often necessary to perform a splenectomy. The aim of this study is to correlate intraoperative and histological findings of patients with AOC undergoing splenectomy.

Method

All consecutive patients with AOC undergoing primary, interval or secondary cytoreductive surgery and who underwent splenectomy between 01/2010 and 03/2017 at the NGOC (Gateshead, UK) were included. Demographic and surgico-pathological data were extracted from medical records.

Results

Of 129 patients, 73 (56.6%) underwent primary, 44 (34.1%) interval and 12 (9.3%) secondary cytoreductive surgery. Median age was 65 years (24-91) and median Surgical Complexity Score (Aletti) 8 (4-15). Cytoreduction to RD<1cm was obtained in 116 (89.9%). Indication for splenectomy was: direct involvement by tumor in 97 (75.2%), preoperative radiological involvement of spleen in 4 (3.1%), intraoperative splenic capsule injury in 15 (11.6%), to facilitate en-bloc resection of peri-splenic disease in 13 (10.1%). Histologically, 84 (65.1%) had hilum, 80 (62.0%) had capsule and 27 (20.9%) had parenchyma involvement. 10/15 (66.7%) spleens removed for intraoperative injury had positive histological involvement (60% hilum, 60% capsule and 10% parenchyma).

Conclusion

Splenectomy is an important procedure in the surgical management of AOC. Intra-operative detection of spleen involvement is not always reliable and this may be due to adhesions/poor access preventing adequate assessment. A low threshold for removal is required if there is suspicion of splenic disease in a patient where CSR is to be achieved.
Aims

The process of epithelial-mesenchymal transition (EMT) has been implicated in many cancers, including ovarian, enabling epithelial cells to acquire motile and invasive characteristics which are essential for metastatic spread. We aimed to investigate the role of caldesmon (CALD1) gene, which encodes an important regulator protein of microfilament network, in epithelial ovarian cancer (EOC) pathogenesis.

Method

Reverse transcription quantitative real-time PCR (RT-qPCR) was used to determine CALD1 expression levels in 48 EOC and 19 benign ovarian formalin fixed paraffin embedded (FFPE) specimens. The median patients’ age in both groups was 57 years. The differences in CALD1 gene expression between these two subgroups and its association with various clinicopathological features were assessed by Mann-Whitney test and Spearman’s rank correlation test. P value <0.05 was considered significant.

Results

We found that CALD1 expression levels were lower in malignant compared to benign ovarian tissue (p<0.0001), while CALD1 gene was also significantly lower expressed in high vs. low-grade ovarian carcinomas (p=0.0440). Lower CALD1 expression was observed in higher FIGO stage, tumors with metastases and ascites, as well as in tumors from patients who relapsed, although without statistical significance.

Conclusion

Study findings suggest that CALD1 gene, an important regulator of cell motility, could be a potential biomarker in the prognosis of ovarian tumors.
DOES BREAST CANCER AFFECT PROGNOSIS IN A BRCA-MUTATED OVARIAN CANCER COHORT? THE MITO 21 STUDY - A SUBGROUP ANALYSIS

Aims

MITO (multicenter-Italian-trials-in-ovarian-cancer) 21 is a retrospective observational study aimed at exploring genotype-phenotype correlations in a cohort of BRCA mutation-carrying ovarian cancer (OC) patients. We present an ad interim analysis that characterizes the breast and ovarian cancer (BOC) subgroup and investigates if breast cancer (BC) co-occurrence affects prognosis compared to OC alone.

Method

Fifteen Italian centers participated in the study. Retrospective chart review was used to identify patients carrying a BRCA mutation who were diagnosed with OC between 1995 and 2016 and to collect relating clinical data.

Results

Of the 319 patients included in the study, 72 (23%) were diagnosed with BOC and 247 (77%) with OC only. In the BOC sub-cohort, BC and OC were the first malignancy in 56 (78%) and 16 (22%) cases, respectively. Median age at diagnosis was 50yr (range 32-81yr) for BC and 57yr (range 42-84yr) for OC. The median interval between first and second primary cancer was shorter when BC followed OC than when it preceded it (31m vs. 100m). Forty-seven (65%) patients carried a BRCA1 mutation and 25 (35%) a BRCA2 mutation—mostly frameshift mutations causing a premature stop. Overall survival (OS) did not depend on the mutated gene and was longer in the BOC group compared to the OC only group (168m vs. 65m, p<0.00001).

Conclusion

We describe the largest Italian cohort of BRCA mutation carriers with BOC. Most patients carried a BRCA1 mutation. BC more often preceded OC diagnosis. OS analysis suggests that patients with BOC live longer.

PERFORMANCE OF HE4, CA-125, ROMA, IOTA-LR2, ANDEX, RMI AND COPENHAGEN INDEX TO DETERMINE RISK OF MALIGNANCY OF ADNEXAL MASSES

N. Carreras Diéguez1, M. Angeles1, P. Fusté1, B. Gil1, M. del Pino1, P. Jaume1, R. Molina2, A. Torné1

1Hospital Clínic de Barcelona, Gynecology- Obstetrics and Neonatology, Barcelona, Spain
2Hospital Clínic de Barcelona, Biomedical Diagnostic Center, Barcelona, Spain

Aims

To study the diagnostic accuracy of several models (ROMA, IOTA-LR2, ADNEX, RMI, Copenhagen) and biomarkers (CA-125, HE4) to assess the risk of malignancy of adnexal masses.

Method

Retrospective study including a cohort of women who underwent surgery for adnexal masses in our centre. Patient data (age, menopausal status, ultrasound features, serum markers) was collected to calculate studied indexes. According to histological findings, the main outcome was defined as presence of malignant tissue in removed masses. We plotted ROC curves and AUC for CA-125, HE4, ROMA, IOTA-LR2, ADNEX, RMI and Copenhagen. Sensitivity and specificity for such indexes were calculated for different cutoff points, as for a combination of ROMA and IOTA-LR2 models (considering high risk of malignancy patients with ROMA>15 or IOTA-LR2>15).

Results

835 patients were included: 674 women had benign or borderline masses, while 161 had malignant disease. Isolated ADNEX and IOTA-LR2 models showed higher AUC (table 1) and sensitivity (92.5%, 95%CI: 87.1-95.8% and 94.5%, 95%CI: 89.5-97.2% respectively), but higher specificity was found for RMI (96.3%, 95%CI: 94.3-97.5%) and HE4 (95.5%, 95%CI: 93.4-96.9%, at cutoff 120). When combining IOTA-LR2 and ROMA, maximum sensitivity was achieved (96.2%, 95%CI: 91.9-98.2%).

<td>687</td>
</tr>
</tbody>
</table>

Conclusion

Considering the objective of ruling out malignancy, ADNEX and IOTA-LR2 perform better in women with adnexal masses. Sensitivity increases up to 96.2% by combining IOTA-LR2 and ROMA.

MIRNA181A-5P EXPRESSION AS A BIOMARKER OF TGFβ PATHWAY ACTIVATION ASSOCIATED WITH ONCOLOGIC OUTCOME AND TUMOR DIFFUSION IN HIGH GRADE SEROUS EPITHELIAL OVARIAN CANCER

L. Ceppi1,2, S. Palazzi1, C. Romualdi3, P. Dilorenzo1,2, T. Grassi1,2, E. Biagioli4, L. Paracchini4, R. Milani1,2, A. Buda2, M. D’Incalci4, S. Marchini4, R. Fruscio1,2

1University of Milano-Bicocca, Department of Medicine and Surgery, Piazza dell’Ateneo Nuovo 1- 20126 Milan, Italy
2San Gerardo Hospital, Clinic of Obstetrics and Gynecology, Via Pergolesi 33- 20900 Monza, Italy
3University of Padova, Department of Biology, Via U. Bassi 58/b- 35121 Padova, Italy
4Istituto di Ricerche Farmacologiche “Mario Negri” - IRCCS, Department of Oncology, Via La Masa 19- 20156 Milan, Italy

Aims

Activation of TGFβ pathway in advanced epithelial ovarian cancer has been found to be a predictor of residual tumor and survival. miRNA181a-5p expression in EOC has been identified as a stable readout of TGFβ activation, here further analyzed as outcome biomarker.

Method

A consecutive series of high grade serous EOC (HGSEOC) from the snap-frozen ‘Pandora’ tumor tissue biorepository (2004-2012) has been included for miRNA analysis with relative real time-PCR. Tumor diffusion was categorized using an established semi-quantitative disease score (DS). The prognostic value of miRNA181a-5p was analyzed using a Cox proportional-hazards regression model; non-parametric tests to analyze the association between mRNA 181a-5p and clinical features were used.

Results

84 HGSEOC patients with a median follow-up of 50.7 months entered the study. Using Cox proportional-hazards regression model an optimized threshold of miR181a-5p expression to group patients according to their prognosis was identified (miR-low and miR-high), with progression free survival (PFS) of 20.9 v. 9.6months[Hazard Ratio(HR)=2.451(1.454-4.133), p=0.0008] and overall survival (OS) of 60.3 v. 23.3months[HHR= 2.812 (1.632 - 4.847), p=0.0008], respectively. High DS grouped the highest miRNA181a-5p expressors. Residual tumor >1cm was significantly related to high miRNA181a-5p expression (p=0.041, p=0.029).

In multivariate Cox proportional-hazards regression models DS high and miR-high were related to worse PFS[HR=2.95(95%CI1.65-5.29), p=0.0002];[HR=2.31(95%CI1.05-5.13), p=0.036]; miR-high also negatively affected OS [HR=2.18 (95%CI1.22-3.89), p=0.007].

Conclusion

miR181a-5p confirms to be a reliable prognostic biomarker associated to PFS and OS in HGSEOC. Thus, a prospective validation of its role is urgently needed. A translational ancillary study has been designed to the TRUST trial (NCT # 02828618).

THE ROLE OF USP10 IN EPITHELIAL OVARIAN TUMORS

H. Cho¹, D.B. Chay², J.Y. Chung³, S.M. Hewitt³, J.H. Kim¹

¹Gangnam Severance Hospital - Yonsei University College of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Yongin Severance Hospital, Department of Obstetrics and Gynecology, Yongin, Republic of Korea
³National Institutes of Health, Laboratory of Pathology, Bethesda, USA

Aims

Ubiquitin-specific protease 10 (USP10), a deubiquitinating enzyme, has been pronounced in malignancies. However, the role of USP10 in epithelial ovarian cancer has not been elucidated yet. Here, we investigated the expression and clinical significance of USP10 in ovarian cancer.

Method

Immunohistochemical analyses of USP10 and p14ARF were performed using tissue microarray analysis of 336 ovarian tumors and compared the data with clinicopathologic variables, including the survival of ovarian cancer patients. We also examined USP10 and p14ARF methylation near the putative transcriptional start site (TSS) in the 5' CpG islands of the genes in ovarian cancer cells and fresh frozen tissues.

Results

USP10 and p14ARF expression was significantly decreased in ovarian cancer than normal ovarian epithelium (both p<0.001). Immunoreactivity significantly correlated with tumor stage (USP10, p=0.001) and tumor grade (p14ARF, p=0.007). USP10 expression showed strong positive correlation with that of p14ARF (Spearman's rho = 0.430, p < 0.001) in cancer patients. Using cox proportional hazards model, low USP10 expression [HR=3.77 (95% CI, 1.65–8.60), p=0.002] and a combined USP10/p14ARF expression [HR=4.35 (95% CI, 1.58–11.90), p = 0.005] were the independent prognostic factors. Methylation specific PCR analysis showed that the USP10 and p14ARF CpG island was highly methylated in cancer tissues (62% and 87%, respectively) and cells (both 95%) and at lower percentages in normal tissues (3% and 13%, respectively).

Conclusion

Low expression of USP10 or combined USP10/p14ARF is an indicator of bad prognosis in ovarian cancer, suggesting their potential utility as prognostic tests in clinical assessment.
EXPRESSION PATTERNS OF Nrf2 AND Keap1 IN OVARIAN CANCER CELLS AND THEIR PROGNOSTIC ROLE IN DISEASE RECURRENCE AND PATIENT SURVIVAL

H.Y. Cho

Dongtan Sacred-heart Hospital, Obstetrics and Gynecology, Hwasung, Republic of Korea

Aims

This study evaluated the expression patterns of nuclear factor erythroid 2-related factor 2 (Nrf2) and Kelch-like ECH-associated protein 1 (Keap1), and assessed their clinical value as prognostic indicators in ovarian cancer.

Method

The expression patterns of Nrf2 and Keap1 were determined in 100 epithelial ovarian cancers by immunohistochemistry analyses. The associations of Nrf2 and Keap1 expression with clinicopathological characteristics of patients were evaluated. All patients received platinum-based chemotherapy. Chemoresistance was defined as recurrence within 6 months of first-line chemotherapy.

Results

Cytoplasmic expression of Nrf2 and Keap1 was observed in 95% and 72%, respectively, of all 100 epithelial ovarian cancers examined. Low Keap1 expression (intensity<1) was strongly associated with disease recurrence ($P=0.046$) and death ($P=0.002$). Chemoresistance was associated with high Nrf2 expression (intensity=3) ($P=0.833$, HR 1.202, 95% CI 0.217-6.667) and low Keap1 expression ($P=0.862$, HR 0.899, 95% CI 0.270-2.994). However, these associations were not statistically significant. Survival analysis indicated that high Keap1 expression (intensity≥1) was strongly predictive of better overall survival ($P=0.049$) and disease-free survival ($P=0.004$). Cox's regression analysis indicated that Keap1 expression was an independent prognostic factor for overall survival ($P=0.012$, HR 0.349, 95% CI 0.153-0.797). Although patients with high Nrf2 expression displayed better overall survival and disease-free survival, the association was not statistically significant.

Conclusion

High cytoplasmic Keap1 expression, which might prevent nuclear translocation of Nrf2 in ovarian cancer cells, was associated with lower disease recurrence and death rate. Survival analysis suggested a probable role of Keap1 expression in predicting the prognosis of ovarian cancer.

A TAILORED STRATEGY USING CA125 AND HE4 STRATIFIED BY MENOPAUSAL STATUS FOR DIFFERENTIATING BENIGN AND MALIGNANT ADNEXAL TUMORS

B.G. Kim1, H.J. Choi1, D.S. Bae1

1Samsung medical center, Obstetrics and gynecology, Seoul, Republic of Korea

Aims

This study aimed to compare the diagnostic performances between CA125 alone and a combination of CA125 and HE4, and to tailor the combination method using CA125 and HE4 for Korean women with ovarian tumors.

Method

We enrolled 327 epithelial ovarian cancer (EOC) patients and 322 benign ovarian tumor patients. In this study, we used the risk of ovarian malignancy algorithm (ROMA) and the simple dual-marker method (DualM) as combination methods. DualM identified a result as positive when either CA125 or HE4 was higher than the cut-off. Optimized cut-off values for tumor markers were evaluated according to patient menopausal status.

Results

The optimized cut-off values of CA125, HE4, and ROMA were 89.6 U/ml, 53.7 pmol/L, and 11.1% in premenopausal women (PreMP) respectively. In PreMP, DualM and ROMA yielded higher sensitivity (SN) than CA125, but the opposite trend was seen for specificity (SP) (CA125: SN=61.3% and SP=94.7%, DualM: SN=78.7% and SP=88.9%, ROMA: SN=70.7% and SP=92.2%). In PostMP patients, the optimized cut-off values for CA125, HE4, and ROMA were 23.4 U/ml, 64.3 pmol/L, and 25.3%, respectively. DualM yielded improved SN without decreasing SP in PostMP compared with CA125 alone. ROMA did not yield improved performance compared with CA125 alone (CA125: SN=85.3% and SP=94.9%, DualM: SN=90.5% and SP=88.5%, ROMA: SN=85.3% and SP=97.4%).

Conclusion

DualM performed better than CA125 alone in PostMP patients by increasing sensitivity via optimized cut-off values.

GENOMIC LANDSCAPE OF BRAIN METASTASIS FROM OVARIAN/ PERITONEAL CANCER

H.J. Kang¹, J.S. Park², S.Y. Hur², Y.J. Choi³
¹College of Medicine- The Catholic University of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea
²Seoul St.Mary's Hospital- The Catholic University of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea
³Seoul St. Mary's Hospital- The Catholic university of Korea, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Brain metastasis from ovarian cancer is a rare disease entity which leads to dismal prognosis. However, the genomic alterations of primary ovarian/ peritoneal cancer and the brain metastasis have not been fully elucidated.

Method

We performed whole-exome sequencing of three matched brain metastases and ovarian/peritoneal cancers.

Results

We detected increased number of genomic alterations from brain metastases when compared to ovarian/ peritoneal cancers (range: 88-155 and 52-74, respectively). All the ovarian/ peritoneal and brain tissues encompassed TP53 non-silent mutations and SEC16B non-silent mutations were harbored in two of the three cases. In addition, genetic alterations of ADGRB1, a tumor suppressor gene that is known to be related to glioblastomas, were detected only in brain metastases (two of the three cases).

Conclusion

Our data revealed that brain metastasis from ovarian/ peritoneal cancer harbors a somatic mutation known to be associated with glioblastomas, suggesting that brain-specific genetic alterations may exist.

RANDOMIZED, NON-COMPARATIVE, PHASE II TRIAL OF BEVACIZUMAB AND TRAJECTEDIN WITH OR WITHOUT CARBOPLATIN IN PARTIALLY PLATINUM-SENSITIVE OVARIAN CANCER (ROC) WOMEN

N. Colombo1, M.O. Nicoletto2, A. Lissoni3, G. Scambia4, G. Tognon5, E. Galli6, E. Biagio1, E. Rulli6, R. Fossati6, M. D’Incalci6

1IEO - European Institute Of Oncology, Gynecologic Oncology, Milano, Italy
2Instituto Oncologico Veneto- IOV-IRCCS, Oncology, Padova, Italy
3Ospedale S. Gerardo, Oncology, Monza, Italy
4Ospedale Policlinico Gemelli, Oncology, Roma, Italy
5Universita’ degli Studi di Brescia, Oncology, Brescia, Italy
6IRCCS Istituto di ricerche farmacologiche Mario Negri, Oncology, Milan, Italy

Aims

Trabectedin interferes with cancer cells division and decreases the number/function of tumor-associated macrophages (TAMs). Since TAMs produce several angiogenic factors, trabectedin might be synergistic with bevacizumab.

Method

Women with disease progression between 6-12 months since the last 1st/2nd line platinum-based therapy were randomized to Arm-A (trabectedin 1.1 mg/m² and bevacizumab 15 mg/kg q3w) or Arm-B (carboplatin AUC-4 plus trabectedin 0.8 mg/m² and bevacizumab 10 mg/kg q4w). In both arms responding patients from Cycle 7 onward could continue with trabectedin and bevacizumab until progression as in Arm-A. The study would open to the second-stage accrual if 7 and 13 of the first 17 patients in Arm-A and 8 and 13 patients in Arm-B remain progression-free at 6 months and without severe toxicities (primary end-points), respectively.

Results

In Arm-A and Arm-B, 11/17 and 14/17 patients remained progression-free at 6 months and achieved a median PFS of 9.4 and 23.1 months, respectively. At 6 months, 14 patients in Arm-A and 11 patients in Arm-B remain without severe toxicities. In Arm-B, 4 patients had grade 4 thrombocytopenia, 2 had grade 4 neutropenia, and 5 had hypersensitivity reaction to carboplatin. Despite this severe myelotoxicity, 11/12 patients without hypersensitivity reaction were able to complete 6 cycles after dose adjustment.

Conclusion

The combination of trabectedin/bevacizumab±carboplatin is highly effective in ROC. Arm-A completed second-stage accrual and the mature results on safety and efficacy will be presented. Arm-B did not meet the toxicity criteria to access second-stage accrual, but its remarkable median PFS of 23.1 months warrants further study with adapted schedules.
SURVIVAL IMPACT OF SURGICAL STRATEGY IN STAGE III OR IV EPITHELIAL OVARIAN CANCER

B. Delga¹, E. Lambaudie¹, G. Houvenaeghel¹, N. Andrieux², J.M. Classe²
¹Institut Paoli Calmettes, Department of Surgical Oncology, Marseille, France
²Institut de Cancerologie de l'Ouest, Department of Surgical Oncology - Centre René Gauducheau, Saint-Herblain, France

Aims

To evaluate the evolution of practices and the influence of surgical strategy on survival for patients with stage III or IV epithelial ovarian cancer (EOC).

Method

Prospective data collection in two french national cancer centers. Our analysis concerned clinicals information, completeness of surgery, definitive pathology, Overall Survival (OS) and Disease Free Survival (DFS). Three surgicals strategies were compared: Primary Debulking Surgery (PDS), Interval Debulking Surgery (IDS) after 3 courses of neoadjuvant chemotherapy and Final Debulking Surgery (FDS) after at least 6 chemotherapy’s courses. We analysed 4 periods: <2000, 2000-2004, 2005-2009 and >2009.

Results

Median age at diagnosis was 61 (17-94). 1473 patients managed for FIGO stage III (80%) or IV (20%) EOC between 1985 and 2015 were included. We compared the 4 periods: The rate of non-operated patients increased (10,1% vs 22,6% p<0,001) between first and last period. Neoadjuvant chemotherapy increased from 20,1% to 52,2% (p<0,001). Complete resection rate increased from 37% to 66,2% (p<0,001).

For patients who underwent surgery, OS increased in case of complete resection (HR=2,123 CI95% [1,816-2,481] p<0,001) but time of surgery didn’t impact median OS (month): PDS 44,9; IDS 50,3; FDS 42 (p=0,410).

For patients with complete surgery, DFS was significantly shorter of 3 months in case of FDS compared to PDS (p<0,001).

Conclusion

A significative improvement of OS and DFS has been observed during our study in relation with complete resection rate. We did not observe any difference between PDS, IDS and FDS in term of OS but a reduction of DFS for FDS.

ESGO7-0621

CARCINOID TUMOR OF THE OVARY: A CLINICOPATHOLOGIC STUDY OF 67 CASES

L. Deligdisch1, D. Feingold2, A. Mares3, M. Shafir2

1Icahn School of Medicine at Mount Sinai, Department of Pathology, Department of Obstetrics, Gynecology and Reproductive Science, New York, USA
2Icahn School of Medicine at Mount Sinai, Department of Surgery, Division of Surgical Oncology, New York, USA
3New York Medical College, Department of Pathology, Valhalla, USA

Aims

To correlate tumors' pathological characteristics with clinical behavior and survival of patients diagnosed with ovarian carcinoid tumors, a rare group of ovarian neoplasms.

Method

Histologic slides of 67 cases of ovarian carcinoid tumors diagnosed at the Mount Sinai Hospital between 1994 and 2015, were reviewed and correlated with clinical outcomes.

Results

Of 67 patients, 29 had primary and 38 had metastatic carcinoids to the ovary. Primary tumors were unilateral in 93% cases, 66% were associated with ovarian teratoma, 22% were malignant (3 mucinous, 1 insular, 2 undifferentiated). Mean age was 48.7 years, overall survival was 86%. Carcinoid syndrome was present in one patient with malignant tumor. Metastatic tumors were bilateral in 72% cases, 82% were of gastrointestinal primary, of which 52% were from small bowel. Mean age was 53, overall survival was 50%. Carcinoid syndrome was present in 45%. Surgery was performed in 95% cases and 74% had adjuvant treatments. For the entire cohort, histologically severe cellular atypia was present in only 6 cases; immunoreactivity was positive for neurosecretory granules in all cases, p53 positive in one metastatic tumor, and Ki67 was relatively low in most cases.

Conclusion

The natural history of ovarian carcinoid (neuroendocrine tumors) is different, being more indolent than the common ovarian carcinomas. Carcinoid syndrome was far more common in the metastatic cases. The rather low-grade histologic features of carcinoid do not always correlate with the metastatic potential of the tumors and patients’ survival, requiring personalized therapeutic strategies.
Aims

It has now been established that low grade serous carcinoma of the ovary is a distinct entity by itself distancing itself from the high grade serous carcinomas in many aspects. Being in a unique heterogenous Southeast Asian country where the population comprises of 4 different races namely, Chinese, Malay, Indian and Eurasian, we examined the characteristics of the low grade serous ovarian carcinomas in our institution.

Method

Data was collected retrospectively from the KK Gynaecologic oncologic database from the KK Women's and Children's hospital, the biggest women's tertiary hospital in Singapore. The data of 34 patients with confirmed low grade serous carcinoma of the ovar y was collected from 1991 – 2015. The data analysed using SPSS system software.

Results

A total of 34 patients were analysed with low grade serous carcinoma. The patients’ ages ranged from 23 – 84.8 years. The mean age was 47.9 years. Majority (55.9%) of patients presented as stage 3 disease, 29.4% of patients presented as stage 1 disease, 8.8% as stage 3 disease and 2.9 % as stage 2 and unstaged. Overall survival was 182 months for all stages. The 5 years survival rate was 68.8% and 10 years survival rate, 62.3%. There was no significant difference between patients receiving chemotherapy and overall survival, p = 0.58.

Conclusion

Similar to the Caucasian population, low grade serous carcinoma in a heterogenous Asian population also appears to present earlier, are fairly resistant to conventional chemotherapy. Hence, more needs to be done to elucidate this distinct entity of ovarian serous carcinoma.

RE-APPRAISAL OF THE ROLE OF DELAYED DEBULKING SURGERY IN PATIENTS WITH STAGE 3C/4 EPITHELIAL OVARIAN CANCER AFTER 6 CYCLES OF UPFRONT CHEMOTHERAPY

S. Elorbany1, R. Tozzi2, D. Barton3

1St George’s University Hospital, Obstetrics and Gynaecology, London, United Kingdom
2Oxford University, Obstetrics and Gynaecology, Oxford, United Kingdom
3Royal Marsden Hospital and St George’s University Hospital, Obstetrics and Gynaecology department, London, United Kingdom

Aims

The aim of the study is to evaluate the feasibility and the outcomes of cytoreductive surgery in a particular group of stage 3C/4 Epithelial ovarian cancer patients who received up to 6 cycles of chemotherapy rather than the traditional 3-4 cycles of neoadjuvant chemotherapy.

Method

This is a retrospective service evaluation (observational) study that included 182 patients who received their treatment in Oxford University hospital NHS trust from 2009 till 2015. 88 patients had 6 cycles of chemotherapy followed by delayed debulking surgery (group 1) and 94 patients had only 6 cycles of chemotherapy (group 2). Patients who had <6 cycles of chemotherapy due to progressive disease were excluded from the study.

Results

Group 1 had significantly higher overall survival compared to Group 2; 34 months (95% CI: 21m-46m) and 17 months (95% CI: 15-19m) respectively. Progression free survival was also significantly higher in group 1; 16 months (95% CI: 10.7m-17m) and 10 months (95% CI: 9 m-11m) respectively. Complete cytoreduction was feasible in 75% of the patients eligible for surgery and residual disease of <1cm was achievable in 88.6% of those patients. The main reason for not proceeding with surgery was unresectable disease by CT scan +/- diagnostic laparoscopy. Diagnostic laparoscopy in patients with stable disease by CT scan improved the selection of patients for surgery.

Conclusion

Surgery still provides significant survival benefit and should still be offered to all suitable candidates. Diagnostic laparoscopy improved the selection of patients for surgery and reduced the number of futile laparotomies.

IMMUNONUTRITION: A NEW TOOL IN THE MANAGEMENT OF OVARIAN CANCER?

V. Marola¹, M. Geuna², L. Fusó³, D. Vassallo⁴, N. Santoro², G. Menato¹, A. Ferrero¹

¹Mauriziano Hospital, Academic Division of Gynaecology and Obstetrics - University of Turin, Turin, Italy
²Mauriziano Hospital, Laboratory of Immunopathology - Division of Pathology, Turin, Italy
³Mauriziano Hospital, Academic Division of Gynaecology and Obstetrics - University of Turin, Turin, Italy
⁴Mauriziano Hospital, Division of Dietetics, Turin, Italy

Aims

Immunonutrition has been proved to stimulate the immunological, inflammatory and nutritional response in different tumours, decreasing postoperative mortality and morbidity. Alterations in lymphocyte subpopulations, particularly the Treg cell subpopulation and the expression of PD1, could be a key factor in determining the status of tumour microenvironment. Patients with ovarian cancer are most effectively treated by radical surgery, that carries a high risk of postoperative complications. The aim of this study is to evaluate the effects of preoperative immunonutrition on patients with ovarian cancer undergoing surgery.

Method

Our pilot study involved 11 patients with ovarian cancer who underwent primary debulking surgery between 2016 and 2017. Enteral immunonutrition was prescribed for 5 to 7 days preoperatively. The following parameters were evaluated before and after immunonutrition: monocytes, granulocytes, lymphocyte subpopulations (CD3+/4+/5+/8+/19+/20+/25+/56+), prealbumin, serum total protein, C-reactive protein (CRP), creatinine, length of hospital stay (LOS) and postoperative complications. The expression of PD1 was assessed on CD4+, CD8+ and Treg cell subpopulations.

Results

After immunonutrition, granulocytes and lymphocytes B CD19+ were significantly increased (p<0.05). CD3+ and CD8+ T cell showed an increasing trend (p>0.05). The expression of PD1 on CD8+ cell subpopulation decreased (p>0.05). CRP and creatinine significantly decreased (p<0.05), while prealbumin significantly increased (p<0.05). In comparison with patients with ovarian cancer who underwent surgery between 2013 and 2016 without preoperative immunonutrition, LOS and the G2-G3 postoperative complications were reduced, (8 vs 6.9 p>0.05) and (40.0% vs 9.1%, p=0.04) respectively.

Conclusion

Preoperative immunonutrition may represent a promising approach in the management of ovarian cancer.
Aims

To compare the diagnostic accuracy of ultrasound, CT, and MRI in ovarian cancer staging.

Method

Patients planned for ovarian cancer surgery were enrolled. They underwent preoperative staging with ultrasound, CT, and MRI, following evaluation form. Findings were compared to intraoperative and histopathological evaluation forms. The evaluation assessed peritoneal spread in 17 sites and metastatic lymph nodes in 7 sites.

Results

Twenty-one patients were enrolled between March and August 2016. Ultrasound showed the best results in detection of pelvic carcinomatosis and depth of rectosigmoid infiltration, followed by MRI and CT (AUC 0.85, 0.79, and 0.72). In the abdomen, ultrasound had the best results in the detection of peritoneal carcinomatosis in the upper abdomen (spleen, liver, lesser omentum) and in greater omentum (AUC of 0.82 and 1.00), in contrast with MRI (AUC 0.73 and 0.93) and CT (AUC 0.71 and 0.88). Ultrasound also reached the highest AUC in the detection of bowel mesentery (AUC 0.78) compared to MRI and CT (AUC 0.66 and 0.62) and was comparable to MRI in the assessment of bowel surface (AUC 0.76), followed by CT (0.73). Ultrasound had the lowest AUC in detection of parietal carcinomatosis (diaphragm, paracolic gutters, anterior abdominal wall) in comparison to MRI and CT (AUC 0.72, 0.86, and 0.78). In the assessment of retroperitoneal lymph nodes, all three methods showed similar results (AUC of 0.80).

Conclusion

This is the first prospective study to date documenting the potential role of ultrasound in ovarian cancer staging, compared to the method of choice (CT) and a novel technique (WB-DWI/MRI).

COMPLETE GROSS RESECTION AT PRIMARY VERSUS INTERVAL SURGERY FOR ADVANCED OVARIAN CANCER IMPROVES PROGRESSION-FREE SURVIVAL

N. Fleming¹, S. Westin¹, R. Coleman¹, P. Soliman¹, K. Schmeler¹, B. Fellmann², P. Ramirez¹, K. Lu¹, A. Sood¹
¹MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA
²MD Anderson Cancer Center, Biostatistics, Houston, USA

Aims

To determine effect of complete gross surgical resection (R0) of tumor on progression-free survival at primary versus interval tumor reductive surgery in advanced ovarian cancer.

Method

We prospectively triaged patients from April 2013 to December 2016 with suspected advanced stage ovarian cancer to laparoscopic scoring assessment to determine primary resectability. Medically inoperable or those with distant metastatic disease received neoadjuvant chemotherapy (NACT). 20 gynecologic oncologists from a single institution performed all scoring. Predictive index value (PIV) scores ≥8 were dispositioned to primary surgery and ≥8 to NACT. Clinicopathologic and adjuvant treatment data was collected prospectively. Univariate and multivariate analysis was performed for effects on progression-free survival (PFS).

Results

658 patients presented with presumed advanced ovarian cancer. 488 patients were found to have pathologically confirmed stage II-IVB high-grade epithelial ovarian cancer and triaged to NACT/no scope (n=243), NACT/scope (n=105), and primary surgery (n=138). Patients undergoing primary surgery had improved PFS (HR=0.52, 95% CI 0.31-0.85, p=0.02) compared to interval surgery after NACT. Patients undergoing R0 resection at primary surgery had significant improved PFS compared to those undergoing R0 resection at interval surgery (23.5 vs. 12 months, p<0.001). On multivariate analysis, ECOG performance status (p=0.03), R0 resection (p=0.01), and primary surgery (p=0.01) had significant effects on PFS.

Conclusion

Complete surgical resection at primary surgery in advanced ovarian cancer is associated with superior progression-free survival compared to NACT and interval surgery. Laparoscopic scoring assessment allows for appropriate triage of patients to primary surgery.
IMPLEMENTATION OF A LAPAROSCOPIC SCORING ALGORITHM PRIOR TO CYTOREDUCTIVE SURGERY IN PATIENTS WITH ADVANCED OVARIAN CANCER

N. Fleming¹, P. Ramirez¹, S. Westin¹, R. Coleman¹, P. Soliman¹, L. Meyer¹, K. Schmeler¹, K. Lu¹, A. Sood¹

¹MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA

Aims

To determine the surgical outcomes and concordance rates of patients undergoing laparoscopic scoring assessment for presumed advanced stage ovarian cancer.

Method

We prospectively triaged patients from April 2013 to April 2017 with suspected advanced stage ovarian cancer to laparoscopic scoring assessment to determine primary resectability. Medically inoperable or those with distant metastatic disease received neoadjuvant chemotherapy (NACT). 20 gynecologic oncologists from a single institution performed all scoring. Predictive index value (PIV) scores <8 were dispositioned to primary surgery and ≥8 to NACT. Two surgeons scored each patient in a blinded fashion, and a third surgeon score was available to assess cases with a discrepancy. Descriptive statistics were used to report surgical and scoring outcomes.

Results

672 patients presented with presumed advanced ovarian cancer and 292 patients underwent laparoscopic scoring assessment. 21 patients (3%) were diagnosed with a non-ovarian primary malignancy. Surgical complications included GI trocar injury (n=6, 2%), port site metastasis (n=12, 4%), and wound infection (n=9, 3%). 184 patients (63%) had a PIV<8 and 100 patients (34%) a PIV ≥8. PIV score could not be determined in 8 patients (3%). Two-surgeon scoring (n=200) resulted in qualitative agreement in 94% of cases, and a third surgeon was called in 10 cases (5%). The third surgeon agreed with the second surgeon in 4 cases, giving a discordance rate of 2%.

Conclusion

Laparoscopic scoring assessment in presumed advanced stage ovarian cancer is associated with acceptable surgical outcomes and low complication rates. Concordance is high amongst surgeons experienced with the scoring algorithm.
PHASE 2, RANDOMIZED CONTROLLED STUDY OF PEGYLATED LIPOSOMAL DOXORUBICIN AND CARBOPLATIN VERSUS GEMCITABINE AND CARBOPLATIN IN PLATINUM-SENSITIVE RECURRENT OVARIAN CANCER (GOTIC003/INTERGROUP STUDY)

11Iwate Medical University, Department of Obstetrics and Gynecology, Iwate, Japan
12Kosei Hospital, Department of Obstetrics and Gynecology, Tokyo, Japan
13Tohoku University School of Medicine, Department of Obstetrics and Gynecology, Miyagi, Japan

Aims

To compare the efficacy, safety and tolerability profiles of pegylated liposomal doxorubicin and carboplatin (PLD-C) with those of gemcitabine and carboplatin (GC) for the treatment of patients with platinum-sensitive recurrent ovarian cancer (PSROC).

Method

Patients with histologically proven ovarian cancer with recurrence >6 months after first-line platinum and taxane-based therapies were randomly assigned to PLD-C (PLD 30 mg/m² plus carboplatin area under the curve [AUC] 5 on day 1) every 4 weeks or GC (gemcitabine 1,000mg/m² on day 1 and 8 plus carboplatin AUC 4 on day 1) every 3 weeks for at least 6 cycles. The primary endpoint was progression-free survival (PFS), with overall response rate, overall survival, toxicity and dose administration as secondary endpoints.

Results

One hundred patients (49 PLD-C; 51GC) were randomly assigned. With a median follow-up of 27 months, the median PFS was 12.0 months (95%CI, 9.2 to 15.0) for PLD-C and 9.8 months (95%CI, 8.9 to 12.3) for GC. The overall survival data are immature. Response rate was 57.1% (95%CI, 41.0 to 72.3) for PLD-C and 56.4% (95%CI, 39.6 to 72.2) for GC. No obvious differences in toxicity (G3/4) were noted between arms. Treatment completion rate for 6 cycles was higher for PLD-C (63.3%:95%CI, 48.3 to 76.6) than for GC (31.4%:95%CI, 19.1 to 45.9).

Conclusion

PLD-C and GC are both good treatment candidates for PSROC patients; however, the dose intensity was lower for GC than for PLD-C. PLD-C seems to have a more favorable risk-benefit profile than does GC for the patients in this study.

THE ASSOCIATION BETWEEN EXPRESSION OF TBX2 AND SENSITIVITY TO PLATINUM-BASED CHEMOTHERAPY FOR OVARIAN SEROUS CARCINOMA

R. Tasaka1, T. Fukuda1, Y. Inoue1, M. Shimomura1, H. Matsubara1, T. Wada1, M. Kawanishi1, T. Yasui1, T. Sumi1

1Osaka City University Graduate School of Medicine, Obstetrics and Gynecology, Osaka, Japan

Aims

We examined the correlation between TBX2 (T-box2) expression and the sensitivity to platinum-based chemotherapy for ovarian serous carcinoma.

Method

We reviewed 54 cases of ovarian serous carcinoma stage III-IV from 2005 to 2013. Cases were divided into two groups: one group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and did not recur within 6 months after initialization of chemotherapy (group A; n=27), and another group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and recur within 6 months (group B; n=27). TBX2 expression was examined immunohistochemically in paraffin-embedded sections using the avidin-biotin peroxidase complex method. This study was approved by the institutional review board in our facility.

Results

The expression of TBX2 was significantly higher in the group B than in the group A (p=0.005). Cases were divided into two groups: one group in which TBX2 expression was low level (weighted score≤6, n=44), and another group in which TBX2 expression was high level (weighted score≥8, n=10). Low TBX2 expression group might be sensitive to platinum-based chemotherapy than high expression group (p=0.02). The overall survival of Low TBX2 expression group was significantly longer than High TBX2 expression group (p=0.023).

Conclusion

It is suggested that the expression of TBX2 might be associated with sensitivity to platinum-based chemotherapy and predictor of prognosis of advanced ovarian serous carcinoma.
THE ASSOCIATION BETWEEN EXPRESSION OF UCP2 AND SENSITIVITY TO PLATINUM-BASED CHEMOTHERAPY FOR OVARIAN SEROUS CARCINOMA

M. Kawanishi¹, T. Fukuda¹, Y. Inoue¹, M. Shimomura¹, H. Matsubara¹, T. Wada¹, R. Tasaka¹, T. Yasui¹, T. Sumi¹
¹Osaka City University Graduate School of Medicine, Obstetrics and Gynecology, Osaka, Japan

Aims

We examined the correlation between UCP2 (uncoupling protein 2) expression and the sensitivity to platinum-based chemotherapy for ovarian serous carcinoma.

Method

We reviewed 51 cases of ovarian serous carcinoma stage III-IV from 2005 to 2012. Cases were divided into two groups: one group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and did not recur within 6 months after initialization of chemotherapy (group A; n=26), and another group in which maximum debulking surgery followed by platinum-based chemotherapy was performed and recur within 6 months (group B; n=25). UCP2 expression was examined immunohistochemically in paraffin-embedded sections using the avidin-biotin peroxidase complex method. This study was approved by the institutional review board in our facility.

Results

The expression of UCP2 was significantly higher in the group B than in the group A (p=0.027). Cases were divided into two groups: one group in which UCP2 expression was low level (weighted score≤6, n=24), and another group in which UCP2 expression was high level (weighted score≥8, n=27). Low UCP2 expression group might be sensitive to platinum-based chemotherapy than high expression group (p=0.007). The overall survival of Low UCP2 expression group was significantly longer than High UCP2 expression group (p=0.006).

Conclusion

It is suggested that the expression of UCP2 might be associated with sensitivity to platinum-based chemotherapy and predictor of prognosis of advanced ovarian serous carcinoma.

ESG07-0358

EFFICACY AND OUTCOMES OF MINIMAL ACCESS SURGERY (MAS) VERSUS LAPAROTOMY (LAP) IN RE-STAGING OF APPARENT EARLY-STAGE OVARIAN AND FALLOPIAN TUBE CARCINOMA
A.G. Eriksson1, Y. Wang1, G. Fallaas Dahl1, B. Eyjolfsdottir1
1Oslo University Hospital- The Norwegian Radium Hospital, Department of Gynecologic Oncology, Oslo, Norway

Aims
To compare efficacy and outcomes of MAS to LAP in re-staging of epithelial ovarian or fallopian tube carcinoma.

Method
All cases with presumed early-stage adnexal carcinoma referred to our institution for re-staging were identified from 02/2006-02/2017. Patient and tumor characteristics, operative findings, complications and recurrences were documented. Appropriate statistical tests were applied.

Results
Among 98 cases, 53 (54%) underwent LAP and 45 (46%) MAS; 29 (64%) robotic, 16 (36%) laparoscopic. When comparing the LAP and MAS groups, there was similar age, body mass index, stage, histologic subtypes, number of patients who underwent omentectomy and hysterectomy, number of pelvic lymph nodes removed, omental weight, detection of nodal and omental metastasis, number of patients who were upstaged, and number and sites of recurrences. Mean estimated blood loss (287ml± 208 vs 76ml±58, p<0.001) and hospital stay (7.4 days ±3.2 vs 3.9 ±2.8, p<0.001) were lower for MAS, operative time (162minutes ±49 vs 216minutes ±69, p<0.001) was longer. Mean number of para-aortic nodes removed was 4.7±4.4 (LAP) versus 8.7±5.9 (MAS) (p=0.005) respectively. There were similar operative- and 30-day complication rates for both groups. Mean time from re-staging until initiation of adjuvant therapy was 40.5 days (±62.4) in the LAP group and 21.3 days (±11.2) in the MAS group (p=0.064). There was no difference in PFS or OS between groups.

Conclusion
Re-staging of adnexal carcinoma by MAS is feasible and safe without compromising efficacy or oncologic outcome. Time from re-staging to initiation of adjuvant chemotherapy trended towards being shorter in patients operated by MAS.
ADVANCED OVARIAN CANCER: ARE WE UNDERSTAGING OUR PATIENTS? THE ROLE OF FDG-PET/CT BEFORE PRIMARY TREATMENT

A.G. Glickman¹, B. Gil Ibañez¹, P. Paredes², L. Buñesch³, M.C. Sebastià³, I. Nicolas¹, A. Rodriguez-Trujillo¹, M. Munmany¹, M. Del Pino¹, P. Fuste¹, J. Pahisa¹, A. Torne¹

¹Hospital Clinic de Barcelona, Gynaecology Oncology Unit, Barcelona, Spain
²Hospital Clinic de Barcelona, Nuclear Medicine Department, Barcelona, Spain
³Hospital Clinic de Barcelona, Radiodiagnosics Department, Barcelona, Spain

Aims

FDG-PET/CT has been suggested as a feasible but not yet broadly recommended tool to workup epithelial ovarian cancer (EOC) before primary treatment. The aim of this study was to evaluate the rate of upstaging introduced by the use of FDG-PET/CT for the initial assessment of suspected advanced EOC.

Method

Between 08/2012 and 07/2016, 48 patients presented, according to abdomino-pelvic CT and confirmed by histology, advanced EOC and were evaluated with whole-body FDG-PET/CT. Patient data were collected before primary treatment.

Results

The median age at diagnosis was 60 years (range 38-83). The median CA125 value was 1161.7 U/mL and median HE4 was 845.5 pmol/L. 60.4% showed moderate or massive ascites.

When evaluated using standard abdomino-pelvic CT we found 36 cases of suspected stage III (75%) and 12 suspected stage IV patients (25%). After FDG-PET/CT we identified that 19 patients were upstaged (39.6%), finding 21 stage III cases (43.8%) and 27 stage IV cases (56.3%). FDG-PET/CT detected patients with either cardiophrenic, internal mammary, mediastinal, supraclavicular, submandibular or axillary FDG-avid lymph nodes and patients with either pleural, splenic, adrenal and/or hepatic FDG-avid nodes suggestive of metastasis. None of these had been found by standard abdomino-pelvic CT.

Conclusion

More than one third of advanced EOC patients were upstaged by the use of FDG-PET/CT. Randomized studies should be used to clarify the role of FDG-PET/CT in the preoperative assessment of advanced EOC. We should discuss if we are staging advanced EOC patients correctly and therefore providing them with an accurate treatment.
Aims

Ovarian cancer is the deadliest of gynecologic cancers. Therefore, FIGO and the WHO classifications were revised. Both classifications are essential criteria for the treatment decision. We sought 1) to compare the major changes between the both classifications; 2) to examine the effects on the therapeutic and prognosis of the Ovarian, Fallopian Tubes and Peritoneum cancer in our sample.

Method

We performed a case series observational descriptive study of 210 patients who have been diagnosed with and/or treated for a malignant ovarian tumor at University Clinic Hospital of Salamanca from 2010-2016.

Results

According to the new FIGO subdivision of stage IC, we obtained 2.52% in substage IC2. The vast majority of ovarian cancer cases are in III FIGO stage. In the new WHO classification, the main change to the Serous group was the increase in the HGSC percentage. In the previous classification we had 6.48% of endometrioid malignant tumor and in the new classification this rate has decreased to 2.78%. Concerning Serous tumors, the separating line between adenomas and borderline tumors (SBOT) has been refined in the current WHO classification. In our study, the HGSC has reached 55.56% in the new WHO classification thanks to the incorporation of serous malignant adenocarcinoma (1988 WHO classification). We found 1.85% of Seromucinous Borderline Tumors. We found that 4.2% of the previous Stage IIIC patients have changed to stage IIIA2 or stage IIIB and this group of patients has a better prognosis and a superior survival rate.

Conclusion

This study demonstrated that the new-created WHO and FIGO classifications have improved the ability to predict the prognosis and consequently to change the therapeutic managements in Ovarian cancer patients.

ESGO7-1082

STAGING SURGERY IN EARLY-STAGE OVARIAN MUCINOUS TUMORS ACCORDING TO EXPANSILE AND INFILTRATIVE TYPES

1Gustave Roussy, Surgery, Villejuif, France
2Gustave Roussy, Oncology, Villejuif, France
3Hospices Civils de Lyon, Pathology, Lyon, France
4Gustave Roussy, Pathology, Villejuif, France

Aims

To determine the value of surgical staging for the two histologic types (expansile or infiltrative) of apparent stage I mucinous ovarian carcinoma.

Method

We retrospectively analyzed patients treated from 1976 and 2016 for apparent macroscopic stage I ovarian mucinous carcinoma. Extra-ovarian disease and tumors that metastasized to the ovaries were excluded. Two expert pathologists performed pathologic reviews of tumor data, according to 2014 WHO classification criteria. Tumors were typed as expansile or infiltrative and clinical and histologic characteristics were studied. The value of staging procedures (peritoneal and nodal) was based on the rate of microscopic involvement in macroscopically normal specimens.

Results

Of 114 cases reviewed, 46 were excluded (26 with macroscopic stage >I; 20 inaccessible for pathologic review). Of 68 patients included, 29 had expansile and 39 had infiltrative types. 27 patients received one-step surgery and 41 received restaging surgery. 52 patients received “complete” peritoneal surgical staging (including cytology, peritoneal biopsies, and an omentectomy or large omental biopsies). 24 underwent appendectomies and 31 underwent lymphadenectomies (8 expansile and 23 infiltrative). Before histologic analyses of staging specimens, 35 had “initial” stage IA and 33 had IC disease. After histologic analyses of lymph nodes, 4 cases (17%, all infiltrative) had nodal involvement, and 2 showed microscopic peritoneal disease (1 omentum and 1 right diaphragm peritoneum). Three patients were upstaged based on isolated positive peritoneal cytology.

Conclusion

Peritoneal staging procedures are required for both types of mucinous ovarian carcinoma. Lymphadenectomy could be omitted in expansile, but required in infiltrative type.

ESGO7-1292

EVALUATION OF OLAPARIB SERUM CONCENTRATIONS IN PATIENT WITH TERMINAL RENAL INSUFFICIENCY AND DIALYSIS TREATED FOR PLATIN-SENSITIVE RECURRENT BRCA POSITIVE HIGH GRADE SEROUS OVARIAN CANCER.

J.P. Grabowski1, J. Glajzer1, R. Richter1, D. Zickler2, J. Sehouli1

1Charité - Universitätsmedizin Berlin, Department of Gynecology- European Competence Center for Ovarian Cancer, Berlin, Germany
2Charité - Universitätsmedizin Berlin, Department of Nephrology and Internal Intensive Medicine, Berlin, Germany

Aims

Olaparib, a PARP inhibitor, is a recommended maintenance therapy in BRCA mutated patients with relapsed, platinum sensitive high-grade serous ovarian cancer. Until now, there are lacking data of olaparib in patients with terminal renal failure (GFR< 30 ml/min) and dialysis.

Method

The serum concentrations of olaparib in a 75 year old patient with platin-sensitive recurrent high-grade ovarian cancer and terminal renal insufficiency (GFR< 15 ml/min) were measured systematically. The blood samples were taken prior, 1, 1.5, 2, 3, 4 and 6 hours after medication intake on a dialysis- and a non-dialysis day. Subsequently, the serum concentrations were analyzed.

Results

The patient is under olaparib therapy since March 2016 in a reduced dose of 200mg daily. She suffered from terminal renal insufficiency due to postoperative kidney failure after primary cytoreductive surgery by initial FIGO IIIC stage. Mild nausea and fatigue were present at the beginning of the therapy and released after few weeks. The patient is after a follow up of 14 months in a complete remission. The analysis revealed a median olaparib serum concentration of 1.46 µg/ml on dialysis and 2.93 µg/ml on non-dialysis day. No statistical significant difference between concentrations variations on these days was found (p=0.200; Mann- Whitney- U- Test).

Conclusion

To our knowledge, this is the first report evaluating olaparib serum concentration in terminal renal insufficiency and dialysis situation. Our analysis shows olaparib therapy as feasible and safe in those patients. Given to no concentrations variations differences on both days, the elimination seems to be independent from dialysis.

11San Raffaele Hospital, Department of Obstetrics and Gynecology, Milan, Italy
12Ospedale S. Giovanni Calibita Fatebenefratelli, Medical Oncology Unit, Rome, Italy

Aims

To evaluate the impact of tertiary cytoreductive surgery (TCS) on survival in recurrent epithelial ovarian cancer (EOC), and to determine predictors of complete surgical cytoreduction.

Method

A multi-institutional retrospective study was conducted within the MITO Group on a 5-year observation period. Patients were considered eligible if they met the criteria listed in Table 1.

Table 1. Enrollment criteria.

</tr>
</tbody>
</table>

EOC: Eastern Cooperative Oncology Group; ROC: relapsed ovarian cancer; TFI: treatment-free interval.

Results

A total of 103 EOC patients undergoing TCS were included (Table 2). Complete cytoreduction was achieved in 71 patients (68.9%), with severe post-operative complications in 9.7%, and no 30-day operative mortality. Multivariate analysis identified the complete tertiary cytoreduction as the most potent predictor of survival followed by FIGO stage I-II at initial diagnosis; exclusive retroperitoneal recurrence; TCS performed ≥3 years after primary diagnosis (Table 3). Patients with complete tertiary cytoreduction had a significantly longer overall survival (median OS: 43 mos, 95% CI 31 – 58) compared to those with residual tumor (median OS: 33 mos, 95% CI 28 – 46; p < 0.001). After multivariate adjustment, the following variables were the most significant predictors of complete surgical cytoreduction: single lesion; good performance status (ECOG 0) (Table 3).
Conclusion

Only one further large retrospective study on TCS has been published so far. The achievement of postoperative no residual disease is confirmed as the primary objective also in a TCS setting, when considering surgical efforts aiming at improvement of survival, with acceptable morbidity. Accurate patient selection is of utmost importance to have the best chance of complete cytoreduction.

OVARIAN CANCER

ESGO-0875

FACTORS ASSOCIATED WITH A DEVIATION FROM STANDARD SURGICAL TREATMENT IN ELDERLY PATIENTS TREATED FOR OVARIAN TUMOR.
G. Babin¹, D. Querleu¹, F. Lecuru², A.S. Bats², G. Cordeiro Vidal¹
¹Institut Bergonié, Surgery, Bordeaux, France
²Hôpital Européen Georges Pompidou, Surgery, Paris, France

Aims

To compare two groups of elderly patients treated for an epithelial ovarian cancer, to understand the outcomes leading to a deviation to standard therapy and to isolate predicting factors of this outcome.

Method

It's a retrospective, bi-centric study, about all patients over 70 years old treated for an epithelial ovarian cancer between January 2005 and January 2014. We studied the pre therapeutic data of the patients, their treatment and the outcome of it depending on the standard treatment for ovarian cancer.

Results

222 patients were included. 93 patients received a complete standard treatment and 129 had a deviation to standard therapy. The encountered causes of deviation were: the spreading of the disease in 87 cases (67.4%), a medical refusal due to co morbidities in 36 cases (27.9%), surgical complications in 19 cases. An oncogeriatric analysis was performed in 22% of the cases in the group with standard therapy and in 38% in the group with deviation \( p = 0.02 \). When the oncogeriatric analysis did not promote a standard therapy, no patient had a standard treatment. There weren't more complication in surgery despite a more aggressive surgery in the group with standard treatment. Patients without deviation had an extended, survival hazard ratio 0.23 (0.14-0.39), \( p < 0.001 \).

Conclusion

Standard management of advanced EOC is associated with a substantial survival benefit in the elderly patient when it can be achieved. The main obstacle to complete a standard treatment remains the spread of the disease and the impact of aggressive surgery in frail patients.
EXPRESSION OF ACID CERAMIDASE (ASAH1) AS A PROGNOSTIC FACTOR IN OVARIAN CANCER

1University Lübeck, Gynecology and Obstetrics, Lübeck, Germany
2Tuebingen University Hospital, Department of Women’s Health, Tuebingen, Germany
3Goethe University Frankfurt, Department of Obstetrics and Gynecology, Frankfurt, Germany
4Bethesda Hospital, Department of Gynecology, Mönchengladbach, Germany
5BCCA Cancer Research Centre, Department of Molecular Oncology, Vancouver, Canada
6University Hospital Bonn, Institute of Pathology, Bonn, Germany

Aims

Acid ceramidase (AC), encoded by the ASAH1 gene, is a key enzyme of sphingolipid metabolism and frequently overexpressed in a variety of cancer types. In the present study, we investigated the expression of AC and its prognostic impact in ovarian cancers.

Method

Tissue micro arrays constructed using formalin-fixed paraffin-embedded tissue of primary ovarian cancers (n = 789) were obtained. Immunohistochemical analysis of AC was performed, and the results were correlated with clinico-pathological characteristics and survival.

Results

High AC expression was shown to significantly correlate with optimal tumour resection (p < 0.001). Kaplan-Meier analysis further revealed that low AC levels were associated with reduced progression-free survival (PFS; 44.82 months [95% confidence interval (CI): 32.21-55.43] vs. 86.49 months [95%CI: 63.01-109.97], p < 0.001) and overall survival (OS; 68.25 months [95%CI: 59.14-77.35] vs. 108.69 months [95%CI: 85.79-131.58], p < 0.001). Subsequently, the prognostic value of AC expression together with clinical factors (i.e. FIGO stage, age, and residual tumour burden after surgery) was substantiated in univariate Cox regression analysis (PFS: hazard ratio (HR) = 1.36 [95%CI: 1.15-1.63], p < 0.001; OS: HR = 1.4 [95%CI: 1.7-1.68], p < 0.001).

Conclusion

Our results suggest that AC expression is a prognostic factor in ovarian cancer, and that low AC expression might be associated with cancer progression and suboptimal tumour debulking. To corroborate these findings, however, our results need to be validated in an independent patient cohort.
DETECTION AND CHARACTERIZATION OF P53 PRIONS IN HIGH-GRADE SEROUS OVARIAN CANCER

N. Heinz¹, E. Maritschnegg¹, K. Koziel², R. Horvat¹, J. Sehouli³, I. Braicu⁴, I. Vergote⁵,⁶, E. van Nieuwenhuysen⁵,⁶, S. Mahner⁷,⁸, E. Obermayr⁴, E. Schuster⁴, B. Holzer⁴, N. Concin², R. Zeillinger¹

¹Medical University of Vienna, Department of Obstetrics and Gynaecology, Vienna, Austria

³Medical University of Vienna, Department of Pathology, Vienna, Austria
⁴Charité University Hospital, Department of Gynecology, Berlin, Germany
⁵University Hospitals Leuven, Department of Gynecology and Obstetrics, Leuven, Belgium
⁶KU Leuven, Division of Gynecological Oncology, Leuven, Belgium
⁷University Medical Center Hamburg-Eppendorf, Department of Gynecology, Hamburg, Germany
⁸Ludwig-Maximilian University of Munich, Department of Gynecology and Obstetrics, Munich, Germany

Aims

About 96% of high-grade serous ovarian cancers (HGSOC) harbor TP53 mutations. Recent evidence showed that several TP53 mutations lead to aggregation into prion-like amyloids, resulting in dominant-negative activity and oncogenic gain-of-function. This process could be involved in HGSOC initiation, progression and platinum-resistance. An ELISA-based technique was applied to detect p53 prions and to evaluate their prevalence and clinical relevance.

Method

Fresh-frozen tumour tissue of 123 HGSOC patients from the OVCAD study (at least five years follow-up) was analysed. An ELISA previously applied in the diagnosis of mad cow disease was optimized for the analysis of p53 prions. Data were analysed using Kaplan-Meier curves and Log-rank test.

Results

Samples carrying TP53 missense mutations showed a significantly higher prion signal compared to wild-type or frameshift mutated samples. In 37/46 (80.4%) of missense mutated cancers a p53 prion specific signal was detected. The ELISA results varied significantly between different tumours carrying the same missense mutation. A significantly diminished overall survival was observed for patients with moderate aggregation compared to patients with no p53 prions (p=0.031). In contrast, extensive p53 aggregation resulted in a prolonged overall (p=0.025) and progression-free survival (p=0.014).

Conclusion

We demonstrated the validity of the established ELISA in detecting p53 prions and their high abundance in HGSOC. Our data indicate that missense mutations alone are not sufficient and other cofactors are involved in the formation of prions. The significant correlation between survival and p53 prion levels demonstrates that the understanding of the biology of p53 prions is of high importance.
INTERACTION BETWEEN TWIST1 EXPRESSION AND TUMOR MICROENVIRONMENT FOR ANGIOGENESIS IN OVARIAN CARCINOMA

J.H. Hong1, Y.T. Ouh1, H.W. Cho1, J.K. Lee1

1Guro Hospital Korea University College of Medicine, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Twist1 is a transcription factor that is involved in cancer metastasis and recurrence, but little is known about the mechanisms underlying these processes. This study aimed to investigate the role of Twist1 in tumor angiogenesis in epithelial ovarian cancer (EOC) and to identify key molecules involved in the Twist1 pathway.

Method

A Twist1 siRNA was transfected into the EOC cell line that showed the highest expression to silence the gene, while a cDNA vector was transfected into human ovarian surface epithelial cells to generate a Twist1-overexpressing cell line. To evaluate the change in angiogenesis, HUVEC tube formation assays were performed using the control and the transfected cell lines. In addition, a cytokine array was used to determine the molecules involved in Twist1-mediated angiogenesis.

Results

After Twist1 knockdown in A2780 cells, the number of tubes formed by HUVECs significantly decreased. In a cytokine array, Twist1 downregulation inhibited the expression of the CXC chemokine ligand 11 (CXCL11), which was confirmed by both an enzyme-linked immunosorbent assay and a western blot assay. In contrast, Twist1 overexpression increased the secretion of CXCL11. Furthermore, the ability of Twist1-expressing A2780 cells to induce angiogenesis was inhibited after CXCL11 knockdown by CXCL11-siRNA in a tube formation assay. Conversely, CXCL11 downregulation did not inhibit Twist1 expression.

Conclusion

Our findings demonstrate that Twist1 plays an important role in angiogenesis in EOC and is mediated by a novel pro-angiogenic factor, CXCL11. Downregulation of CXCL11 can inhibit tumor angiogenesis, suggesting that an anti-CXCL11 therapy may offer an alternative treatment strategy for Twist1-positive ovarian cancer.
COMPARISON OF PET-MRI AND MRI ALONE PREDICTING CARCINOMATOSIS IN OVARIAN CANCER USING PERITONEAL CANCER INDEX (PCI)

1 Uppsala University, Department of Women’s and Children’s Health, Uppsala, Sweden
2 Uppsala University, Department of Surgical Sciences - Section of Radiology, Uppsala, Sweden
3 Uppsala University, Department of Surgical Sciences, Uppsala, Sweden
4 Uppsala University, Department of Women’s and Children’s Health - Uppsala University, Uppsala, Sweden

Aims

It is difficult to estimate carcinomatosis in ovarian cancer and identify inoperable patients. The purpose of this study was to evaluate the ability of integrated PET-MRI and MRI alone in estimating carcinomatosis using peritoneal cancer index (PCI) with the surgical PCI as gold standard.

Method

Whole-body PET-MRI was performed on 24 patients with presumed carcinomatosis of a gynecologic origin, planned for surgery. The radiologist evaluated PCI on MRI (including DWI) and PET-MRI scans separately. The surgeon estimated PCI intraoperatively. The radiologist and the surgeon were blinded to each other results.

Results

The median total PCI was 16.5 for MRI (p = 0.01), 22 for PET-MRI (p = 0.725) and 24 for surgery. Bias between radiologic and surgical PCI was for MRI 4.96±6.15 (p = 0.73) and for PET-MRI -0.04 ± 4.71 (p = 0.32). The sensitivity calculated for each region ranged from 36.8-87.5% for MRI and 53.3-95.8% for PET-MRI. In the four inoperable patients the estimated median PCI for region 9-12 (small bowel, max score 12) was 3.5 for MRI and 10 for PET-MRI respectively, surgical PCI being 9.5.
Conclusion

PET-MRI and MRI have a good ability evaluating carcinomatosis, PET-MRI slightly exceeding MRI. Possibly the most interesting finding is the indication of better sensitivity of PET-MRI to detect carcinomatosis in the small bowel, which is crucial in deciding operability.

SURGICAL OUTCOMES AND MORBIDITY AFTER RADICAL SURGERY FOR OVARIAN CANCER: OUR EXPERIENCE IN ABERDEEN ROYAL INFIRMARY, THE NORTHEAST OF SCOTLAND GYNAECOLOGIC ONCOLOGY CENTRE

E. Kalampokas1, H. Young2, A. Bednarek3, M. Gurumurthy1, M. Cairns1

1NHS Grampian, Gynaecologic Oncology, Aberdeen, United Kingdom
2NHS Grampian, NHS Grampian, Aberdeen, United Kingdom
3NHS Grampian, Obstetrics and Gynaecology, Aberdeen, United Kingdom

Aims

Ovarian cancer (OC) is the second commonest gynaecological cancer, characterized by patients' diversity to treatment and high mortality rate. Usually presents late in advanced stage which pose challenges to management. Recently, better understanding of the disease biology and application of aggressive surgery to achieve no visible residual has led to longer survival amongst these patients. Purpose of our study is to examine the clinical and demographic characteristics, surgical morbidity and outcomes of patients undergoing radical surgery for OC.

Method

A retrospective cohort study of women undertaking debulking surgery for OC between February 2014 and September 2016 at Aberdeen Royal Infirmary (ARI).

Results

121 women in total had debulking surgery for OC. 43 (35.6%) were stage I, 20 (25.7%) stage II, 53 (43.8%) stage III and 5 (4.1%) were stage IV. 78 (64.5%) women had radical surgery. Of these, 40 (51.3%) women had primary vs. 38 (48.7%) women who had interval debulking surgery. Commonest procedures that were performed as part of radical surgery include rectosigmoid resection (n=20, 25.6%), small bowel resection (n=10, 12.8%), splenectomy (n=9, 11.5%). Commonest morbidity outcomes included blood loss >1.5 lt. (n=17, 21.8%), hospitalization >7days (n=40, 51.2%), sepsis (n=14, 17.9%). Surgery outcomes were: no macroscopic residual disease (n=61, 78.2%), ≤10mm disease (n=6, 7.7%), and ≥10mm disease (n=8, 10.3%).

Conclusion

Identification of patients who will benefit from radical surgery avoiding unnecessary morbidity and mortality is a real challenge. We suggest that radical surgery for OC is related to acceptable morbidity after careful case selection.

CAN COPENHAGEN INDEX REPLACE RISK OF OVARIAN MALIGNANCY ALGORITHM (ROMA) IN A TRIAGE OF PATIENTS WITH PELVIC MASS?

M. Katsyuba¹, R. Khasanov¹, G. Usmanova², E. Ratner³, G. Muratova⁴, N. Nigmatulina⁵

¹Kazan State Medical Academy, oncology, Kazan, Russia
²Tatarstan Regional Clinical Cancer Center, laboratory, Kazan, Russia
³Tatarstan Regional Clinical Cancer Center, oncology, Kazan, Russia
⁴Kazan Federal University, Physics and mathematics, Kazan, Russia
⁵Kazan Federal University, Fundamental Medicine and Biology, Kazan, Russia

Aims

to comprehensively compare two algorithms, predicting ovarian cancer in patients with pelvic mass: Copenhagen index (CPH-I) and Risk of Ovarian Malignancy Algorithm (ROMA).

Method

We prospectively enrolled 320 patients with pelvic mass, which were consecutively scheduled for surgery in a single institution. Prediction results by ROMA and CPH-I, obtained before surgery, were compared to final histological diagnoses.

Results

Histological analysis revealed 26 epithelial ovarian cancers (EOC), 15 borderline ovarian tumors, 8 non-epithelial malignancies, 2 cases of ovarian metastases and 260 benign diseases. On comparing ROC-AUC, CPH-I was not inferior to ROMA neither in pre- nor in postmenopausal patients. At standard cut-off points ROMA provides a tailored specificity of about 90% in all subgroups (89.6 and 89.7% in pre- and post-menopause, respectively), whereas CPH-I in premenopausal patients demonstrated an extremely high specificity of 96.3% (95%CI: 91.6-98.4) to the detriment of sensitivity. The sensitivity of CPH-I and ROMA for EOC was 87.5% and 100%, respectively, in premenopausal patients; 92.9% and 96.4%, respectively in postmenopausal patients; and 91.7% and 97.2%, respectively.

Conclusion

Both CPH-I and ROMA are excellent algorithms for triaging patients, diagnosed with pelvic mass, with the aim of referring high-risk patients to a tertiary centers. Non-inferiority of CPH-I’s ROC-AUC relative to ROMA’s is not to be doubted. However, when using standard cut-off points, ROMA was slightly superior to CPH-I and showed more balanced specificity and sensitivity. Thus, more research aimed at a thorough validation of CPH-I’s standard cut-off level is still needed for the widespread introduction of CPH-I into clinical practice.
THE SIGNIFICANCE OF PREOPERATIVE SERUM CANCER ANTIGEN 125 IN MALIGNANT OVARIAN GERM CELL TUMORS

J.Y. Park¹, J.H. Kim¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam²
¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea
²Asan Medical Center, Seoul, Korea, Republic of Korea

Aims

To determine the prognostic value of preoperative serum cancer antigen 125 (CA 125) in malignant ovarian germ cell tumors (MOGCTs).

Method

Using information from medical databases, we investigated 161 patients with histologically diagnosed MOGCTs between 1993 and 2014. We chose the optimal cut-off value of CA 125 by using a receiver operating characteristic (ROC) curve.

Results

The median patient age was 24 years (range, 6-52 years). The most common histologic type was immature teratoma. Forty-eight patients had a normal range of serum preoperative CA 125 (<35U/mL). Most patients had stage I disease. Fertility-sparing surgery was performed for 138 patients, and staging surgery in 118 patients. The median tumor size was 15 cm. Ninety-four patients had ascites at surgery. Spillage of the tumor was observed in 51 patients. Fourteen patients had positive cytology, 12 had lymph node metastasis, and 61 patients had ovarian surface involvement. Six patients had residual tumors. We determined the reference level of CA 125 (>78 U/mL) using a ROC curve. On univariate analysis, lymph node metastasis, positive cytology, ascites, ovarian surface involvement, tumor rupture, age, tumor size, and stage were significantly associated with elevated serum preoperative CA 125 levels (>78 U/mL). Patients with an elevated serum preoperative CA 125 level (>78 U/mL) had poorer disease-free survival, but this was not statistically significant. However, elevated preoperative CA 125 (>78 U/mL) was significantly associated with poorer overall survival.

Conclusion

Elevated preoperative serum CA 125 is associated with poorer prognostic factors and may have prognostic value in patients with MOGCTs.

ESGO7-0464

POST-DEBULKING CIRCULATING TUMOR CELL AS A POOR PROGNOSTIC MARKER IN ADVANCED STAGE OVARIAN CANCER

1Soon Chun Hyang University Hospital, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
2Seoul National University Bundang Hospital, Department of Obstetrics and Gynecology, Seongnam, Republic of Korea
3Korea Advanced Institute of Science and Technology KAIST, Department of Bio and Brain Engineering, Daejeon, Republic of Korea

Aims

To evaluate the association between the presence of perioperative circulating tumor cell (CTC) and clinical outcomes of ovarian cancer.

Method

In 30 patients who were going to undergo staging operation for ovarian cancer, peripheral blood samples were collected before and after primary debulking surgery. CTC was isolated using the tapered-slit filter (TSF) platform. Association between the presence of CTC and tumor characteristics was evaluated. The impact of the presence of perioperative CTC on progression-free survival (PFS) outcomes was also analyzed.

Results

The median age at diagnosis was 58 years (range, 24-77 years), and the median follow-up period was 15 months (range, 0-21 months). Overall, CTC positive rate was not different between pre- and post-operative peripheral blood samples (23/30 [76.7%] vs. 16/28 [57.1%], p=0.673). The presence of preoperative (6-month PFS rate, 90.5% vs. 83.3%, p=0.216) and postoperative CTC (6-month PFS rate, 80.0% vs. 100%, p=0.121) was not significantly associated with PFS outcomes. In a subgroup analysis of advanced stage, however, patients with postoperative CTC had significantly poorer PFS outcome than those without (6-month PFS rate, 75.0% vs. 100%, p=0.031). In this group of patients with advanced stage disease, postoperative CTC was more frequently detected in patients who had lymph node metastasis than those who did not (7/7 [100%] vs. 3/10 [30.0%], p=0.010).

Conclusion

The presence of postoperative CTC on the TSF platform might be associated with poorer PFS outcome in patients with advanced stage ovarian cancer. Further study with larger number of patients is needed to confirm our study results.
TOWARD OPERATIVE FLUORESCENCE IMAGING OF C-MET FOR PERSONALISED THERAPY IN OVARIAN CANCER

D M Klotz1, P Wimberger1, A Ahmed2

1University Hospital / TU-Dresden, Gynaecology and Obstetrics, Dresden, Germany
2University of Oxford, Weatherall Institute of Molecular Medicine and Nuffield Department of Obstetrics and Gynaecology, Oxford, United Kingdom

Aims

Despite an initial therapeutic response with optimal surgical debulking, most women diagnosed with ovarian cancer will experience a recurrence, typically with peritoneal metastases. To develop novel targeted therapies, biomarker selection is a key criterion.

Method

We studied the expression of the c-Met oncogene in ovarian cancer. We stained tissue microarrays generated from individual 40 high-grade and 40 low-grade serous ovarian cancers (Gynecological Oncology Targeted Therapy Study 01). A modified cyanine 5–tagged peptide, GE137, with a high in vitro affinity for the human c-Met protein, was tested in ovarian cancer cell lines. Finally, the feasibility of detecting peritoneal metastases in vivo was tested through the intravenous injection of GE137 into mice with tumour xenografts.

Results

The histopathological analysis revealed a differential expression pattern of c-Met, indicating the importance of tumour heterogeneity for patient selection. Importantly, c-Met expression was also significantly increased in peritoneal tumour deposits compared to normal peritoneum. Next, we showed that GE137 co-localises to c-Met in SKOv3 (ovarian cancer) cells without activating downstream c-Met signalling pathways, such as AKT phosphorylation. After intravenous injection of GE137, tumour xenografts were readily detectable at a sub-millimeter resolution with the fluorescent signal being maintained for at least 8 hours.

Conclusion

This study established the expression of c-Met as biomarker in ovarian cancer and peritoneal deposits, providing a proof-of-concept of c-Met-targeted therapeutic strategies. This suggests that intraoperative optical imaging could provide a new paradigm for selecting cancer patients suitable for appropriate targeted therapies.
SHOULD AROMATASE INHIBITORS BE USED AS MAINTENANCE TREATMENT IN HIGH-GRADE SEROUS OVARIAN CANCER PATIENTS?

V. Heinzelmann-Schwarz, A.M. Knipprath-Mészáros, J. Francis, S. Stadlmann, F. Vigo, A. Schoetzau, G. Singer, M. Vetter

1University Hospital Basel, Gynecological Cancer Center, Basel, Switzerland
2Ovarian Cancer Research Center, Department of Biomedicine, Basel, Switzerland
3Cantonal Hospital Baden, Institute of Pathology, Baden, Switzerland

Aims

Endocrine therapy is used in ER positive breast cancer and has been proposed as effective treatment in G1 serous ovarian cancer. The aim of this study was to determine the expression rate of ER in a high-grade advanced stage serous ovarian cancer cohort (HGSOC) and whether a maintenance antihormonal therapy adds a benefit in relation to the time of recurrence.

Method

We retrospectively examined ESR1 expression in breast and ovarian cancer as well as ER expression in a cohort of HGSOC. In addition, matched primary and recurrent HGSOC samples collected between 1985-2003 were inserted in a Tissue Microarray and IHC for ER expression. Furthermore, newly diagnosed HGSOC FIGO III/IV since 2013 were assessed prospectively for ER expression and when positive, offered a maintenance therapy with Letrozole 2.5mg/d in an off-label fashion. We assessed the time of first recurrence in correlation with the use or not of Letrozole using Kaplan-Meier analysis.

Results

ESR1 was strongly expressed in similar levels in HGSOC as in breast cancer. Strong ER expression in HGSOC is similar in chemotherapy-resistant primary tumors as in their recurrent counterparts. The use of Letrozole as maintenance treatment was associated with a significant prolonged recurrence free interval, with 75% of patients recurrence free after 24 months when taking Letrozole vs 40% in the control group (p= 0.01).

Conclusion

Primary HGSOC have a high ESR1 and ER expression which is similar to breast cancer where Aromatase inhibitor maintenance is routine for decades. Here we demonstrate evidence for the usefulness of a similar rationale in HGSOC.
Aims
Epidemiologic evidence suggests that aspirin use is associated with a reduction in the risk of developing ovarian cancer among women in the general population. No studies that evaluated this relationship among high-risk women. We evaluated the relationship between aspirin use and BRCA-associated ovarian cancer.

Method
We conducted a matched case-control study which included 986 cases of ovarian cancer and 3,069 controls with a BRCA1 or BRCA2 mutation. Detailed information regarding lifetime medication use (prescriptions and over-the-counter) was collected from a routinely administered questionnaire. Conditional logistic regression was used to evaluate the association between ever aspirin use, as well as, cumulative duration of aspirin use and the risk of developing ovarian cancer.

Results
Among BRCA1 and BRCA2 mutation carriers, aspirin use was not associated with the risk of developing ovarian cancer (odds ratio [OR] for ever vs. never use = 1.19; 95% confidence intervals [CI] 0.56-2.50; P = 0.65). Among women with a history of aspirin use, the risk of developing ovarian cancer associated with lifetime aspirin use for less than one year was 0.50 (95% CI 0.06-4.23) and was 1.45 (95% CI 0.65-3.24) for lifetime use of more than one year. Findings did not vary by BRCA mutation type.

Conclusion
Our findings do not support a role of aspirin for the prevention of ovarian cancer among women carrying BRCA mutations. Prophylactic bilateral salpingo-oophorectomy is the most effective primary prevention strategy for this high-risk population.

2Medical University of Vienna, Department of Obstetrics and Gynaecology, Vienna, Austria
3Innsbruck Medical University, Division of Clinical and Functional Anatomy- Department of Anatomy- Histology and Embryology, Innsbruck, Austria

Aims

The recently discovered propensity of p53 proteins to exhibit prion-like behaviour may play an important role in initiation and progression of ovarian cancer. The aim of the present study was to establish reliable methodology to detect p53 prion-like aggregates in ovarian tumours.

Method

Three techniques to analyse p53 prion-like protein aggregates were established, i.e. immunofluorescence co-localization and co-immunoprecipitation based on 1) anti-aggregates antibodies and 2) on Seprion methodology. In a first step 10 ovarian cancer cell lines were tested, followed by analysis in tissues of patients with borderline tumours and malignant ovarian carcinomas (OC) of different histological subtypes. This included paraffin-embedded tissues (n=77) and a subset of fresh frozen tissues (n=30).

Results

p53 prion-like aggregates were found in 5/10 ovarian cancer cell lines consistently with all 3 different techniques. All positive cell lines harboured p53 missense mutations. With respect to patients samples, 3/11(27%) borderline tumours were positive for p53 prion-like aggregates and 34/66(52%) invasive OCs. 30/34(88%) positive OCs harboured p53 missense mutations, 1 showed a frameshift mutation and 3 were p53 wild-type. In the big majority of tissue samples consistency between the 3 techniques was found.

Conclusion

We demonstrated a high prevalence of p53 prion-like aggregates among the spectrum of different ovarian tumours, mainly associated with p53 missense mutations. High consistency and therewith reliability of the 3 established techniques was achieved. In a next step we plan to investigate the clinical relevance of p53 prion-like aggregates in a large homogenous cohort of prospectively collected high-grade serous OC cases.
GHOST ILEOSTOMY IN THE MANAGEMENT OF MODIFIED POSTERIOR EXENTERATION: A RELIABLE OPTION IN OVARIAN CANCER

V. Lago Leal¹, L. Matute Tobias¹, S. Domingo Del Pozo¹, P. Padilla Iserle¹, M. Gurrea Soteras¹, C. Díaz García¹
¹Hospital Universitario y Politecnico La Fe, Gynecologic Oncology, Valencia, Spain

Aims

Our objective was to determine the usefulness of the ghost ileostomy associated with sequential postoperative rectoscopy (SPR) in patients in which modified posterior exenteration was performed due to ovarian cancer.

Method

After modified posterior exenteration (MPE) and colorectal anastomosis were performed, a loop ileostomy was created to minimize the clinical impact of colorectal anastomotic leak instead of a real ileostomy. A SPR was performed in 4º-5º postoperative (PO) day. CRP and Procalcitonin serum levels were also monitored in 1º and 3º PO day.

When anastomotic leakage was suspected, the ghost ileostomy was converted into a defunctioning ileostomy. In case of uncomplicated PO course, the loop was removed before discharge.

Results

Between January 2015 and April 2017, 139 cytoreductive procedures due to ovarian cancer were performed. In 30 out of 48 cases of MPE, a ghost ileostomy was created. SPR, CRP and Procalcitonin levels were found normal except in one patient (1/30; 3,3%). In this single case anastomotic leakage was confirmed in SPR. In consequence, real defunctioning ileostomy was created with an uncomplicated PO course.

Conclusion

Not only ghost ileostomy prevents all the complications related to defunctioning ileostomy but also presents its advantages in case of anastomotic leakage.
Aims

To compare survival outcomes following robotic-assisted and abdominal surgery in patients with ovarian cancer.

Method

Retrospective analysis of consecutive ovarian cancer patients seen by a single surgeon between January 2008-March 2016. Intention-to-treat analysis was conducted using chi-square and t-test with significance <0.05. Kaplan-Meier survival curves were compared using the Mantel-Cox-log-rank test.

Results

Robotic-assisted cases were (n=122) were similar to abdominal surgery (n=49) on age, BMI, uterine weight, parity, prior pelvic surgery and intra- and post-operative complications (p>0.05). More robotic-assisted cases (vs. abdominal) had neoadjuvant chemotherapy (47.5% vs. 24.5%, p=0.004), were stage I (37.7% vs. 20.4%, p=0.03) and had no evidence of disease after surgery (79.5% vs. 40.8%, p<0.001). In early stage cancer (I/II), optimal debulking (<0.5 cm residual disease) was achieved in 98.1% and 80.0% of robotic-assisted vs. abdominal surgeries respectively (p=0.27). In advanced cases (III/IV), optimal debulking was attained in significantly more in robotic than abdominal surgeries (85.3% vs. 61.8%, p=0.009).

Survival distributions showed robotic surgery patients had better overall survival (p=0.02), but only for early stage cancers (p=0.003) and not advanced cancers (p=0.38) (Figure 1). There were no differences in progression-free survival by surgical approach either overall (p=0.56) or by early (p=0.63) or advanced stage (p=0.73) disease.

Conclusion

Overall and progression-free survival were at least as good in patients who underwent robotic-assisted compared to abdominal procedures, at all stages of ovarian cancer.

AGE IS NOT AN INDEPENDENT PROGNOSTIC FACTOR IN OPERATED STAGE III-IV EPITHELIAL OVARIAN CARCINOMA

A. De Nonville¹, B. Delga², R. Sabatier³, F. Rousseau¹, P. Viens¹, G. Houvenaeghe², J.M. Classe³, E. Lambaudie²

¹Institut Paoli-Calmettes- Aix-Marseille Univ- CNRS- INSERM- CRCM, Department of Medical Oncology, Marseille, France
²Institut Paoli-Calmettes- Aix-Marseille Univ- CNRS- INSERM- CRCM, Department of Surgical Oncology, Marseille, France
³Institut René Gauducheau, Department of Surgical Oncology, St Herblain, France

Aims

Recent data shows that older women are less likely to have complete surgery for stage III-IV ovarian Carcinoma. Moreover, this undertreatment has been linked to higher rates of mortality. Many publications have suggested that age may be a prognostic factor in ovarian carcinoma. Most of them are old and extrapolated overall survival data instead considering ovarian cancer-specific survival (OC-SV). The objective of this study was to evaluate if age is an independent prognostic factor in stage III-IV operated epithelial ovarian carcinoma.

Method

A total of 1,259 patients who underwent surgery at 2 French centres between 1985 and 2015 were identified. The primary endpoint was OC-SV. A multivariate Cox model was built including age, FIGO stage, CA125 level, surgery and chemotherapy.

Results

Median follow-up was 33 months. Median age at diagnosis was 60 (17-90). 242 (19%) patients were over 70 years of age. Patient characteristics were as follows (≥70 vs. <70y): proportions of FIGO IV were 23 vs. 17% (p=0.042), CA125>500: 55 vs. 58% (p=0.54), incomplete surgery: 42 vs. 27% (p<0.001) and 5 vs. 1% didn’t had chemotherapy (p<0.001). Age<70y, FIGO III, CA125<500, complete surgery and chemotherapy were significantly associated with a better OC-SV in univariate analysis (p<0.05, Log-rank test). Only age>70y was not an independent prognostic factor of OC-SV in multivariate analysis (Hazard Ratio=1.16; 95%CI [0.84,1.6]; p=0.372).

Conclusion

This study did not identify age ≥70y as an independent prognosis factor in this population. Our results suggest that age related poor prognosis is more link to suboptimal treatment of elderly patients.

PROGNOSTIC SIGNIFICANCE OF ENDOMETRIOID OVARIAN CANCER SUBTYPE: RESULTS OF AN INTERNATIONAL MULTI-INSTITUTIONAL RETROSPECTIVE STUDY
A. de Nonneville1,2, E. Lambaudie2,3, F. Cannone4, G. HouvenaegheF,3, R. Sabatier1,2
1Institut Paoli-Calmettes, Department of Medical Oncology, Marseille, France
2Aix Marseille Univ, CNRS U7258-INSERM U1068- Institut Paoli-Calmettes- CRCM, Marseille, France
3Institut Paoli-Calmettes, Department of Surgical Oncology, Marseille, France
4Garibaldi Nesima Hospital, Department of Obstetrics and Gynecology, Catania, Italy

Aims
The prognostic significance of endometrioid ovarian cancer (OvC) subtype is unclear. We compared histoclinical characteristic of patients with OvC by pathological subtype and correlate them with overall survival (OS).

Method
Patients with endometrioid or serous OvC diagnosed in two cancer centers in Italy and France between 2000 and 2016 were retrospectively identified. Data were collected in a systematic manner. A multivariate Cox model was built, including age, year of diagnosis, surgery, FIGO stage and adjuvant treatment, to determine the impact of pathological subtype on OS.

Results
Six hundred and sixty-eight cases were retrieved including 86 (12.9%) endometrioid carcinoma and 582 (87.1%) serous controls. Women with endometrioid cancer were younger (median age 55.9 vs. 61.6 years; p<0.001), had less aggressive tumors (64.5% of grades I or II vs. 28.9%; p<0.001), less advanced stage (III-IV) cancers (47.9 vs. 84.2%; p<0.001) and were less likely to receive chemotherapy (87 vs. 96.5%; p=0.001). No significant difference for complete surgery or year of diagnosis were found. Five-year OS rates were 60% in the endometrioid group and 45% in the serous group, respectively (p=0.001). In multivariate analysis, the lower risk of death from endometrioid cancer compared to serous ovarian cancer was no longer significant [HR=0.957 (IC95:0.612-1.494); p=0.846].

Conclusion
In this large cohort, the better clinical baselines characteristic seem to explain the better survival of endometrioid OvC cases. The endometrioid subtype is not an independent prognostic factor. Further analyses are needed to understand why endometrioid OvC patients are diagnosed at a younger age and at earlier stage.
A PROVEN MODEL FOR IMPROVEMENT IN GENETIC COUNSELING REFERRALS FOR OVARIAN CANCER PATIENTS IN A COMMUNITY HOSPITAL CANCER CENTER

G. Cantuaria1, K. Lang2, B. Benigno3, G. Feuer4, S. Yap1, M. Burrell1, M. Jones3, D. Hayes4, P. Huggins4, P. Owens4

1Northside Hospital Cancer Institute, Gynecologic Oncology, Atlanta, USA
2Northside Hospital Cancer Institute, Genetics, Atlanta, USA
3Northside Hospital Cancer Institute, Oncology Analytics, Atlanta, USA
4Northside Hospital Cancer Institute, Cancer Institute, Atlanta, USA

Aims

Despite guidelines recommending genetic counseling (GC) referrals for ovarian cancer patients, rates within US academic centers (15-30%) and worldwide (15-20%) remain low. While most US cancer patients receive treatment at community centers, there is little research on genetics referrals in this setting. With changes to clinical pathways in 2013, our goal was 100% referral rate to GC within 1 year from diagnosis.

Method

In October 2013, the Gynecologic Oncology Steering Committee (GOSC) implemented a multidisciplinary approach to improve education, communication, and care integration for ovarian referrals to GC. Compliance was monitored and reported. Missing referral notifications were sent regularly and status presented bi-monthly at GOSC for two years. Baseline 2013 referrals were compared to those in 2014 and 2015.

Results

In 2013, 35% (41/116) of ovarian patients were referred. In 2014, 90% (71/79) of eligible ovarian patients received GC and testing. Sixty-four (81%) of these were in-house referrals, 4 patients were seen at an outside institution, and 3 were tested through a clinical trial. The 8 (10%) missed referrals were due to 2 deaths, 2 lost to follow-up, and 4 were never referred. This demonstrates a 157% increase over baseline. In 2015, in-house referrals remained high at 73% (72/99).

Conclusion

Improvement in ovarian genetics referrals can be sustained in community setting through a multidisciplinary approach and regular reporting. Physician engagement and accountability are key to success. Our impressive growth in GC referrals within a large community cancer center benefits patients and can serve as a model for guideline compliance.

MORBIDITY OF RECTOSIGMOID RESECTION IN CYTOREDUCTIVE SURGERY FOR OVARIAN CANCER. RISK FACTOR ANALYSIS

C. Huchon¹, A.S. Bats², A. Berger², F. Lecuru², M. Fournier²
¹Hopital Poissy, Gynecology, Poissy, France
²HEGP, Gynecology, Paris, France
³HEGP, General Surgery, Paris, France

Aim: Rectosigmoid resection is often performed during cytoreductive surgery for ovarian cancer, to achieve the goal of no residual tumour. Here, we evaluated the morbidity associated with rectosigmoid resection and the underlying risk factors.

Method: We retrospectively assessed consecutive patients managed with rectosigmoid resection during cytoreductive surgery for ovarian cancer at our centre in Paris, France, between 2005 and 2013. All previously identified risk factors were analysed. Major complications were defined as grade III-IV in the Clavien-Dindo classification.

Results: Of 228 patients, 116 had primary and 112 interval surgery; 43/228 [18.9%] experienced major complications, and these were more common after primary surgery [24.1% vs. 13.4%, p=0.04]. The 69 patients who had rectosigmoid resection [33 primary vs. 36 interval surgery, p=0.32] had a higher morbidity rate compared to the other patients [30.4% vs. 14.6%, p=0.006]. The anastomotic leakage rate was 2.89%. By multivariate logistic regression, independent risk factors for morbidity were postmenopausal status [adjusted odds ratio (aOR), 13.7; 95% confidence interval (95%CI), 1.2;161.9], surgery after neoadjuvant chemotherapy [aOR, 4.4; 95%CI, 1.1;18.8], and peritoneal stripping of the left paracolic gutter [aOR, 11.3; 95%CI, 2.3;54.3].

Conclusion: The morbidity of rectosigmoid resection during cytoreductive surgery for ovarian cancer seems acceptable. Ileostomy does not seem associated with a lower risk of major complications or adjuvant bevacizumab with a higher complication rate.

ONCOLOGIC AND OBSTETRIC OUTCOMES OF CONSERVATIVE SURGERY FOR BORDERLINE OVARIAN TUMORS IN WOMEN OF REPRODUCTIVE AGE.

C. Lee¹, S.Y. Lee¹, K. Bo Ram¹, C. Min Chul¹, J. Sang GUN¹, S. Seung Hun¹, H. Park¹, J. Won Duk¹, L. Je Ho¹
¹CHA Bundang Medical Center - CHA University, Comprehensive Gynecologic Cancer Center, Seongnam, Republic of Korea

Aims

To compare the oncologic and obstetric outcomes in reproductive-age females with borderline ovarian tumors (BOTs) treated with cyst enucleation (CE) or unilateral salpingo-oophorectomy (USO).

Method

The medical records of patients with BOTs treated between 1998 and 2014 were retrospectively reviewed. The recurrence rates in the USO and CE groups were compared, and the postoperative obstetric outcomes were assessed via telephone survey.

Results

Eighty-nine patients with BOTs underwent USO, and 19 underwent CE. Of these, six patients had recurrent BOTs. The recurrence rate was significantly lower in the USO group (3/89, 3.4%) than in the CE group (3/19, 15.8%) (P=0.032).

All patients with recurrent disease were successfully treated with further surgery. Of the 76 patients interviewed by telephone, 71 (93.4%) resumed regular menstruation after surgery. Twenty-six of the 32 patients (81.3%) who attempted to conceive had successful pregnancies. USO (19/24, 79.2%), like CE (7/8, 87.5%), resulted in favorable pregnancy rates for patients with BOTs.

Conclusion

USO is a suitable fertility-preserving surgery for women with BOTs. CE is also an acceptable option for select patients.

IMPACT OF TIME INTERVAL BETWEEN COMPLETION OF NEOADJUVANT CHEMOTHERAPY AND THE INITIATION FOR POSTOPERATIVE ADJUVANT CHEMOTHERAPY IN ADVANCED OVARIAN CANCER

Y.J. Lee1, Y.S. Chung1, J.Y. Lee1, E.J. Nam1, S.W. Kim1, S. Kim1, Y.T. Kim1

1Yonsei University College of Medicine - Women's Life Medical Science, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The aim of our study was to investigate the relationships between the time interval from the end of neoadjuvant chemotherapy (NAC) to initiation of postoperative adjuvant chemotherapy (POAC) and survival outcomes.

Method

We retrospectively investigated 220 patients with pathologically confirmed epithelial ovarian cancer who received NAC at Yonsei Cancer Hospital between 2006 and 2016. Time interval was defined as the time from completion of NAC through interval debulking surgery to initiation of POAC. Time interval was analyzed and correlated with outcomes.

Results

Median time interval was 42 (range 16-178) days; 103 patients (53.1 %) had POAC within 42 days after NAC, 91 patients (46.9 %) after more than 42 days. There were no significant differences of patient characteristics between two groups. Kaplan-Meier curve showed that patients with longer time interval (>42 days) had poorer progression-free survival (PFS) and overall survival (OS) (P = 0.039 and P = 0.005, respectively). Multivariate analyses identified poorer PFS (HR, 1.39; 95% CI, 0.98 - 1.96) and OS (HR, 1.83; 95% CI, 1.11 - 3.02) among patients with longer time interval, although PFS was not statistically significant. When patients were categorized by quartile based on time interval (<37, 37-42, 42-50, >50 day), patients with a longer time interval had at higher risk of recurrence and death (p for trend = 0.001 and <0.001, respectively).

Conclusion

Time interval from the completion of NAC to initiation of POAC seem to influence survival outcome. Efforts to reduce time interval might be needed to improve outcomes in ovarian cancer patients undergoing neoadjuvant chemotherapy.

EXPRESSION OF MACROPHAGE MIGRATION INHIBITORY FACTOR, CD74 AND Ki-67 IN OVARIAN TUMOR

M. Joeng¹, C. Kim¹, E. Park², Y.S. Lee³
¹The catholic university of Korea, Obstetrics and gynecology, Seoul, Republic of Korea
²the catholic university of Korea, obstetrics and gynecology, seoul, Republic of Korea
³College of Medicine - The Catholic University of Korea - Seoul St.Mary's hospita, Gynecologic Oncology, Seoul, Republic of Korea

Aims

Macrophage migration inhibitory factor (MIF), CD74 and Ki-67 emerge as important players in pathogenesis and angiogenesis of several types of malignant tumors. The purpose of this study was to evaluate the expression of MIF, CD74 and Ki-67 in ovarian borderline tumor and ovarian cancer and explore the potential roles they play in ovarian tumor.

Method

Macrophage migration inhibitory factor, CD74 and Ki-67 expression was assessed by immunohistochemistry in 102 cases with various degrees of ovarian tissues, including 10 normal ovarian tissue, 46 borderline tumor, 48 ovarian cancer. Correlation between immunostainings and clinicopathological parameters, as well as the follow-up data of patients, was analyzed statistically.

Results

Immunohistochemical analysis showed that CD74 expression was significantly higher in ovarian cancer(26/48) than borderline ovarian tumor(10/46) and normal samples(0/10) (P< 0.01). Ki-67 expression was higher in ovarian cancer (18/48) than borderline ovarian tumor(2/46) and normal samples(0/10). (P< 0.001). MIF expression was high in all three group (40/48 vs 38/46 vs 10/10). Correlation analysis revealed that high CD74 expression in tumor cells were associated with advanced clinical stage, and worse prognosis of patients.

Conclusion

Correlation analysis revealed that high CD74 expression in tumor cells were associated with advanced clinical stage of patients
IS SELECTIVE INTERVAL DEBULKING SURGERY REALLY A FAULT IN THE MANAGEMENT OF ADVANCED HIGH-GRADE SEROUS OVARIAN CARCINOMAS (HGSOC)?

D. Hudry1, V. Garcia Pineda1, Y. Borghesi1, B. Gachon1, L. Bresson1, P. Quincy1, F. Narducci1, E. Leblanc1

1Department of Gynecologic Oncology- Centre Oscar Lambret, Lille, Lille, France

Aims

Survival assessment of a series of HGSOC patients in a tertiary cancer center.

Method

We retrospectively reviewed the data of 228 consecutive patients diagnosed with advanced stages (FIGO stages IIIIC and IV) HGSOC, managed between 2008 and 2013 in our center.

Primary debulking (PDS) or Interval debulking surgeries (IDS) after chemotherapy were performed after a decisional laparoscopy for biopsy and tumor load assessment using Sugarbaker’s peritoneal cancer index (PCI), with the intent to perform a macroscopically complete (CC0) and safe surgery. During follow up, secondary surgery might have been indicated and repeated in selected recurrent diseases.

Results

PDS was possible in 28.6% and 71.3% for IDS, but 43 patients could never be operated. Median PCI was 10 (3-24), 24 (3-39) and 30.3 (8-39) in PDS, IDS and no surgery group respectively. CC0 was obtained in 92.5% cases and in 90.2% for PDS and IDS group respectively. With 36 months median follow-up, OS and DFS were 94.2/32.9, 67.9/20.5 months in PDS and IDS respectively.

During follow-up, 74.1% of patients recurred (50.9% and 83.3% in PDS and IDS respectively). For those who could be (optimally) operated, 79.7% were alive 5 years after the diagnosis versus 42.7% if surgery was not possible (p<0.0001).

Conclusion

In optimally cyto-reduced advanced HGSOC, initial tumor load is a more important survival factor than the moment of surgery. A centralized surveillance seems necessary as secondary surgical efforts represent an important factor to increase OS in these patients.
THE SAFETY AND EFFICACY OF BLEOMYCIN, ETOPOSIDE AND CISPLATIN (BEP) CHEMOTHERAPY IN PATIENTS WITH MALIGNANT OVARIAN GERM CELL TUMOR

G.W. Lee¹, S.W. Lee¹, J.Y. Park¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹asan medical center, obstetrics and gynecology, Seoul, Republic of Korea

Aims

The safety and efficacy of bleomycin, etoposide, and cisplatin (BEP) chemotherapy have rarely been evaluated in malignant ovarian germ cell tumor (MOGCT) because of its rarity. The aim of this study was to evaluate the safety and efficacy of BEP chemotherapy in MOGCT patients.

Method

This was a retrospective study including 150 patients with MOGCT who underwent surgery followed by adjuvant BEP chemotherapy at Asan Medical Center (Seoul, Korea). The safety of BEP chemotherapy was evaluated by Common Terminology Criteria for Adverse Events (CTCAE) v 4.03. Response rates and survival outcomes were analyzed.

Results

150 patients received 687 cycles of BEP chemotherapy after surgery. 112 patients had stage I/II (74.7%) disease while 38 patients had stage III/IV (25.3%) disease. Ninety-three (62.0%) patients had grade 3-4 hematologic toxicity and 16 patients (10.7%) had grade 3-4 non-hematologic toxicity. Twenty-five patients (16.7%) suffered from neutropenic fever. Dose reduction due to toxicity was required in 7 patients (4.7%), and schedule delay due to toxicity was required in 7 patients (4.7%). Bleomycin was deleted during chemotherapy due to toxicity in 22 patients (14.7%). Cisplatin was replaced with carboplatin during chemotherapy due to toxicity in five patients (3.3%). 141 patients (94.0%) achieved complete response; one patient showed a partial response, three patients had stable disease, and eight patients experienced progression of disease with BEP chemotherapy. 14 patients had recurrent disease, and four patients died of disease. Overall survival rate was 94.7%.

Conclusion

BEP chemotherapy was highly effective and showed acceptable toxicity profile for patients with MOGCT.

A panel of microRNAs, identified with global microarray, may provide prognostic information for patients with ovarian cancer

K.P. Prahm

1Herlev Hospital, Molecular Unit- Dept. of Pathology, Copenhagen, Denmark

Aims

Ovarian cancer is the leading cause of gynecologic cancer deaths in the Western world. Prognosis of the disease is mainly related to stage at diagnosis, surgery and sensitivity to chemotherapy. The purpose of the current study was to identify microRNAs associated with prognosis and resistance to chemotherapy in patients with ovarian cancer.

Method

Patients who were surgically treated for epithelial ovarian cancer, diagnosed between September 2004 and January 2010 were enrolled in the study. MicroRNA expression profiles were identified from tumor tissue using microarray analysis. In the primary statistically analyses miRNA index predictors of survival and resistance to chemotherapy were developed with adaptive index models, adjusted for known prognostic variables.

Results

A total of 198 patients with epithelial ovarian cancer were included. Of these, 170 patients had received platinum-based chemotherapy as first-line treatment after primary surgery, and were eligible for analyses of resistance to chemotherapy. In the multivariate adaptive index model analyses combinations of three different miRNAs were identified to be significant and independent predictors of survival and time-to-progression. One miRNA were found to be significant for chemotherapy-resistance.

Conclusion

In the current study combinations of either one or three miRNAs were identified as significant predictors of survival, time-to-progression and chemotherapy-resistance for patients with epithelial ovarian cancer. This approach could potentially give important information of prognosis and thereby support patient management towards a more individualized treatment.

ONCOLOGIC OUTCOMES AND REPRODUCTIVE SUCCESS AFTER FERTILITY SPARING MANAGEMENT IN WOMEN WITH MALIGNANT OVARIAN GERM CELL TUMORS

1University of Athens- “Alexandra” Hospital, 1st Department of Obstetrics & Gynecology, Athens, Greece

2University of Athens- “Alexandra” Hospital, Department of Histopathology, Athens, Greece

Aims

Malignant ovarian germ cell tumors (MOGCTs) represent a relatively rare malignancy that mostly affects young women with strong desire for fertility-preserving management. The aim of our study is to identify the oncologic and clinicopathologic characteristics of MOGCT, and report the prognostic factors and reproductive outcomes of patients treated with conservative surgery.

Method

Medical records from 42 women diagnosed and treated for MOGCTs between 1997 – 2015 in our hospital were analyzed retrospectively. Fisher's exact tests were used for the comparison of proportions and life table analysis for survival calculations.

Results

Mean age at diagnosis was 23.5 years. Thirty-one cases (74%) were stage I; 7 cases (17%) stage II; and 4 cases (9%) stage III. Immature teratoma represented the most common histological type (n = 18) followed by dygerminomas, mixed tumors, and endodermal sinus tumors. Thirty-five patients underwent fertility-sparing surgery defined by unilateral oophorectomy, lymphadenectomy, and peritoneal biopsies. Adjuvant chemotherapy was administered in 29 patients with BEP (bleomycin, etoposide, and cisplatin). After a median follow-up period of 9.2 years, 4 patients (11.5%) had disease recurrence and 3 died. The overall survival rate was 94.1% for women in early stage (I/II) and 87.1% for women in advanced stages. During the follow-up period, 31% (11/35) of the women tried for a pregnancy, and 45% (5/11) of them resulted in normal deliveries.

Conclusion

Our data demonstrate that MOGCTs, if detected in early stages, have excellent survival outcomes with fertility-preserving surgery and chemotherapy. Patients maintain future reproductive potential and appear to achieve favorable reproductive outcomes.

EXPRESSION OF miR-146a IN PRIMARY TUMOUR AND OMENTAL IMPLANTS IN OVARIAN CANCER PATIENTS AND ITS CORRELATION WITH CLINICOPATHOLOGICAL FEATURES, PROGNOSIS AND CHEMO-RESISTANCE

M. Wilczyński1, E. Żytko2, B. Szymińska3, M. Dzieniecka4, J. Danielska5

1Polish Mothers Health Center Research Institute, Department of Operative Gynecology- Endoscopy and Gynecologic Oncology, Łódź, Poland
2Polish Mother’s Health Center Research Institute, Department of Gynecology and Oncological Gynecology, Łódź, Poland
3Medical University of Łódź, Central Scientific Laboratory CoreLab, Łódź, Poland
4Polish Mother’s Health Center Research Institute, Department of Pathology, Łódź, Poland
5Medical University of Łódź, Radiotherapy Department, Łódź, Poland

Aims

To study the miR-146a expression in primary tumour and omental implants of ovarian serous cancer, and to investigate the correlation with clinicopathological features, including chemosensitivity and survival.

Method

MiRNA-146a was evaluated in formalin-fixed, paraffin-embedded (FFPE) samples collected from 48 patients operated for advanced (FIGO III/IV stage) ovarian cancer. The reference group included 48 normal ovary samples. Total RNA was extracted from FFPE tissue using Roche High Pure miRNA Isolation Kit. The yield and quality of RNA were measured using PicoDrop spectrophotometer. Reverse transcription to cDNA was carried out according to the miRCURY LNA Universal RT micro RNA PCR instruction. PCR amplification was performed using primer set for hsa-miR-146a-5p. U6 snRNA and SNORD48 were internal controls. Reactions were performed on a 7900HT Fast Real-Time PCR System. Relative expression was calculated according to the Cq method $2^{-\Delta\Delta Cq}$.

Results

MiR-146a expression in primary tumour was increased in comparison to normal ovaries (p=0.02) and implants (p=0.01). Negative correlation was found between miR-146a expression in primary tumours and serum levels of CA125 (R=-0.37, p=0.03) and ROMA index (R=-0.79, p<0.0007). Overall survival (OS) positively correlated with the miR-146a expression in the primary tumour (R= 0.38, p=0.01). Probability of survival was decreased in patients with lower miR-146a expression (HR=0.21, p=0.003) in the primary tumour. In multivariate analysis lower levels of miR-146a expression correlated with shorter progression-free survival (PFS) (p=0.04) in primary tumour and with platinum-resistance in implants (p=0.006).

Conclusion

MiR-146a expression could be a prognostic marker for chemosensitivity and survival in serous ovarian cancer.

1Nagoya University Graduate School of Medicine, Obstetrics and Gynecology, Nagoya, Japan

Aims

PRIMA-1MET is a small molecule compound that restores wild-type p53 to mutant p53, and is recently confirmed to be safe at therapeutic plasma levels. The aims of this study were to identify the anti-tumour activity of PRIMA-1MET on epithelial ovarian cancer (EOC) cells and elucidate the underlying mechanism in vitro.

Method

We used nine EOC cell lines and their chronic cisplatin/paclitaxel-resistant cells and performed cell viability assay and cell apoptosis assay to evaluate the efficacy of PRIMA-1MET. Moreover, we assessed the functional role of reactive oxygen species (ROS) and their scavenger in the EOC cells.

Results

We examined the viability of the total 13 EOC cells after 48 h treatment with PRIMA-1MET. Measuring the half maximal inhibitory concentration (IC50) of EOC cells revealed that the sensitivity was heterogeneous, and did not correlate with TP53 status. PRIMA-1MET induced apoptosis, PARP cleavage, and intracellular ROS accumulation in a p53-independent manner. The anti-tumour effects of PRIMA-1MET were completely rescued by a ROS scavenger, N-acetyl cysteine. Furthermore, PRIMA-1MET reduced the expression of antioxidant enzymes, PRX3 and GPX1, in a dose-dependent manner.

Conclusion

We demonstrated that PRIMA-1MET had an anti-tumour effect on EOC cells regardless of TP53 status and chemo-resistance. PRIMA-1MET is a promising therapeutic agent for chemo-resistant EOC patients and may contribute to a better prognosis in the future.
PREVENTION OF GYNAECOLOGIC CANCER

ESG07-0048

ASSESSING THE RISK OCCULT CANCERS AND 30-DAY MORBIDITY IN BRCANESS WOMEN UNDERGOING RISK-REDUCING SURGERY: A PREDICTIVE MODEL AND NOMOGRAM

G. Bogani\textsuperscript{1}, E. Tagliabue\textsuperscript{1}, A. Ditto\textsuperscript{1}, F. Martinelli\textsuperscript{1}, M. Signorelli\textsuperscript{1}, V. Chiappa\textsuperscript{1}, U. Leone Roberti Maggiore\textsuperscript{1}, D. Lorusso\textsuperscript{1}, R. Francesco\textsuperscript{1}

\textsuperscript{1}National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To investigate the incidence and predictive factors of 30-day surgery-related morbidity and occult precancerous and cancerous conditions in patients undergoing risk-reducing surgery

Method

This is a prospective cohort study evaluating BRCAness (BRCA 1 and 2 mutation carriers and BRCAX) women undergoing minimally invasive risk-reduction surgery. A nomogram has been created in order to assess the risk of diagnosis of occult precancerous and cancerous malignancies at the time of surgery

Results

Overall, 85 BRCAness women had risk-reducing surgery: 30 (35\%) and 55 (75\%) women had hysterectomy plus bilateral salpingo-oophorectomy (BSO) and BSO alone, respectively. Overall, 6 (7\%) patients were diagnosed with undiagnosed cancers: three early stage ovarian / fallopian tube cancer, two advanced stage ovarian cancer (stage IIIA and IIIB) and one serous endometrial carcinoma. Additionally, 3 (3.6\%) patients had incidental diagnosis of serous tubal intraepithelial carcinoma (STIC). A nomogram of predicting factors for the risk of having occult malignancies was built (Figure). Regarding 30-day morbidity, we observed 4 postoperative complications that were managed conservatively, including fever (n=3) and postoperative ileus (n=1). No severe (grade 3 or more) complication occurred among patients having risk-reduction surgery. Only presence of occult cancer correlated with an increased risk of developing postoperative complications (p=0.02); basically, due to the adjunctive staging procedures needed.

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{nomogram.png}
\end{figure}

Conclusion

Minimally invasive risk-reducing surgery is a safe and effective strategy to manage BRCA mutation carriers. Patients should have to be counseled about the high prevalence of undiagnosed cancers observed at the time of surgery

OPPORTUNISTIC SALPINGECTOMY: A SURVEY OF KNOWLEDGE AND ATTITUDES IN HEALTHCARE PROFESSIONALS

J. Bellamy1, A. Page2, S. Taylor3, M. Tischkowitz4, R. Crawford5, H. Bolton1

1Cambridge University Hospitals NHS Foundation Trust - Addenbrookes Hospital, School of Clinical Medicine- University of Cambridge, Cambridge, United Kingdom
2Cambridge University Hospitals NHS Foundation Trust - Addenbrookes Hospital, School of Clinical Medicine- University of Cambridge, Cambridge, United Kingdom
3Cambridge University Hospitals NHS Foundation Trust - Addenbrookes Hospital, School of Clinical Medicine, Cambridge, United Kingdom
4Cambridge University Hospitals NHS Foundation Trust - Addenbrookes Hospital, Department of Medical Genetics, Cambridge, United Kingdom
5Cambridge University Hospitals NHS Foundation Trust - Addenbrookes Hospital, Gynaecological Oncology, Cambridge, United Kingdom

Aims

The tubal origin of high-grade serous ovarian cancer (HGSC) represents an opportunity to reduce the risk of ovarian cancer. The Royal College of Obstetrics and Gynaecology advises that ‘women who have completed their families should be carefully considered for prophylactic removal of the fallopian tubes …at the time of gynaecological or other intra-peritoneal surgery’. We aimed to evaluate current knowledge and attitudes of relevant healthcare professionals to the concept of the tubal origin of HGSC, and opportunistic salpingectomy.

Method

We carried out surveys of professionals who may be involved in women undergoing gynaecological or abdominal surgery, including primary health care providers, obstetricians, gynaecologists and general surgeons who carried out pelvic surgery.

Results

19 of 21 primary care practitioners, and 12 of 15 surgeons were totally unaware of the tubal origin of HGSC. Obstetricians & Gynaecologists were better informed (17 of 26 were well informed). There was a lack of confidence in discussing or offering opportunistic salpingectomy across all specialties for a variety of reasons. The majority of professionals surveyed volunteered that written information for healthcare professionals and patients would be helpful, along with teaching sessions or direct surgical training from a specialist.

Conclusion

There is limited knowledge around the tubal origin of HGSC amongst healthcare professionals who may be in a position to counsel or offer opportunistic surgery. Strategies to educate and alter attitudes of healthcare professionals may be required before we see a paradigm shift in offering the choice of this potentially life-saving opportunity to women.
HUMAN PAPILLOMAVIRUS VACCINE UPTAKE IN SOUTH KOREA
J.Y. Choi², M. Kim², B.S. Kwon³, S.J. Jeong⁴, D.H. Suh², K. Kim², Y.B. Kim², J.H. Na²
¹Chungbuk National University Hospital, Obstetrics and Gynecology, Cheongju-si, Republic of Korea
²Seoul National University Bundang Hospital, Obstetrics and Gynecology, Seongnam si, Republic of Korea
³Pusan National University School of Medicine and Biomedical Research Institute- Pusan National University Hospital, Obstetrics and Gynecology, Busan, Republic of Korea
⁴Korea University, Statics, Seoul, Republic of Korea

Aims

This study aimed to assess the human papillomavirus (HPV) vaccine uptake rate in South Korean women and to identify factors affecting vaccination rate before initiation of the national HPV vaccination program.

Method

A nationwide online survey of 2,000 9–59-year-old women collected information on their HPV vaccination status and associated correlates such as age, residential region, education, and socioeconomic status. The regional and age distribution of subjects was based on the South Korean census data.

Results

The overall HPV vaccine uptake rate was 23.1%, and the highest rate of vaccination was observed in women aged 20–29 years (38.6%), followed by those aged 30–39 years (36.9%), 9–19 years (16.9%), 40–49 years (14.2%), and 50–59 years (12.5%). Women from the metropolitan cities showed a higher vaccination rate than those from rural areas (26.2% vs 20.5%, P=0.003). A multivariate regression analysis showed that HPV vaccine uptake was independently associated with age, residential region, educational level, regular influenza vaccination, clinic visit within the last 6 months, and a high family income. The main barriers to HPV vaccination were the cost of vaccination (24.3%), and concerns regarding vaccine safety (23.1%).

Conclusion

HPV vaccine uptake was low among the South Korean women, especially among women aged 9–19 years and women living in rural areas. The national HPV vaccination program will improve vaccine uptake rate by overcoming barriers to vaccination.
QUALITY OF LIFE AFTER TREATMENT OF GYNACEOLOGIC CANCER

SELF-COMPASSION AND CLIMACTERIC SYMPTOMS IN OOPHORECTOMIZED BRCA1/2 MUTATION CARRIERS

M. Arts-de Jong¹, L. Van Westerop¹, N. Hoogerbrugge², L. Massuger¹, A. Maas³, M. Van Beek⁴, J. de Hullu¹
¹Radboud university medical center, Obstetrics & Gynaecology, Nijmegen, The Netherlands
²Radboud university medical center, Human Genetics, Nijmegen, The Netherlands
³Radboud university medical center, Cardiology, Nijmegen, The Netherlands
⁴Radboud university medical center, Psychiatry, Nijmegen, The Netherlands

Aims

To reduce ovarian cancer risk, BRCA1/2 mutation carriers are advised to undergo risk-reducing salpingo-oophorectomy (RRSO) around the age of 40, which may induce severe climacteric symptoms. Dealing with these symptoms may be difficult and success is related to several coping strategies. Successful coping depends in part on self-compassion. This describes a positive and caring way of relating toward the self when facing difficult experiences; it is a skill that can be taught. The aim of this study was to explore the association between climacteric symptoms and self-compassion in late postmenopausal BRCA1/2 mutation carriers.

Method

This cross-sectional study using questionnaire data examined climacteric symptoms, self-compassion, physical fitness in 165 BRCA1/2 mutation carriers who underwent an RRSO ≤ 45 years, at least 5 years ago.

Results

Late postmenopausal BRCA1/2 mutation carriers reported low levels of climacteric symptoms and being highly self-compassionate. Higher self-compassion was associated with less climacteric symptoms. Furthermore, anti-depressant use was associated with more climacteric symptoms, whereas physical fitness with less symptoms.

Conclusion

Being self-compassionate and physically fit, and not using anti-depressants was associated with less climacteric symptoms in oophorectomized BRCA1/2 mutation carriers. Future research is needed to investigate the effect of self-compassion training on climacteric symptoms after RRSO in BRCA1/2 mutation carriers.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0910

LONG-TERM OUTCOMES AFTER CONSERVATIVE AND RADICAL TREATMENT OF BORDERLINE OVARIAN TUMOURS

V. Sirvydytė¹, M. Gedgaudaitė², A. Gaurilčikas²

¹Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania
²Lithuanian University of Health Sciences, Obstetrics and Gynaecology, Kaunas, Lithuania

Aims

1. To evaluate the remote outcomes of patients with borderline ovarian tumours (BOTs) after radical (RS) and conservative (CS) surgery: survival and recurrence rates and their dependence on surgery type, patients age, FIGO stage, histological tumour type, preoperative CA 125 levels.
2. To assess the pregnancy rate after conservative surgery.
3. To evaluate the Quality of life (QOL) after CS and RS.

Method

Retrospective data analysis of 56 patients treated for BOT in Oncogynaecology Department of LUHS Hospital. According to the surgery type, patients were divided into CS and RS groups. For QOL evaluation, the validated EORTC–QLQ30–OV28 questionnaire was used. The results were compared between CS and RS groups.

Results

The 5-year survival rate was 97.6% and recurrence rate – 17.9% (10 patients). BOTs significantly more often recurred after CS (80% vs. 20% respectively), and among younger patients (36.9 vs. 46.4 years), 21 patients had CS, 6 (28.57%) of them tried to get pregnant. The pregnancy rate was 66.7% (4 patients). QOL evaluation showed that patients after CS had less symptoms (30.3 vs. 26.0 points), however, the difference is not significant. Nevertheless, sexual function was evaluated significantly better in the RS group (73.0 vs. 53.3, p<0.05).

Conclusion

The 5-year survival rate was 97.6%. Recurrence rate was 17.9%, more often after fertility sparing surgery and among younger patients. Pregnancy rate was 66.7% among patients who tried to conceive after CS. Despite the fact that overall QOL was similar between two groups, sexual function was evaluated better among RS patients.

DOES BLOODCARE POWDER PREVENT POSTOPERATIVE CHYLOUS ASCITES AFTER RETROPERITONEAL LYMPHADENECTOMY FOR GYNECOLOGICAL MALIGNANCIES?
K. Gungorduk1, O. Gungorduk2, A. Ozdemir3, M. Gokcu4, M. Sancı4
1Muğla Sıtkı Koçman University Education and Research Hospital, Department of Gynecologic Oncology, Muğla, Turkey
2Muğla Sıtkı Koçman Education And Research Hospital, Department of Gynecologic Oncology, Muğla, Turkey
3Bakırköy Dr. Sadi Konuk Education and Research Hospital, Department of Gynecologic Oncology-, Istanbul, Turkey
4İzmir Tepecik Education and Training Hospital, Department of Gynecologic Oncology, İzmir, Turkey

Aims

To evaluate the effect of an intraoperative hemostatic cellulose agent (BLOODCARE powder®) on reducing the incidence of postoperative chylous ascites (PCA) after complete pelvic and para-aortic lymphadenectomy (PPALN) in patients with gynecological cancers.

Method

This case control study reviewed 150 patients (75 patients each in the control and case groups) with gynecological cancer who underwent retroperitoneal PPALN. In the case group, BLOODCARE powder® was applied via the left renal vein and bilateral obturator fossa. In the control group, no sealant agent was used after the procedure, such as fibrin glue or a hemostatic cellulose agent.

Results

The demographic and surgical characteristics of the patients in both groups were similar (Table 1). Chylous ascites occurred in nine (6%) cases. The incidence of PCA was lower in the case group [1 (1.3 %) vs. 8 (10.7%); P = 0.03]. Logistic regression analysis indicated that using BLOODCARE powder® during the surgery independently protected against the development of PCA (Table 2)
Conclusion

Using BLOODCARE powder® during retroperitoneal surgery may prevent PCA. This simple, effective agent should be used after retroperitoneal PPALN for gynecological cancers.
IMPACT OF HORMONE REPLACEMENT THERAPY ON PATIENTS WITH OVARIAN OR CERVICAL CANCER

S. Jiang

1Shandong Cancer Hospital and Institute, Department of Gynecologic Oncology, Jinan, China

Aims

To investigate the influence of HRT on patients with ovarian or cervical cancer.

Method

158 patients with ovarian/cervical cancer were involved and divided into HRT and NHRT groups. 65 patients (31 with ovarian cancer, 34 with cervical cancer) underwent HRT treatment while 93 (44 with ovarian cancer, 49 with cervical cancer) did not undergo HRT after surgery/radiotherapy. PR, ER and its subtypes were detected in cancer tissues by immunohistochemical staining assay. And the serum concentration of calcitonin and TGF were detected by radio-immunity and ELISA. The data were analyzed by Kaplan-Meier survival curve and Cox’s proportional hazard model. Quality of life was measured by EORTC-C30 and other scale made by ourselves.

Results

There was no statistical significance between HRT and NHRT groups in survival interval. Cox model showed that HRT is not an independent factor for prognosis. There were no statistical significance between positive expression group of ER, ERα,ERβ, PR and negative expression group of them for survival interval. The serum concentration of TGF had no statistical significance between HRT and NHRT groups whether pre, post surgery, or half to one year after surgery. The serum calcitonin concentration of NHRT group is higher than HRT group. For HRT group, there’s no statistical significance for serum calcitonin concentration pre and post surgery. HRT could improve quality of life.

Conclusion

HRT has no detrimental effects on patients. HRT maybe stabilize calcitonin concentration in serum and improve quality of life. TGF concentration and ER, ERα,ERβ, PR expression have no association with prognosis.

POSTOPERATIVE RECOVERY AFTER ABDOMINAL SURGERY FOR GYNECOLOGIC MALIGNANCY WITH INTRATHECAL MORPHINE OR EPIDURAL ANALGESIA. A RANDOMIZED TRIAL

P. Kjölhede1, O. Bergdahl1, N.B. Wodlin1, L. Nilsson2

1Department of Obstetrics and Gynecology, Department of Clinical and Experimental Medicine, Linköping, Sweden
2Department of Obstetrics and Gynecology, Department of Obstetrics and Gynecology, Norrköping, Sweden
3Department of Anaesthesiology and Intensive Care, Department of Medical and Health Sciences, Linköping, Sweden

Aims

To determine whether the use of regional analgesia with intrathecal morphine (ITM) in an enhanced recovery program (ERAS) gives a shorter duration of hospital stay with a similar health-related quality of life (QoL) to epidural analgesia (EDA) in women after laparotomy for proven or assumed gynecological malignant tumors.

Method

An open-label, randomized, controlled single center study. Eighty women undergoing midline laparotomy for proven or assumed gynecological malignant tumors were included. ERAS with standardized perioperative routines including a standardized general anesthesia was used. The allocated treatment (ITM or EDA) was applied immediately preoperatively. The ITM group received morphine, clonidine and bupivacaine intrathecally; the EDA group an epidural infusion of bupivacaine, adrenalin and fentanyl.

Results

The length of hospital stay did not differ between the groups (median 3.3 vs. 4.3 days) but the time to meet the standardized discharge criteria was significantly shorter for the ITM group (3.0 vs. 4.0 days). Significantly, more women allocated to ITM were discharged on day 3, 62.5% vs. 30%. The ITM group used significantly less opioids whereas no differences were observed in pain assessment or QoL. No serious adverse events were attributed to the ITM or EDA.

Conclusion

Compared with EDA, ITM reduces the duration of hospital stay and the opioid consumption postoperatively with an equally good pain alleviation and QoL. ITM is even effective as EDA for postoperative analgesia in gynecological cancer surgery and is easier to administer.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER

ESGO7-0784

CONSERVATIVE TREATMENT OF POSTOPERATIVE CHYLOUS ASCITES IN GYNECOLOGIC CANCER SURGERIES.
Y.S. Kwon1, H.J. Roh1, S.H. Lee1, J.Y. Kwack1
1Ulsan University Hospital, Obstetrics and Gynecology, Ulsan, Republic of Korea

Aims

This study aimed to evaluate the efficacy of conservative treatment with the formula for postoperative chylous ascites in patients with gynecologic surgeries.

Method

We retrospectively analyzed 107 patients who underwent pelvic and/or para-aortic lymphadenectomy for gynecologic malignancies at Ulsan University Hospital from March 2011 to February 2013.

Results

The 107 cases consisted of 41 cervical cancers, 24 endometrial cancers, 34 ovarian cancers, and eight other cancers. Among the 107 cases, 81 patients underwent pelvic and para-aortic lymphadenectomy, 23 patients underwent pelvic lymphadenectomy without para-aortic lymphadenectomy, and three patients underwent only para-aortic lymphadenectomy. Postoperative chylous ascites occurred in 13/81 of patients who received pelvic and para-aortic lymphadenectomy, in 2/3 patients who received only para-aortic lymphadenectomy, and none of the patients who received only pelvic lymphadenectomy.

The average age of the patients was 55.8 yr. The mean time interval between the operation and the appearance of chylous ascites was 2.8 days (range, 2–5 days). All cases of postoperative chylous ascites were treated with the conservative treatment with our department formula. The cure rate of chylous ascites with the conservative therapy was 100%. None of the cases had recurrent chylous ascites during follow-up.

Conclusion

In gynecologic surgeries, para-aortic lymphadenectomy induced postoperative chylous ascites could be treated in high cure rate by the formula of effective conservative strategy.
TRANSLATIONAL RESEARCH

ESGO7-1011

IMPACT ON SURVIVAL OF INTEGRATIVE SYSTEMIC AND LOCAL METABOLOMICS IN HIGH-GRADE SEROUS OVARIAN CANCER

S. Aust¹, A. Bachmayr-Heyda¹, K. Auer¹, S. Meier², K. Schmetterer², S. Dekan¹, C. Gerner², D. Pils⁴

¹Medical University of Vienna, Department for Gynecology and Gynecologic Oncology- Gynecologic Cancer Unit- Comprehensive Cancer Centre, Vienna, Austria
²University of Vienna, Dept. of Analytical Chemistry- University of Vienna, Vienna, Austria
³Medical University of Vienna, Clinical Institute of Laboratory Sciences, Vienna, Austria
⁴Medical University of Vienna, Center for Medical Statistics- Informatics- and Intelligent Systems & Dept. of Surgery, Vienna, Austria

Aims

Little is known about how and wherefrom cancer cells get fuel, building blocks, and reducing equivalents for their increased cell growth and division.

Method

Targeted metabolomics of preoperative and follow-up sera, ascites, and tumor tissues, RNA sequencing of isolated tumor cells, local and systemic chemokine, and local immune cell infiltration data from up to 65 high-grade serous ovarian cancer patients and 62 healthy controls were correlated to overall survival and integrated in a Systems Medicine manner.

Results

43 mainly (poly)unsaturated glycerophospholipids and 4 essential amino acids (citrulline) were significantly reduced in patients with short survival. The glycerophospholipid fingerprint is identical to the fingerprint from isolated (very)low-density lipoproteins (vLDL), indicating that the source of glycerophospholipids consumed by tumors is (v)LDL. A glycerophospholipid-score (HR0.46; P=0.007) and a 100-gene signature (HR0.65; P=0.004) confirmed the independent impact on survival in training (n=65) and validation (n=165) cohorts. High concentrations of LDLS and glycerophospholipids were independent predictors for favorable survival. Patients with low glycerophospholipids presented with less adaptive immune cell tumor infiltration, less oxygenic respiration and increased triglyceride biosynthesis in tumor cells, and lower histone expressions, correlating with higher numbers of expressed genes and more transcriptional noise - a putative neo-pluripotent tumor cell phenotype.

Conclusion

Low serum phospholipids and essential amino acids are correlated with worse outcome in ovarian cancer, accompanied by a specific tumor cell phenotype (figure.1).
MYELOID DERIVED SUPPRESSOR CELLS (MDSC) DETERMINE OUTCOME IN OVARIAN CANCER.

T. Baert¹², A. Van Hoylandt¹², P. Busschaert¹, I. Vergote¹²³, A. Coosemans¹²
¹UZ Leuven, Department of Gynaecology and Obstetrics- Leuven Cancer Institute, Leuven, Belgium
²KU Leuven, Department of Oncology- Laboratory of Tumor Immunology and Immunotherapy- ImmunOvar Research Group, Leuven, Belgium
³KU Leuven, Department of Oncology- Laboratory of Gynecologic Oncology, Leuven, Belgium

Aims

Immunotherapy trials in ovarian cancer have so far yielded poor results, possibly due to severe immunosuppression. Macrophages are abundant in ovarian cancer (OC) and a predominance of M2 macrophages is correlated with poor survival. Clodronate Liposomes (CL) are a commonly used drug, which effectively depletes macrophages.

Method

Tumorbearing ID8-fLuc-C57BL/6 and ID8-fLuc-Rag1tm1Mom mice were treated with weekly CL. Immune-monitoring on ascites was performed by fluorescent activated cell sorting (FACS). Furthermore peripheral blood mononuclear cells were collected prospectively in 39 patients at diagnosis of OC.

Results

Mice treated with CL died significantly faster compared to immunocompetent mice (p=0.004), whereas the survival was not altered in mice lacking T- and B-cells (Rag1tm1Mom). After treatment with CL, macrophages were nearly absent. There were no significant changes in T- and B-cell populations. After treatment with CL, monocytic myeloid derived suppressor cells (mMDSC) (CD11b+Ly6CHi) increased significantly (p=0.004), whereas granulocytic MDSC (CD11b+Ly6C-Ly6GHi) decreased. In patient samples, we observed a decrease in progression free survival in patients with a high number of mMDSC (CD11b+HLA- DR-CD14+) (17.5 vs 20 months).

Conclusion

In OC mice the absence of adaptive immune system did not influence survival. Depletion of macrophages by CL significantly reduced survival in tumorbearing mice. This could be explained by a significant rise in mMDSC in mice. The increase was also observed in patients with OC. Our research demonstrates for the first time a prominent role for mMDSC as the driver of immunosuppression in OC, which is a new concept in the field of OC.
CLINICAL RELEVANCE OF CIRCULATING TUMOR CELLS IN OVARIAN, FALLOPIAN TUBE AND PERITONEAL CANCER

M. Banys-Paluchowski1, H. Neubauer2, N. Krawczyk2, A. Kaczerowsky Flores de Sousa1, P. Paluchowski3, F. Meier-Stieger2, A. Abdel-Kawi4, T. Fehm2, G. Gebauer1

1Marienkrankenhaus Hamburg, Obstetrics and Gynecology, Hamburg, Germany
2University Duesseldorf, Gynecology, Duesseldorf, Germany
3Regioklinik Pinneberg, Gynecology, Pinneberg, Germany
4Assiut University, Faculty of Medicine, Assiut, Egypt

Aims

Presence of circulating tumor cells (CTCs) is associated with impaired clinical outcome in a variety of cancers. Limited data are available on the significance of CTCs in gynaecological malignancies. Aims of the present study were to evaluate the dynamics of CTCs in patients with ovarian, fallopian tube and peritoneal cancer during chemotherapy and to assess the clinical relevance of these changes.

Method

50 patients with ovarian (n=40), fallopian tube (n=5) and peritoneal (n=5) cancer were included. All patients received chemotherapy in the first-line setting (n=25) or tumor recurrence (n=25). CTC analysis was performed prior to chemotherapy, after three and six cycles and analysed using CellSearch.

Results

26 patients had at least one CTC/7.5ml blood at baseline. Positivity rate was 18% in patients with first-line setting and 35% in those with tumor recurrence (p=0.216). Presence of CTCs was not correlated with other prognostic factors, such as the FIGO stage, nodal status, or grading. CTC positivity declined to 5% after three cycles of cytotoxic therapy and no patient was CTC positive after 6 cycles of chemotherapy. 15 patients died during follow-up. Patients with CTCs at baseline had significantly shorter overall survival compared with CTC negative patients (p=0.014; median OS 3.1 vs. 13.4months). In the subgroup of patients with primary cancer, CTC positivity was significantly associated with OS in univariate analysis (p=0.046).

Conclusion

Hematogenous dissemination is a common phenomenon in ovarian, fallopian tube and peritoneal cancer. Patients with CTCs at time of diagnosis are more likely to die than those who are CTC-negative at baseline.
Aims

A randomized multicenter controlled study showed a significant benefit of front line carboplatin paclitaxel oregovomab (CIT) relative to carboplatin/paclitaxel (SOC) in optimally debulked ovarian cancer (Ferrandina G, ASCO Proceedings 2017). The present study evaluated peripheral blood for immune correlates.

Method

97 FIGO 3/4 ovarian cancer patients (CA125 >50U) were randomized to 6-cycles SOC with or without addition of oregovomab 2mg IV at cycle 1, 3, and 5 and cycle 5+12 weeks. Peripheral blood mononuclear cells were evaluated at baseline, cycle 5, and cycle 5+13 weeks. Patients were followed for disease progression and survival. Immune cell populations and CA125-specific IFN-γ producing CD8+ T cells (sensitized using autologous dendritic cells loaded with oregovomab/CA-125 immune complexes) were evaluated by flow cytometry.

Results

CIT (N=47) prolonged relapse free survival (RFS) relative to SOC (N=50) (median RFS: N.E. [21.3, N.E.] vs 15.4 m [10.9,19.3] p=0.0009 log rank). Early survival data is consistent with RFS. Safety/toxicity was similar in both arms. CIT increased percentage and absolute cell count of CA125-specific IFN-γ producing CD8+ T cells (p=0.01 and p=0.02, respectively) at cycle 5. The neutrophil-monocyte/lymphocyte ratio (NMLR) cutoff 3.612 at baseline predicted outcome in the CIT population with HR 9.75 (p<0.001).

Conclusion

Peripheral blood analyses of patients on SOC and CIT indicate that appearance of treatment-emergent CA-125 specific IFN-γ producing CD8+ T cells is associated with treatment efficacy and that baseline NMLR is useful as a predictive marker for clinical response.
PRECLINICAL EVALUATION OF A NOVEL ALPHA-PARTICLE EMITTING THERAPEUTIC AGENT FOR SELECTIVE INTRAPERITONEAL THERAPY OF PERITONEAL METASTASES

T. Bønsdorff1, S. Westrøm1, Ø.S. Bruland2, R.H. Larsen3

1Oncoinvent AS, Oncoinvent, Oslo, Norway
2The Norwegian Radium Hospital- Oslo University Hospital, Institute of Clinical Medicine- Department of Oncology, Oslo, Norway
3Sciencons AS, Sciencons AS, Oslo, Norway

Aims

Intraperitoneal radionuclide therapy with β-emitting 32P-colloid has been previously used in treatment of ovarian cancer. It was then shown to be as effective as adjuvant cisplatin therapy for some groups of patients, but late bowel complications occurred more frequently, most likely caused by a combination of long half-life and several millimeters range of electrons from 32P. We have developed a composition of a microparticle and an α-emitting radionuclide, with a considerable shorter range in tissues, specifically designed for local treatment of peritoneal carcinomatosis. Biocompatible microparticles, with no antigen-targeting, act as carriers for the α-emitter 224Ra. This novel α-radiation therapy has a range in tissue of less than 100 µm and is designed to confine the zone of radiation exposure to the intraperitoneal cavity including peritoneal surfaces and liquid volumes. The therapeutic efficacy and safety of the 224Ra-microparticles in murine models are presented.

Method

Radium-224 loaded onto calcium carbonate microparticles was evaluated in immunodeficient athymic nude mice inoculated with human ovarian cancer cells in the peritoneal cavity. Different activities of 224Ra-microparticles were administered intraperitoneally. Tumor growth, survival and tolerance of the treatment were assessed.

Results

Intraperitoneal treatment with 224Ra-microparticles resulted in considerable survival benefit. An advantageous discovery was that only a few kilobecquerels per mouse were needed to yield therapeutic effects. The treatment was well-tolerated up to doses of 1000 kBq/kg and no clinical signs of toxicity were observed.

Conclusion

Intraperitoneal α-therapy with 224Ra-microparticles demonstrated a significant potential for treatment of residual microscopic intraperitoneal disease with a very promising safety profile.
TARGETED PROTEOMICS IDENTIFIES PROTEOMIC SIGNATURES IN LIQUID-BIOPSIES OF THE ENDOMETRIUM TO DIAGNOSE ENDOMETRIAL CANCER AND ASSIST IN THE PREDICTION OF THE OPTIMAL SURGICAL TREATMENT

1Hospital Universitari Vall d’Hebron, Gynecologic Oncology, Barcelona, Spain
2Vall d’Hebron Institut de Recerca VHIR, Biomedical Research Group in Gynecology, Barcelona, Spain
3Luxembourg Institute of Health LIH, Luxembourg Clinical Proteomics Center LCP, Strassen, Luxembourg
4University Hospital Arnau de Vilanova- and University Hospital Bellvitge- IRBLLEIDA and Idibell- University of Lleida., Pathological Oncology Group and Pathology Department, Lleida, Spain
5University Medical Center- Albert-Ludwigs-University, Department of Obstetrics and Gynecology, Freiburg, Germany
6University of Santiago de Compostela, Faculty of Mathematics, Santiago de Compostela, Spain
7International University of Catalonia, Basic Sciences Department, Barcelona, Spain

Aims

Endometrial cancer (EC) diagnosis relies on the observation of tumor cells in endometrial biopsies obtained by aspiration (i.e., uterine aspirates), but it is associated with 22% undiagnosed patients and up to 50% of incorrectly assigned EC histotype and grade. We aimed to identify biomarker signatures in the fluid uterine aspirates to overcome these limitations.

Method

The levels of 52 proteins were measured in the fluid fraction of uterine aspirates from two independent cohorts of patients of 38 and 116 patients by LC-PRM, the latest generation of targeted mass-spectrometry acquisition. A logistic regression model was used to assess the power of protein panels to differentiate between EC and non-EC patients and between EC histological subtypes. The robustness of the panels was assessed by the "leave-one-out" cross-validation procedure performed in the cohort of 116 patients and 38 patients.

Results

The levels of 28 proteins were significantly higher in EC patients (n=69) compared to controls (n=47). The combination of MMP9 and KPYM exhibited 94% sensitivity and 87% specificity for detecting EC cases. This panel perfectly complemented the standard diagnosis, achieving 100% of correct diagnosis in this dataset. Nine proteins were significantly increased in endometrioid EC (n=49) compared to serous EC (n=20). The combination of CTNB1, XPO2 and CAPG achieved 95% sensitivity and 96% specificity for the discrimination of these subtypes.

Conclusion

We developed uterine aspirate-based signatures to diagnose EC and classify tumors in the most prevalent histological subtypes. This will improve diagnosis and assist in the prediction of the optimal surgical treatment.
LONG-TERM FOLLOW-UP AFTER SENTINEL LYMPH NODE BIOPSY IN EARLY-STAGE VULVAR CANCER

N. Agustí, A. Rodríguez-Trujillo, E. Mensión, P. Fusté, M. Del Pino, B. Gil-Ibariez, M. Munmany, I. Nicolás, A. Glickman, A. Torné, J. Pahisa

1Hospital Clinic, ICGON, Barcelona, Spain

Aims

To evaluate the long-term follow-up in patients with early-stage vulvar cancer undergoing sentinel lymph node biopsy (SLNB).

Method

Retrospective cohort study performed in patients with squamous cell vulvar cancer ≤ 4 cm without suspected inguinofemoral lymph node metastases admitted to our center from June 1998 to July 2004 who underwent SLNB. Complete inguinofemoral lymphadenectomy was performed when SLNB was positive intraoperatively or non-detected. In midline tumors with unilateral drainage complete lymphadenectomy of the opposite side was performed. Adjuvant radiotherapy or re-excision was applied if margins were affected in histological examination. Only patients without lymph node metastases assessed by only SLNB were considered.

In order to compare the recurrence rate and disease-specific 10-year survival this cohort was compared to another cohort without lymph node metastases assessed by inguinofemoral lymphadenectomy, sharing both groups the same tumor’s characteristics and adjuvant treatment.

Results

Thirty patients had negative lymph node after performing SLNB and 51 after lymphadenectomy. The median follow-up was 62.8 months (range 2.9 – 131). We observed no significant differences in recurrence rates between patients with negative SLNB and negative lymphadenectomy (43.3% vs 51%, p=0.646) as well as in the disease-specific 10-year survival rate (76.7% vs. 84.3%, p=0.394). The location of first recurrence in negative SLNB were in 33.3%, 6.7% and 3.3% of patients, local, groin and distant recurrence respectively, being in negative lymphadenectomy 45.1%, 5.9% and 0 respectively, being these differences not significant (p=0.441).

Conclusion

SLNB seems to be, in oncological terms, as safe as inguinofemoral lymphadenectomy to assess lymph node status in early-stage vulvar cancer.

SENTINEL LYMPH NODE MAPPING FOR VULVAL CANCER: PRIOR WIDE LOCAL EXCISION DOES NOT IMPAIR NODAL MAPPING.
R. Bharathan¹, O. Devaja¹, A. Corrigan¹, M. Coutts¹, A. Papadopoulos¹, S. Montalto¹
¹West Kent Oncology Centre- Maidstone Hospital, Department of Gynaecological Oncology, Maidstone, United Kingdom

Aims

To determine the performance of sentinel lymph node (SLN) mapping technique in staging vulval cancer in women who have undergone an earlier wide local excision (WLE).

Method

Since 2005, women with vulval cancer of stage 1B or greater have undergone central surgery with SLN mapping. We have performed SLN mapping with the combined technique using Tc-99m colloid and methylene blue dye. Patients had preoperative SPEC/CT. If patients presented with clinically suspicious nodes, these nodes were debulked and subsequently treated with radiotherapy +/- chemotherapy. If the SLN was negative, then the specimen was ultra-staged by a single pathologist.

Results

Median age was 67 years and the median body mass index was 28.6. In our study of 32 patients both the SPEC/CT and gamma probe identified SLN in 100% of patients. Methylene blue identified SLN in 97% of cases. 21 patients had stage 1B disease, 4 had stage 2 and 7 had stage 3 cancer. 90% were diagnosed with squamous cell cancer. Median size of the lesion was 15 mm and depth of invasion was 2.5 mm. LVSI present in 28% of cases. LN were positive in 25% cases. The median number of SLN in central tumours was 1 per LN basin and in lateral tumours, it was 2. False negative rate was 3.1%

Conclusion

SLN is a feasible and safe technique even in those who have had prior WLE.

18F-FDG PET/CT IN PREOPERATIVE NODAL STAGING OF VULVAR CANCER PATIENTS: IS IT REALLY NEEDED?

A. Buda¹, C. Crivellaro², G. Di Martino¹, F. Elisei², M. La Manna¹, S. Magni², P. Di Lorenzo¹, L. Guerra²

¹Gynecologic Oncology Unit - ASST-Monza- San Gerardo Hospital- University of Milano-Bicocca- Monza- Italy,
Department of Obstetrics and Gynecology, Monza, Italy
²University of Milano-Bicocca- Tecnomed Foundation-, Department of Nuclear Medicine- Monza- Italy, Monza, Italy

Aims

Aim of this study was to assess the role of PET/CT in nodal staging of vulvar cancer patients.

Method

29 pts (68 years; range 51–83) with vulvar cancer (clinical stage I-II), underwent preoperative FDG-PET/CT scan followed by radical vulvectomy and bilateral (or monolateral in case of tumour >2 cm from midline) inguinal lymphadenectomy or sentinel node biopsy. PET/CT images were analyzed by three examiners in consensus and correlated to histological findings according to a pt-based and a groin-based analyses. SUVmax of the nodal uptake of each inguinal area (if present) has been calculated and correlated to histological findings.

Results

PET/CT analysis in consensus resulted negative at inguinal LN level in 18 pts (10 TN, 8 FN) and positive in 11 pts (6 TP, 5 FP). Incidence of LN metastases resulted 48%. On pt-based analysis, sensitivity, specificity, accuracy, negative and positive predictive value of PET/CT in detecting LN metastases were 43%, 67%, 55%, 55%, 56%. On a groin-based analysis, considering overall 50 LN sites, sensitivity, specificity, accuracy, negative and positive predictive value of PET/CT were 53%, 85%, 73%, 67%, 76% respectively. The mean value of SUVmax was 4.1 (range 0.7–9.3) for metastatic nodes, whereas 1.6 (range 0.7 – 5.4) for reactive/negative lymph-nodes (p=0.0005).

Conclusion

In vulvar cancer FDG PET/CT showed low sensitivity and moderate specificity for lymph node staging, therefore it is not an accurate tool for the nodal status assessment.

V-Y ADVANCEMENT FLAP VERSUS LOTUS PETAL FLAP FOR PLASTIC RECONSTRUCTION AFTER SURGERY IN CASE OF VULVAR MALIGNANCIES: A RETROSPECTIVE SINGLE CENTER ITALIAN EXPERIENCE.

A. Buda1, R. Gilardi2, P.L. Confalonieri2, G. Di Martino1, J.H. Lee2, F. Dell’Orto1, M. Del Bene2

1Unit of Gynecologic Oncology, Department of Obstetrics and Gynecology- University of Milano-Bicocca, Monza, Italy
2Unit of Plastic Surgery- San Gerardo Hospital, Department of Surgery, Monza, Italy

Aims

This study retrospectively reviewed patients with primary or recurrent vulvar malignancies that had undergone vulvoperineal reconstruction using the V-Y advancement flap and the two variant of the lotus petal flap (LPF) in terms of surgical outcome and postoperative complications.

Method

Between 2000 and 2016, 234 women operated at San Gerardo Hospital in Monza were included in the study. 128 of them having undergone V-Y flap, whereas 106 underwent LPF (58), or it tunneled variant (48). Overall, 365 flaps were harvested (214: 59% V-Y; 151: 41% LPF). Two hundred and sixty-two (262) flaps were bilateral, (47% V-Y, 24% LPF) whereas 103 flaps were monolateral (11% V-Y, 17% LPF).

Results

The average length of follow-up was 84 months (range, 6 - 180 months). Overall, postoperative complications occurred in 21.5% of patients including 27/128 (21%) of the V-Y group and in 14/106 (13%) of the LPF group. No statistically differences were recorded in terms of complications between the groups when comparing V-Y and LPF’s overall (p=0.588), or by comparing the primary (p=0.202), or the recurrent setting (p=0.281). Site of recurrence are listed in table 3. No statistically difference were found between the groups overall (p=0.974), or when comparing the primary (p=0.873), or the recurrent setting (p=0.971).

Conclusion

V-Y flap and the LPF represent two feasible techniques for vulvoperineal reconstruction after surgery for primary or recurrent vulvar malignancies. The associated rates of complications are reasonable for both procedures. LPF represents the treatment of choice in our department for vulvar reconstruction producing the best aesthetic and functional results.

Copyright © 2017 by IGCS and ESGO. Unauthorized reproduction of this article is prohibited.
Aims

Inguinal radiotherapy with or without concomitant chemotherapy is considered standard for patients who have had wide local excision and inguinal lymphadenectomy, and are found to be node positive.

We were interested in outcomes, toxicity and patterns of failure in this group of patients.

Method

We analysed our databases for patients who had received adjuvant (chemo)radiotherapy to inguinal nodes either unilateral or bilateral. We queried our systems (Aria and Chemocare) and collected patients from 1st January 2007 to 1st September 2015. Further details on patients were collected through case notes, Clinical Portal, SCI Store and Trakcare.

Results

We found 21 patients that fulfilled the above criteria, median age 66 yrs (range 28-84 years). Sixteen patients (76%) had concomitant chemoradiotherapy. Dose of radiotherapy was 50Gy in 60% of the total cohort. About 30% of patients had grade 3 tumours and lymphovascular space invasion (LVSI) was seen in 66%.

Lymphoedema was the only late toxicity, observed in 24% of patients. There was no bowel or bladder related toxicity beyond Grade 1.

Just over half the patients are alive and disease free after a median follow up of 18 months. The median follow up for those who are disease free is 30 months.

Seven patients out of the total of 10 with any relapse, and all patients who had a distant relapse, had LVSI in their initial specimen.

Conclusion

Our results show that chemo-radiation to the inguino-femoral region is well tolerated. LVSI is a strong predictor for relapse.
A COMPARATIVE STUDY OF VIDEO ENDOSCOPIC INGUINAL LYMPHADENECTOMY AND CONVENTIONAL OPEN INGUINAL LYMPHADENECTOMY IN TREATING VULVAR CANCER

J. Ding¹, M. Zhang², K. Hua³

¹Obstetrics and Gynecology Hospital of Fudan University, Department of Gynecology, Shanghai, China
²the Obstetrics and Gynecology Hospital of Fudan University, the Department of Gynecology, Shanghai, China
³the Obstetrics and Gynecology Hospital of Fudan University, huakeqin@126.com, Shanghai, China

Aims

To compare the complications, oncological outcomes, cosmetic satisfaction and quality of life between video endoscopic inguinal lymphadenectomy (VEIL) and conventional open inguinal lymphadenectomy (COIL) in women with vulvar cancer.

Method

Patients with vulvar cancer who underwent COIL (n=27) or VEIL (n=21) in our hospital between 2003 and 2016 were included in this retrospective cohort study. The perioperative data, postoperative complications, oncological outcomes, cosmetic satisfaction and quality of life between COIL and VEIL groups were compared.

Results

20 patients (74.1%) in COIL group and 19 patients (90.5%) in VEIL group returned for their follow-up after the operation. The median follow-up time was 73 months (8-162 months) for the COIL group and 28 months (8-58 months) for the VEIL group. The inguinal lymph node yield in the VEIL group was comparable with that in the COIL group (15±5 VS 18±6, P=0.058). The VEIL group had similar recurrence rate and death rate with the COIL group. The wound complication rate is significantly lower in the VEIL group than that in the COIL group. The VEIL group had higher body image scores (16.27 ± 1.20 VS 13.16 ± 0.87, P < 0.0001) and cosmetic scores (20.13 ± 0.98 VS 16.92 ± 0.72, P < 0.0001) than the COIL group. The patients in the VEIL group had a higher life quality scores by the FACT-V questionnaire than those in the COIL group (165.9±6.3 VS 160.5±6.0, P=0.026).

Conclusion

Comparing with conventional open inguinal lymphadenectomy, video endoscopic inguinal lymphadenectomy can effectively reduce the postoperative wound complications, improve patients’ cosmetic satisfaction and life quality without compromising the therapeutic efficacy.
IMPLICATION OF HISTOLOGICAL TUMOR-FREE MARGIN (hTFM) AND RE-EXCISION ON SURVIVAL IN PRIMARY VULVAR CANCER WITH ADJACENT VULVAR INTRAEPITHELIAL NEOPLASIA (VIN III)  
K. Gasimli¹, M. Straussner¹, I. Schmeil¹, S. Becker¹, R. Winkelmann², K. Thomas¹, A. El-Balat¹  
¹University Hospital Frankfurt, Department of Gynecology, Frankfurt, Germany  
²University Hospital Frankfurt, Institute of Pathology, Frankfurt, Germany

Aims

hTFM in vulvar cancer is an important prognostic factor. Ideally, a diameter of >8mm should be achieved after primary surgery. The role of VIN III persistence after primary surgery is still unclear. The main objective of the current study was to compare differences in disease free survival among patients with different hTFM and the role VIN III re-excision in primary vulvar cancer.

Method

Forty-one patients with remaining VIN III after primary surgery for vulvar cancer which were operated between 1996 and 2016 in our clinic were enrolled in this retrospective study. Re-excision rates for VIN III were calculated. According to the histological margin patients were divided into three group: <3mm, 3-8mm and >8mm. Univariate and multivariate survival analyses were conducted using the Kaplan-Meier method and Cox proportional hazards models, respectively.

Results

The vast majority of patients had pT1b stage (58.5%), grading G2 (70.7%) and node-negative (78.0%) disease at first diagnosis. The re-excision rate was 56.0% (23 cases). The 5-year disease-free survival (PFS) rates in patients with <3mm, 3-8mm and >8mm hTFM were 50.0%, 60.0% and 82.6%, respectively (p=0.05). The 5-year PFS rates in patients with re-excision and without re-excision for VIN III were 78.3 and 61.1%, respectively (p=0.17). Histological margin >8mm and node-positive disease were the only independent factors for PFS in multivariate analysis (p=0.01 and p=0.02, respectively).

Conclusion

hTFM is a potential prognostic indicator for PFS in vulvar cancer patients. Re-excision for VIN III could not carry any additional benefit on PFS after primary surgery.

VULVAR CANCER: TWO PATHWAYS WITH DIFFERENT LOCALIZATION AND PROGNOSIS

F. Hinten1, A. Molijn2, L. Eckhardt1, L. Massuger1, W. Quint1, P. Bull3, H. Buiten4, W. Melchers4, J. de Hullu1

1Radboudumc, Obstetrics & Gynaecology, Nijmegen, The Netherlands
2Delft Diagnostic Laboratory, Delft Diagnostic Laboratory, Delft, The Netherlands
3Radboudumc, Pathology, Nijmegen, The Netherlands
4Radboudumc, Medical Microbiology, Nijmegen, The Netherlands

Aims

Two etiologic pathways for vulvar squamous cell carcinoma (SCC) are described: in a background of lichen sclerosus and/or differentiated vulvar intraepithelial neoplasia and related to high-risk human papillomavirus (HPV) infection with high grade squamous intraepithelial lesion (HSIL) as precursor. The aim was to compare the predilection site and survival of HPV-related to non HPV-related vulvar SCCs.

Method

Data of patients treated for primary vulvar SCC at the Radboudumc between March 1988 and January 2015 were analyzed. All histological specimens were tested for HPV with the SPF10/DEIA/LiPA25 system assay and p16INK4a staining was performed using CINtec® histology kit. Vulvar SCCs were considered HPV-related in case of either >25% p16INK4a expression and HPV positivity or >25% p16INK4a expression and HSIL next to the tumour. Tumour localization, disease specific survival (DSS), disease free survival (DFS) and overall survival (OS) of patients with HPV-related and non HPV-related vulvar SCC were compared.

Results

In total 318 patients were included: 55 (17%) had HPV-related (Group 1) and 263 (83%) had non HPV-related vulvar SCC (Group 2). The tumours in Group 1 were significantly more often located at the perineum compared to Group 2, 30% and 14%, respectively (p = 0.001). The DSS, DFS and OS were significantly better in HPV-related than in non HPV-related vulvar SCC patients.

Conclusion

HPV-related vulvar SCCs are more frequently located at the perineum and have a favourable prognosis compared to non HPV-related vulvar SCCs. Both localization and the HPV relation could explain this favourable prognosis. HPV-related vulvar SCC seems to be a separate entity.

EVALUATION OF RISK FACTORS FOR WOUND BREAKDOWN AFTER INGUINAL LYMPH NODE DISSECTION IN VULVAR CANCER

M. Kranawetter¹, C. Grimm¹, R. Schwameis², S. Polterauer¹, A. Reinthaller¹

¹Medical University of Vienna, Gynecology and Obstetrics, Vienna, Austria
²Medical University of Vienna, Gynecology and Obstetrics, Vienna, Austria

Aims

The aim of this study was to evaluate risk factors for wound complications after inguinal lymph node dissection in patients with vulvar cancer.

Method

We retrospectively identified all patients with Vulvar Cancer treated at the Medical University of Vienna between 1995 and 2015. Clinical data including age, type of operation, number of resected lymphnodes and lymphnodestatus, drainage, use of antibiotics, body mass index (BMI), co morbidities and postoperative morbidities e.g. cellulitis, wound breakdown, lymphcyst formation and lymphedema were obtained by chart review. Statistical calculations were performed using chi- square test and logistic regression analysis.

Results

147 patients and a total number of 254 groin operations were enrolled in this study. 107 patients had bilateral, 40 patients unilateral groin node dissection. The mean age was 69.5 (SD 13.0). 156 (61.4%) cases were performed as complete inguinal lymphadenectomy, 98 (38.6%) cases as sentinel node biopsies. The mean BMI was 27.6 (SD 5.8). 22 patients (8.7%) developed wound breakdown and 53 patients (20.1%) lymph cysts. Univariat analysis showed BMI >30 (p=0.004) and more than five resected lymph nodes (p=0.04) significantly correlated with wound breakdown. In multivariate analysis BMI >30 (OR 5.0 [1.6-16.0], p=0.006), diabetes (OR 3.7 [1.4-10.1], p= 0.01) and more than five resected lymph nodes (OR 4.1 [1.5-11.1], p=0.005) were shown as independent risk factors for postoperative wound breakdown.

Conclusion

Wound breakdown is a frequently seen complication after inguinal lymph node dissection. Obesity, diabetes and an extended number of removed lymph nodes were shown to be independent risk factors for developing wound complications.

3Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain
4Hospital Ntra. Sra. del Rosario, Gynecology and Obstetrics, Madrid, Spain
5Ntra. Sra. del Rosario Hospital-Doce de Octubre University Hospital, General and Colorectal Surgery, Madrid, Spain
6Advance Tecniques Cancer Center, Radiation Oncology, Madrid, Spain

Aims

Describe the surgical technique of transposition flaps, among the different types of flaps in vulvar reconstruction.

Method

Retrospective study of 23 cases of vulvar cancer diagnosed between April 2008 and July 2016. We present the surgical technique: transposition flaps with surgical images and diagrams that make understandable the design and the displacement of the flap.

Results

Limberg flap is very useful by allowing transpose woven from 4 different adjacent zones. It is designed with a geometric basis and are transposing the estetic-functional or loose skin that we choose the possible 4. The design consists of drawing a diamond containing tumor with angles of 60° and 120°. From one of the two angles of 120 degrees is projected an incision of length same to the distance between those angles of 120° and, from here, we can orient to one or other side according to the anatomical area and the distensibility of the skin, through another incision parallel and equal in length to the side of the rhombus. We present an example to cover the area dehiscent after radical vulvectomy and inguinal bilateral lymphadenectomy in patient with vulvar cancer stage pTII pN0 M0 (0/19).

Dufourmentel flap is used for rhomboid defects, is but its angles are 60 degrees, but oscillating between 60-90°. We present images of inguinal node metastases lymphadenectomy treated for squamous cell vulvar cancer, stage IIA1 (pN0/9) M0.

Conclusion

Transposition flaps allow excellent coverage in recurrences with big defects of vulvar cancer, with an optimal morpho-functional reconstruction.

3Infanta Leonor University Hospital, Obstetrics and Ginecology, Madrid, Spain
4Pathologic Center, Pathology, Madrid, Spain
5Ntra. Sra. del Rosario, Gynecology Oncology, Madrid, Spain
6Toco-Gyn Gynecological Center, Obstetrics and Ginecology, Alcalá de Henares, Spain
7Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain

Aims

To study of outcomes and complications of the oncoplastic techniques in reconstructive surgery for vulvar cancer.

Method

Retrospective study of 23 cases of vulvar cancer. 15 cases were treated through radical vulvectomy (8), hemivulvectomy (5) and expanded lumpectomy (2). Arise with images and diagrams the technical realization of flaps fasciocutaneos, local or neighborhood, with vascular pattern axial and randomized, described according to the type of mobilization performed. Surgical variables, complications and disease-free survival (DFS) and overall survival (OS) were assessed using Kaplan-Meier survival curves and a multivariate analysis.

Results

Oncoplastic techniques for reconstruction were performed in 13 cases (86.6%). The mean age was 76.9 years, 87% of the tumors was squamous cell type and the most frequent stage was IIIA1 (26.1%), followed by stages IB and II (21.7%). The most commonly used flaps were transposition flap of interpolation, straight inner flap, flap of Martius and flaps of progress (V-Y, Z). Bilateral inguinal lymphadenectomy was performed in 9 cases and homolateral in 3 cases, with a mean removed lymph nodes of 12.8. Mean operative time was 219.6 minutes and mean blood loss was 1012 ml. There were no major complications: 3 patients had dehiscence, 1 case presented necrotizing fasciitis and another case of flap necrosis. 6 patients required re-intervention (26.1%). OS was 35,7% and DFS was 22,1% at 3 years.

Conclusion

Fasciocutaneos flaps allow a proper morpho-functional reconstruction and good local sensitivity. A protocol of perioperative management is essential to reduce the rate of complications.

GENOMIC CHARACTERISATION OF VULVAR (PRE)CANCERS IDENTIFIES DISTINCT MOLECULAR SUBTYPES WITH PROGNOSTIC SIGNIFICANCE

L. Nooij1, N. ter Haar2, D. Ruano2, N. Rakislova3, V. Smits2, B. Trimbos1, J. Ordi3, M. van Poelgeest1, T. Bosse6

1LUMC, Gynaecology, Leiden, The Netherlands
2LUMC, Pathology, Leiden, The Netherlands
3Barcelona Centre for International Health Research CRESIB, Pathology, Barcelona, Spain

Aims

Vulvar cancers (VC) are classified on the presence of human papilloma virus (HPV). HPV- VC are associated with TP53 mutations, but little is known about other genetic alterations. In an effort to further delineate the molecular landscape of VC, we comprehensively assessed somatic mutations in a large series of vulvar (pre)cancers.

Method

We performed targeted next generation sequencing (17 genes), p53 immunohistochemistry and HPV testing on 36 VC and 82 precursors. Subsequently, the prognostic significance of HPV and p53 status was assessed in a series of 236 VC patients (follow-up cohort).

Results

Frequent recurrent mutations were identified in HPV- VC and precursors in TP53 (42% and 68%, respectively), NOTCH1 (28% and 39%, respectively) and HRAS (20% and 32%, respectively). Mutation frequency in HPV+ vulvar (pre)cancers was significantly lower (p-value = 0.001). Furthermore, a substantial subset of the HPV- precursors (35/60, 58.3%) and VCs (9/28, 32%) were TP53 wildtype, suggesting a third molecular subtype. Clinical outcomes in the 3 different groups (HPV+, HPV-/p53-WT, HPV-/p53-abn) were evaluated in the follow-up cohort. Local recurrence rate was 5.3% for the HPV+ patients, 16.3% for HPV-/p53-wt patients and 22.6% for HPV-/p53-abn patients (p=0.044). HPV positivity remained an independent prognostic factor for favourable outcome in multivariable analysis (p=0.020).

Conclusion

HPV- and HPV+ vulvar (pre)cancers display striking differences in somatic mutation patterns. HPV-/p53wt VC appear to be a distinct clinicopathologic subgroup with frequent NOTCH1 mutations. HPV+ VC have a significant lower local recurrence rate, independent of clinicopathological variables, opening opportunities for future studies on possible reduction of overtreatment in VC.
BREAST CANCER II

ESGO7-0097

STROMAL B7-H3 AND B7-H4 EXPRESSION CORRELATIONS WITH TUMOR PROGRESSION AND T-CELL INFILTRATION IN PHYLLODES TUMOR OF THE BREAST

J.S. Lee¹, N.I. Kim¹, G.E. Kim¹
¹Chonnam National University Hwasun Hospital, Pathology, Hwasun, Republic of Korea

Aims

The aberrant expression of co-inhibitory B7 molecules, B7-H3 and B7-H4, in the tumor microenvironment has been attributed to reduced anti-tumor immunity and immune evasion, prompting the development of immunotherapeutic approaches. This study was undertaken to detect the expression of B7-H3 and B7-H4 in phyllodes tumors (PTs) and its association with the grade and clinical behavior of PTs. In addition, the association of B7-H3 and B7-H4 with the CD3 and CD8+ T lymphocytes was also assessed to investigate their roles in the regulation of tumor immune surveillance.

Method

Immunohistochemistry was applied to examine the expressions of B7-H3, B7-H4, CD3, and CD8 in 60 benign, 26 borderline, and 15 malignant PTs.

Results

Stromal high B7-H3 and B7-H4 expression was noted in 31 (51.7 %) and 0 (0 %) of 60 benign PTs, 20 (76.9 %) and 2 (7.7 %) of 26 borderline PTs, and 13 (86.7 %) and 9 (20.0 %) of 15 malignant PTs, respectively. Stromal B7-H3 and B7-H4 expression increased continuously as PTs progress from benign through borderline to malignant PTs, respectively ($P = 0.003$ and $P = 0.001$). The recurrence rate was higher in the stromal high B7-H3 or B7-H4 expression group than in the low expression group but this difference was not statistically significant. B7-H3 expression inversely correlated with the intensity of CD3 and CD8+ T cells ($P = 0.001$ and $P = 0.027$, respectively).

Conclusion

B7-H3 and B7-H4 are involved in the progression of PTs and B7-H3 may play a role in immune surveillance mechanisms of PTs.
BREAST CANCER II

USE OF UNDERARM COSMETIC PRODUCTS AND BREAST CANCER: A CASE-CONTROL STUDY

1Medical University of Innsbruck, Department of Medical Statistics - Informatics and Health Economics, Innsbruck, Austria
2Medical University of Innsbruck, Division of Clinical Biochemistry- Biocenter, Innsbruck, Austria
3Medical University of Innsbruck, Department of Plastic- Reconstructive & Aesthetic Surgery, Innsbruck, Austria
4Keele University, The Birchall Centre- Lennard-Jones Laboratories, Keele, United Kingdom
5Medical University of Innsbruck, Department of Obstetrics and Gynaecology, Innsbruck, Austria

Aims

We conducted a 1:1 age-matched case-control study to investigate the risk for breast cancer (BC) in relation to self-reported use of underarm cosmetic products (UCPs) containing aluminium salts. Our study for the first time also included analysis of aluminium concentrations in a big series of breast tissues.

Method

Structured BC risk interviews were conducted. History of UCP use was compared between 209 BC patients (cases) and 209 age-matched healthy women (controls). Aluminium concentration was analysed in breast tissues of 100 cases and 52 controls who underwent mastectomy for BC or reduction mammoplasty for non-cancer reasons, respectively. Multivariable conditional logistic regression analysis was performed to determine relative risks, estimated as odds ratios (ORs) with 95% confidence intervals (CIs), adjusting for established BC risk factors.

Results

Case-control comparisons confirmed established risk factors for BC. Self-reported use of UCP was significantly associated with an increased risk of BC (p=0.036). BC risk increased by an OR of 3.88 (95% CI 1.03-14.66) in women who reported using UCP's more than once daily starting at an age <30. Aluminium in breast tissue was significantly associated to self-reported UCP use (p=0.003) in both cases and controls. Median (interquartile) aluminium concentration was significantly higher (p<0.001) in cases than in controls (5.8, 2.3-13.1 versus 3.8, 2.5-5.8 nmol/g).

Conclusion

Frequent use of UCPs may lead to accumulation of aluminium in breast tissue. Extensive use of UCPs particularly at young age was associated with increased risk of BC. Of note, we herein report on pure correlation analyses and not on causal links.
BREAST CANCER II

ESGO7-0459

T. Link1, K. Kast1, P. Wimberger1, C. Sadowski1

1Medizinische Fakultät Carl Gustav Carus an der TU Dresden, Gynecology, Dresden, Germany

Aims

Diagnosis of leptomeningeal metastasis (LM) has become increasingly common because of longer survival of patients by better systemic control. However, treatment options are very limited and their appearance implies a very poor prognosis. Treatment options are intrathecal and systemic chemotherapy, radiotherapy. This report of our single center experience investigates clinical features and determines prognostic factors in a cohort of patients with breast cancer.

Method

Single center data from 43 patients with breast cancer and LM between 2009 and 2016 were retrospectively analyzed with focus on characteristics, clinical outcome and treatment.

Results

Mean interval between diagnosis of breast cancer and diagnosis of LM was 17,5 month (range 0-149 months). LM was diagnosed by MRI and cerebrospinal fluid cytology (CSF) 69,8%, MRI alone 25,6% or CSF 4,7% alone. Treatment included intrathecal therapy alone 48,8%, radiotherapy alone 20,9% or the combination of both 14%. 42% patients had triple negative (TNBC) breast cancer, 9,3 % were Her2-positive (HER2+) and 48,8 % had a hormone receptor positive and Her2-negative disease (HR+/HER2-). Median survival was 1,6 month for TNBC, 13,3 months for HER2+ and 7,4 months for HR+/HER2- disease. 58,1% died due to progression of LM und 23,3% due to systemic progression. 1 patient (Her2+) is still alive 18 months after diagnosis of LM.

Conclusion

Despite the improvement of treatment options for breast cancer within the last years, appearance of LM is still associated with a poor survival. Survival differs between subtypes. More research needs to be done to identify factors for possibly new systemic therapies that improve survival.
Aims

Based on the central role of biomarkers in planning the mammary cancer therapy, we investigated 412 cases, randomly selected, to emphasize the relationship between peritumoral lymphangiosis carcinomatosa in molecular subtypes in breast cancer and axillary lymph node metastasis.

Method

We have selected cases that are ordered under the four molecular subtypes of breast cancer. We noticed that the majority of mammary carcinoma are part of the Luminal A subtype. For this subtype we analyzed the behaviour between peritumoral carcinomatosa lymphangiosis and axillary lymph nodes.

Results

L1 status has a HIGH RISK of nodule METASTASIS (HRM)
L0 status has a LOW RISK of nodule METASTASIS (LRM) allowing that the size and biology of the tumor have favorable criteria

Conclusion

Peritumoral lymphangiosis carcinomatosa can be used as a prediction factor in a high or low risk metastasis of axillary lymph nodes, as well as a prognostic factor.

The presence of peritumoral lymphangiosis implies a direct relationship with the metastasis of lymph nodes and their increase in number.

In case of a Luminal A L0 situation we expect few axillary nodes metastasis, which makes possible to even forego the axillary dissection.
ULTRASOUND-GUIDED ONCOPLASTIC SURGERY IN NON-PALPABLE BREAST LESIONS
C. Gianella¹, D. Martínez Campo², H. García Briz¹, G. Costa Martínez¹, R. Barriga¹, P. Garbayo Sesma², L. Gonzalez Gea²,
I. Perez Martín², L. Rabadán¹, B. Santacruz Martín²
¹Hospital Universitario de Torrejón, Unidad de mama, Madrid, Spain
²Hospital Universitario de Torrejón, Ginecología Oncológica, Madrid, Spain

Aims

To evaluate the rate of malignant margins in the oncoplastic surgery of non-palpable ultrasound-guided breast lesions.

Method

- Observational, descriptive and retrospective study. All patients diagnosed with non-palpable malignant breast lesions from October 2011 to May 2015 were included in the study. Patients with neoadjuvant therapy were also included as long as the tumor was not palpable at the time of surgery.

Results

114 patients were included. 66.6% corresponded to infiltrating ductal carcinoma, 22.8% to ductal carcinoma in situ and 10.6% to all other lesions (special and lobular carcinomas). The oncoplastic techniques used were Fisher-type tumorectomy and remodeling (52.6%), circular mammoplasty (16.6%), vertical mammoplasty (14.9%). The malignant margins rate was 7.01% (8 patients).

Conclusion

Reviewing the literature, there is still insufficient evidence to conclude that intraoperative ultrasonography in nonpalpable lesion surgery is a superior technique. Lack of randomized clinical trials are available. There is evidence to conclude that it is a simple, reproducible technique with a short learning curve and that does not generate pain to the patient. The published localization rates are around 100%. Studies should be performed comparing currently available techniques.
MAJOR HISTOCOMpatibility COMPLEX CLASS I-RELATED CHAIN A (MICA) EXPRESSION AS A MARKER FOR BREAST EPITHELIAL PRECANCEROUS AND CANCEROUS LESIONS

P. Masadah¹, N. Nurkhairaty¹, J.M. Kandouw¹, S. Rau²
¹Hasanuddin University, Pathology Anatomy, Makassar, Indonesia
²Hasanuddin University, Obstetric and Gynecology, Makassar, Indonesia

Aims

To analyse the expression of MICA in various breast epithelial lesion in order to support the diagnosis of precancerous and cancerous lesions, and to gain the knowledge of breast cancer pathogenesis and the role of immune system in cancer.

Method

One hundred and six of paraffin blocks tissue samples was analysed by immunohistochemistry using monoclonal MICA antibody. Samples have been categorized histopathologically as atypical duct hyperplasia, ductal carcinoma insitu, ductal carcinoma invasive (low, moderate, and highly differentiated).

Results

there was a significant differentiation of MICA expression between atypical duct hyperplasia and invasive ductal carcinoma moderate and highly differentiated of the breast. There was as significant differentiation of MICA expression between ductal carcinoma insitu and invasive ductal carcinoma moderate and highly differentiated of breast (p < 0.05).

Conclusion

MICA expression could be used to differentiate precancerous and cancerous lesions of breast.

ADDITIONAL CAVITY SHAVES MARGINS IN BREAST CANCER

L. Achouri¹, H. Bouzaine¹, N. Tounsi¹, B. Lamouri¹, H. Henchiri², R. Doghri², M. Hechiche¹, J. Ben Hassouna¹, R. Khaled²

¹Salah Azaize, Department of Surgery Carcinologique, Tunis, Tunisia
²Salah Azaize, Department of Pathology, Tunis, Tunisia

Aims

The aim of our study is to evaluate our management strategy for tumor shave in anatomopathological examination after breast-conserving surgery and discuss the role of additional re-excision margin.

Method

We undertook a retrospective review, throughout 2012, of 319 women who underwent lumpectomy with shaving margins for stage 0-III breast cancer.

At our institution, patients who had breast conservation had a lumpectomy with routine CSM with extemporaneous anatomopathological study at the time of initial surgery, associated with an axillary lymph node dissection. If CSM was tumor, the radical surgery was realized. No additional re-excision margin was performed.

Results

The median age was 50 years old. The median clinical tumor size was 30 mm. The median histological size was 20 mm. The infiltrating ductal carcinoma was the most common histological type.

All our patients underwent a lumpectomy with systematic cavity shaving. Tumor in shavings was revealed in 106 (33.2%) patients. It was discovered in extemporaneous examination in 63 (59,5%) cases. In 43(40.5%), it was revealed in the definitive anatomopathological examination and additional mastectomy was necessary. Among these patients who had radical mastectomy, the final histological examination concluded to a residual cancer in 58 (54,7%) cases.

Conclusion

Taking additional CSM at the time of lumpectomy is advocated by some as a way to decrease re-excision rates. Despite these findings, a minority of surgeons have adopted this practice.
PREOPERATIVE AXILLARY LYMPH NODE STAGING IN BREAST CANCER

L. Achouri¹, H. Bouzaine¹, S. Kacemi¹, N. Tounsi¹, I. Zemni¹, H. Hantousse², M. Hechiche¹, J. Ben Hassouna¹, K. Rahel²
¹Salah Azaize, Department of Surgery Carcinologique, Tunis, Tunisia

Aims

To evaluate the reliability of physical examination in predicting the axillary lymph node involvement in breast cancer, study the factors that may interfere with it and ask about the benefits of means other than the physical examination to have an accurate lymph node status.

Method

A retrospective review was performed of 730 consecutive patients diagnosed with breast carcinoma between January 2012 and December 2012 who had physical examination of the axilla. Definitive histopathological evaluation of lymph nodes has been performed for 654 patients.

Results

A total of 377 (57%) patients had one or more positive lymph nodes, 80.2% of whom were identified preoperatively by physical examination. The sensitivity of physical examination in evaluating the axillary node involvement was 80.2%. Its specificity was 46%. An underestimation was noticed for T0 and an overestimation for T1, T2, T3 and T4 tumors.

Conclusion

Physical examination is useful for preoperative axillary staging and treatment planning. Nonetheless, it is an inadequate definitive predictor of axillary lymph node involvement, especially that the examiner is not blinded to the breast tumor size which will inexorably influence his assessment.
CHAMOMILE CAN REDUCE THE METASTATIC PROPERTIES OF HUMAN BREAST CANCER CELL LINE THROUGH IMPACT ON VEGF AND MMP ENZYMES ACTIVITY

M. Nikseresht\textsuperscript{1}, R. Mahmoudi\textsuperscript{1}, A. Sabet Eghlidi\textsuperscript{1}, F. Sane\textsuperscript{2}

\textsuperscript{1}Yasuj University of Medical Sciences, Cellular and Molecular Research Center, Yasuj, Iran
\textsuperscript{2}Kazerun Azad University, Medical Faculty, Kazerun, Iran

Aims

Today there is a special focus on traditional medicine for preventing and treatment of diseases. Herbal medicine has the central role in the traditional medicine and there are different kinds of medicinal plants, which use for this purpose. One of these plants is chamomile. Various studies have reported the anticancer effects of this plant. In this study, the effects of hydroalcholic extract of chamomile on angiogenic factor, VEGF, and MMP enzymes activities were investigated in human breast cancer cell lines.

Method

MCF-7 and MDA-MB-468 cell lines were cultured and treated with hydroalcholic extract of chamomile. Cell viability were evaluated by using MTT assay. VEGF gene expression were analysed by Real Time PCR. Enzyme activity of MMP-2 and MMP-9 evaluated by zymography assay. Data were analyzed by one-way ANOVA in SPSS software.

Results

MTT assay on MCF-7 and MDA MB468 showed IC50 at 1000 and 1400 μg/ml respectively. At the IC50 doses, VEGF expression and secretion is reduced compared to the control by the cell lines. Treatment of MDA-MB-468 cell line with 1400 μg/ml of chamomile extract caused depletion of MMP-9 and MMP-2 enzyme activity in the cell culture medium.

Conclusion

The results show hydroalcholic extract of chamomile can reduce the expression of VEGF gene and MMP enzyme activity and so inhibit the angiogenesis progression by these cells. This study was in vitro study and must be tested in vivo by clinical approaches but the use of such these plants in daily diet may be useful for preventing and increase viability in breast cancer.
COMPLEMENTARY BREAST MAGNETIC RESONANCE IMAGING FOR TUMOR SIZE ASSESSMENT AND SURGICAL PLANNING IN WOMEN WITH EARLY BREAST CANCER

F.C. Pop1, C. Stanciu Pop2, M. Radermeker3, C. Vandemerckt4, D. Noterman1, M. Moreau4, D. Larsimont5, J.M. Nogaret1, I. Veys1

1Jules Bordet Institute, Surgery, Brussel, Belgium
2CHU UCL-Université catholique de Louvain-Belgium, Pathology, Yvoir, Belgium
3Jules Bordet Institute, Radiology, Brussel, Belgium
4Jules Bordet Institute, Statistic, Brussel, Belgium
5Jules Bordet Institute, Pathology, Brussel, Belgium

Aims

The size and the focality of the primary tumor in breast cancer (BC) influence therapeutic decisions. The purpose of this study is to evaluate if preoperative breast magnetic resonance imaging (MRI) is helpful for the assessment of tumor size and for surgical planning in early BC.

Method

We performed a retrospective review of a prospectively collected database of 174 women with invasive BC who had a complete documentation of the tumor size from mammography (MMG), ultrasonography (US), and MRI.

Results

A total of 186 breast tumors were analyzed. The mean tumor size was different by imagistic method: 14.7 mm by MMG, 13.8 mm by US and 17.9 mm by MRI. The concordance between tumor size in breast imaging techniques (BIT) and pathology size with a cut-off +/- 2 mm was 34.8% for MRI, 32.1% for US and 27.2% for MMG. The concordance was the same in premenopausal women for MRI and US at 35%, in postmenopausal women it was higher with MRI. Correlation between size of BIT and histopathological size remain best with MRI (0.59), than US (0.56) or MMG (0.42). MRI examination revealed additional lesions in 13.8% of patients, with 69% malignancy in those lesions. MRI has change the surgical planning in 15 patients (8.6%) with increased mastectomy rate of 6.6%.

Conclusion

MRI can estimate BC size more accurately, but a significant overestimation exists. Complementary MRI examination could improve the concordance for tumor size between BIT and histopathological size with 16.5% and allowed a more appropriate treatment for 8% of patients.
PAPILLARY CARCINOMA OF MALE BREAST: AN UNCOMMON PATHOLOGY OF BREAST CANCER

M. Rezgani¹, O. Adouni², O. Jaidane¹, I. Bettaieb², H. Salhi¹, M. Ghalleb¹, H. Bouaziz¹, H. Bouzaïene¹, T. Dhieb¹, J. Ben Hassouna¹, O. Gamoudi², K. Rahal²

¹Institut Salah Azaiez, Departement of oncological surgery, Tunis, Tunisia
²Institut Salah Azaiez, Department of pathological anatomy, Tunis, Tunisia

Aims

Male breast cancers constitute less than 1% of all the breast cancers. Papillary carcinoma is a very rare tumour of the male breast accounting for between 5 and 7.5% in men versus 0.5 and 2.4% in women.

The aim of this study is to investigate the clinico-pathological features and the treatments of papillary carcinoma of the breast in male.

Method

We retrospectively reviewed in this study eleven cases of papillary carcinoma of the male breast treated between 1994 and 2011 at Salah Azaiez institute.

Results

The median age at diagnostic was 65 years. The median tumor size was 45 mm. Ten patients underwent total mastectomy and one has a simple mastectomy because he was initially metastatic (lungs). Only two patients had positive lymph nodes. Hormonal receptors were positive in five cases.

Four patients were lost of sight during chemotherapy. Five patients completed adjuvant treatment involving local radiation and chemotherapy. Five had hormonal therapy. One patient had a synchrone adenosquamous carcinoma of the papilla of Vater and hepatocellular carcinoma. He was lost of sight after the abdominal surgery.

For the six remaining patients, they had a median follow up of 64 months (range 24 to 150). One developed regional recurrence, three developed metastases and one had adenocarcinoma of the stomach five years after the first cancer.

Conclusion

Papillary carcinomas have an indolent clinical course. The mainstay of treatment in these carcinomas is surgical excision. Furthermore, novel gene panels may serve as a potential decision tool in this rare entity especially in male population.
EXPRESSION DISTRIBUTION OF CANCER STEM CELL MARKER, CD44 WITHIN MOLECULAR SUB TYPES OF BREAST CARCINOMA IN INDIAN PATIENTS

K. Singh¹, M. Jain¹, K. Agarwal¹, O.P. Pathania²
¹Lady Hardinge Medical College, Department of Pathology, New Delhi, India
²Lady Hardinge Medical College, Department of Surgery, New Delhi, India

Aims

To determine cancer stem cell marker, CD44 expression in breast carcinoma and to see the association of CD44 expression with molecular subtypes

Method

N = 60 breast carcinoma patients in the Department of Surgery, LHMC were included between December 2013 till March 2015. Tru-cut biopsy was performed on cytologically proven cases. Immunohistochemistry for ER/PR/Her2/EGFR/Ki67/CK5/CD44 expression was performed.

Results

Mean age of presentation was 48.87±11.43 years. 56/60 (93.33%) were infiltrating duct carcinoma, not otherwise specified. Frequency of molecular subtypes: 13.33% Luminal A, 15.0% Luminal B, 25% Luminal Her2neu, 23.33% Her2neu Classic, 5% Basal phenotype, 18.33% non basal, normal breast like phenotype. Non basal normal breast like phenotype, Basal phenotype and Luminal Her2neu showed statistical significant correlation with age group <50 years (p=0.025). CD44 was positive (>10% positive tumor cells) in 32/60 (53.33%) cases. Significant negative statistical correlation between CD44 positive cases and ER, PR status (p=0.002 and p=0.011 respectively). The mean percentage of Ki67 positive cells in CD44 positive cases was higher (43.34%±27.43) than CD44 negative cases (33.75%±26.34) but was not significant. Significant positive CD44 correlation with Her2neu Classic and normal breast like phenotype subgroup and a significant negative CD44 correlation with Luminal A and Luminal B (p=0.016). No statistical significant correlation when CD44 positive molecular subtypes were scored 1+, 2+ and 3+ (p=0.131)

Conclusion

Higher number of CD44 positive cells in triple negative and Luminal Her2neu cases and lower in luminal subtype emphasize the tumor aggressiveness in Indian patients. CD44 can be used as independent marker and as target for development of novel therapies.
COST-EFFECTIVENESS OF BREAST CANCER SCREENING AND PREVENTION – A SYSTEMATIC REVIEW OF DECISION-ANALYTIC MODELS FOR EUROPEAN SETTINGS

N. Mühlberger1, G. Sroczynski1, A. Gogollari1, B.J. Beate Jahn1, N. Pashayan2, M. Widschwendter3, U. Siebert1,4,5,6
1UMIT - University for Health Sciences- Medical Informatics and Technology- Inst, Institute of Public Health- Medical Decision Making and Health Technology Assessment- Department of Public Health- Health Services Research and Health Technology Assessment, Hall in Tirol, Austria
2UCL - University College London, Faculty of Population Health Sciences, London, United Kingdom
3UCL - University College London, Department of Women’s Cancer, London, United Kingdom
4ONCOTYROL - Center for Personalized Cancer Medicine, Division of Health Technology Assessment and Bioinformatics, Innsbruck, Austria
5Harvard Medical School, Institute for Technology Assessment and Department of Radiology- Massachusetts General Hospital, Boston, USA
6Harvard T.H. Chan School of Public Health, Center for Health Decision Science- Department of Health Policy and Management, Boston, USA

Aims

To review cost-effectiveness studies evaluating primary and secondary prevention strategies for breast cancer in the European health care setting with specific interest on risk-adapted strategies.

Method

Relevant databases (Medline/Embase/Cochrane Library/CRD/EconLit) were systematically searched for decision-analytic modelling studies evaluating the cost-effectiveness of breast cancer screening and/or prevention strategies in the European health care context. Study characteristics, methodological details and results including the incremental cost-effectiveness ratios (ICER) in cost per quality-adjusted life years gained (QALY) or per life year gained (LYG) were extracted into standardized evidence tables. Economic results were converted to 2015 Euros using the GDP-PPP and CPI.

Results

Twenty five studies evaluating breast cancer screening and two studies evaluating breast cancer prevention strategies were included. The studies varied in terms of target population and evaluated strategies, time horizon, discount rate, and perspective. Among the screening studies, only one considered a risk-adapted screening approach. In all studies the ICERs of currently established breast cancer screening strategies, like biennial or triennial mammography screening age 50-70, fall far below 30,000 Euros/QALY or LYG, which is considered to be cost-effective in most European countries. Prevention studies considered women at high risk for breast and ovarian cancer evaluating prophylactic surgery in BRCA mutation carriers or genetic testing in Ashkenazi Jewish women with prophylactic surgery for mutation carriers. Results suggest that prevention in these populations is cost-effective.

Conclusion

Based on the included studies, breast cancer screening and prevention can be considered cost-effective in the European setting. Future research should include risk-adapted screening and prevention strategies.
BREAST CANCER II

ESGO7-0838

REAL-TIME ULTRASOUND ELASTOGRAPHY OF AXILLARY LYMPH NODES IN CLINICALLY NODE NEGATIVE BREAST CANCER

P. Kleditzsch1, T. Reimer1, S. Hartmann1, J. Stubert1, B. Gerber1, A. Stachs1

1Universitätsmedizin, Breast Department, Rostock, Germany

Aims

Axillary lymph node status remains an important prognostic factor in early breast cancer. Ongoing studies i.e. INSEMA trial deal with the question whether sentinel lymph node biopsy (SLNB) can be avoided without reducing oncological safety. The aim of this study was to evaluate real-time ultrasound elastography for prediction of axillary lymph node metastases in patients with planned SLNB.

Method

In this prospective study 97 patients undergoing breast surgery with SLNB were included. Before surgery, all patients underwent axillary ultrasound with measuring of cortical thickness and elastography of axillary lymph nodes using a high end ultrasound device (Philips iU22). Elastographic strain ratio (SR) was determined and results were compared to histological findings of the removed lymph nodes.

Results

Axillary metastases were found in 33 of 97 patients (34%). The stiffness measurements were significantly different between the group of nodal negative and nodal positive patients (SR mean p= 0.016, SR max p=0.009). The areas under the ROC curves were 0.66 (95% confidence interval [CI]: 0.54-0.79) for SR mean, 0.68 (95% CI 0.56-0.80) for SR max and 0.58 (95%CI 0.45-0.72) for cortical thickness, respectively. Sensitivity/specificity/positive predictive value and negative predictive value were 74.1%/50.9%/41.7% and 80.6% for SR max in comparison with subjective axillary ultrasound evaluation, which reached 33.3%, 98.4%, 91.7% and 74.1%.

Conclusion

In a subgroup of patients with low prevalence of lymph node metastases elastographic strain ratio could improve diagnostic performance of axillary ultrasound by increasing sensitivity and negative predictive value. Further studies with higher number of cases are necessary to confirm these promising results.
HOW IMPORTANT ARE TUMOR MARGINS OF THE DUCTAL CARCINOMA IN SITU, AN EARLY FORM OF BREAST CANCER?
FINE-TUNING OF THE VAN NUYS PROGNOSTIC INDEX

A. Van Cleef1,2, A. Sevilay1, M. Huizing1, W. Tjalma1
1Antwerp University Hospital UZA, Oncology, Edegem, Belgium
2University of Antwerp, Medicine and Health Sciences, Antwerp, Belgium

Aims

We investigated whether the Van Nuys Prognostic Index (VPNI), prospectively applied, is a reliable guideline for the treatment of patients with ductal carcinoma in situ (DCIS) in our hospital. Furthermore, we are going to try to refine the VPNI and thus also our policy. We will do this by using the combination of the obtained VPNI and the more specific score of the tumor margins. Our goal is to keep local recurrence rate less than 20% at 12 years.

Method

From 2004 to 2014, 142 patients diagnosed, treated and followed at the University Hospital of Antwerp are included in our analysis. Exclusion criteria are male gender, treatment with chemo- or endocrine therapy and invasive cancer. Kaplan-Meier plots were used to estimate the probability of remaining free of local recurrences. The statistical significance between the survival curves was determined by the log-rank test.

Results

108 patients were treated according to the VPNI. The local recurrences were 6%, 4% and 4% for group 1, 2 and 3, respectively. The local recurrences in the subgroup of patients who score 9, have margins < 1 mm and were treated with excision and radiotherapy was 20%.

Conclusion

With low numbers of local recurrences we can conclude that the VPNI is a reliable guideline for the treatment of patients with pure DCIS. Mastectomy is required for patients who score 9 and have margins < 1 mm and for all patients who score 10, 11, or 12 to keep the local recurrence rate less than 20% at 12 years.
GAIN OF 3q26 AS A PROGNOSTIC BIOMARKER FOR HIGH-GRADE CERVICAL INTRAEPITHELIAL NEOPLASIA

M.M. Koeneman1,2, I.T. Ovestad3, E.A.M. Janssen4, M. Ummelen2,5, R.F.P.M. Kruitwagen1,2, A.H. Hopman2,5, A.J. Kruse1,2

1Maastricht UMC+, Department of Obstetrics and Gynecology, Maastricht, The Netherlands
2Maastricht University, GROW - School for Oncology and Developmental Biology, Maastricht, The Netherlands
3Stavanger University Hospital, Department of Pathology, Stavanger, Norway
4University of Stavanger, Department of Mathematics and Natural Science, Stavanger, Norway
5Maastricht University, Department of Molecular Cell Biology, Maastricht, The Netherlands

Aims

Approximately 20-40% of high-grade cervical intraepithelial neoplasia (CIN) lesions show spontaneous regression. Nonetheless, most high-grade lesions are treated by surgical excision, because the prognosis of an individual lesion is unpredictable. This leads to overtreatment and associated complications. Gain of the 3q26 gene locus, which contains the human telomerase RNA gene, is frequently found in CIN and cervical carcinoma and has prognostic properties in low-grade CIN. The aim of this study is to assess 3q26 gain as a prognostic biomarker in high-grade CIN lesions.

Method

Patients were extracted from a study database, consisting of patients with histologically confirmed high-grade CIN who were conservatively managed for a median period of 16 weeks, after which they underwent loop excision. Punch biopsies taken at baseline were analyzed by fluorescence in situ hybridization to determine the 3q26 gene copy number.

Results

Nineteen women were included in the study (table 1). Mean age and biopsy-cone interval did not differ between patients with and without disease regression. Gain of 3q26 was found in 16 out of 19 patients (table 2). All patients with disease persistence showed gain of 3q26, whereas all patients without 3q26 gain showed disease regression. The positive and negative predictive values of 3q26 gain for disease persistence are 63% and 100%, respectively.

Table 1. Patient characteristics

<table>
<thead>
<tr>

<tr>
<td>Total</td>
<td>19</td>
<td>9</td>
</tr>
</tbody>
</table>

Conclusion

The absence of 3q26 gain may serve as a biomarker for the identification of high-grade CIN with a high probability of disease regression. Additional research in a larger patient population is necessary.
THE CLINICAL UTILITY OF SENTINEL LYMPH NODE MAPPING IN THE CONSERVATIVE MANAGEMENT OF EARLY STAGE CERVICAL CANCER

I. KOUTROUMPA1, N. THOMAKOS1, M. SOTIROPOULOU2, D.E. VLACHOS1, M. LIONTOS3, D. HAIDOPOULOS1, G. VLACHOS1, A. RODOLAKIS1

1University of Athens, 1st Obstetrics & Gynaecology Department- Division of Gyn/Oncology- Alexandra Hospital-, Athens, Greece
2University of Athens, Department of Hystopathology- Alexandra Hospital, Athens, Greece
3University of Athens, Department of Clinical Therapeutics- Alexandra Hospital, Athens, Greece

Aims

Lymph node (LN) metastasis is a critical attribute to prognostic recurrence in cervical cancer (CaCx). Our aim consists of a single algorithm detecting the sentinel lymph nodes (SLNs) and combining SLNs status with individual metastatic factors as an enhancement in the conservative management of early stage CaCx.

Method

Prospective study including patients with CaCx, stage IA1-IB2 (tumour size, TZ 0.5-3cm). Intracervical superficial injection of patent blue, after induction of anaesthesia, detection and removal of dyed LNs, sent for frozen section biopsy, bilateral pelvic lymphadenectomy/radical hysterectomy and correlation with final histopathology.

Results

Fifty five patients were included in our study. At least one SLN (range 0-6) was identified in 87.3% (48/55), whereas bilateral detection was succeeded in 78.2% (43/55). SLNs were located at the external (62.6%) or internal iliac region (11.2%), obturator fossa (16.1%), and ventral to the hypogastric vessels (10.1%), whereas 8.3% found in an unexpected area (parametrium) in certain cases. False negative SLN and micrometastasis was identified in only two cases (TS ≥2.2 cm). Frozen section biopsy was positive in 4 cases (4.3%) and the procedure was aborted. Sentinel lymph node sensitivity in detection of metastasis was 100% for TS < 2.2 cm, LVSI negative and DOI <5 mm. Median follow-up was 18.2 months (range 1-32) and all patients remain without evidence of disease.

Conclusion

Our technique is established as adequate in clinical significance of SLN mapping in early stage cervical cancer and support a more conservative surgery with greater safety in cases with small tumours.
EXPLORING IMMUNE REGULATORY NETWORKS CONTRIBUTING PRECANCER AND EARLY-STAGE CERVICAL CANCER PROGRESSION

O. Kurmyshkina1, P. Kovchur1, L. Schegoleva2, T. Volkova1
1Petrozavodsk State University, Institute of High-Tech Biomedicine, Petrozavodsk, Russia
2Petrozavodsk State University, Institute of Mathematics and Information Technologies, Petrozavodsk, Russia

Aims

Regulatory relationships between diverse types of cells involved in tumor-induced immune reactions are being successfully studied at molecular level using various experimental approaches. In an organism, these simultaneously acting mechanisms form a complex immune regulation network that may differ from experimental systems and thus requires special investigation for each type and stage of cancer. In this sense, cervical cancer-associated alterations in cellular immunity are one of the least understood.

Method

60 women with cervical intraepithelial neoplasia grade 3 or microinvasive cervical carcinoma and 30 healthy women were involved. Multicolor flow cytometry was used to phenotype peripheral blood lymphocytes from controls and patients before any treatment. Mathematical tools were applied to the results to explore putative relationships between functionally different types of circulating lymphocytes.

Results

We analyzed the percentages of several rare but having potent regulatory properties cell populations, specifically CD4 and CD8 regulatory T cells (CD25pos/highCD127dim/negFoxP3pos), regulatory natural killers (CD3negCD16dim/negCD56bright), and CD3bright (including CD56pos) populations, and observed statistically significant expansion of immunosuppressive cell types in cancer patients. Additional evidence of regulatory disbalance came from decreased CD8/CD4CD25FoxP3 T-cell and CD56dim/CD56bright NK-cell ratios. As a direct effect of this disbalance, upregulation of apoptotic markers in circulating T- and NK-cell subsets was evaluated. Another feature of altered activation status of T cell subpopulations was found to be Stimulator of Interferon Genes expression.

Conclusion

Statistical analysis suggested systemic alterations of regulatory networks affecting different immune cell subsets may contribute the earliest stages of cervical cancer progression. The work was supported by the Russian Scientific Foundation (project No.17-15-01024).

ESGO7-0161

RISK SCORING SYSTEM FOR THE PREOPERATIVE ESTIMATION OF PELVIC LYMPH NODE METASTASIS IN PATIENTS WITH FIGO STAGE IA-IIA CERVICAL CANCER

H.J. Lee1, D.Y. Kim2

1Kangwon National University School of Medicine, Department of Obstetrics and Gynecology, Chuncheon-si, Republic of Korea
2University of Ulsan College of Medicine- Asan Medical Center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To develop a risk scoring system (RSS) for preoperative estimating pelvic lymph node (PLN) metastasis in patients with the International Federation of Gynecology and Obstetrics (FIGO) stage IA-IIA cervical cancer.

Method

A total of 255 patients with FIGO stage IA-IIA cervical cancer undergoing hysterectomy and PLN dissection from January 2013 to January 2016 were included retrospectively reviewed. Model-development cohort (n=162) and validation cohort (n=93) were composed according to the date of operation; pre- and post-2015, respectively. Univariate and multivariate analyses of preoperative clinicopathological factors were performed to identify predictors for PLN metastasis, and a RSS was developed and validated.

Results

Multivariate analysis with backward elimination method identified PLN metastasis assessed by 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT, odds ratio [OR] 8.423; 95% confidence interval [CI] 3.295-21.513; P < 0.001) as an independent predictor. And tumor size (OR 1.327; 95% CI 0.992-1.774; P = 0.057) and cervical invasion depth (OR 6.360; 95% CI 0.809-49.989; P = 0.079) appeared to be marginally significant. The concordance indices of the RSS including these three predictors were 0.850 (95% CI 0.788-0.912) in the model-development cohort and 0.749 (95% CI 0.648-0.851) in the validation cohort, respectively. RSS-predicted probabilities of PLN metastasis revealed good agreement with observed probabilities in calibration plots of both datasets.

Conclusion

We developed the RSS for preoperative estimation of PLN metastasis in patients with FIGO stage IA-IIA cervical cancer. After external validation, it could provide valuable information for predicting the risk of PLN metastasis to gynecologic oncologists before surgery.

PREDICTIVE VALUE OF p16/Ki-6DUAL-STAINED CYTOLOGY FOR THE PROGRESSION OF CERVICAL DYSPLASIA

Y.K. Lee1
1Cheil General Hospital, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

The objective of this study was to investigate the predictive value of p16/Ki-67 dual-stained cytology for the progression of disease.

Method

Cytology p16/Ki-67 dual-staining test was performed on 250 liquid-based residual samples from a cohort of women with ASC-US/LSIL and co-testing human papillomavirus (HPV) positive. Study end points were atypical squamous cells-cannot exclude high-grade lesion (ASC-H) or high-grade squamous intraepithelial lesion (HSIL) detection in 1 and 2 year’s follow-up.

Results

Positivity of p16/Ki-67 dual stained cytology was well correlated to progression of disease compared with positivity of HPV 16/18. During 1 year follow-up, 23 of 250 women experienced progression of disease into ASC-H or HSIL. For positivity of p16/Ki-67 dual stained cytology, Sensitivity (60.9%) for the detection of ASC-H or HSIL and specificity (81.5%) for normal or low grade cytology was higher than those of HPV 16/18 tests (13.0% and 89.0%, respectively) (p<0.001). During 2 years follow-up, 11 of 190 women experienced progression of disease into ASC-H or HSIL. For positivity of p16/Ki-67 dual stained cytology, Sensitivity (45.5%) for the detection of ASC-H or HSIL or specificity (82.1%) for normal or low grade cytology was also higher than those of HPV 16/18 tests (18.2% and 89.9%, respectively) (p=0.025).

Conclusion

p16/Ki-67 dual stained cytology could provide both high sensitivity and specificity for the prediction of ASC-H or HSIL in Pap cytology in the future. Positive p16/Ki-67 dual-stained cytology in low grade cytology was highly associated with the progression of disease in 1 or 2 years follow-up.

POSTOPERATIVE CLINICOPATHOLOGICAL FACTORS AFFECTING CERVICAL ADENOCARCINOMA: STAGE I-II B

H. Lou¹, J. Zhou¹
Zhejiang Cancer Hospital, Gynecology oncology, Hangzhou, China

Aims

Currently, cervical adenocarcinoma receives the same, but not suitable, standard treatments as squamous cell carcinoma. The present study was conducted to discriminate the prognostic role of postoperative clinicopathological factors in patients with stage I–II B cervical adenocarcinoma.

Method

All consecutive patients consisted of 312 patients with stage I to IIB cervical adenocarcinoma who underwent radical hysterectomy, including pelvic lymphadenectomy, at our institutions between Oct. 2006 and Sept. 2014. Overall survival and relapse-free survival was analyzed by the Kaplan–Meier method. Sites of recurrence were classified as local and distant locations.

Results

The 5-year OS and RFS rates were 88.2% and 83.8%, respectively. And the 5-year OS rates for patients with FIGO stage IA, IB, IIA, and IIB were 100.0%, 90.7%, 82.8%, and 55.6%, respectively, in adenocarcinoma. Cox model identified No. of positive pelvic nodes and Age at surgery as independent prognostic factors for survival, and No. of positive pelvic nodes and post-operation tumor diameter (4cm) as independent prognostic factors for relapse. 35 women suffered a cancer recurrence. The top three recurrence sites were pelvis, vaginal stump and lung.

Conclusion

A more aggressive therapeutic strategy, which was different from current adopted for cervical cancer, is urgently required for cervical adenocarcinoma. As a new prognostic factor, post-operation tumor diameter should be paid special attention in adenocarcinoma treatment.

COMPARISON BETWEEN ROBOT-ASSISTED AND LAPAROSCOPIC PARA-AORTIC LYMPHADENECTOMY IN 217 PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER

L. Loverix1, R. Salihi2, E. Van Nieuwenhuysen2, N. Concin2, S. Han2, I. Vergote2
1University Hospital Leuven, Gynaecology and Obstetrics, Leuven, Belgium
2University Hospital Leuven, Gynaecological oncology, Leuven, Belgium

Aims

To compare robot-assisted (RPAO) with laparoscopic (LPAO) para-aortic lymphadenectomy in patients with locally advanced cervical cancer (LACC).

Method

In this monocentric retrospective study, we included 217 patients with LACC (FIGO-stage IB2-IVA or IB1 with suspicious pelvic LN), who underwent a para-aortic lymphadenectomy up to the inferior mesenteric artery (LPAO, N=162; RPAO, N=55) between 1994-2016 (RPAO starting from December 2012).

Results

Median age for LPAO and RPAO respectively (53 years vs 49 years), BMI (24.7 vs 24.4) were similar. FIGO-stage for RPAO was IB1, IB2, IIA, IIB, III and IV15%, 6%, 17%, 53%, 9% and 0, and for LPAO5%, 12%, 23%, 44%, 14% and 2%, respectively. In RPAO and LPAO 85% and 83% were squamous carcinomas, respectively. RPAO had a higher ASA-score (ASA2: 62% vs 56% and ASA3: 20% vs 2%, p<0.001) and more prior major abdominal surgery (18% vs 6%, p<0.001), less estimated blood loss (median, 25.0 mL vs 62.5 mL, p<0.001), more removed PAO LNs (11 vs 6, p<0.001) and shorter postoperative stay (1.8 vs 2.5 nights, p<0.002), and a tendency for more patients with metastatic PAO LNs (13% vs 5%, p=0.065), compared with LPAO respectively. There was no difference in complications. Overall survival (OS), progression free survival (PFS) and time-to-progression were similar.

Conclusion

RPAO resulted in less blood loss, shorter postoperative hospitalization, higher amount of sampled PAO LNs and tendency for a higher number of positive PAO LNs compared to LPAO.
PRELIMINARY RESULTS OF EXTENDED FIELD IMRT CHEMO-RADIOThERAPY OR PELVIC IMRT CHEMO-RADIOThERAPY FOLLOWED BY OPERATION IN PATIENTS WITH MULTIPLE PELVIC LYMPH NODE METASTASIS (PHASE II CLINICAL TRIAL)

W. Luo¹, G. Ke², Y. Li³, X. Wu², X. Huang²
¹Minhang Branch of Fudan University Shanghai Cancer Center, Department of Radiation Oncology, Shanghai, China
²Fudan University Shanghai Cancer Center, Department of Gynecologic Oncology, Shanghai, China

Aims

We use prospective randomized method to analysis the response rate and side effect rate of EF-IMRT and pelvic-IMRT combined with cisplatinum chemotherapy in patients with multiple pelvic lymph node metastasis.

Method

From 2012 to 2015, 96 cases enrolled into this study. Median Age was 46 years old. ECOG score was 0-2. FIGO stage was IB1-II A2. Histology included squamous 87 cases, adenocarcinoma 3 cases, squamous-adenocarcinoma 2 cases, low grade 4 cases. No adjuvant chemotherapy was done. All patients underwent radical operation, 20 cases of them were preserved both ovaries, 2 cases were preserved one ovary. Para-aortic LN resection was done in 21 cases, while biopsy was done in one case. The median number of lymph nodes was 26 (11-39). Patients were randomized into two groups: group A (EF-IMRT) or group B (pelvic-IMRT). The tumor dose was 45Gy/1.8-2Gy/25Fx, combined with cisplatinum 40mg/m² weekly for 5 cycles. We used CTCAE3.0 to analysis the side effect.

Results

All the patients fulfilled the whole therapy. 49 cases of them were enrolled into group A and 47 cases into group B. Blood and GI system were mainly side effects. Grade 4 of blood effect occurred only in one case group (A). Grade 1-2 of GI effect occurred in 10 cases (group B) and 20 cases (group A). With regards to acute or late toxicities, no statistically significant difference was observed between the two treatment groups.

Conclusion

Postoperative EF radiotherapy plus concurrent chemotherapy was effective and acceptable for treating patients with FIGO Stage IB1-II A2 cervical cancer displaying multiple pelvic lymph node metastases. This clinical trial is ongoing and long-term follow up is needed.

DIFFERENT OPTIONS OF FERTILITY-SPARING TREATMENT FOR EARLY STAGE CERVICAL CANCER: CASE SERIES

V. Matylevich1, S. Mavrichev1, E. Zavrid2

1NN Alexandrov National Cancer Centre, Gynecologic Oncology Department, MINSK, Belarus
2NN Alexandrov National Cancer Centre, Medical Oncology Department, Minsk, Belarus

Aims

Evaluating the short-term results of fertility-preserving options for early cervical cancer patients in childbearing age.

Method

A total of 46 patients with early cervical cancer were included. The patients were stratified into three groups with regards to the organ-sparing therapy option. Eight women with stage IA1LVSII-IA2 (group 1) underwent ultraconservative surgery: amputation of uterine cervix with lymphadenectomy. Group 2 (31 patients with stage IA2-IB1, tumor size up to 2.0 cm) were subjected to radical abdominal trachelectomy. Seven women of group 3 (four with stage IB1 and tumor size more than 2 cm and three with stage IIA1) received multimodality therapy with neoadjuvant chemotherapy followed by radical abdominal trachelectomy.

Results

The follow-up time was 7 to 62 months. To prevent inflammatory and commissural changes in the small pelvis in the postoperative period, enzymatic drugs containing streptokinase-streptodornase were used. Pregnancy occurred in three women of the 1st group, two of them gave birth of time with no complication, one had a miscarriage at 15 weeks.

Conclusion

Our data suggest that less radical surgery than radical trachelectomy in patients with early low-risk cervical cancer improve the chances of reproductive function implementation; in case of early high-risk cervical cancer, multimodality treatment offers opportunities for radical surgical intervention of the organ-sparing option. However, the application of the mentioned methods of organ-sparing therapy is possible only after a thorough patient selection assessing all the risks in the selling of a highly-specialized cancer institution arranging multidisciplinary panel including an expert morphologist, a trained MRI specialist and qualified gynecologic oncologist.

INCIDENCE OF LYMPH NODE METASTASES IN WOMEN WITH LOW-RISK EARLY CERVICAL CANCER WITHOUT LYMPH-VASCULAR INVASION

L. Minig1, A. Fagotti2, G. Scambia2, G. Salvo3, M.G. Patrono4, C. Zorrero1, D. Haidopoulos5, S. Maria6, I. Zapardiel7, C. Arispe7, D. Santiago8, I. Juárez Pallarés8, G. Chisholm3, P.T. Ramirez3

1Instituto Valenciano de Oncología, Gynecology department, Valencia, Spain
2Catholic University of the Sacred Heart, Department of Women’s and Children’s Health, Rome, Italy
3The University of Texas MD Anderson Cancer Center MDACC, Department of Gynecologic Oncology and Reproductive Medicine, Huston, USA
4Hospital Italiano de Buenos Aires, Gynecology Department, Buenos Aires, Argentina
5Alexandra University Hospital, Gynecology Department, Athens, Greece
6Alexandra University Hospital, Pathology Department, Athens, Greece
7La Paz University Hospital, Gynecological Department, Madrid, Spain
8La Fe Hospital, Gynecology Department, Valencia, Spain

Aims

To determine the incidence of lymph node (LN) metastasis in women with low-risk cervical cancer stage IA2, and IB1 (<2 cm) without lymph-vascular space invasion (LWSI) stratified by histology, depth of stromal invasion and tumor grade.

Method

A multicenter retrospective study was performed in patients who underwent radical or simple hysterectomy, conization, or tracheectomy plus pelvic lymphadenectomy for cervical cancer between January 2000 and June 2016.

Results

A total of 271 patients were included in the study. Mean (SD) age and BMI was 47.3 (12.9) years and 25.4 (5.1) kg/m²; respectively. Twenty-two patients had stage IA2 (8.1%), 247 (91.1%) had stage IB1, and 2 (0.7%) had stage IIA. The median tumor size was 14 (range, 5-20) mm. Tumor grades were 1 (n=63; 23.2%), 2 (n=120; 44.3%), 3 (n=63; 23.2%), and missed (25; 9.2). Mean (SD) depth stromal invasion was 8.1 (4.4) mm. Histology subtypes included squamous (n=171, 63.1%), adenocarcinoma (n=92, 33.9%), and adenosquamous (n=8, 3.0%). Overall incidence of LN metastasis was 2.9%. The incidence of LN involvement in G1, G2 and G3 was 0% (0/63), 5% (2/120) and 3.1% (2/63); respectively. Multivariate analysis did not identify any independent factor predicting LN metastasis.

Conclusion

No patient with G1 (well differentiated) cervical cancer less than 2 cm and without lymph vascular space invasion had lymph node metastasis. In such low-risk patients, there may not be a need for lymph node evaluation. Consideration for sentinel lymph node alone should be a standard in the setting of patients with grade 2 and 3 disease.

ESGO7-1042

PRE-THERAPEUTIC NUTRITIONAL STATUS FOLLOW-UP FOR PREDICTING SEVERE ADVERSE EVENTS IN PATIENTS WITH CERVICAL CANCER TREATED BY CHEMO-RADIOThERAPY

E. Miralpeix1, S. Gayeter2, S.S. Josep Maria2, C. Ramon2, M. Gemma2

1Hospital Del Mar, Obstetrics and gynaecology department, Barcelona, Spain
2, Barcelona, Spain

Aims

Cervical carcinoma remains a significant health problem for women worldwide. Locally advanced cervical cancer (LACC) (stage IB2 to IVA) is a common presentation. Chemo-radiation with a platinum-based agent is the recommended treatment for LACC. Palliation with platinum agent remains the standard of care for inoperable patients who have metastatic or recurrent disease. Malnutrition is common in patients with cervical cancer and it may be related to severe adverse toxicity as a result of radiotherapy. The aim was to investigate nutritional screening factors for severe adverse events.

Method

A retrospective analysis over patients newly diagnosed of cervical cancer from 2015 to 2016 in Hospital del Mar Barcelona was recruited. Patients with locally advanced cervical cancer who underwent chemo-radiotherapy were included to predict severe adverse events. The pre-treatment nutritional parameters evaluated were hemoglobin (Hb), serum albumin (Alb), total protein (Prot), total lymphocyte counts (TLC) and Prognostic Nutritional Index (PNI).

Results

Of 38 patients diagnosed of cervical cancer, 25 were treated by chemo-radiotherapy for LACC and 24 patients were included in the pre-therapeutic nutritional analysis. Approximately 20% of the patients were manourished before treatment. A total of 6 patients (24%) presented severe adverse events according to EORTC definition. The pre-treatment nutritional parameters were not found to be significant predictors of chemo-radiotherapy severe adverse events.

Conclusion

Although nutritional status could be considered a useful predictor for cervical cancer survival; our results suggest that nutritional status not predict severe adverse events in patients underwent chemo-radiotherapy. However more studies are needed to confirm that preliminary results

Volume 27, Supplement 4
THE ADDITIONAL ROLE OF DIFFUSION WEIGHTED MAGNETIC RESONANCE IMAGING FOR THE ASSESSMENT OF PARAMETRIAL INVASION OF CERVICAL CARCINOMA, A PROSPECTIVE STUDY

J. Mongula¹, F. Bakers², C. Mihl², T. van Gorp¹, R. Kruitwagen¹, B. Slangen¹

¹Maastricht University Medical Centre, Gynecologic Oncology, Maastricht, The Netherlands
²Maastricht University Medical Centre, Radiology, Maastricht, The Netherlands

Aims

The treatment of cervical cancer is dependent on FIGO stage, with conventional staging, 15-25% of parametrial invasion is missed. MRI is increasingly used to optimize staging for cervical cancer. This study aimed to evaluate the diagnostic performance of diffusion weighted MRI in addition to conventional T2 weighted sequences and fusion images for the assessment of parametrial invasion.

Method

Prospective cohort study; conventional T2W MRI, the addition of high B-value diffusion weighted MRI sequences and fusion images (T2W with diffusion weighted MRI) for assessing parametrial invasion. Two blinded radiologists independently scored the likelihood of parametrial invasion with a 6-point confidence scale. The reference standard consisted of surgical-pathologic results after radical hysterectomy with pelvic lymphadenectomy. Diagnostic performance was evaluated by ROC curve analyses. P-values <0.05 were considered statistical significant. Ethical board approval was obtained.

Results

The cohort consisted of 65 patients, 8 patients showed parametrial invasion after surgery. Both observers (1-2) showed a statistical increase in diagnostic performance for the assessment of parametrial invasion, especially decreasing false positive findings. The corresponding areas under the ROC curve were .80-.67 for T2W MRI compared to .94-.94 for fusion imaging (p<0.05). Positive predictive value increased significantly 29-23% versus 50-50%. No significant difference was found between T2W imaging and T2W imaging with high B-value sequences without fusion images.

Conclusion

This is the first prospective study showing conventional T2 weighted MRI combined with diffusion weighted MRI to result in an increase in diagnostic performance for the assessment of parametrial invasion in suspected early-stage cervical carcinoma.

DIFFUSION WEIGHTED MAGNETIC RESONANCE IMAGING OF CERVICAL CARCINOMA: APPARENT DIFFUSION COEFFICIENT MEASUREMENT TECHNIQUES RELATED TO PARAMETRICAL INVOLVEMENT AND LYMPH NODE METASTASES

J. Mongula\(^1\), C. Mihl\(^2\), F. Bakers\(^2\), T. van Gorp\(^1\), R. Kruitwagen\(^1\), B. Slangen\(^1\)

\(^1\)Maastricht University Medical Centre, Gynecologic Oncology, Maastricht, The Netherlands
\(^2\)Maastricht University Medical Centre, Radiology, Maastricht, The Netherlands

Aims

Staging of cervical cancer is dependent on FIGO stage, advanced imaging as diffusion weighted MRI is increasingly used to optimize staging for cervical cancer. Apparent Diffusion Coefficient (ADC) is a potential interesting quantitative parameter for assessing tumor aggressiveness. This study aimed to compare different ADC measurement techniques for cervical cancer and to assess mean ADC as a predictor for parametrial involvement and lymph node metastases.

Method

This was an ethical board approved prospective cohort study. Two blinded readers independently scored ADC\(_{\text{mean}}\) within the range of interest (ROI). The ROI was defined as total tumor ADC, single slice freehand ROI or a single round like ROI at the largest tumor diameter. The reference standard consisted of surgical-pathologic results after radical hysterectomy with pelvine lymphadenectomy. Diagnostic performance was evaluated by ROC curve and regression analysis. P-values <0.05 were considered statistically significant.

Results

The cohort consisted of 65 patients, 3 patients were excluded due to unavailability of ADC map. Interrater agreement (preliminary analyses) was excellent for assessing ADC\(_{\text{mean}}\). The predictive value did not significantly differ between the three used measurement techniques. The area under the curve for ADC\(_{\text{mean}}\) for assessing parametrial invasion and lymph node metastases was good-excellent (AUC 0.76-0.84) In our preliminary uni- and multivariate analyses ADC\(_{\text{mean}}\) was superb and independent compared to other predictive criteria (HR: 10.6 (1.2-92)).

Conclusion

The potential of ADC\(_{\text{mean}}\) as an independent parameter for predicting parametrial invasion and lymph node metastases is suggested by our results. The definitive analyses will be available at the ESGO 2017 Meeting.
LOW VALUE OF PET/CT IN PREDICTING TUMOR RESPONSE IN LOCALLY ADVANCED CERVICAL CANCER UNDERGOING NEOADJUVANT CHEMOTHERAPY

Aims

To assess the ability of PET/CT in predicting tumor response to neoadjuvant chemotherapy (NACT) in patients affected by locally advanced cervical cancer (LACC)

Method

This is a prospective study involving LACC patients undergoing NACT plus radical surgery between 2013 and 2016. Data of SUV max detected by PET/CT, at pre- and post-NACT examinations were compared with pathological findings. Concordance was used to assess the ability of PET/CT to predict tumor response.

Results

Overall, 37 patients were included. There were very low concordances between pre- and post-NACT SUV max on cervical tumor with response to chemotherapy (concordance <0.2). Similarly, concordance between pre- and post-NACT SUV max on pelvic lymph nodes was low (concordance < 0.2). Considering the ability of PET/CT in assessing lymphatic disease, we observed that post-NACT PET/CT was characterized by a relative low positive predictive value (0.66) but a high negative predictive value (0.92). One (1/67 negative pelvic sides; 1.5%) false positive result was observed. Five false negative (5/7 positive pelvic sides; 71.4%) results were observed. True positive and true negative accounted for (2/7 positive pelvic side; 28.5%) and (66/67 negative pelvic sides; 98.5%) 

Conclusion

SUV Max is not adequate in predicting tumor response of LACC patients undergoing NACT. A negative PET/CT is likely to correlate with negative nodes; however, the positive predictive value of PET/CT is not adequate. Further tools are needed to better predict response to treatment in LACC
HPV-NEGATIVE CARCINOMA OF THE UTERINE CERVIX: CLINICAL IMPLICATIONS

1Hospital Clínic de Barcelona- IDIBAPS, Department of Gynecology, Oncology Unit, BARCELONA, Spain
2Hospital Clínic de Barcelona- IDIBAPS, Department of Pathology, BARCELONA, Spain

Aims

Almost all studies focus on cervical cancer (CC) found that a small proportion is negative for human papillomavirus (HPV). It has been suggested that HPV-negative CC may represent a biologically distinct subset of tumors carrying a poorer prognosis. However, the significance of HPV-negativity in CC remains unclear. We aimed to provide insight into the differential clinical-pathological characteristics of the unusual HPV-negative CCs.

Method

A cohort of 215 women with CC diagnosed in the Hospital Clinic (Barcelona) from 1999 to 2014 underwent HPV/DNA detection and genotyping using a highly sensitive polymerase chain reaction (PCR): SPF10PCR/DEIA/LiPA25 system and p16INK4a immunostaining. Clinical, histological and immunological characteristics of the cases included were recorded.

Results

21 out of 215 tumors (9.8%) were negative for HPV detection. Nine of them (9/21; 42.9%) showed a negative p16INK4a immunostaining result. These double negative tumors were considered as confirmed HPV-negative CC and all of them were diagnosed at advanced FIGO stage. Within the confirmed HPV-negative CC, 5 were squamous carcinoma, 2 were adenocarcinoma and 2 were neuroendocrine.

Patients with confirmed HPV-negativity had significantly worse disease free survival than women with HPV-positive tumours [47.46 months (95%CI: 8.7-86.22 months) vs. 130 months (95%CI: 116.66-143.33 months); p=0.01] and overall survival (OS) [72.1 months (95%CI 25.44-118.80 months) vs. 151.4 months (95%CI 139.70-163.05 months); p=0.056].

Conclusion

DNA-HPV negative result is an uncommon finding in women with CC, and in almost half of these cases p16INK4a immunostaining shows a positive result. Confirmed HPV-negative CC seems to be associated with advance FIGO stages and worse prognosis.

¹Hospital Clinic de Barcelona- IDIBAPS, Department of Gynecology, Oncology Unit, BARCELONA, Spain
²Hospital Clinic de Barcelona- IDIBAPS, Department of Pathology, BARCELONA, Spain

Aims

It is hypothesized that human papillomavirus (HPV) genotype may have a role in prognosis of patients with uterine cervical cancer (CC). Results of previous studies on this topic are not conclusive. The aim of this study is to analyze whether there are clinical or prognostic differences in women diagnosed of CC depending on the HPV genotype.

Method

Women diagnosed of CC in the Hospital Clinic (Barcelona) from 1999 to 2014 underwent HPV/DNA detection and genotyping using a highly sensitive polymerase chain reaction (PCR): SPF10/DEIA/LiPA 25 system. Within the 215 women eligible, 194 had an HPV-positive CC and were finally included in the study. Clinicopathological features, disease-free survival (DFS) and overall survival (OS) were analyzed using SPSS version 23.

Results

Mean age at diagnosis was 50.52 years. Squamous cell carcinoma was the most frequent histological diagnosis (156/194;80.4%). Advanced FIGO stage was found in 110 (56.7%) cases. HPV-16 was the most frequent genotype (142/194;73.2%) followed by HPV-18 (25/194;12.9%). Multiple infection was observed in 30 women. From them, 12 showed co-infection with HPV-16/18. No differences were observed in terms of DFS and OS according to HPV genotype.

HPV: Human papillomavirus. HR: High risk. OS: Overall Survival. DFS: Disease Free survival. CI: Confidence Interval.

Conclusion

HPV 16 was the most frequent genotype in our series. HPV genotype does not seem to have any impact on prognosis in women with CC.
INVESTIGATION THE FACTORS OF RADIO-RESISTANCE FOR CERVICAL CANCER

M. Nishimura¹, A. Mineda¹, T. Kawakita¹, A. Abe¹, M. Irahara¹
¹Tokushima University, Obstetrics and Gynecology, Tokushima, Japan

Aims

The purpose of this study is to investigating the factors of failure of local control of radiotherapy for cervical cancer

Method

122 cases who received radiotherapy and examined the effect of treatment during 2011-16. Concurrent chemoradiotherapy (CCRT) was done for patients under 80 years old. Weekly cisplatin (40mg/m²) was given before August 2014, and weekly paclitaxel (50mg/m²) and cisplatin (30mg/m²) was given for the patients with non-SCC after September 2014.

Results

Clinical stages are as follows, 1B 14, 2A 5, 2B 47, 3A 2, 3B 28, 4A 5, 4B 21. Histological subtypes are as follows, SCC 97, adenocarcinoma and adenosquamous carcinoma (non-SCC) 19, others 6. Local recurrence rate are as follows 1B 1/14(7%), 2A 0/5(0%), 2B SCC 3/38 (8%), 2B non-SCC 4/8(50%), 3B SCC 3/21 (14%), 3B non-SCC 6/9 (67%). Local recurrence was significantly frequent in non-SCC than SCC of same stage (p<0.01). For the relation with tumor diameter, local recurrence was 5/78(6%) in SCC (<7cm), 6/18 (33%) in SCC (≥7cm), 0/1 in non-SCC (<4cm), 11/19 (58%) in non-SCC (≥4cm). For the relation with treatment period, local recurrence was occurred 11/32 in patients who took 50 days or more for treatment, but 14/92 in patients with completed within 49 days (p<0.05). For the patients received weekly TP, tumor residue was seen in mucinous types of adenocarcinoma.

Conclusion

Improvement of treatment was necessary for large tumor patients (SCC with over 7cm and non-SCC with over 4cm). Management of adverse event is needed to complete the treatment within 49 days.

ESGO7-0438

CYCLES OF CISPLATIN AND ETOPSIDE AFFECT TREATMENT OUTCOMES IN PATIENTS WITH EARLY-STAGE SMALL CELL NEUROENDOCRINE CARCINOMAS OF THE CERVIX

X. Pei

Fudan University Shanghai Cancer Center, Department of Gynecological Oncology, Shanghai, China

Aims

To explore the outcomes and prognostic factors in patients with FIGO stages I-II small cell neuroendocrine carcinoma of the cervix (SCNEC), and to determine the effects of adjuvant treatment on survival after radical surgery.

Method

A single-institution retrospective analysis was carried out in 92 patients receiving radical surgery for SCNEC. All clinico-pathological variables and treatment strategies were reviewed. Kaplan-Meier and Cox regression methods were used for survival analyses.

Results

After a median follow-up of 38 months (23.6-52.4), 43 (46.7%) patients experienced disease recurrence, of which, distant metastases was documented in 35 patients. The 5-year recurrence-free survival (RFS) was 45.2% and the median RFS was 39 months. In multivariate analysis, lymph node metastasis and parametrial extension were confirmed to be independent prognostic factors for disease recurrence. Adjuvant treatment containing etoposide plus platinum (EP) and its analogs for at least 5 cycles (n=39) was associated with improved 5-year RFS compared to other treatments (n=46) (Kaplan-Meier: 67.6% vs 20.9%, p<0.001; Cox regression HR: 3.68, 95% CI, 1.81-7.50, p<0.001). Additional radiotherapy or concurrent chemoradiation failed to validate further improved RFS in patients with EP 5+. It was consistent in subset of patients with high-risk factors (positive lymph node or positive parametrium).

Conclusion

Half of the stages I-II SCNEC patients experienced disease failure within 3 years and distant metastases is an outstanding issue. EP combination therapy for at least 5 cycles is beneficial for long-term recurrence-free survival after radical surgery. Additional radiation therapy seems unnecessary even in patients with high risk factors.
THE VALUE OF PRETREATMENT SERUM PSEUDOCHOLINESTERASE LEVEL AS NOVEL PROGNOSTIC BIOMARKER IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER

N. Poetsch1, A. Sturdza2, S. Aust1, S. Polterauer1, C. Grimm1, R. Schwameis1, H. Koelbl1, A. Reinthaller1, V. Seebacher1

1Medical University of Vienna, Department of Gynaecology and Gynaecologic Oncology- Comprehensive Cancer Center – Gynaecologic Cancer Unit, Vienna, Austria
2Medical University of Vienna, Department of Radiotherapy- Comprehensive Cancer Center – Gynaecologic Cancer Unit, Vienna, Austria

Aims

Deficiency in pseudocholinesterase (PChE), a condition commonly noticed in liver damage, inflammation, and malnutrition, has previously been associated with impaired prognosis in different malignancies, such as oral and upper tract urothelial cancer. The aim of the present study was to investigate the value of pretreatment serum PChE levels as prognostic biomarker in patients with locally advanced cervical cancer (LACC).

Method

Data of a consecutive series of patients with LACC treated with primary (chemo-)radiotherapy between 1998 and 2015 were retrospectively analyzed. Pre-treatment serum PChE levels were correlated with clinico-pathological parameters and response to treatment. Uni- and multivariate survival analyses were performed to assess the association between decreased serum PChE levels and progression-free (PFS), cancer-specific (CSS), and overall survival (OS).

Results

A total of 365 patients could be included into the present analysis. The median (IQR) pretreatment serum PChE level was 6180 (4990 – 7710) IU/l. Median pretreatment serum PChE levels were significantly decreased in patients with lower body mass index, advanced FIGO tumor stage, and disease progression under (chemo-) radiotherapy (p<0.001, p=0.004, p=0.004, respectively). In uni- and multivariate analyses decreased pretreatment serum PChE levels were independently associated with shorter PFS (HR 1.7 [1.2 –2.5]; p= 0.006), CSS (HR 2.0 [1.3 –3.2], p = 0.002), and OS (HR 1.8 [1.3 -2.7]; p= 0.001).

Conclusion

Decreased pretreatment serum PChE level is associated with advanced tumor stage and impaired response to treatment, and serves as independent prognostic biomarker for shorter PFS, CSS and OS in patients with LACC.

ESGO7-0133

TOPOGRAPHIC DIFFERENCES OF THE AUTONOMIC NERVES IN THE POSTERIOR LEAF OF VESICOUTERINE LIGAMENT

P. Radlović1, A. Ćetković1, S. Nikolić1, V. Galogaža1
1Institute for Oncology and Radiology of Serbia, Clinic for Surgical Oncology, Belgrade, Serbia

Aims

The posterior leaf of the vesicouterine ligament (PLVUL) contains autonomic nerve fibers which innervate the bladder. Fujii was described surgical anatomy of PLVUL and emphasized importance of preserving the bladder branch of the inferior hypogastric plexus (IHP) for saving bladder function after radical hysterectomy (RH). In our population, we noticed that the bladder branch of IHP could be divided in two or three branches which also pass through PLVUL. There is one main branch located dorsomedially from the inferior vesical vein (IVV) and one or two small additional branches positioned lateral of the IVV.

Method

In this study, we evaluate the operative findings at 98 cervical cancer patients surgically treated in Institute of Oncology and Radiology of Serbia, from January 2013 till December 2015 using Fujii-Okabayashi technique of nerve-sparing RH. The surgery was performing without magnifying glass and implies complete bilateral dissection and selective resection of PLVUL. In all patients the main bladder branch of IHP was successfully preserved bilaterally.

Results

In the lateral part of PLVUL, before separation of the IVV we noticed at least one small additional nerve branch at 61 patients (62.2%), what was also confirmed on the other side at 52 patients (53.1%). In 15 patients (15.3%) we recognized two additional nerve branches what could be seen bilaterally in 6 of them (6.1%).

Conclusion

Anatomical variation according the number of nerve branches in PLVUL may exist in significant number of patients. Resection of small nerve branches and sparing the main one is the safe method of preserving bladder function.
EVALUATION OF CONIZATION HIGH ASSOCIATED WITH FREE MARGINS FOR MICROINVASIVE CERVICAL CARCINOMA TREATMENT

A.H. Caio¹, J.C. Teixeira¹, L.D.A. Andrade², O.F. Rangel³, M.S.C. Gurgel³, J.F.B. Bragança¹

¹, Campinas, Brazil
², Department of Pathological Anatomy, Campinas, Brazil

Aims

The definitive diagnosis of micro invasion must be obtained by histopathological analysis of cervical conization specimens, either cold knife conization (CKC) or loop electrosurgical excision procedure (LEEP). The aim of this study is to evaluate the clinical and pathological factors related to free margins in women with cervical microinvasive carcinoma submitted a conization.

Method

603 patients diagnosed and treated for squamous cervix microinvasive carcinoma, FIGO stage IA1 and IA2 (MIC), from 1975 to 2013 were included. CKC was performed in 333 patients (55.2%) and 270 (44.8%) LEEP.

Results

The analysis of surgical resection margins showed 489 (81.1%) free ectocervical margins and 331 (54.8%) endocervical margins. Univariate analysis showed that conization height, age ≥40yr (OR=2.55, p<0.001), LEEP (OR=1.75, p<0.001) and micro invasion depth > 3mm (OR=3.74, p=0.006) were associated with conization margins involvement. Multivariate analysis showed: conization height, age ≥40yr (OR=3.47, p<0.001), LEEP (OR=1.99, p<0.001) and micro invasion depth > 3mm (OR=3.99, p=0.007), were independent risk factors for conization margins involvement. Higher proportion of positive conization margins was observed in women who underwent LEEP, when compared to CKC (p<0.001). Specimens from CKC were larger than in LEEP (p<0.001) for all patients.

Conclusion

Free conization margins was statistically associated with conization depth bigger than 18.9 mm in women < 40yr and 20.6mm in women ≥ 40 yr, (p<0.001). ROC curve for the prediction of free conization margins by conization height, was 0.664 (p<0.001). Conization height with best performance was 19.5mm.

IS NODAL RECURRENCE INCREASED AFTER SENTINEL LYMPH NODE BIOPSY IN PATIENTS WITH EARLY-STAGE CERVICAL CANCER?

A. Rodríguez-Trujillo1, B. Gil-Ibañez1, S. Escura1, P. Fusté1, M. del Pino1, J. Pahisa1, M. Munmany1, I. Nicolás1, A. Glickman1, A. Torné1

1Hospital Cínic de Barcelona, Gynecology, Barcelona, Spain

Aims

To describe recurrences in women with early-stage cervical cancer with negative nodes who were primarily treated by radical surgery and pelvic bilateral lymphadenectomy (LDN) or only sentinel lymph node biopsy (SLNB).

Method

A total of 134 patients with FIGO stage IA1-IB1/IIA1 cervical cancer were treated in our hospital. Of them, 121 had negatives nodes (73 LDN and 45 SLNB). From February 2001 until May 2011 patients underwent SLNB followed by complete pelvic LDN as part of their primary treatment. Between 06/2011 and 10/2016, patients underwent only SLNB. The SLNB was achieved by laparoscopic approach after intracervical injection with radiocolloid and blue dye. Patients in whom sentinel lymph nodes were detected unilaterally or non-detected underwent a complete lymphadenectomy of the failed mapped side. SLN were evaluated by pathologic ultrastaging. Follow-up data were prospectively recorded. SPSS 20.0 was used for statistical analysis.

Results

No differences regarding age at diagnosis, size of the tumor (≤ 2cm vs. > 2cm), FIGO stage, histology type and type of surgery were seen between both groups. In both groups the pattern of recurrence and metastases was similar. Ten patients recurred, 3 patients in the SLNB group and 7 in the LDN group. After SLNB there were 1 nodal recurrence, 1 loco-regional recurrence and 1 distant metastasis. After LDN, 3 nodal recurrences, 3 loco-regional recurrences and 1 metastasis were diagnosed. These differences were not statistically significant.

Conclusion

The rate of nodal recurrence was not increased after SLNB in early-stage cervical cancer
IS THE ONCOLOGIC OUTCOMES OF CERVICAL CANCER PATIENTS WHO UNDERWENT SIMPLE HYSTERECTOMY WORSE THAN THOSE OF PATIENTS WHO DIAGNOSED AND SURGERY PROPERLY?

Ruengkhachorn¹, N. Phithakwatchara², K. Nawapun², S. Hanamornroongruang³, B. Viriyapak¹

¹Faculty of Medicine Siriraj Hospital- Mahidol University, Division of Gynecologic Oncology- Department of Obstetrics & Gynecology, Bangkok, Thailand
²Faculty of Medicine Siriraj Hospital- Mahidol University, Division of Maternal-Fetal Medicine- Department of Obstetrics & Gynecology, Bangkok, Thailand
³Faculty of Medicine Siriraj Hospital- Mahidol University, Department of Pathology, Bangkok, Thailand

Aims

To evaluate clinical characteristics, causes, and survival outcomes of cervical cancer patients who underwent simple hysterectomy.

Method

Medical records of patients who underwent surgical treatment for presumed leiomyomas, from January 2006 to December 2014, were retrospectively reviewed. Clinical characteristics, subsequent treatment, and outcomes were analyzed by descriptive statistics. This study includes follow-up data through December 31, 2016.

Results

A total of 565 medical records of cervical cancer patients who underwent primary surgery. Of which 52 patients (9.2%) were inadvertent hysterectomy. Comparable with FIGO stage IA2, IB1, IB2 and IVB in 3, 44, 3, and 2 patients, respectively. Histopathology was classified as squamous cell carcinoma in 29 patients, adenocarcinoma in 21 patients, endometrioid carcinoma in 1 patient, and neuroendocrine types in 1 patient. Median age was 48.0 years (IQR 42.0-56.0 years). Causes of inadvertent hysterectomy were represent in Table 1. 9/52 patients were refused further treatment. Forty-three patients were prescribed the following treatment: radiation in 39 patients, surgery in 1 patient, and chemotherapy in 1 patient, and 2 patients were appropriate for long term surveillance. The median time before definite treatment was 1.6 months (IQR 0.5-9.2 months). 42/43 patients had complete response and one patient was disease progression. Two patients had recurrent disease and none patients died of their disease. The median overall survival (OS) was 58.5 months (IQR 7.2-114.4 months).

Conclusion

9.2% of cervical cancer patients were inadvertent hysterectomy. Treatment outcome was favorable with almost 4.6% of recurrence rate, and median OS was nearly 5 years.
EVALUATION OF THE EFFECT OF HUMAN PAPILLOMA VIRUS (HPV) POSITIVITY ON PATIENT ANXIETY

G. Sahin1, T.T. Ilhan2, S. Akar1, A. Gül1, Ç. Celik1, O. SECİLMİS KERIMOGLU1
1SELÇUK UNIVERSITY, gynecologic oncology, KONYA, Turkey
2MERSİN RESEARCH AND TRAINİNG HOSPİTAL, Gynecologic oncology, Mersin, Turkey

Aims

It is known the relationship between Human papilloma virus (HPV) and cervical cancer. HPV screening is used for screening of cervical cancer and preinvasive lesions. The aim of this study was to evaluate the effect of HPV positivity on patient anxiety.

Method

This study was carried out at the Selcuk University Medical Faculty, Gynecology and Obstetrics Department. 300 patients were included in this study. Patients divided into the two groups, 150 patients were HPV positive group and 150 patients were HPV negative group as a control group. The patients were filled with an immediate and continuous anxiety scale questionnaire (STAI FORM-1 and STAI FORM-2). The results were assessed statistically.

Results

The mean age of HPV positive group was 42.2 years and the HPV negative group was 45.3 years. 68 patients were HPV 16-18, 82 patients HPV others in the HPV positive group. The HPV positive group had higher anxiety level than the HPV negative group. There was statistically significant difference in the comparison of the immediate anxiety scale questionnaire (51.27± 5.4 and 45.31± 4.2, p< 0.05).

Conclusion

The immediate and continuous anxiety scale levels of patients with HPV screening positive were detected high compared to HPV negative patients. Patients should be informed before and after screening to reduce anxiety.

COMPARISON OF THE EFFECT OF HUMAN PAPILLOMA VIRUS (HPV) SCREENING ON PATIENT ANXIETY WITH CONVENTIONAL METHODS

T.T. Ilhan¹, G. Sahin², S. Akar², A. Guf², C. Celik², M.G. UCAR²

¹Mersin Research and Training Hospital, gynecologic oncology, MERSIN, Turkey
²Selcuk Univercity Medical Faculty, Gynecologic Oncology, KONYA, Turkey

Aims

After identification of the relationship between Human papilloma virus (HPV) and cervical cancer, screening and treatment methods for sexually transmitted disease have been identified. HPV screening is used for screening of cervical cancer and preinvasive lesions. The purpose of this study was to compare the effectiveness of this screening method on patient anxiety with the conventional methods.

Method

This study was carried out at the Selcuk University Medical Faculty and Mersin Research and Training Hospital. The HPV group consisted of 255 patients who were referred to the outpatient clinic for HPV screening test and the Smear group included 250 patients who were referred to the outpatient clinic as a result of Smear scan. A total of 505 patients were included in this study. Before treatment, the patients were filled with an immediate and continuous anxiety scale questionnaire. The results were evaluated statistically.

Results

The mean age of HPV group was 45.3 years and the smear group was 47 years. 75 patients were HPV 16-18, 180 patients HPV others in the HPV group. 115 patients were ASCUS, 35 patients ASC-H, 75 patients were LGSIL, 25 patients were HGSIL in the smear group. The HPV group had significantly higher anxiety level (57.9±6.1 and 36.1±4.2, p< 0.001). There was no statistically significant difference in anxiety level among the HPV subgroups.

Conclusion

The anxiety levels of the patients with HPV results were higher than smear group. There was no difference in the subgroup comparisons made by the type of HPV-detected patients.
SENTINEL NODE MAPPING WITH FLUORESCENCE INDOCYANINE GREEN IS PROMISING IN 94 PATIENTS WITH CERVICAL OR ENDOMETRIAL CARCINOMA

R. Salihi, E. Van Nieuwenhuysen, K. Leunen, N. Concin, I. Vergote

UZ Leuven, Leuven, Belgium

Aims

Retrospective study on sentinel lymph node (SLN) mapping with fluorescence indocyanine green (ICG) in early stage cervical (CC) and endometrial cancer (EC), using robot-assisted minimal invasive endoscopy.

Method

We included all patients who underwent SLN mapping by ICG and fluorescence imaging from 12/2014, to 03/2017. Ninety-four patients were analysed, 50 with EC (47pts FIGO-stage I and 3pts FIGO-stage II) and 44 with CC. Eighteen patients with EC and all patients but two with CC underwent a complete pelvic lymphadenectomy. In all cases, we injected 1mL of diluted ICG(2mg) into the 4 quadrants of the cervical stroma. In CC the injection was submucosal, in EC it was given 1cm deep in the cervical stroma. All SLNs were ultra-staged on final pathology.

Results

Twenty CC patients(45%) underwent neoadjuvant chemotherapy (NACT) (19 Ib2-IIB and 1 Ib1). Excluding NACT CC patients (2 IA2(5%) and 22 Ib1(50%)), 92% had bilateral mapping and 8% unilateral. NACT CC resulted in a worse SLN detection (bilateral:60%, unilateral:20%). Eight EC patients had a too deep (intrapertoneal) IGC-injection (N=6) or had fibrosis due to previous surgery(N=3). Excluding them, bilateral mapping was observed in 33(81%), unilateral in 4(10%) and no sentinel in 3 cases(7%). 12 positive sentinels were found (CC:9, EC:3). Only one patient, with a clinical stage II carcinosarcoma of the endometrium, had a false negative SN node. No recurrences in the pelvic lymph nodes were observed.

Conclusion

Fluorescence imaging with ICG using the robotic approach shows promising results in cervical and endometrial cancer. NACT seems to decrease the reliability of the technique.

COMMON AORTIC AND OBTURATOR LYMPH NODE METASTASES MAY PREDICT PARAORTIC NODE INVOLVEMENT IN CERVICAL CARCINOMA

I. Selcuk¹, E. Sari¹, Z.F. Cuylan¹, N. Cetinkaya¹, T. Gungor¹, M.M. Meydanli¹
¹Zekai Tahir Burak Women's Health Education and Research Hospital, Gynaecologic Oncology, Ankara, Turkey

Aims

To evaluate the risk factors associated with paraaortic lymph node metastasis in cervical carcinoma patients.

Method

A total of 205 consecutive cervical carcinoma patients with a histopathologic diagnosis of squamous cell or adenocarcinoma or adenocarcinoma were analysed retrospectively at Zekai Tahir Burak Women's Health Education and Research Hospital. Type 3 hysterectomy and bilateral pelvic paraaortic lymphadenectomy was the standard surgical procedure. Pathologic characteristics that were revealed with final pathology reports were analysed within univariate and multivariate analysis.

Results

Median age of the patients was 52.5 and most of the patients were having a squamous cell carcinoma (n=161, 78.5%). Median tumor diameter, pelvic and paraaortic lymph node counts were 3.5cm, 39 and 14 respectively. Paraortic lymph node metastasis was detected in 15 (7.3%) patients. In univariate analysis paraaortic lymph node metastasis was significantly related with parametrial involvement, lymphovascular space invasion and pericervical, obturator, external iliac, presacral and common aortic lymph node involvement (p<0.05). However multivariate logistic regression analysis showed that common iliac (p=0.003 OR:1.61, 95% CI:2.59-10) and obturator (p=0.021 OR:1.51, 95% CI:1.49-14) lymph node metastases were the only significant parameters of paraaortic lymph node involvement.

Conclusion

Common iliac and obturator lymph nodes may be used for the prediction of paraaortic lymph node metastasis during surgery for cervical carcinoma.
PTEN DOWN REGULATION INDUCE APOPTOSIS AND CELL CYCLE ARREST BY AN ACTIVATION OF P53 IN UTERINE CERVICAL CANCER CELL.

J.W. Shin

1Gachon University Gil Medical Center, Obstetrics and gynecology, Incheon, Republic of Korea

Aims

PTEN and p53 are known as tumor suppressor proteins that are frequently mutated or down regulated in various human cancers. Down regulation of PTEN, however, may induce anti proliferative effect via p53 activation.

The authors investigate the proliferation and apoptosis of cancer cells after down regulation of PTEN in cervical cancer cell.

Method

Cervical cancer cells, HeLa and CaSki, were cultured with 10% FBS in culture medium. Before starting each experiment, the cells were cultured for 48 hours as fasting state for cell cycle synchronization. The siRNA for PTEN and control were constructed and transfected with Lipofectamine. The experiments were FACS for investigating cell cycles, Western blot for proteins analysis, and MTT assay for cell proliferation.

Results

Apoptosis cell portion was significantly increased(p<0.001) and S1 phase cell portion was significantly decreased in PTEN down regulated cells(p<0.001) on FACS analysis. Expression of p53, p27, p21, p-ERK, and cleaved Caspase 3 were increased and expression of cyclin A2 and cyclin D1 decreased in PTEN down regulated cells on western blots. Cell viability was significantly lower in PTEN down regulated cells than control(p=0.002) on MTT assay.

Conclusion

Down regulation of PTEN induce apoptosis and block G1/S shifting of cell cycle in cervical cancer cell and could be a new strategy for cervical cancer treatment.

PROGNOSTIC EVALUATION OF NERVE-SPARING RADIAL HYSTERECTOMY IN TREATING LOCALLY ADVANCED CERVICAL CANCER

T. Shu, 1 Y. Wang, 1 S. Liu, 1 D. Zhao, 1 P. Li, 1 B. Li 1

1National Cancer Center/Cancer Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Gynecological Oncology, Beijing, China

Aims

The study aimed to evaluate clinical security and prognosis of nerve-sparing radical hysterectomy (NSRH) for locally advanced cervical cancer (LACC).

Method

A retrospective cohort analysis was conducted in National Cancer Center of China. Patients with LACC (stage in Ib2 or Iia2) were recruited from Jan.1, 2008 to Dec.31, 2014. Of all the patients, 69 cases underwent NSRH, while other 320 cases underwent conventional radical hysterectomy (RH). Clinical-pathological characteristics and operative parameters as well as bladder function were compared. After median 67 months’ follow-up, PFS and OS were evaluated.

Results

Basic information on two groups were matched. Multivariate analysis showed that lymph-vascular space invasion (LVSI) (P<0.001) and SCC level at diagnosis (P<0.01) were independent prognostic factors of PFS. Moreover, LVSI (P<0.001), SCC level (P<0.05) and efficacy evaluation of neoadjuvant therapy (P<0.05) were independent prognostic factors of OS. Compared to RH, patients who underwent NSRH presented less blood loss (366ml vs. 457ml, P<0.05), shorter urethral catheterization time (11.0 days vs. 15.5 days, P<0.01) and lower proportion of bladder dysfunction (6.1% vs. 16.3%, P<0.05). For patients in need of adjuvant radiotherapy, there was no superiority to the recovery of bladder function 1 year after NSRH (P=0.311).

Conclusion

NSRH is safe and feasible for patients with LACC. More importantly, compared with RH, NSRH not only demonstrated similar prognosis, but also improve operation quality as well as bladder function for patients with LACC. However, there is limited benefit at the recovery of bladder function for patients who underwent NSRH followed by pelvic radiotherapy.

ESGO7-0177

THE ROLE OF HPV TESTING WITH HPV16/18 GENOTYPING IN FOLLOW-UP OF CERVICAL CANCERS STAGES IA2-IIA2

J. Slama1, D. Cibula1, D. Fischerova1, A. Germanova1, M. Zikan1, R. Kocian1, F. Fruhauf1
1General University Hospital and First Faculty of Medicine - Charles University, Gynecologic Oncology Center, Prague, Czech Republic

Aims

The aim of our study was to evaluate the role of HPV testing with HPV 16/18 genotyping for detection of local recurrence in patients who underwent surgical treatment for cervical cancers in stages IA2-IIA2.

Method

Patients underwent primary surgical treatment including radical or simple hysterectomy or fertility sparing procedure (trachelectomy or conization) and pelvic lymphadenectomy with sentinel lymph node biopsy. Adjuvant chemoradiotherapy was administered in patients with positive nodes. All women were followed in 3 months interval for the first 2 years and then semiannually. HPV tests (Cobas, Roche) were collected between 6-12 month of follow-up.

Results

Altogether 108 patients were included (IA2 - 20, IB1 - 80, IB2 - 7, IIA1 - 1), from them 51 underwent radical hysterectomy, 14 simple hysterectomy and 43 fertility sparing surgery (FSS). Four patients had subsequent adjuvant chemoradiotherapy. In 11 patients HPV test was positive. Disease recurred in vagina or cervix in 10 patients with 9 recurrences in patients after FSS. Six of them were HPV 16/18 positive. The rest 4 recurrences were detected within 6 months after the treatment before HPV testing.

Conclusion

Local recurrences were detected predominantly in patients after FSS. Nearly half of recurrences were detected before HPV test collecting. No case of recurrence were detected within HPV negative women.
IMPACT OF EXTENDED FIELD IRRADIATION ON ACUTE HEMATOLOGICAL TOXICITY IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER UNDERGOING RADIOCHEMOTHERAPY USING VOLUMETRIC MODULATED ARC THERAPY

S. Smet1,2, K. Johnson3, M. Buschmann4, E. Umbrarescu4, Y. Seppenwoolde1, M. Schmid1, A. Sturdza1
1Medical University of Vienna- Comprehensive Cancer Center, Department of Radiation Oncology, Vienna, Austria
2University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium
3University of Manitoba, CancerCareManitoba Radiation Oncology, Winnipeg- Manitoba, Canada
4Hospital Santa Creu i Sant Pau, Department of Radiation Oncology, Barcelona, Spain

Aims

To evaluate the impact of para-aortic (PA) irradiation on acute hematological toxicity (HT), overall treatment time (OTT) and number of chemotherapy cycles in patients with locally advanced cervical cancer (LACC) undergoing concurrent radiochemotherapy using volumetric modulated arc therapy (VMAT).

Method

We analyzed 54 consecutive patients (Jan 2015 – March 2017) undergoing primary radiochemotherapy with weekly Cisplatin 40mg/m². Based on nodal involvement, irradiation fields included pelvic nodal irradiation in 29 patients and pelvic + PA nodal irradiation in 25 patients. Impact of PA irradiation was evaluated on HT, OTT and missed chemotherapy cycles. HT was assessed using the common terminology criteria for adverse events v.4.0. Dosimetric parameters (V10Gy, V20Gy, V30Gy, V40Gy, mean dose) were calculated for pelvic and lumbar bone marrow, which were contoured for each patient.

Results

Grade 3 leucopenia was observed in 20% vs 21% (with vs without PA irradiation), grade 2 in 36% vs 34%, and grade 1 in 32% vs 34%. Grade 3 anemia was not observed, grade 2 in 56% vs 37%, and grade 1 in 40% vs 41%. Bone marrow doses were acceptable, irrespective of field borders. For all but 1 patient, OTT of 50 days was respected. 75% got 4 to 5 chemotherapy cycles. There was no significant difference in HT (p=0.76), OTT (p=0.76), or chemotherapy cycles (p=0.45) among irradiation fields using linear mixed models.

Conclusion

PA irradiation using VMAT for LACC results in acceptable bone marrow doses, does not lead to increased HT, respects OTT and enables high compliance to concurrent chemotherapy.

PATHOLOGICAL ULTRASTAGING OF SENTINEL AND NON-SENTINEL LYMPH NODES CAUSES STAGE MIGRATION IN EARLY STAGE CERVICAL CANCER

M. Śniadecki1, S. Wojtylak2, E. Wycinka3, S. Sawicki1, M. Liro1, J. Kobierski2, N. Śniadecka4, D. Wydra1

1Medical University of Gdańsk, Gynecology- Gynecologic Oncology and Gynecologic Endocrinology, Gdańsk, Poland
2Medical University of Gdańsk, Patomorphology, Gdańsk, Poland
3University of Gdańsk- Faculty of Management, Statistics, Sopot, Poland
4Gdansk University of Technology- Faculty of Chemistry, Chemical Technology, Gdansk, Poland

Aims

The aims of study were to assess the impact of pathological ultrastaging (PU) processing on postoperative staging (TNM system) and to assess influence of PU on prognosis of patients with early stage cervical cancer according to International Federation of Gynecology and Obstetrics (FIGO) classification (IA2-IB1).

Method

In the study group (n1=27 patients) at least one sentinel lymph node (SLN)/patient was detected with blue dye. All extracted LNs in this group were subjected to PU (4 µm slices/150 µm intervals) with hematoxylin-eosin staining and immunohistochemistry (AE1-AE3 antibodies). Control group (n2=27 patients) had no SLN concept used nor PU. All patients underwent radical hysterectomy and systemic lymphadenectomy. Effect of PU in “n1” group was expressed as (pu)TNM and compared to FIGO classification. Disease-free (DFS) and overall survival (OS) were calculated for PU LN-event (isolated tumor cells, ITC, micrometastases, MICs, or macrometastases, MACs), PU LN-non-event and “n2” groups in median time of 4.2 years.

Results

Five-hundred-sixteen LNs were extracted (66 SLNs, 36% bilaterally). MIC or ITC were detected in 34 of 482 LNs (7.1%). False negative rate was 11.2%. PU revealed 5 cases of inconsistency between FIGO and (pu)TNM. Both N and M features were changed in two separate cases (from pN0 to puN1 - detection of MIC in pelvic nSLN, and pMx to puM1 - MIC in para-aortic nSLN). No differences in DFS and OS were found for any of the groups.

Conclusion

Underestimation of stage (staging bias) by FIGO classification in early stage cervical cancer, disclosed in PU, has no predictive nor prognostic significance.
SENTINEL LYMPH NODE DETECTION IN A SOUTH AFRICAN CERVICAL CANCER POPULATION

L. Snyman¹, G. Lindeque²

¹University of Pretoria, Gynaecologic Oncology Unit- Department Obstetrics & Gynaecology, Pretoria, South Africa
²University of Pretoria, Gynaecologic Oncology Unit- Department Obstetrics & Gynaecology, Pretoria, South Africa

Aims

To determine the detection rate, bilateral detection rate, sensitivity, specificity, positive and negative predictive values of sentinel lymph nodes in cervical cancer, with sub-group analysis to identify characteristics impacting on detection rates.

Method

Seventy-eight women were recruited. Methylene blue, Ninety-nine Technesium nanocolloid and indocyanine green were used to detect SLNs. Standard full pelvic lymphadenectomy was performed on all and ultrastaging on SLN negative women.

Results

Data of 72 women were available for analysis with 65% HIV positive. The mean age was 47.2 years; HIV-negative women 52.8 years compared to 44.2 years for HIV-positive women (p<0.0001). The mean BMI was 27.5 kg/m² (SD 5.41). The mean tumour diameter was 24 mm. Forty-eight patients (66.67%) were stage IB1 and 11 (15.3%) were IB2. Eighteen patients (25%) had pelvic lymph node metastases. The mean pelvic lymph node count was 25.16.

The SLN detection rate was 65.3% and the bilateral detection rate was 30.5%. The SLN detection rate in HIV positive was 68% and 60% in HIV negative women (p = 0.49). The sensitivity, specificity, positive and negative predictive values were 85.7%, 100%, 100% and 98.33% respectively.

Detection rates in women with tumour size < 2cm, early stage, node negative and BMI < 25 kg/m² were 77.1%, 74.5%, 72.2% and 77.7% respectively.

Conclusion

This is the first SLN study in African cervical cancer women of which large proportion had HIV infection. The SLN detection rate is much lower in this group compared to the published literature. Sensitivity, specificity, PPV, and NPV are comparable to the published literature.

NATIONWIDE CERVICAL CANCER SCREENING IN KOREA: DATA FROM THE NATIONAL HEALTH INSURANCE SERVICE CANCER SCREENING PROGRAM AND NATIONAL CANCER SCREENING PROGRAM, 2009–2014

J.H. Suh1, S.H. Chae2, S.H. Shim2, H. Kim3, S.J. Lee2, S.N. Kim2, K. Lee1, S. Chang1

1Kun-kuk univ. medical center, Obstetric and gynecology, Seoul, Republic of Korea
2Konkuk university medical center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
3Konkuk University School of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea

Aims

We sought to determine rates of participation and of abnormal results in the Korean nationwide cervical cancer screening.

Method

Using the database of the National Health Insurance Service, participation rates and abnormal result rates in the cervical cancer screening test were determined during the study period (2009–2014).

Results

The participation rate increased from 41.10% in 2009 to 51.52% in 2014 (APC = 4.126%; 95% CI = 2.253–6.034). During the study period, women aged ≥70 years showed the lowest rate (ranging from 21.7 to 31.9%) and those aged 30–39 years showed the second-lowest (ranging from 27.7 to 44.9%). The participation rates of National Health Insurance beneficiaries (ranging from 48.6 to 52.5%) were higher than those of Medical Aid Program (MAP) recipients (ranging from 29.6 to 33.2%). Abnormal result rates were 0.65% in 2009 and 0.52% in 2014, with a decreasing tendency in all age groups except the youngest group (30–39 years). In every year, abnormal result rates tended to decline from the group aged 30–39 years to the group aged 60–69 years, but rose again in those >70 years old. The ratio of ASC-US to SIL increased from 2.71 in 2009 to 4.91 in 2014.

Conclusion

Differences were found in participation rates and abnormal result rates by age and over time. Further efforts are needed to encourage participation in cervical cancer screening, especially for MAP recipients and elderly women and women aged 30–39 years. Additionally, quality control measures for cervical cancer screening programs should be enforced consistently.

CHARACTERISTIC FINDINGS OF HIGH-GR ADE CERVICAL INTRAEPITHELIAL NEOPLASIA OR MORE ON MAGNIFYING ENDSCOPY WITH NARROW BAND IMAGING

Y. Takahashi1, K. Uchita2, A. Kawada2, K. Hirano1, H. Kobara2, N. Nishiyma3, K. Kanenishi4
1Kochi Red Cross Hospital, Department of Obstetrics and Gynecology, Kochi shi, Japan
2Kochi Red Cross Hospital, Department of Gastroenterology, Kochi shi, Japan
3Kagawa University- Faculty of Medicine, Department of Gastroenterology, Takamatsu shi, Japan
4Kagawa University- Faculty of Medicine, Department of Gynecology, Takamatsu shi, Japan

Aims

Colposcopy, which is a standard modality for diagnosing cervical intraepithelial neoplasia (CIN), can have limited accuracy due to poor visibility. Currently, magnifying endoscopy with narrow band imaging (ME-NBI) has excellent diagnostic accuracy for early gastrointestinal neoplasms and is expected to be highly useful for CIN diagnosis. This study aimed to determine the characteristic findings and evaluate the diagnostic ability of ME-NBI using gastroscopy for lesions ≥ CIN 3.

Method

A total of 24 patients who underwent cervical conization with a preoperative diagnosis of high-grade squamous cell intraepithelial lesions (HSILs) or lesions ≥ CIN 3 were enrolled. Prior to conization, still images and video of ME-NBI were captured to investigate the cervical lesions. The images were retrospectively reviewed based on histological examination of the resected specimens. The NBI-ME images revealed the following abnormal findings: (1) light white epithelium (l-WE), (2) heavy white epithelium (h-WE), and (3) atypical intraepithelial papillary capillary loop (IPCL).

Results

Pathological examination of the resected specimens confirmed cervical lesions ≥ CIN 3 in 21 patients. The ME-NBI findings were classified into four groups, l-WE, l-WE with atypical IPCL, h-WE, and h-WE with atypical IPCL, at rates of 0%, 23.8%, 9.5%, and 66.7%, respectively. Additionally, all 3 patients with MIC showed strongly irregular IPCLs.

Conclusion

The detection of h-WE or l/h-WE with atypical micro-vessels using ME-NBI can be indicative for diagnosing lesions ≥ CIN 3. This study indicates that ME-NBI may have novel value for CIN diagnosis.

IMMUNE CHECKPOINT SYSTEM FOR EARLY STAGE CERVICAL CANCER WITH HIGH-RISK FACTORS
M. Takekuma1, O. Takuma2, A. Masato2, M. Ayako1, Y. Emi1, K. Yuka1, K. Nobuhiro1, T. Nobutaka1, A. Masakazu1, H. Yasuyuki1
1Shizuoka Cancer Center, Gynecology, Shizuoka, Japan
2Shizuoka Cancer Center, Pathology, Shizuoka, Japan

Aims

The aim of this study was to evaluate the relationship between the expression of PD-L1 and survival in early stage cervical cancer with high-risk factors.

Method

Patients with high-risk factors of recurrence due to pathologically confirmed parametrial invasion and/or pelvic lymph node metastasis from 2002 to 2012 were included. Formalin-fixed, paraffin-embedded material of each patient was obtained through extraction after radical hysterectomy. Standard immunohistochemical staining was done using PD-L1 antibody. We also tested each tissue specimen for PD1 to evaluate the status of tumor-infiltrating lymphocytes (TILs). At least 1% of tumor cells expressing PD-L1 was defined as PD-L1(+). 50% or more TILs expressing PD1 was defined as high-PD1, less than 50% TILs expressing PD1 was defined as low-PD1, and no TILs expressing PD1 was defined as non-PD1.

Results

In total, 96 patients were enrolled. Patients with PD-L1(+) numbered 29 (30.2%), in which 12 (12.5%) had at least 50% of tumor cells expressing PD-L1. Patients with high-PD1 numbered 16 (16.7%). There were significantly more PD-L1(+) patients than PD-L1(-) patients with high PD1 (41.4% vs 6.0%, p=0.001). The 5-year progression free survival (PFS) rate of all patients in this study was 70.0%. The 5-year PFS rate of high-PD1 was higher than non-, and, low-PD1 (87.5% vs. 66.4%, p=0.054). 5-year PFS rate of patients with PD-L1(+) had no difference with PD-L1(-) (79.3% vs. 65.9%, p=0.101).

Conclusion

In patients with early stage cervical cancer, the patients with high-PD1 would tend to have a longer survival duration. The expression of PD-L1 would not affect the survival duration.
THE PLACE OF ENDOCERVICAL CURETTAGE ADJUVANT TO HPV POSITIVE PATIENTS WITH ASCUS CYTOLOGY AND NORMAL COLPOSCOPY

A. Tal¹, S. Romano¹,², Y. Ben David¹,²
¹Emek Medical center, Obstetrics and Gynecology, Afula, Israel
²Technion Rappaport Faculty, Medicine, Haifa, Israel

Aims

To examine the additive information of ECC in the management of patients with ASCUS cytology, normal colposcopy and positive HPV result.

Method

A population based cohort study conducted at a single institution in the north of Israel between January 2007 and December 2014. All women with ASCUS cytology on routine PAP screen referred to colposcopy. All women with normal colposcopy were tested for HPV. Women with positive HPV referred to ECC.

Results

Of 11100 PAP smears taken in the study period, 980 (8.8%) were diagnosed as ASCUS. 910 of them had normal colposcopy and 260 of the normal colposcopy group (28.5%) were HPV positive. The mean age was 33 (18-55) and 85% of them were Jewish. HPV 16 was the most prevalent type (30%) in these patients. All the patients with positive HPV, had ECC test and 67 (25.7%) had cervical dysplasia – LGSIL or HGSIL. In 2 patients, squamous cell carcinoma in situ and adenocarcinoma in situ were found ultimately.

Conclusion

Performing ECC to women with ASCUS cytology, normal colposcopy and positive HPV enable us to detect precancerous dysplasia and even carcinoma in situ and it is justified in these patients.
OVARIAN PRESERVATION IS ASSOCIATED WITH BETTER SURVIVAL IN YOUNG PATIENTS WITH T1N0M0 CERVICAL ADENOCARCINOMA: A SEER-BASED STUDY

X. Tang1, H. Xu1, J. Qiu1, X. Zhang1, J. Ding1, K. Hua1
1Obstetrics and Gynecology Hospital of Fudan University, Department of gynecology, Shanghai, China

Aims

Ovarian preservation is controversial in patients with cervical adenocarcinoma due to the risk of ovarian metastasis. The aim of this study is to evaluate the association of ovarian preservation with survival outcomes in young patients with T1N0M0 cervical adenocarcinoma.

Method

Women at 45 years old or younger with T1N0M0 cervical adenocarcinoma from 1988 to 2013 recorded in the Surveillance, Epidemiology, and End Results (SEER) Database who underwent hysterectomy were included. Propensity score weighting was used to balance the intragroup differences in baseline demographic and clinical characteristics. Cause-specific survival (CSS) and overall survival (OS) were compared through Kaplan-Meier estimates. Multivariate cox model was used to adjust for covariates including propensity score.

Results

A total of 1368 patients with T1N0M0 cervical adenocarcinoma, including 1090 (79.7%) patients underwent oophorectomy and 278 (20.3%) patients preserved ovaries were identified. Patients who preserved ovaries were younger, with lower T classification and less likely to undergo pelvic lymphadentectomy (all p<0.05). The median follow-up was 89 months for oophorectomy group versus 91 months for ovarian preservation group. In weighting cohort, ovarian preservation group had better CSS (5-year 98.8% versus 97.1%, 10-year 98.0% versus 95.2%, p=0.0370) and OS (5-year 98.8% versus 97.1%, 10-year 96.5% versus 93.5%, p=0.0025). After adjusting for covariates, the CSS benefit of ovarian preservation was marginally significant (p=0.051) and OS benefit was still significant (p=0.006).

Conclusion

Among young women with T1N0M0 cervical adenocarcinoma, ovarian preservation is associated with better survival.

AWARENESS ON HPV AND HPV VACCINE AND ACCEPTANCE OF VACCINATION AGAINST HPV AMONG HIGH SCHOOL STUDENTS AND THEIR PARENTS: A PRIVATE HIGH SCHOOL BASED STUDY

B. Tulpar¹, E. Gucer², S. Ceydeli³, Z. Yılmaz⁴

¹Robert College High School, 11th Grade, Istanbul, Turkey
², 10th Grade, Istanbul, Turkey
³, 9th Grade, Istanbul, Turkey
⁴, Department of Obstetrics and Gynecology, Istanbul, Turkey

Aims

The aim of this study was to evaluate the awareness, knowledge, and risk perception about HPV and HPV vaccines among high school students and their parents. Another aspect assessed was the parent’s acceptance of the vaccine and willingness to vaccinate their children against HPV.

Method

Two different standardised electronic questionnaires, one for the students and one for the parents, were sent out. All subjects were students currently in school and their parents. Questionnaires were first sent in December 2016 and then twice more with 4 week intervals. All data from answered questionnaires were stored automatically by a computer program designed for the study (E.G.).

Results

The overall response rate was 34% for students and 27% for parents. The proportion of students who knew what the symptoms of HPV were was 21%, while 32% of students had heard about HPV only namely. 26% knew that there was a vaccine for the prevention of cervical cancer. Only 9.9% had been vaccinated against HPV, 86% vaccinated students were female. 70% of the students would like to be further informed.

Among parents, 74% had heard about HPV. Of 96 parents who have daughters in RC, 15 (16%) had vaccinated their child already. Reimbursement of HPV vaccine may influence on the decision of vaccination in 86% of parents.

Conclusion

This study is the first study evaluating the knowledge on HPV and the HPV vaccine among the high school students and their parents. Compared to vaccination rates in USA and Canada the vaccination rate in our population is very low.

NEOADJUVANT-CHEMOTHERAPY IN LOCALIZED BULKY CERVICAL CANCER: A SINGLE INSTITUTION EXPERIENCE

Z. Vaknin, M. Yekutieli, S. Kovel, D. Schneider

1Yitzhak Shamir Medical Center- Zerifin- affiliated to the Sackler Faculty of Medicine- Tel Aviv University- Tel-Aviv- Israel, Obstetrics and Gynecology, Beer-Yakov, Israel

2Yitzhak Shamir Medical Center- Zerifin- affiliated to the Sackler Faculty of Medicine- Tel Aviv University- Tel-Aviv- Israel, Oncology, Beer-Yakov, Israel

Aims

Cervical cancer is very rare in Israel. Radical-surgery is usually reserved for small localized lesions. The aim of this work is to present our experience with neoadjuvant-chemotherapy (NACT) in highly-selected patients (Bulky I-B1/IIA1 and I-B2/IIA2, with negative lymph-nodes per PET-CT).

Method

In 2004-2016 we treated 12 patients fulfilling the above-mentioned criteria with NACT prior to planned radical-surgery. All were included in the retrospective analysis. All NACT was IV platinum-based mostly with paclitaxel for at least 3-cycles. Response rate was measured according to RECIST-criteria. The need for adjuvant radiation-therapy was decided according to Seldis-criteria.

Results

Median age was 42 years (range, 26-68). Overall toxicity was very low, while clinical-response was high (10 patients, 83%). Two patients (17%) had stable-disease and were subsequently treated with chemoradiation. Clinical-response was defined as complete in 6 patients (50%) and as partial in 4 patients (33%). All these patients had radical-surgery. As for the pathological response: 7 patients had suboptimal-response (stromal-invasion >3 mm), 2 had complete-response and one had minimal residual-disease (<3 mm stromal-invasion). Only two patients required adjuvant radiation-therapy. Overall, 3 patients (25%) had persistent-disease, 2 patients that weren’t eligible to surgery and one patient that had surgery and needed adjuvant radiation-therapy. Two of these patients (one in each group) died of the disease.

Conclusion

In highly-selected patients with early, localized bulky cervical cancer, neoadjuvant-chemotherapy can generate high clinical-response which allows radical-surgery without subsequent radiation. This approach can achieve satisfactory outcomes, with few benign complications. We believe it could be applied as a valid alternative to primary chemoradiation.

CHANGES IN EPIDEMIOLOGY OF OPERATED CERVICAL CANCER AT PRETORIA ACADEMIC HOSPITAL COMPLEX: 2000 VS 2010

G. Dreyer¹, D. Fosu-Amoah¹, J. Biko¹, A. Mouton¹, L.C. Snyman¹, B.G. Lindeque¹, C. Visser¹
¹University of Pretoria, Department of Obstetrics & Gynaecology, Pretoria, South Africa

Aims

Our objective was to compare and evaluate epidemiology data on cervical cancer patients collected during two periods, ten years apart, at the Pretoria Academic Hospital Complex.

Method

Data were collected on cervical cancer patients with FIGO stage Ib1 – IIa during two retrospective descriptive studies, each study extending over a 5-year interval and performed ten years apart. Data obtained included demography, HIV status, FIGO stage, tumour histology type & grade and referral for adjuvant therapy.

Results

The first study (A) included 188 patients treated 1 Jan 1999 to 31 Dec 2003, while the second study (B) included 242 patients treated 1 Jan 2008 to 31 Dec 2012. Age distribution was comparable in both studies. HIV positivity rates were 2.5-fold higher in the second study: 9.4% vs 24.9%. FIGO stage Ib1 (43.5% vs 48.3%) and stage IIa (22.6% vs 17.8%) differed in the respective studies (A vs B), but stage Ib2 was similar in both (33.9%). Histological type differed slightly (A vs B): squamous- (76.6% vs 68.8%); adeno- (13.3% vs 20.2%) and adenosquamous carcinoma (10.1% vs 5.8%). Referral for adjuvant therapy were higher in study B: 40.4% vs 51.7%.

Conclusion

Longitudinal data from operated cervical cancer patients indicate a favourable trend toward downstaging. This could be due to increased screening, mainly targeting HIV positive women.

PATHOLOGY REVIEW OF 159 CASES OF MICROINVASIVE CERVICAL CANCER
B. Vranes1, A. Stefanovic1, S. Kadija1, K. Jeremic1, V. Kesic1, A. Jovic Vranes2

1Clinical Center of Serbia, Clinic for gynecology and obstetrics, Belgrade, Serbia
2University of Belgrade School of medicine, Institute of social medicine, Belgrade, Serbia

Aims

Current FIGO definition of microinvasive cervical cancer (MICC) from 1994, limits stages IA1 and IA2 to 3 and >3<5 mm of invasion, respectively. Treatment options have greatly varied and changed within this period, new techniques have evolved, and the data of case series and reviews are becoming more available. Our study reviews the pathology in 159 cases in both stages of MICC primarily focusing on the possible spread of the disease beyond cervix and the spread pathways.

Method

Retrospective study of patients primarily treated for MICC where pathology review excluded over 100 due to missing data and primary pathology not complying with up to date standards, leaving 159 cases to review fulfilling all the criteria for MICC, including the „third dimension“ measure not exceeding 7 mm. Most of the excluded patients would have had to be staged as small IB1 on the basis of requirements of our pathology review.

Results

Of 159 reviewed pathologies 126 were stage IA1 and 33 IA2. Most frequent surgical treatment was radical hysterectomy, followed by simple hysterectomy and cone biopsy. LVSI in 12 patients and invasion to the middle third in one patient were registered. Pelvic nodes were found positive in 2 patients, both with LVSI, whilst parametrial invasion was not found in analyzed group. Positive pelvic nodes correlate with LVSI and deeper stromal invasion.

Conclusion

Despite current surgical treatment standard of modified radical hysterectomy or radical trachelectomy for stage IA2 patients it seems like an unnecessary procedure leading to over treatment of patients with possible complications.
BOWEL-, BLADDER- AND SEXUAL FUNCTION AFTER ROBOTIC ASSISTED RADICAL HYSTERECTOMY FOR EARLY STAGE CERVICAL CANCER- A ONE YEAR PROSPECTIVE STUDY

E. Wallin1, K. Bergmark2, H. Falconer1, A. Flöter Rådestad1
1Karolinska Institute, Dep of Women’s and Children’s Health, Stockholm, Sweden
2Oncology and Pathology, Oncology Salgrenska Academy, Gothenburg, Sweden

Aims

To prospectively assess the impact of robot-assisted laparoscopic radical hysterectomy (RRH) for early stage cervical cancer on sexual-, bowel-, bladder and lymphatic function. Further to investigate the impact of RRH on androgen levels and ovarian reserve.

Method

Women consecutively scheduled for RRH during 2011-2013 were included in the study. Participants answered a validated questionnaire regarding psychological well-being, sexual-, bladder-, bowel-function and lymphoedema at baseline and one year after treatment. At the same time, serum samples for sex hormones and anti-Müllerian hormone were measured.

Results

50 women were included in the study and 32 were eligible for analysis one year after surgery. Six women needed adjuvant treatment. Vitality, anxiety and depression deteriorated in 50-60% of the women. Further, a significant proportion of the women treated with surgery alone (n=26) reported distress of sexual function including shortness and numbness of the vagina and deep dyspareunia. Lymphoedema was reported by 50% and micturition problems by 32% of the women. Sexual arousal and orgasm were significantly impaired among women receiving adjuvant treatment. FSH and LH levels were significantly increased and AMH decreased one year after surgery in women <45 years with preserved ovaries.

Conclusion

RRH is associated with sexual distress as well as micturition problems, lymphoedema and affects the ovarian function. Adjuvant treatment worsens the situation. Identifying women with impaired sexual and natural functions after RRH is important in order to provide adequate counseling and treatment. Patient reported experience measures should be incorporated in the follow-up after RRH for cervical cancer.
THE CLINICAL SIGNIFICANCE OF THE CD163+ AND CD68+ TUMOR-ASSOCIATED MACROPHAGES IN HIGH-RISK HPV-RELATED CERVICAL CANCER

W. Wang1, X. Chen1, J. Ma1, L. Han2
1Nanfang Hospital- Southern Medical University, Department of Obstetrics and Gynecology, Guangzhou, China
2Shanghai First Maternity and Infant Hospital- Tongji University School of Medicine, Department of Minimally Invasive Gynecologic Surgery, Shanghai, China

Aims

Objective. To explore the influence of M2-polarized tumor-associated macrophages (TAMs) on high-risk human papillomavirus (hr-HPV) related cervical carcinogenesis and metastasis.

Method

Methods. CD68+/CD163+ macrophages were examined immunohistochemically in a series of 129 samples, including 26 cases of normal cervical tissues, 59 cases of cervical intraepithelial neoplasia (CIN) and 44 cases of squamous cell carcinoma (SCC). Hr-HPV testing was carried out using the Hybrid Capture 2 assay (HC-II).

Results

Results. High counts of CD68+/CD163+ macrophages were associated with hr-HPV infection (both \(p<0.05\)) and positively correlated with cervical carcinogenesis (Spearman’s rho=0.478, \(p=0.000\); Spearman’s rho=0.676, \(p=0.000\), respectively). The immunostaining pattern of CD163 exhibited cleaner background compared with CD68. Notably, a high index of CD163+ macrophages is significantly associated with higher FIGO stages and lymph node metastasis (\(p=0.009\), \(p=0.007\), respectively), while CD68+ macrophages not (\(p=0.101\), \(p=0.070\), respectively).

Conclusion

Conclusions. Our study supported a critical role of TAMs as a prospective predictor for hr-HPV-related cervical carcinogenesis. CD163, as a promising TAMs marker, is superior to CD68 for predicting the malignant transformation and metastatic potential of cervical cancer.
NEOADJUVANT CHEMOTHERAPY (NACT) AND ABDOMINAL RADICAL TRACHELECTOMY (ART) FOR STAGE IB1 CERVICAL CANCER WITH TUMOR SIZE ≥2CM: PRELIMINARY RESULTS FROM CHINESE PATIENTS

X. Wu¹, J. Li¹
¹Fudan University Shanghai Cancer Center, Dept. Gynecologic Oncology, Shanghai, China

Aims

To assess the effectiveness of NACT and ART for IB1 cervical cancer with tumor size ≥2cm

Method

From April 2016 to March 2017, all patients with IB1 cervical cancer whose tumor≥2 cm and fit the inclusion criteria for ART were considered for this study. Laparoscopic lymphadenectomy was performed before NACT to rule out lymph node metastasis. Three courses with cisplatin 50mg/m², paclitaxel 135 mg/m² were followed by ART, and 3 more cycles after surgery.

Results

Seven young women considered eligible for ART were included. Median age was 30 years and tumor size before treatment was 31.4 mm. One (14.3%) had positive lymph node confirmed by frozen section during laparoscopic lymphadenectomy and converted to hysterectomy, although her PET-CT showed no suspicious lymph node before surgery. Adenocarcinoma was present in 1 (14.3%) and squamous carcinoma in 6 (85.7%). Pathological microinvasive residual tumor was observed in 2 cases, and 3 patients had tumor less than 2cm by final pathology. After a median follow-up of 7.1 months no relapses were observed. No patients had ever attempted to conceive.

Conclusion

Preliminary results from our data didn’t suggest a perfect pathological response although the regimen was well tolerated. We are now planning a further study with dose-dense regimen, to explore more effective pre-surgery treatment for reducing the tumor volume and performing less radical surgery.
CERVICAL CANCER II

ESGO7-1194

ERBB2 MUTATION: A PROMISING TARGET IN NON-SQUAMOUS CERVICAL CANCER

L. Xiang\(^1\), H. Yang\(^1\), S. ye\(^1\), W. Jiang\(^1\)

\(^1\)Fudan University Shanghai Cancer Center, Gynecology Oncology, Shanghai, China

Aims

Oncogenic mutations of ERBB2 have emerged as promising therapeutic targets in human cancers, whereas KRAS and PIK3CA mutations are predictors of resistance. ERBB2 mutations have been found in a subset of invasive cervical cancer (ICC). Nevertheless, the prevalence, mutation spectrum, clinicopathological relevance, human papillomavirus (HPV)-genotype association, prognostic significance, and other genetic background information of ERBB2-mutated ICCs have not been well established.

Method

In this study, ICC samples (N=1015) were assessed for mutations in ERBB2, KRAS, and PIK3CA by cDNA-based Sanger sequencing and were measured for HPV genotype by TaqMan fluorescent quantitative PCR. In addition, 157 ICC specimens were examined for HER2 overexpression and amplification by immunohistochemistry and fluorescence in situ hybridization.

Results

Somatic ERBB2 mutations were detected in 3.15% patients. The ERBB2 mutation rate was significantly higher in adenocarcinoma (4.52%, 7/155), adenosquamous carcinoma (7.59%, 6/79) and neuroendocrine carcinoma (10.34%, 3/29) than that in squamous carcinoma (2.14%, 16/749) (P=0.004, Fisher exact test). In addition, 18.75% of the patients carrying ERBB2 mutations concomitantly harbored PIK3CA or KRAS mutations. Patients with ERBB2-mutated ICCs tended to have a worse prognosis than those with wild-type or PIK3CA-mutated ICCs but a better prognosis than those with KRAS-mutated ICCs. The ERBB2 overexpression/amplification rate was 3.82% in ICCs.

Conclusion

This study provided a promising rationale for the clinical investigation of tyrosine kinase inhibitors for the treatment of cervical cancer with ERBB2 mutations. Patients with non-squamous cell carcinomas have priority as candidates for ERBB2-targeted therapy. Concurrent PIK3CA/RAS mutations should be considered in the design of clinical trials.

DOES SIZE MATTER? MICROSCOPIC VERSUS GROSS TUMOR IN STAGE IB1 CERVICAL CANCER TREATED WITH RADICAL HYSTERECTOMY: IS THERE A DIFFERENCE?

N. Zhou1, A. Palileo2, S.S. Tedjarati3, Y.C. Lee2, T.S. Pradhan1

1Westchester Medical Center, Obstetrics and Gynecology, Hawthorne, USA
2SUNY Downstate Medical Center, Obstetrics and Gynecology, New York, USA

Aims

There is ongoing debate regarding the extent of radical dissection for stage IB1 cervical cancer. However, limited data exists regarding microscopic versus gross tumor presentation. This study compares pathologic outcomes of microscopic and gross stage IB1 cervical cancer in patients undergoing primary Type 3 radical hysterectomy (RH) at two large U.S. academic medical centers.

Method

All patients (1995-2017) with stage IB1 cervix cancer undergoing RH with pelvic lymphadenectomy were retrospectively analyzed using clinical and pathologic data. Pathology slides were reviewed by gynecologic pathologists. Squamous cell, adenocarcinoma, and adenosquamous carcinoma were included. Mann-Whitney U test was used to define age differences. Chi-squared test was utilized to calculate differences in pathologic variables with two-tailed \( p<.05 \) considered statistically significant.

Results

A total of 71 patients were identified, 60 met inclusion criteria. Mean age at diagnosis in the microscopic vs gross tumor cohort was 51.1 vs 49.5, \( p = .20 \). For microscopic confirmation of IB1 disease, 22 of 33 patients (67%) underwent cone biopsy or LEEP prior to RH.

</table>

Conclusion

Though limited by low numbers, no parametrial invasion was seen in the microscopic cohort. According to our analysis, microscopic and gross IB1 have similar incidences of intermediate and high-risk features, affirming FIGO staging criteria. Further studies are warranted to better individualize treatment according to tumor burden to lessen treatment related adverse effects without compromising clinical outcomes.
Aims

The aim of this study was to evaluate outcomes after conservative management of precancerous lesions of cervix in 10 year period.

Method

Cone biopsy after biopsy of target lesions in selected cases were replaced with cytology and colposcopy examinations every six months. Initial pathohistological findings were compared with findings during follow up to see whether there was a progression, persistence or regression of lesions.

Results

A total number of 786 patients with HSIL cytological findings were included in study. In first 5 year period between 2002 and 2006, cone biopsies were performed in 264 out of 450 patients. In a second five year period from 2007 to 2012 selected cases were managed conservatively with reduction in number of cone biopsy procedures, 50 out of 336 patients. During 5 year follow up in first group there was a 4% progression rate. However in a group managed conservatively there were no cases with progression of findings.

Conclusion

Due to continuous development of team work and acquisition of the diagnostic equipment of higher quality, with mentioned conservative approach we were able to significantly reduce number of conisations, as well as the number of patients with progression to higher grade lesions in ten year period.
EXPRESSION OF Nod1 AND Nod2 DURING PROGRESSION OF HUMAN CERVICAL NEOPLASIA AND THEIR CORRELATION WITH P16INK4a EXPRESSION

Nod1 and Nod2 are cytosolic receptors which recognize pathogen-associated molecular pattern (PAMPs) and initiate the innate immune response. In this study, we examined the expression of Nod1 and Nod2 to determine whether their expression is associated with the tumor progression in cervical neoplasia.

Method

The expression of Nod1 and Nod2 was evaluated by immunohistochemistry (IHC) in 80 formalin-fixed paraffin-embedded cervical tissues; 20 normal cervical specimens, 20 low-grade cervical intraepithelial neoplasias (CINs), 20 high-grade CINs, and 20 invasive squamous cell carcinomas (ISCCs).

Results

IHC staining showed that Nod1 was constantly expressed in normal cervical epithelium, CINs, and ISCCs with variable staining intensity. However, Nod2 expression was detected in 40.0% of normal cervical epithelium (8/20), 45.0% of low-grade CIN (9/20), 70.0% of high-grade CIN (14/20) and 55.0% of ISCC (11/20). Interestingly, the Nod2 expression was more frequently observed in the high-grade CINs and ISCCs compared with that in normal cervical epithelium, but this association was not statistically significant. In addition, Nod2 expression was significantly more frequent in high Nod1 expression group compared to low Nod1 expression group (P=0.044) and increased frequency of Nod2 expression was associated with increased expression of P16INK4a (P=0.033) which is believed to be associated with human papillomavirus (HPV)-induced transformation of cervical tissue.

Conclusion

Our results showed the increased frequency of Nod2 expression in CINs compared with that in normal cervical epithelium and suggests Nod2 may be associated with the cervical tumor progression of CINs.
CORRELATION OF HPV, CYTOLOGICAL AND HISTOPATHOLOGICAL FINDINGS WITH DIFFERENT COLPOSCOPIC IMAGES

V. Krsic¹, B. Jocić Pivac¹, J. Krsic², J. Milojevic³, D. Jovanovic¹, V. Jovanovic⁴
¹Clinic Ob Gyn Narodni Front, OB GYN, Belgrade, Serbia
²Military Academy belgrade, chirurgico department, Belgrade, Serbia
³Hospital Lazarevac, obgyn, Belgrade, Serbia
⁴Higher education school of professional health studies, obgyn, Belgrade, Serbia

Aims

The aim of this study is to determine the level of correlation between present of HPV infection and cytological and histopathological findings with different colposcopic images.

Method

Chi square test were used to determine the level of correlations among 1927 examined patients.

Results

Altogether 612 women (31.76%) were positive for one or more HR HPV types. HPV16 (11.36%) and 33 (6.43%) were the most prevalent types. HPV31 in 5.24%, HPV18 in 5.03% and HPV51 in 3.68% of all with normal colposcopic findings. 82.31% had normal cytology and 17.69% had abnormal cytology and among them 2.1% were HRHPV positive. There was a statistical difference between the findings of colposcopy and cytology in patients with HRHPV (x²=35.33, p=0.000). Abnormal colposcopy findings and normal cytology had 49.71%, among them there were 29.5% HRHPV positive and 9.5% LRHPV. There was no statistically significant difference between coposcopic and cytological findings (x²=0.394, p=0.530). Patients with normal colposcopy findings had histologically LGSIL changes in 53.81%, 11.95% were HRHPV positive. There was statistically significant difference between histopathology and colposcopy in patients with HRHPV (x²=10.17, p=0.001). 438 patients had abnormal colposcopy images and histopathological LSIL (71.51) and 2 patients had normal colposcopic images and histological HSIL. There was no statistically significant differences between histopaological and colposcopic exam in LRHPV patients (x²=1.71, p=0.190). HPV16 type was found in LGSIL statistically significant presence and in group age >35 years, HPV33 was the most often in age group 24 till 34 years. Abnormal findings on colposcopy was found in 93.3% patients with LGSIL and 68.05% patients with LGSIL had normal cytology and that 70.15% was HRHPV negative.

Conclusion

Our study showed that HPV testing could help for better screening for preinvasive lesions.
**Aims**

There has been a recent shift from cytology-only screening to HPV DNA testing in cervical cancer screening. The aim of this study is to identify outcomes of women with positive oncogenic HPV.

**Method**

This is a retrospective study of 4867 women who underwent HPV testing as part of cervical cancer screening between January 2013 and December 2016 in a tertiary institution in Singapore.

**Results**

Cotesting was performed in 58.1% and HPV primary screening in 23.5% of women. Of the 42 positive HPV 16 results, 2 had biopsy-proven CIN1 and 4 had biopsy-proven CIN2+. Two patients with normal colposcopy had negative random punch biopsies. Of the 15 positive HPV 18 result, 2 had biopsy-proven CIN1 and 3 had biopsy-proven CIN2+. One patient with normal colposcopy had negative multiple random biopsies and another had a negative diagnostic LEEP procedure. One patient had both HPV 16 and HPV 18 positivity and underwent diagnostic LEEP procedure of which histology was negative. Of the 183 positive non 16/18 HPV results, 1 had biopsy-proven CIN1 and 7 had biopsy-proven CIN2+. Two patients with normal colposcopy had negative diagnostic LEEP and another had negative hysterectomy. The sensitivity, specificity, positive predictive value and negative predictive value were 100%, 94.39%, 4.48%, 100% for HPV primary testing and 100%, 93.40%, 4.48%, 100% for co-testing respectively.

**Conclusion**

While HPV DNA tests can increase detection of high grade CIN, there is a need to strike a balance between increased sensitivity and over-treatment that may lead to recognised future fertility implications.
LAVAGE OF THE UTERINE CAVITY FOR OVARIAN CANCER DIAGNOSIS: A FEASIBILITY STUDY

E. Maritschnegg¹, N. Pecha², F. Heitz², A. Bartakova³, F. Trillsch⁴, C. Grimm¹, R. Zeillinger¹, P. Speiser⁴

¹Medical University of Vienna, Department of Obstetrics and Gynecology, Vienna, Austria
²Kliniken Essen Mitte, Department of Gynaecology and Gynaecologic Oncology, Essen, Germany
³Charles University in Prague, Department of Gynecology and Obstetrics, Pilsen, Czech Republic
⁴University Medical Center Hamburg-Eppendorf, Department of Gynecology and Gynecologic Oncology, Hamburg, Germany

Aims

75% of ovarian cancer patients are diagnosed at an advanced stage. We previously introduced a new diagnostic concept, based on a lavage of the uterine cavity to collect shed cancer cells. After the design of a new catheter specifically for this purpose we conducted a feasibility study.

Method

In the course of the study the performance of the catheter (n=93), as well as the level of pain compared to the insertion of an intrauterine device (IUD) (n=18) which was placed four weeks afterwards were evaluated. 16 gynecologists of four centers performed the uterine lavage, using four different batches of the catheter.

Results

In 92/93 cases it was possible to collect a uterine lavage sample. Dilatation had to be applied in a lower proportion of pre-menopausal, compared to post-menopausal women (p=0.0088). Insertion of the catheter was more difficult in patients with cancer, than women with benign, or no gynecological diseases (p=0.009). The discomfort experienced during the uterine lavage was rated with a median VAS score of 1.6, the insertion of an IUD with 1.0, both using local anesthesia. No participant had to use medication, developed a fever or other symptoms requiring a doctor’s visit. Both procedures took 6.5 minutes on average.

Conclusion

The results of the feasibility study show that the catheter, together with the lavage protocol represents an easy and reliable way of collecting target cells present in the uterine cavity. The procedure is well tolerated. Therefore, it carries the potential to be used as a screening tool.
DIAGNOSTICS AND PREINVASIVE DISEASE II

ESGO7-0257

TYPES AND MULTIPLE INFECTION OF HPV ARE RELATED TO VIRAL PERSISTENCE AND CIN RECURRENCE AFTER LASER SURGERY

A. Nishikawa¹, T. Mariya², A. Baba¹, S. Ayumi¹, I. Yamanaka¹, T. Nihei¹
¹Sapporo Medical Center NTT EC, Obstetrics and Gynecology, Sapporo, Japan
²Obihiro kyoukai hospital, Dept. OB/GYN, Obihiro- Hokkaido, Japan

Aims

In order to elucidate the factors related to HPV persistence and CIN recurrence after Laser surgery, we examined the details of infected HPV genotypes in 334 cases with CIN.

Method

Cases were recruited from CIN cases treated in our hospital from 2007 to 2011, and observed until December 2014. One hundred and four of the cases were treated by laser conization, while the other 230 cases by laser vaporization. Surgical procedure was selected on the basis of colposcopic examination, pathological grade, and patient's hope for pregnancy. All cases examined infected HPV genotypes before and after treatment using the multiplex PCR method.

Results

There were no significant differences in cure rates, HPV persistence rates or recurrence rates between conization and vaporization. Persistent HPV infection after treatment was the independent risk factor of recurrence (RR, 9.25; 95%CI 3.06-27.98; p<0.001) in multivariate analysis. And, multiple-type HPV infection before treatment was the independent risk factor of the persistence of HPV infection (RR, 2.04; 95%CI 1.10-3.78; p=0.024). Types 16,18 and 33 showed a higher potential for recurrence than the other types of HPV.

Conclusion

Multiple HPV infections are a risk factor of HPV persistence. Furthermore, types 16,18 and 33 infections generate a high risk for the recurrence of CIN. In addition, HPV persistent cases, especially, HPV 16, 18 and 33 showed higher recurrence rates, thus may require more intensive follow up than HPV cleared cases.

### Aims

To compare IOTA logistic regression model (LR2) with Ovarian Malignancy Algorithm (ROMA) in predicting malignancy in women with pelvic masses.

### Method

Multicenter prospective study enrolling consecutively 371 unselected patients (mirroring clinical practice) with suspicious pelvic masses: benign 285pts; borderline 15pts; malignant 71pts (of which epithelial ovarian cancer-EOC 63pts). LR2 and ROMA diagnostic performances were estimated and compared.

### Results

Results. LR2 and ROMA had similar diagnostic performances in discriminating benign from EOC patients both in pre and postmenopause (Table 1; AUC:area under ROC curve).

#### Table 1

</tbody>
</table>

When using clinical recommended cut offs, LR2 and ROMA presented comparable sensitivity and specificity in premenopause. In postmenopause, ROMA showed higher specificity and LR2 higher sensitivity. Risk calculated with LR2 and ROMA slightly agreed in patients with benign disease (pre and postmenopause:Cohen's Kappa 0.07 and 0.20), whereas fairly or moderately agreed in patients with malignancy(pre and postmenopause: Cohen's Kappa0.23 and 0.56). AUC of LR2 and ROMA combination (logistic regression equation) was significantly higher in premenopausal patients compared to AUC for ROMA alone (AUC 0.943 and 0.907;p=0.03).Mean predicted probability of malignancy increased by 0.155 when using LR2+ROMA in comparison to LR2 alone (0.620 vs0.775), whereas decreased by 0.039 for benign tumors (0.095 vs0.056); integrated discrimination improvement was 0.155+0.039=0.194.

### Conclusion

Although LR2 and ROMA used individually show a comparable diagnostic performance, when used in combination they appear to differentiate EOC from pelvic masses more efficiently.
Aims

Recent literature supports the impact of contraceptives (local and systemic) on the cervical canal microbiome and mucous. In relation to the findings we investigated the potential impact of combined oral contraceptives (COC) and intrauterine devices (IUDs) on postoperative bleeding, discharge and pain after conization.

Method

This cross-sectional study analyzes single center data on postoperative complications experienced by patients after conization between the years 2005 to 2015 at the University Medical Center Maribor, Slovenia. Physicians recorded at the follow up exam 4-6 weeks after conization the amount of postoperative pain, bleeding and discharge as well as type of contraception patients were using. Statistical analysis was done through descriptive data analysis and the Mann Whitney-U test using the SPSS programme.

Results

A total of 717 women were included in the study. 69 % of women (n=497) in the study were using COC, 7.8 % (n=56) were IUD users and the rest of women compromised the control group (n=164). There was a significant difference in the amount of moderate discharge between groups (p>0.029) in favor of IUDs (reducing discharge). Whilst not statistically significant, there is a tendency of IUDs also reducing perception of pain (p>0.078). Other parameters between IUD usage and COC usage were statistically insignificant.

Conclusion

IUD properties may present a positive impact on the postoperative discharge following conization. Further studies are needed to evaluate differences between hormone and gold/copper IUDs as well as larger studies on specific oral contraceptive substances.
Aims

To evaluate the feasibility and assess the concordance of the HPV genotyping both in cervical samples and corresponding self-collected urine by PCR-HPV specific detection kit in women with CIN in a colposcopic referral population.
To correlate the genotype detection i both cervical and self-collected urine sample with the grade of CIN.

Method

Design: Cross-sectional single centre study.
Patients: Women undergoing conization for CIN at cervical biopsy.
Intervention: Cervical brush and urine samples were collected before conization. A first void urine specimen was self-collected by patients and brought to the outpatient clinic. Cervical samples was collected with cytobrush. HPV genotype was assessed by Linear Array (Roche) procedure.

Results

134 patients were enrolled. HPV genotypes were detected in 81% of cervical samples and only in 57% of corresponding urine. By classifying the samples on CIN, the worse the grade of CIN the better detection of HPV was observed in both biospecimens. HPV was present in CIN1 (n= 31) in 45% and in 29% of cervical and urine samples, while the percentages raised to 92% and 66% respectively for CIN>1 (CIN2= 47 and CIN3=56). This trend was confirmed by chi-square statistical analysis in CIN1 versus CIN2 and CIN3 (p=0.006 for cervix and p=0.039 for urine). A statistically significant increase of poly-infection was observed in CIN>1 compared to CIN1 in both samples (p=0.001 cervical, p= 0.008 urine).

Conclusion

This study shows that urine can be used for HPV genotyping in CIN2+ lesions. The concordance of HPV genotype detection between cervical and urine samples depend on the grade of CIN.
SUBJECTIVE ULTRASOUND ASSESSMENT AND MULTIVARIABLE-PREDICTIVE MODELS IN DISCRIMINATING MALIGNANT FROM BENIGN OVARIAN TUMORS IN REFERRAL CENTER FOR GYNECOLOGIC ONCOLOGY

M. Stukan¹, M. Badocha²
¹Gdynia Oncology Center - Pomerania Hospitals, Gynecologic Oncology Department, Gdynia, Poland
²Gdańsk University of Technology, Department of Probability and Biomathematics, Gdańsk, Poland

Aims

The aim was to develop a predictive model and compare it with subjective ultrasound assessment (SUA) in preoperative discriminating malignant from benign ovarian tumors, thus enabling optimal treatment planning in referral center for gynecologic oncology.

Method

A prospective, observational study on 280 consecutive patients undergoing surgery for adnexal masses (53.1% malignant) and preoperative standardized transvaginal and abdominal ultrasound examination with predefined definitions was performed. Stepwise logistic regression (SLG) with lowest possible AIC and BIC (Akaike and Bayesian information criterion) values were used to develop the model on 160 cases. On an independent group of 120 patients the model was tested and compared with SUA, risk of malignancy (RMI) and International Ovarian Tumor Analysis (IOTA) models: ADNEX, LR2.

Results

Univariate analysis revealed that age, hormonal status (HS), ascites, bilateral (BL) and multilocular lesions, solid components (SC), metastases in abdominal cavity, Doppler parameters: color score (CS), resistance (RI), pulsatility indices, peak systolic velocity, Cancer Antigen (CA) 125, platelet count and D-dimer level were significant in predicting malignancy. SLG revealed final model consisting of 6 factors (SC, BL, HS, CA125, CS, RI)- area under the receiver operator characteristic curve (AUC) 0.974. In a testing set, sensitivity, specificity and positive predictive values were 77.0%, 93.2%, 92.1% respectively. For other models – ADNEX: 81.9%, 93.2%, 92.6%; LR2: 63.9%, 96.6% (88.4-99.0), 95.1% (83.8-98.6); RMI: 77.0%, 89.8%, 88.7%; for SUA: 90.1%, 93.2% (83.8-97.3), 93.2% (83.8-97.3) respectively.

Conclusion

SUA by gynecologist oncologist has better or comparable clinical usefulness as multivariable-predictive models in discriminating malignant from benign ovarian tumors.
ESG07-0664

IS GENOTYPING OF UGT1A1 REALLY USEFUL FOR GYNECOLOGIC CANCER PATIENTS TREATED WITH IRINOTECAN-BASED CHEMOTHERAPY?

M. Takano¹, T. Yoshikawa¹, M. Morikazu², A. Tadashi³, S. Hiroaki², K. Kento², I. Hiroki², I. Hideki², N. Masaya³, S. Takahiro², N. Takahiro², M. Hiroko², G. Tomoko², S. Hidenori², K. Yoshihiro², F. Kenichi²

¹National Defense Medical College, Clinical Oncology, Tokorozawa, Japan
²National Defense Medical College, Obstetrics and Gynecology, Tokorozawa, Japan
³Ohki Memorial Kikuchi Cancer Institute for Women, Gynecologic Oncology, Tokorozawa, Japan

Aims

Genotyping of UGT1A1*28 and *6 was supported by national insurances since 2008 in Japan, however, there still exists argument which patients receive the test.

Method

Medical records of gynecologic patients treated with irinotecan-based therapy between 2003 and 2015 in our hospital were reviewed. Until 2007, dose reduction of irinotecan was based on physical status or previous myelosuppression (Non-UGT group). Since 2008, doses of irinotecan were modified by choice of physicians according to UGT1A1*28/*6 genotype (UGT group). Adverse effects at the 1st cycle were compared.

Results

217 cases were treated with irinotecan-based therapy: 59 with cervix, 30 with uterine corpus, and 128 with mullerian cancers. 109 patients underwent UGT1A1 genotyping: 66 (61%) with wild-type, 39 (35%) with hetero-type, and 5 (5%) with homo-type/double hetero-type. Irinotecan dose was modified in 25% in UGT group, and 11% in non-UGT group. In UGT group, Grade3/4 non-hematologic (17% vs. 26%, p=0.13) and Grade4 hematologic toxicities (11% vs. 19%, p=0.08) were reduced. Of note, grade4 non-hematologic toxicities were not observed in UGT group (0% vs. 5%, p=0.02).

Conclusion

Tailor-made chemotherapy according to UGT1A1 genotyping enabled us to reduce severe toxicities in gynecologic patients treated with irinotecan. Further investigations including response rates at reduced doses are needed to facilitate UGT1A1 genotyping.
A NOMOGRAM FOR DECISION MAKING OF COMPLETION SURGERY IN ENDOMETRIAL CANCER

S. Bozkurt, T. Tootas, H. Ayik Aydin, T. Simsek, Y. Yavuz

1 Akdeniz University School of Medicine, Department of Biostatistics and Medical Informatics, Antalya, Turkey
2 Antalya Research and Training Hospital, Department of Gynaecological Oncological Surgery, Antalya, Turkey
3 Akdeniz University School of Medicine, Department of Gynaecological Oncological Surgery, Antalya, Turkey
4 Ankara University School of Medicine, Department of Biostatistics, Ankara, Turkey

Aims

To develop a nomogram for decision making of completion surgery based on pathologic characteristics of the hysterectomy specimen in endometrial cancer (EC) patients treated with hysterectomy alone.

Method

Analyses were performed on the dataset of 336 patients. Age, grade, depth of myometrial invasion, lymphovascular space involvement, cervical involvement, positive peritoneal cytology, and histotype were assigned as potential covariates. To investigate associations between covariates and extrauterine disease, logistic regression analyses were performed. Several models were evaluated, and finally, three different models were developed. Accuracies of the models were internally validated in terms of their discrimination, calibration and overall performance. One of the models was selected, its clinical usefulness was quantified by decision curve analysis (DCA), and presented as a nomogram.

Results

Of the patients 67 (19.9%) had extrauterine disease. Performance values of the nomogram were as follows: area under the receiver operating characteristics curve, 0.870 (P<0.001); calibration slope β, 1.0; and Brier score, 0.101. Ten-fold cross-validation revealed a sensitivity of 50.7%, specificity of 95.5%, and positive predictive value of 73.9%. DCA revealed that a reasonable threshold probability for the presence of extrauterine disease that would indicate a completion surgery would be 2%. This cut-off value provided a net benefit of 18 true-positive results per 100 patients without an increase in the number of false-positive results. As compared with "treat all" strategy, it led to 10% fewer surgeries.

Conclusion

Estimation of extrauterine disease and decision making for completion of surgery is possible with high predictive performance using a nomogram involving primary tumor characteristics.
GENETICS OF ENDOMETRIAL CANCER IS GREATER THAN PREVIOUSLY ESTIMATED IN THE OUR LOCAL POPULATION.

A. Benshushan1, N. Gazit1, Y. Goldberg2, T. Peretz2, A. Zik3

1Hadassah-Hebrew University, Gynecology, Jerusalem, Israel
2Hadassah-Hebrew University, Genetics, Jerusalem, Israel
3Hadassah-Hebrew University, Oncology, Jerusalem, Israel

Aims

To expand the data base on the hereditary component of endometrial cancer (EC) in the local population.

Method

The study population included EC patients that visited the oncogenetic clinic in Hasassah Ein-Kerem hospital. The patients were either tested for 18 common germline mutations associated with Lynch syndrome and breast and ovarian cancer syndrome, or known carriers from previous genetic testing. DNA was extracted from blood samples provided by the patients after signing an informed consent form. The Genomic DNA was then analyzed using High Resolution Melting (HRM) method and the results were validated using Sanger sequencing.

Results

Out of a total of 166 endometrial cancer patients included in the study, 41 patients (25%) were found to be carriers of a pathogenic germline mutation (fivefold the expected); 25 patients (15%) were found to be Lynch carriers. 10 patient (6%) were found to be carrier of a BRCA mutation (7 BRCA1 and 3 BRCA2), and 6 carriers of the APC-K1307 mutation. Only 76% of the lynch carriers met The Bethesda criteria at time of EC diagnosis.

Conclusion

The results of this study suggest that the genetic component of EC is greater than previously estimated in the local population, both in lynch and none lynch carriers. Since the women included in the study are of high risk population, the prevalence of pathogenic mutation carriers in the general population cannot be estimated. More women with EC should be referred for genetic counselling in order to conduct further research.

SURGICAL MORBIDITY OF ROBOTIC-ASSISTED SENTINEL LYMPH NODE BIOPSY VS. SYSTEMATIC PELVIC LYMPHADENECTOMY FOR ENDOMETRIAL CANCER STAGING: A PROPENSITY-MATCHED ANALYSIS

J. Casarin1,2, F. Multinu1, A. Weaver1, L. Tortorella1, W. Cliby1, S.C. Dowdy1, J. Bakkum-Gamez1, A. Kumar1, C. Langstraat1, F. Ghezzi2, G. Glaser1, A. Mariani1

1 Mayo Clinic, Gynecologic Oncology, Rochester, MN, USA
2 University of Insubria, Obstetrics and Gynecology, Varese, Italy

Aims

To compare perioperative surgical outcomes and treatment-related morbidity of patients undergoing robotic-assisted sentinel lymph node (SLN) biopsy vs. systematic pelvic lymphadenectomy (PLD) for apparent early stage Endometrial Cancer (EC) staging.

Method

Records of consecutive patients with FIGO stage I-III EC undergoing robotic-assisted staging during 01/01/2009-06/30/2016 were manually reviewed. Perioperative and 30-day surgical outcomes were compared between patients who underwent PLD vs. SLN as actual treatment for staging (i.e. patients who had SLN biopsy followed by pelvic lymphadenectomy were excluded). Inverse probability of treatment weighting (IPTW) derived from propensity scores was used to minimize the allocation bias when comparing outcomes between groups.

Results

423 patients were included in the analysis: 235 (55.6%) PLD and 188 (44.4%) SLN. IPTW analysis balanced for baseline characteristics (age, BMI, ASA score, Charlson comorbidity index, parity, prior C-section and prior abdominal surgery) showed no significant differences in intraoperative and postoperative complications, readmissions and reoperations between the groups. Women who received PLD and SLN had similar conversion to open surgery rates (1.5% vs 0.8%; p=0.48). Patients in SLN group had lower mean operative time (216.2 vs 138.1 minutes) and lower median blood loss (50 vs 100 mL) when compared to PLD (p<0.001). Table 1.
Conclusion

The introduction of SLN biopsy reduces operative times and further improves short-term perioperative surgical outcomes of robotic-assisted staging for apparent early stage EC.
THE TEN YEAR EXPERIENCE OF A REGIONAL SPECIALIST GYNAECOLOGY CANCER GENETICS CLINIC WITH LYNCH SYNDROME

P. Crawford1, B. Newcombe1, H. Bolton1, S.F. Ngu1, S. Freeman2, H. Addley2, M. Jimenez-Linan3, R. Armstrong4, M. Tischkowitz5

1Cambridge University Hospital NHS Foundation Trust, Gynaecological Oncology, Cambridge, United Kingdom
2Cambridge University Hospital NHS Foundation Trust, Radiology, Cambridge, United Kingdom
3Cambridge University Hospital NHS Foundation Trust, Pathology, Cambridge, United Kingdom
4Cambridge University Hospital NHS Foundation Trust, Cancer Genetics, Cambridge, United Kingdom
5University of Cambridge, Clinical Cancer Genetics, Cambridge, United Kingdom

Aims

To review the outcomes from a single institution experience of a regional referral practice in Lynch Syndrome (LS)

Method

Service review. Surveillance was outpatient hysteroscopy, endometrial biopsy, CA 125 and TV ultrasound. Risk reducing surgery (RRS) was laparoscopic hysterectomy and bilateral salpingo-oophorectomy.

Results

Since 2007 60 patients have had RRS and a further 7 patients are undergoing surveillance. There are 18 MLH-1, 17 MSH-2, 7 MSH-6 and 2 PMS-2 mutation carriers having risk reducing surgery with the balance having strong family history. The frequency of surgery is increasing with more referrals. The mean age for RRS is 45 years (range 32-62 yrs). 21 patients opted for surveillance, mean time period 3 years, with the longest screen being 11 years. Forty patients chose RRS, 25 within 6 months of the specialist clinic, 9 within 12 months (1 cancer at surgery aged 54 years), 6 within 24 months (1 cancer at surgery aged 48 years). There has been one ovarian cancer (stage 1A endometrioid) discovered at the time of removing an abnormal ovary at time of colorectal cancer surgery aged 41 years which precipitated diagnosis of LS. Three patients have had endometrial cancer detected at RRS, one stage 2 requiring adjuvant radiotherapy. Prior cancer in carriers include bowel and breast cancer. There have been no deaths.

Conclusion

Centralised services provide excellent care for patients with cancer mutations
IMPACT OF HORMONAL RECEPTOR STATUS AND Ki-67 EXPRESSION ON DISEASE FREE SURVIVAL IN PATIENTS AFFECTED BY HIGH-RISK ENDOMETRIAL CANCER

V. Di Donato¹, V. Iacobelli¹, M. Schiavi¹, I. Pecorella¹, I. Palaia¹, C. Marchetti¹, A. Musella¹, F. Tomao¹, M. Monti¹, L. Muzii¹, L. Tramontano¹, P. Benedetti Panici¹
¹Sapienza University Policlinico Umberto I, Obstetrics and Gynecology, Rome, Italy
²Sapienza University Policlinico Umberto I, Pathology, Rome, Italy

Aims

The aim of this study was to evaluate the immunohistochemical expression of Ki-67, estrogen (ERα) and progesterone (PR) receptors in high-risk endometrial cancer patients and to assess their prognostic impact.

Method

Immunohistochemical (IHC) expression of Ki-67, estrogen (ERα) and progesterone (PR) receptors was evaluated in primary untreated endometrial cancer. The correlation among IHC staining and risk factors of recurrence such as age, FIGO (Federation International of Gynecology and Obstetrics) stage, grading, depth of invasion, and metastatic spread was assessed.

Results

82 patients were available for the analysis. Mean age was 65.05 ± 10.48 years. The IHC assessment revealed a lack of ERα in 46.3%, of PR in 48.7%, and a high Ki-67 in 31.7%. Loss of ERα and PR was associated with a significant higher rate of advanced stage of disease, a higher frequency of G3 tumors and a myometrial invasion >50%. A strong Ki-67 expression correlated with a deeper myometrial invasion. Analysis of the inter-relationship between receptor immunonegativity revealed a relevant association of ERα immunolocalisation with PR and with a high Ki-67 expression. The present study also showed that loss of ERα (p = 0.003), advanced FIGO stage (p < 0.001) and high Ki-67 (p = 0.004) were independent prognostic factors of a shorter DFS. Importantly, loss of ERα, loss of PR and a high Ki-67 were correlated with a higher incidence of distant recurrence.

Conclusion

A systematic immunohistochemistry should be a key step in the therapeutic algorithm and could contribute to the identification of high-risk tumors.
**ENDOMETRIAL CANCER II**

**PROGNOSTIC FACTORS FOR DISEASE RECURRENCE IN EARLY ENDOMETRIAL CANCER**

*S.H. Lee¹, P. Jung-Woo¹, H. Myoungseok¹, C. Yeon Jean¹, K. Su Jin¹
¹Dong-A University Hospital, Obstetrics and Gynecology, Busan, Republic of Korea*

**Aims**

The purpose of this study is to evaluate the clinicopathologic factors of early (International Federation of Gynecology and Obstetrics (FIGO) I-II stage) endometrioid endometrial adenocarcinoma (EM CA) in single institution and to identify factors affecting recurrence and prognosis.

**Method**

A single-center retrospective study of FIGO stage IA-IIB 102 EM CA patients who underwent comprehensive surgical staging from June 1995 to August 2016 was conducted. Non-endometrioid type and double primary cancer were excluded. We selected several clinicopathologic factors including age, CA-125, depth of myometrial invasion (DMI), tumor grade, lymphovascular space invasion (LVSI), and status of estrogen receptor/progesterone receptor (ER/PR). Univariate and multivariate Cox proportional hazard model and Kaplan-Meier estimates were used for analyzing all clinicopathologic factors related to the risk of disease recurrence.

**Results**

The median age was 55.05 years (range, 35 to 81 year). And the median follow-up time was 35 month (range, 2 to 155). Fifteen patients (10.78%) showed disease recurrence. Three patients, distant and 12 patients, locoregional metastasis were included. In univariate analysis, tumor grade (P=0.0045) and LVSI (P=0.0374) were associated with disease recurrence. Multivariate analysis demonstrated an association between any type of recurrence and LVSI (hazard ratio [HR], 6.308; 95% confidence interval [CI], 1.851-11.484).

**Conclusion**

LVSI is highly associated with disease recurrence in early EM CA. As such, the presence of LVSI may indicate the need for adjuvant systemic therapy in patients with early stage disease.

THE OUTCOMES OF FERTILITY SPARING TREATMENT FOR EARLY STAGE WELL-DIFFERENTIATION ENDOMETRIAL ENDOMETRIOID ADENOCARCINOMA

H. Lin1, Y.C. Ou1, C.H. Wu1, S.C. Liu1, H.C. Fu1

1Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.

Aims

The purpose of present study is to evaluate the outcomes of oral progestin treatment in women diagnosed with early stage grade 1 endometrial endometrioid cancer (G1EEC), who wish to preserve their fertility, in a single institute.

Method

We reviewed the medical records of patients that had been treated using oral progestin between 2010 and 2016. Women with disease limited to endometrium and no evidence of metastasis on pelvic magnetic resonance imaging scans were included. Endometrial biopsies were taken at follow-up periods.

Results

We identified 24 young women with G1EEC. The median age was 33 years old (range, 23 to 42), and the median treatment duration was 9 months (range, 3 to 24). Eighteen patients (75.0%) achieved complete remission (CR; median time to CR was 6 months; range, 3 to 12), only 1 patient (5.6%) with CR had recurrence at 40 months. Five patients with CR had subsequent levonorgestrel intrauterine device insertion due to no fertility desired yet. A total of 8 patients finally received surgery (4 non-responders, 2 after childbearing, 1 recurrence, 1 after ART failure). Eight of 16 CR patients attempted conception and 4 (50%) became pregnant with 5 live births. The proportion achieving pregnancy in our study cohort was 16.7% (4 of 24). Till now, all patients are alive with a median follow-up period of 37 months (range, 12 to 81).

Conclusion

We demonstrated high efficacy of fertility-sparing treatment with oral progestin. Low recurrent rate may be related to prolonged use of levonorgestrel intrauterine device. Further studies are necessary for clarification.
IMPORTANCE OF ULTRASOUND MARKERS IN THE RISK ASSESSMENT OF LYMPH NODE INVOLVEMENT IN ENDOMETRIAL CANCER

M. Liro¹, M. Sniadecki¹, S. Wojtylak², E. Wycinka², S. Sawicki³, D. Wydra¹
¹Medical University of Gdansk, Gynecology-Gynecologic Oncology and Gynecologic Endocrinology, Gdansk, Poland
²Medical University of Gdansk, Patomorphology, Gdansk, Poland
³University of Gdansk- Faculty of Management, Statistics, Sopot, Poland

Aims

To evaluate ultrasonographic tumor and invasion markers (myometrial invasion [uMI; ≥ 0.5 myometrium], tumor area [AREA, cm²], tumor volume [SPE-VOL, cm³], tumor free distance [uTFD, mm]) and endomyometrial irregularity [EMIR] as predictors of lymph nodes involvement (LNI) in epithelial endometrial cancer (EC).

Method

One hundred and sixteen consecutive EC patients were included into this prospective study between January 2011 and November 2012. 2D transvaginal ultrasound and surgical treatment according to Mayo Clinic algorithm was applied in all patients. The study group and 86 G1-G2 endometrioid low risk (LR) as well as G3 endometrioid and serous type (high risk, HR) subgroups underwent separate statistical analyses regarding accuracy of ultrasound markers in predicting LNI. P value of <0.05 was statistically significant.

Results

LNI was found in 20/116 (17%) patients. In univariate analysis, only uMI, EMIR and uTFD were significant variables with accuracy of 70.7% (p<0.003), 67.2% (p<0.001) and 63.8% (p<0.02) in predicting LNI, respectively. The model combining ≥ 2 any of the factors did not increase accuracy. For LR tumors significant variables were uMI and EMIR with accuracy of 74.4% (p<0.001) and 70.9% (p<0.02), whereas for HR no of the factors were significant in univariate analysis.

Conclusion

uMI and EMIR may be useful predictive ultrasound markers, especially in LR tumors. The preoperative histology defining HR EC prevails over informative value of ultrasound. It would be of interest whether histologic counterparts of ultrasound factors (i.e. depth of invasion, type of growth) are of independent predictive or prognostic value in LR and HR tumors.
Aims

The aim of this retrospective study was to examine the recurrence rates and patterns in patients with endometrial cancer in our hospital and evaluate the usefulness of routine follow-up procedures for the detection of recurrent disease following treatment of endometrial carcinoma.

Method

We conducted a retrospective descriptive study including all patients with a diagnosis of recurrent endometrial cancer treated at the Department of Gynecologic Oncology from the University Hospital of the Canary Islands between 2000 and 2014.

Results

The mean age of these patients at the time of treatment of their initial tumor was 67.72 years.

The most common site of recurrence was vaginal vault (28.4) followed by lymph nodes in 19 cases (23.45%) and carcinomatosis (23.45%). The distant metastases occurred in 20 cases (24.69%) and in fourteen patients there were more than one site of recurrence.

The recurrences were diagnosed in 66.7% and 80.2% within 2 and 3 years after primary treatment, respectively.

41% of patients had symptomatic recurrent disease (33 cases).

Half of the patients were diagnosed by pelvic examination (51%), the remaining 49% of relapses were found by elevated tumor markers (28/81 cases, 34.56%), by imaging procedures (7/81 cases, 8.64%) and only 5 cases by Papsmears (6.17%).

Conclusion

In our study, the vast majority of relapses occurred in the first three years of follow-up (80.2%). The results show that routine vaginal cytology was only beneficial in 6.2% of recurrences, so it can be concluded that surveillance by vaginal cytology is ineffective for the detection of relapses of endometrial cancer.

¹AOU Città della Scienza e della Salute di Torino, Dept of Surgical Science University of Turin, Turin, Italy
²AOU Città della Scienza e della Salute di Torino, Dept of Pathology, Turin, Italy

Aims

Identify morphological and immunohistochemical features as predictive markers of recurrence in endometrial endometrioid cancer (EEC).

Method

Retrospective study of a single-center clinical series of 72 patients treated for EEC at the Department of Gynecologic Oncology of the University of Turin, between the 1st of January 2012 to 31st of December 2014. The histological specimens have been revalued in blind by a pathologist to define: FIGO stage, histological grading, number of mitosis (at 40HPF and 10HPF), Ki-67% expression and morphological features. In addition the tumor aggressiveness and its recurrence has been analyzed in relation to the proliferation boost: this was defined as the percentage of the cells in mitosis during the interphase.

Results

The analysis revealed a strong association between the Ki-67% expression (p= 0.015) and disease free survival (DFS). Proliferation boost results to be the best marker of recurrence (p= 0.007) with OR 1.93 (95% CI 1.86-1.99; p = 0.013). The only two morphological variables that showed a correlation with the recurrence are the LVSİ (p= 0.032) and the pattern of infiltration (p= 0.012). At multivariate analysis the FIGO stage and the proliferation boost result independent predictors of DFS with OR 4.04 (95% CI 1.41-11.59; p= 0.009) and OR 5.01 (95% CI 1.42-17.75; p= 0.012) respectively.

Conclusion

The integration of FIGO stage and proliferation boost is feasible and could be used as predictive factor of recurrence in EEC.

RISK FACTORS FOR DIFFICULTIES IN OFFICE ENDOMETRIAL CYTOLOGICAL SAMPLING

G.M. Makris¹, C. Siristatidis², N. Margar², C. Chrelias³, T. Sergentanis⁴, P. Karakitsos², N. Papantoniou⁴

¹Attikon University Hospital, Ob/Gyn, Athens, Greece
²Medical School- National and Kapodistrian University of Athens- Greece, Assisted Reproduction Unit- Third Department of Obstetrics and Gynecology- General Hospital “Attikon”, Athens, Greece
³Medical School- National and Kapodistrian University of Athens- Greece, Department of Cytopathology- General Hospital “Attikon”, Athens, Greece
⁴Medical School- National and Kapodistrian University of Athens- Greece, Unit of Gynecological Oncology- Third Department of Obstetrics and Gynecology- General Hospital “Attikon”, Athens, Greece

Aims

Endometrial cytology is useful for the diagnosis of endometrial cancer. This study aims to evaluate factors associated with difficulties in endometrial cytology sampling.

Method

204 women that underwent endometrial cytological sampling with the Endogyn curette (Biogyn S.N.C., Mirandola, Italy) were included in the study. Difficulty (strenuousness) in obtaining the sample was graded into a five-level scale-score. Various risk factors were examined in association with the strenuousness score; multivariate ordinal logistic regression analysis was conducted. Statistical analysis was performed with Stata/SE statistical software (Stata Corp., College Station, TX, USA).

Results

Postmenopausal status (adjusted OR=2.91, 95%CI: 1.72-4.92, p<0.001) and previous invasive/surgical procedures in the cervix (adjusted OR=2.23, 95%CI: 1.20-4.15, p=0.011) were independently associated with higher difficulty score. On the other hand, participants’ phase of the menstrual cycle, endometrial thickness, obesity, current hormone use and the reproductive history of women were not significantly associated with the difficulty in conducting the procedure.

Conclusion

Difficulties during endometrial sampling are observed in postmenopausal women, as well as in women with previous surgical procedures in the cervix.
ENDOMETRIAL CANCER II

SENTINEL NODE MAPPING IN ENDOMETRIAL CANCER: A SINGLE CENTER EXPERIENCE OVER 200 CASES OF HYSTEROSCOPIC INJECTION OF TRACERS

F. Martinelli1, A. Ditto1, G. Bogani1, M. Signorelli1, V. Chiappa1, C. Scaffa1, D. Recalcati1, S. Perotto1, L. Montanelli1, C. Borghi1, D. Lorusso1, F. Raspagliesi1
1Fondazione IRCCS Istituto Nazionale dei Tumori, Gynecologic Oncology, Milano, Italy

Aims

To analyze detection-rate(DR) and diagnostic-accuracy (A) of sentinel-nodes(SLN)s mapping following hysteroscopic-injection of tracer.
To compare DR and A between tracers used: ICG and Tc99m.

Method

Retrospective evaluation of Prospectively collected data of Consecutive patients with endometrial cancer underwent SLNs mapping following hysteroscopic-peritumoral-injection of tracer+/full surgical-staging. Evaluation of DR(overall-bilateral-aortic) and A among the entire cohort and comparison between tracers.

Results

202 procedures were performed. Mean age: 60 years(28-82); mean BMI: 26.8 Kg/m2(15-47). In 133 cases(65.8%) hysterectomy and mapping procedure were performed laparoscopically. The overall-DR of the technique was 93.2%(179/192) (10 cases excluded: 9 equipment failure; 1 vagal reaction). Bilateral pelvic mapping was found in 59.7% of cases(107/179) and was more frequent in the ICG group(72.8%vs 53.3%;p:0.012). In 50.8% of cases(91/179) SLNs mapped both to pelvic and aortic nodes, and in 5 cases(2.8%) only in the aortic area. Mean number of detected SLNs was 3.7(1-8).

22 patients(12.3%) had nodal involvement: 10-(45.5%)macrometastases; 5-(22.7%)micrometastases; 7-(31.8%)ITCs. In 6 cases(27.3%) only aortic nodes were positive; in 5 cases(22.7%) both pelvic and aortic nodes and in 11 cases(50%) only pelvic area was involved.

Three false negative results were found, all in the Tc99m group. All had isolated aortic metastases with negative pelvic nodes.

Overall-sensitivity was 86.4% and overall-negative-predictive-value(NPV) was 98.1%.

No differences in terms of overall-DR, overall-sensitivity and overall-NPV were found between the two tracers. (Table)

| Table: Accuracy of hysteroscopic SLNs procedure |
|------------------|------------------|------------------|------------------|
|                  | Global (192)     | Tc99m (139)      | ICG (87)         |
| Excluded         | 19 (1.9%)        | 8 (5.9%)         | 2 (2.9%)         |
| DR               | 170/192 (90.2%)  | 120/127 (94.5%)  | 104/105 (99.7%)  |
| Overall sensitivity | 88.1% (95%CI 84.4-100) | 98.2% (95%CI 94.8-100) | 98.1% (95%CI 93.1-100) |
| Overall NPV      | 94.1% (95%CI 91-100) | 97.9% (95%CI 93-100) | 100%             |
| Overall FN rate  | 5/22 (22.7%)     | 5/19 (26.3%)     | 0 (0%)           |
*after first 16 cases thanks to equipment improvement DR reached 95.5% (17/18)

Conclusion

Hysteroscopic-injection of tracer for SLNs mapping in endometrial cancer is as accurate as cervical injection with a higher DR in the aortic area. ICG improved bilateral DR. Further investigation is warranted on this topic.
HIGH VISCERAL FAT PERCENTAGE IS ASSOCIATED WITH POOR OUTCOME IN ENDOMETRIAL CANCER

1University of Bergen, Department of Clinical Science, Bergen, Norway
2Haukeland University Hospital, Hormone Laboratory, Bergen, Norway
3Haukeland University Hospital, Department of Radiology, Bergen, Norway
4Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway

Aims

Despite evidence of increased endometrial cancer (EC) risk in obese women, the impact of obesity and fat distribution pattern on clinical and histological phenotype is poorly understood. We therefore evaluated abdominal fat volumes and fat distribution quantified by computed tomography (CT), in relation to tumor characteristics and outcome.

Method

227 EC patients with preoperative contrast-enhanced abdominal CT scans and comprehensive clinicopathological data were included. Total abdominal fat volume (TAV), subcutaneous abdominal fat volume (SAV) and visceral abdominal fat volume (VAV) were quantified, and visceral fat percentage calculated (VAV%=[VAV/TAV]x100). Waist circumference (WC) and liver density (LD) were measured, and body mass index (BMI) calculated. Data for estrogen, progesterone and androgen receptor (ER/PR/AR) expression by immunohistochemistry were available for 149 tumors, and global gene expression data for 105 tumors.

Results

High BMI, TAV, SAV, VAV and WC, and low LD, were associated with markers of less aggressive disease, including low-grade endometrioid tumors and PR and AR positivity (all p≤0.03). High VAV% was associated with high age (p=0.01) and aneuploidy (p=0.01), and independently predicted reduced disease-specific survival (HR 1.05, 95% CI 1.00-1.11, p=0.041). Tumors from patients with low VAV% showed enrichment of gene sets related to immune activation and inflammation.

Conclusion

High abdominal fat volumes and markers of obesity are associated with less aggressive endometrial cancer. High VAV% independently predicts reduced EC survival. Tumors arising in patients with low VAV% show enrichment of immune and inflammation related gene sets, suggesting that the global metabolic setting may be important for tumor immune response.
THE ROLE OF COMPREHENSIVE SURGICAL STAGING IN SEROUS ENDOMETRIAL CANCER: A PROSPECTIVE EXPERIENCE

A. Ditto¹, L. Montanelli¹, G. Bogani², F. Martinelli¹, M. Signorelli¹, V. Chiappa¹, C. Borghi³, U. Leone Roberti Maggiore¹, D. Lorusso¹, F. Raspagliesi¹, C. Scaffa¹

¹IRCCS National Cancer Institute- Milan, Gynecologic Oncology, Milan, Italy
²University of Milano-Bicocca- San Gerardo Hospital- Monza, Department of Obstetrics and Gynecology, Monza, Italy
³University of Ferrara- Sant’Anna University Hospital- Ferrara, Department of Obstetrics and Gynecology, Ferrara, Italy

Aims

To evaluate the role of comprehensive surgical staging in serous endometrial carcinoma

Method

Data of consecutive patients diagnosed with serous carcinoma of the endometrium undergoing surgery between 2000 and 2016 at Fondazione IRCCS Istituto Nazionale Tumori of Milan (Italy) were prospectively collected and reviewed. Disease-free and overall survival outcomes were evaluated using Kaplan-Meier and Cox proportional hazard models.

Results

Overall, 101 patients were included. Forty-nine (48.5%) patients had gross peritoneal disease and they had cytoreductive procedures. Among the 52 (51.5%) patients with apparent uterine confined disease 22 (42.3%) patients were upstaged. Five (9.6%) patients had microscopic disease located in the adnexal regions; while, seven (13.4%) and 10 (19.2%) were upstaged due to the presence of microscopic peritoneal and retroperitoneal disease, respectively. Considering factors predicting disease-free and overall survival, we observed that presence of extra-uterine disease significantly impact on patients’ outcomes (p<0.05). Deep of myometrial invasion (HR: 2.00 (95%CI: 1.16, 3.46); p=0.013), LVSI (HR: 1.99 (95%CI: 0.95, 4.14); p=0.065), and peritoneal disease (HR: 2.09 (95%CI: 1.06, 4.12); p=0.032) were associated with disease-free survival at univariate analysis. Via multivariate analysis, only peritoneal disease influenced disease-free survival (HR: 2.25 (95%CI: 1.11, 4.55); p=0.023). Similarly, peritoneal disease was the only factor predicting for overall survival (HR: 3.28 (95%CI: 1.75, 6.17); p<0.001).

Conclusion

In apparent early stage serous endometrial cancer, peritoneal and retroperitoneal staging allow to identify patients with disease harboring outside the uterus. Owing to the high prevalence of extra-uterine disease in apparent early stage serous endometrial carcinoma, comprehensive staging should be mandatory.
Aims

Two distinct types of endometrial carcinoma (EC) with different etiology, tumor characteristics and prognosis are recognized. We investigated if the prognostic impact of comorbidity varies between these two types of EC. Further, we studied if the recently developed ovarian cancer comorbidity index (OCCI) is useful for prediction of prognosis in EC.

Method

This nationwide cohort study was based on data from 5369 type I and 1219 type II EC patients diagnosed in Denmark in 2005-15. Patients were assigned a comorbidity index score according to the Charlson comorbidity index (CCI) and the OCCI. Kaplan Meier survival statistics and adjusted multivariate Cox regression analyses were used to investigate the differential association between comorbidity and overall survival in type I and II EC.

Results

The distribution of comorbidities varied between the two EC types and a consistent negative association between increasing level of comorbidity and survival was observed for both types. Cox regression analyses revealed a significant interaction between stage and comorbidity indicating that the impact of comorbidity varied with stage. In contrast, the interaction between comorbidity and EC type was not significant. Both the CCI and the OCCI were useful measurements of comorbidity but the CCI obtained a better statistical fit in the multivariate model.

Conclusion

This study demonstrates that comorbidity is an important prognostic factor in type I as well as in type II EC though the overall prognosis differs significantly between the two types of EC. The prognostic impact of comorbidity varies with stage but not with type of EC.

ESGO7-1210

PREOPERATIVE CT AND MR IMAGING TO DETECT LYMPH NODE (LN) METASTASIS AND DEEP MYOMETRIAL INFILTRATION IN ENDOMETRIAL CANCER (EC) PATIENTS

N.J. Nordskar1, A. Ogarkov1, M. Valla2, E. Araya3, G. Aune1, A.K. Engebretsen1, J. Kippervik1, M. Ravlo1, M. Sundset1, S. Tingustad1, B. Hagen1

1St Olavs University Hospital, Section of Gynecologic Oncology- Dept. of Obstetrics and Gynecology, Trondheim, Norway
2St Olavs University Hospital, Department of Imaging, Trondheim, Norway
3St Olavs University Hospital, Department of Pathology, Trondheim, Norway

Aims

In a prospective study of sentinel lymph node (SLN) mapping (1) all patients underwent preoperative imaging with CT (thorax + abdomen) and MR (pelvis). The aim was to evaluate the diagnostic performance of the preoperative imaging.

Method

Consecutive patients with apparently early stage EC were included and underwent robot-assisted laparoscopic HBSO with ICG fluorescence SLN mapping including extended pathology (serial sectioning and immunohistochemistry) on H-E negative SLNs. The result of preoperative CT and MR imaging combined was compared to the histopathologic LN metastasis status and myometrial infiltration depth in the uterine surgical specimen.

Results

Among the 108 patients included in the study 17 (16 %) had LN metastasis. Only 8 had a corresponding true positive imaging result (sensitivity 47 %, PPV 57 %), and among those 92 LN negative patients 6 had a false positive imaging result (specificity 93 %, NPV 91 %). 48 patients (44 %) had > 50 % myometrial infiltration depth on histology, 25 of whom were correctly identified on preoperative imaging. The PPV and NPV were 76 % and 70 %, respectively.

Conclusion

Due to inaccuracy, CT and MR preoperative imaging alone is not sufficient for rational treatment planning.

RISK OF ENDOMETRIAL CANCER IN POSTMENOPAUSAL WOMEN UNDERGOING DIAGNOSTIC HYSTEROSCOPY: ROLE OF AUB AND ENDOMETRIAL THICKNESS

1University of Padua, Department of Woman and Child Health, Padua, Italy
2University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
3University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubliana, Slovenia

Aims

to investigate the predictive value of endometrial thickness on the risk of endometrial cancer in postmenopausal women according to the presence or absence of AUB history. Secondly, to estimate the weight of BMI, hormone replacement therapy, hypertension and diabetes mellitus on the risk of cancer.

Method

We conducted a prospective, observational study from June 2012 to June 2014 on a cohort of postmenopausal patients undergoing diagnostic hysteroscopy with endometrial biopsy. Patients were included if a recent endometrial thickness measurement was available. For each patient we collected general features and history.

Results

435 patients were included in the study; 329 asymptomatic with endometrial thickness $\geq 4$ mm (ET_Group), 106 with AUB (AUB_Group), of which 58 with endometrial thickness $\geq 4$ mm (AUB_Subgroup1) and 48 with ET $< 4$ mm (AUB_Subgroup2). We found higher prevalence of cancer in AUB_Group in comparison to ET_Group (15.2% vs 3.7%; p<0.001) and in AUB_Subgroup1 than AUB_Subgroup2 (20.7% vs 8.5%; p<0.001). Sensitivity and specificity of endometrial thickness for cancer detection in AUB patients resulted 75% and 48.3%. In ET_Group we found a correlation between endometrial thickness and BMI with cancer risk. The best cut-off of endometrial thickness for cancer diagnosis was 11 mm (100% sensitivity and 80% specificity).

Conclusion

In asymptomatic women hysteroscopy should be indicated exclusively when endometrial thickness is $\geq 11$ mm, especially in case of overweight. In women with AUB the risk of cancer is considerably high even if endometrial thickness is $< 4$ mm, therefore diagnostic hysteroscopy is always recommended in these patients.

ENDOMETRIAL SURVEILLANCE IN TAMOXIFEN USERS: ROLE, TIMING AND ACCURACY OF HYSEROSCOPIC INVESTIGATION: OBSERVATIONAL LONGITUDINAL COHORT STUDY
A. Vitagliano1, M. Noventa1, S. Gizzo1, P.S. Litta1, S. Borgato1, V. Bertoldo1, S. Tosatto1, M. Palumbo1, A.S. Laganà2, S.G. Vitale2, B. Koba3, M. Jakimovska3, S. Kostoski3, C. Saccardi3

1University of Padua, Department of Woman and Child Health, Padua, Italy
2University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
3University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubliana, Slovenia

Aims

To determine the role of endometrial hysteroscopy in relation to the ultrasound, clinical and histological features of the endometrium during tamoxifen(TAM) use.

Method

We performed an observational longitudinal cohort study (2007–2012) that investigated the endometrium of 151 TAM users with hysteroscopy and histology. For all patients, ultrasound endometrial thickness(ET), gynecological history, years of adjuvant treatment and indications for hysteroscopy were recorded.

Results

Hysteroscopic findings showed that 100% of patients referred for simple follow-up had no evidence of endometrial disease. A strong correlation was found between history of abnormal uterine bleeding (with or without endometrial thickening) and hysteroscopic suspicion of endometrial atypia, confirmed by histology. Hysteroscopy had 83.3% sensitivity, 99% specificity, 83.3% positive-predictive-value(PPV) and 99% negative-predictive-value(NPV) in detecting endometrial atypia. No correlation was found between ET>5mm without bleeding and histological atypia. Similarly, the duration of treatment was not related to ET and histological atypia. Endometrial stromal hyperplasia was detected by histology in 70.5% of patients with ET between 5 and 10mm. In contrast, no atypia was detected when ET was <5mm. Ultrasound performed using a 5mm cut-off threshold for ET showed 100% sensitivity, 15% specificity, 4% PPV and 100% NPV in detecting endometrial atypia, while a 10mm cut-off threshold resulted in 84% sensitivity, 69% specificity, 10% PPV and 99% NPV.

Conclusion

Low-risk TAM users do not require different endometrial surveillance than general population. Hysteroscopy could play a fundamental role in determining the endometrial status of patients before the initiation of TAM treatment and in assessing the endometrial status of patients when bleeding occurs.
CRUDE LYMPH VASCULAR INVASION (LVSI) IS PROGNOSTIC FOR SURVIVALS AND RECURRENCES IN THE MAINLY NON-RADIATED DANISH ENDOMETRIAL CANCER POPULATION. A DANISH ENDOMETRIAL CANCER DATABASE STUDY

G. Ortoft1, C. Hogdall1, L. Lausten-Thomsen1, M. Dueholm2
1Copenhagen University Hospital, Department of Gynecology, Copenhagen Ø, Denmark
2Roskilde Hospital, Department of Urology, Roskilde, Denmark
3Aarhus University Hospital, Department of Gynecology, Aarhus, Denmark

Aims

LVSI is a strong independent prognostic factor for survivals and recurrences in early stage endometrial cancer. We examine the effect of LVSI on overall (OS), cancer-specific (CSS) and recurrence-free (RFS) survivals in the Danish population of 4521 endometrial cancer patients, only rarely given radiation.

Method

28.9% had lymph node resection (LN-resection). LVSI-status was reported to the database for 1946 cases and another 1521 were found in the pathology reports, leaving 1054 (23.3%) unknown. Therefore, three groups were examined by Kaplan-Meier and COX-analysis; LVSI-positive, LVSI-negative, LVSI-unknown

Results

3467 cases had known LVSI-status and of these 20.4% were LVSI-positive. For stage I, 11.3 % were LVSI-positive and this increased with risk-group (low-risk; 5.7%, intermediate-risk; 20.5%, high-risk: 23.6%). For LVSI-negative/LVSI-positive/LVSI-unknown the 5-years-OS were 85.9%/56.0%/77.7%, CSS: 93.8%/63.9%/86.5% and RFS: 89.2%/55.3%/80.4% and for stage I: OS: 87.8%/72.3%/86.5%, CSS: 95.7%/82.8%/95.5% and RFS: 91.4%/74.2%/91.0%.

In univariate analysis LVSI significantly increased the risk of dying by 4.02, whereas a metastatic lymph node increased the risk by 3.15.

In multivariate analysis LVSI was an independent prognostic factor for survivals and recurrences in all patients, in non-LN-resected, LN-resected and in lymph node metastatic patients. For non-LN-resected stage I, LVSI was an independent prognostic factor for all three risk groups, but in LN-negative LVSI was only a prognostic factor in intermediate-risk not in the low- or high-risk.

Conclusion

LVSI is a strong independent prognostic factor for OS, CSS and RFS. For lymph node negative stage I, LVSI was a strong independent prognostic factor for survivals and recurrences for intermediate risk, but not for low- or high-risk.
ENDOMETRIAL CANCER II

ESG07-1051

2D ULTRASOUND THRESHOLD PREDICTIVE OF FOCAL LESIONS REQUIRING ADVANCED HYSTEROSCOPIC TECHNIQUES IN CASES PRESENTED WITH POSTMENOPAUSAL BLEEDING OR INCIDENTAL ASYMPTOMATIC THICKENED POSTMENOPAUSAL ENDOMETRIUM

F. Gardner1, C. Bell2, O. ALI2
1Queen Alexandra Hospital, OG, Portsmouth, United Kingdom
2West Cumberland hospital, OG, Whitehaven, United Kingdom

Aims

to evaluate the frequency of detecting focal endometrial lesions requiring advanced hysteroscopic technique in PMB by 2D pelvic ultrasound. It assesses the value of Myosure in the outpatient setting compared to the Gynaecare scope.

Method

234 outpatient hysteroscopies done by one experienced operator from March 2014 to March 2017 for PMB and asymptomatic thickened endometrium were analysed for the frequency of finding cancer or precancer against various endometrial thresholds. The cases were analyzed whether done by Gynaecare scope (178/234) vs. Myosure (56/234) comparing outcome measures.

Results

The incidence of cancer was 11/234 (4.7%). The hysteroscopies to pick one cancer or precancer is approximately 6:1. The presence of focal lesion (polyps, fibroid, elevation, abnormally thickened endometrium) raises as the thickness of the endometrium increased; 8% at < 4mm thickness with no cancer and 9.5% at the zone of 4-5mm with one case of precancer (hyperplasia), and 24.2% at the zone of 5-6mm with 50% risk of cancer or precancer. From the thickness of > 6mm the risk of focal lesion is >40% with 39-53% risk of cancer or precancer.

Adverse events happened in 38/234(16.2%) and severe complication in 7/234(2.99%), with no difference in both groups. Only 1.7% were unsatisfied with the experience and satisfaction rate was comparable in both groups with less pain during the procedure and shorter duration in the Myosure group.

Conclusion

The threshold to hysteroscopy in PMB can be set at ET >5mm with a role for pipele under that. The likelihood to need Myosure treatment is > 40% when endometrium is >6mm.
ENDOMETRIAL CANCER II

ESG07-0759

DIAGNOSTIC ACCURACY BETWEEN PREOPERATIVE IMAGING AND SENTINEL LYMPH NODE BIOPSY DURING ROBOTIC OR LAPAROSCOPIC SURGERY IN ENDOMETRIAL AND CERVICAL CANCER LYMPH NODE METASTASIS

G.W. Lee¹, S.W. Lee¹, J.Y. Park¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

Appropriateness assessment of Sentinel Lymph Node Biopsy application in endometrial and cervical cancer.

Method

Performed a retrospective review of patients with cervical cancer and endometrial cancer who diagnosed and treated at a single institute. All cases underwent preoperative PET/CT or MRI followed by definitive robotic (da Vinci®) or laparoscopic surgical therapy including SLNB with Indocyanine green (ICG) fluorescence detection using Firefly® and NIR/ICG.

Results

The 89 patients underwent intraoperative sentinel nodes mapping. Deposition of ICG into at least one lymph node was observed in 100% of studied cases. Most common detected lymph metastasis locations in SLNB were obturator area 50%(9/18). And 35.6% obturator lymph node metastasis was found in all lymph node metastasis. Tumor size was not related with SLNB positive. Sensitivity, specificity, positive predictive value and negative predictive value were evaluated among preoperative PET/CT, preoperative MRI and sentinel lymph node frozen biopsy. In three variables (PET/CT, MRI, SLNB), Overall detection sensitivity were 50.0%, 31.3%, 81.3%. Specificity were 98.0%, 94.0%, 99.3%. Positive predictive value were 72.7%, 35.7%, 92.9%. Negative predictive value were 94.8%, 92.8%, 98.0%. False positive rate were 2.0%, 6.0%, 0.7%. False negative rate was 50.0%, 68.7%, 18.7%.

Conclusion

Individualized treatment to reduce therapy-associated morbidity is an important consideration in the surgical treatment. SLNB with ICG mapping is more accurate method than conventional imaging tools. SLNB has gained more acceptance and may offer an alternative to complete pelvic lymphadenectomy in the future.

PROGNOSTIC FACTORS IN ENDOMETRIAL CARCINOMA TYPE-I AND TYPE-II

M. Esteve1, M. Pérez de Puig1, D. Al-Dali1, A. Pereda1, M. Girvent1, F. Ojeda1
1Fundació Hospital Asil de Granollers, Obstetrics and Gynecology, Granollers, Spain

Aims

Evaluate the surgical prognostic factors of different histological subtypes in endometrial cancer.

Method

Patients diagnosed with endometrial carcinoma that underwent oncological surgery in our hospital from 1st January 2013 to 31st December 2016 were included.

This is a descriptive study, where histological subtypes type-I (endometrioid) and type-II (serous papillary and clear cells) are analyzed, valuing the percentages of myometrial invasion and lymph node metastasis in each cases.

Results

The histologies were 69 Type-I or endometrioid type (77.53%), and 13 Type-II or non-endometrioid type (15.85%): 10 serous papillary (11.23%); 1 clear cell (1.12%), and 2 carcinosarcoma (2.25%). The average age was 68.85.

Myometrial invasion >50% was found in the 46.15% (6/13) of Type-II group, while in patients with Type-I was only 28.98%(20/69). Myometrial invasion <50% was found in the 71.01%(49/69) of patients included in Type-I group, and in the 53.84%(7/13) of patients in the Type-II group.

Regarding lymph node metastasis, there was 30.77%(4/13) of patients with positive lymph node metastasis in Type-II group, while only 2.89%(2/69) were affected by lymph node metastasis in Type-I group.

Conclusion

The main predictors of lymph node and distant metastasis are the depth of myometrial invasion and the degree of tumor differentiation.

Regarding the different histological types of endometrial carcinoma, type-I carcinomas tend to be well differentiated forms of carcinoma, and their prognostic is better, with a higher rate of cure. Type-II carcinomas, on the other hand, generally correspond to more aggressive forms, with a higher percentage of lymph node metastasis and a deeper myometrial invasion, as revealed in our study.
ENDOMETRIAL CANCER II

ESGO7-0617

DOES TUMOR DIAMETER AFFECT SIGNIFICANTLY SURVIVAL OUTCOMES IN STAGE I ENDOMETRIOID ENDOMETRIAL CANCER? A PROSPECTIVE COHORT STUDY.
S. Petousis¹, C. Margioula-Starkou¹, P. Christidis¹, N. Sparangis¹, G. Karavas¹, A. Papanikolaou², A. Athanasiadis¹, I. Kalogiannidis¹
¹Aristotle University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Thessaloniki, Greece
²Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynaecology, Thessaloniki, Greece

Aims

To study the prognostic value of tumor diameter ≥ 2cm on survival outcomes in patients with surgically staged I endometrioid endometrial cancer.

Method

A prospective study was conducted during 1996-2016 enrolling patients with endometrioid endometrial cancer treated in the 3rd Department of Obstetrics and Gynaecology. Epidemiological, histopathological and survival outcome of patients were prospectively recorded in a computerized database. Primary outcome of the study was to assess the prognostic impact of tumor diameter ≥ 2cm on overall survival and recurrence of disease. This was separately studied for low-risk cases (grade 1 or 2 invading<50% of myometrium) and intermediate or high-risk cases (grade 3 and grade 1 or 2 invading ≥ 50% of myometrium). Cox regression analysis was used to examine potential impact of tumor diameter on survival parameters.

Results

There were 183 cases of surgically staged I endometrial cancer treated during the period of the study. Mean age of patients was 62.5 ± 10.4 years. Regarding low-risk cases (N=112), tumor diameter was not significantly correlated with risk for recurrence and overall survival (P=.44 and P=.49). Similarly, no significant impact of tumor diameter ≥ 2cm was indicated on risk for recurrence and overall survival in intermediate or high-risk patients as well (P=.61 and P=.62).

Conclusion

Tumor diameter ≥ 2cm may not to be an independent prognostic factor affecting overall survival and risk for recurrence.

PELVIC VS. PELVIC AND PARAAORTIC LYMPHADENECTOMY FOR INTERMEDIATE AND HIGH-RISK ENDOMETRIAL CANCER: SYSTEMATIC REVIEW AND META-ANALYSIS.
S. PETOUSIS, P. CHRISTIDIS, C. MARGIOULA-SIARKOU, A. PAPANIKOLAOU, A. RODOLAKIS, A. ATHANASIADIS, I. KALOGIANNIDIS

1 Aristotle University of Thessaloniki, 3rd Department of Obstetrics and Gynaecology, Thessaloniki, Greece
2 Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynaecology, Thessaloniki, Greece
3 National and Kapodistrian University of Athens, 1st Department of Obstetrics and Gynecology, Athens, Greece

Aims

To compare overall survival and disease-free survival between intermediate and high-risk endometrial carcinomas treated with pelvic and paraaortic vs. only pelvic lymphadenectomy.

Method

A computerized datasearch was performed in Pubmed and Scopus databases. Terms used for search were “endometrial cancer” or “endometrial carcinoma” or “endometrial adenocarcinoma” AND “para-aortic lymph*” or “paraaortic lymph*”. In the present analysis we included studies having as primary endpoint to compare survival outcomes of intermediate and high-risk endometrial carcinomas treated with pelvic and paraaortic (PVAL) vs. only pelvic lymphadenectomy (PVL). Non-english studies, animal studies, studies involving only low-risk cases and studies restricted to cases of certain surgical stage were excluded. Prospective or retrospective character of study was not set as exclusion criterion. Primary outcomes were overall survival (OS) and disease-free survival (DFS).

Results

Out of 460 studies identified after computerized datasearch with key-phrases, there were 378 remaining after duplicates removed, 112 assessed for eligibility and finally 5 studies included in the meta-analysis. Quality of studies was assessed as low. A total of 1,489 cases were included, of which 633 concerned cases treated with PVAL and 856 treated with PVL. Overall survival was significantly increased in the group of PVAL vs. PVL (RR:1.175 with 95% CI:1.096-1.256, P<.001). Similarly, the group of PVAL presented an 11.9% increase in DFS compared with PVL (RR:1.119 with 95% CI:1.053-1.171, P<.001).

Conclusion

Pelvic and paraaortic lymphadenectomy is associated with improved overall survival and disease-free survival compared with only pelvic lymphadenectomy. Further prospective RCTs should be performed in order to improve quality of evidence.
ADVANTAGES OF LAPAROSCOPIC SURGERY VERSUS OPEN SURGERY IN ENDOMETRIAL CANCER - 3 YEAR SINGLE INSTITUTION DATA

A. Pletnev1, S. Taranenko1, S. Mavrichev1
1N.N. Alexeyev National Cancer Center of Belarus, Gynecologic Oncology Department, Minsk, Belarus

Aims

Laparoscopic surgery is being used in gynecologic oncology for total hysterectomy, bilateral salpingo-oophorectomy and lymph node dissection for endometrial cancer (EC). The purpose of this study is to compare the feasibility and complications among women undergoing open and laparoscopic hysterectomy for endometrial cancer.

Method

We carried out a single center retrospective study using Belarus cancer register database between 2013 and 2016 on all women diagnosed with uterine cancer, classifying women in groups as either laparoscopically or open surgery treated.

Results

Laparoscopic surgery has more advantages versus open surgery in Endometrial Cancer Patients. The total for 3 years 378 laparoscopic and 1724 open hysterectomies were performed, including 56 operations with laparoscopic pelvic lymphadenectomy and 432 with open pelvic lymphadenectomy surgeries. The average duration of laparoscopic operation – 73 min. (40-180 min.), the average volume of blood loss – 51.9 ml (15-330 ml) were registered. Conversion to open surgery was in 4 cases; bladder injury – in 2, trauma of a sigmoid colon – in 1, bleeding – in 1 case. The average duration of open surgery – 74 min (50-174 min), average blood loss – 75.4 ml (20-950ml). Duration of lymphorrhea in laparoscopic operations was 3.4 days vs 6.3 days in open surgery. Laparoscopic surgery has benefits over open surgery in patients with morbid obesity with BMI more than 35 kg/m² in surgical wound complications (1 vs 15) and thromboembolic complications (0 vs 5 cases).

Conclusion

Laparoscopy for EC retains its advantages over open surgery, especially in case of obesity patients.
ETHNIC DIFFERENCES IN THE MUTATIONAL LANDSCAPE OF ENDOMETRIAL CANCER

K. Polymeros¹, D. Guttery¹, S. Macip², E. Moss¹
¹University of Leicester, Cancer Studies, Leicester, United Kingdom
²University of Leicester, Molecular and Cell Biology, Leicester, United Kingdom

Aims

Background: Endometrial cancer (EC) is the commonest gynaecological malignancy in the UK and the incidence in Leicester is particularly high. Our previous work has shown that British South Asian (BSA) and White British (WB) women are diagnosed with a similar distribution of Type I/II cancers but BSA women are significantly younger in age compared to WB women.

Objectives: To determine whether BSA and WB women diagnosed with EC harbour different mutational profiles.

Method

DNA was extracted from formalin-fixed, paraffin embedded (FFPE) tissue from 32 patients. Ion Torrent targeted next generation sequencing (tNGS) was performed using a bespoke tNGS panel interrogating 10 commonly mutated genes in EC.

Results

A total of 99 mutations were found in this cohort (3.1/patient). The most commonly mutated genes were PIK3CA and PTEN with 53% and 47% of patients, respectively. None of the BSA patients carried a POLE mutation compared to 23% of the WB patients (p=0.15). ARID1A mutations were also less frequent in BSA patients (10% versus 36%, p=0.21).

Conclusion

ARID1A and POLE mutations were more frequent in WB versus BSA patients. Although the trend did not reach significance, it raises interesting clinical questions since it is known that POLE mutations are associated with better prognosis. It has been suggested that ARID1A mutations are associated with mutations in the PI3K pathway. Since many targeted therapies are focused on this frequently mutated pathway, a possible implication is that BSA patients may not respond as well to these newer agents. Analysis in a larger cohort is ongoing.

ENDOMETRIAL CANCER TISSUE HAS A UNIQUE PHOSPHOLIPID SIGNATURE IDENTIFIABLE USING DESORPTION ELECTROSPRAY IONISATION (DESI) IMAGING

O. Raglan\textsuperscript{1,2}, L. Doria\textsuperscript{3}, R. Soares\textsuperscript{3}, F. Rosin\textsuperscript{3}, T. Farrokh-Eslamlou\textsuperscript{1}, J. McKenzie\textsuperscript{3}, Z. Takats\textsuperscript{3}, M. Kyrgiou\textsuperscript{1,2}

\textsuperscript{1}Institute of Reproductive and Developmental Biology, Surgery and Cancer- Imperial College London, London, United Kingdom
\textsuperscript{2}Imperial College Healthcare NHS Trust, Imperial College, London, United Kingdom
\textsuperscript{3}Imperial College London, Computational and Systems Medicine- Department of Surgery and Cancer, London, United Kingdom

Aims

Endometrial cancer (EC) is the fourth most common gynaecological cancer in Europe. Strongly associated with obesity, incidence of endometrial cancer is rising. DESI-MSI (Desorption Electrospray Ionisation-Mass Spectrometry Imaging) is one mass spectrometry imaging technique that allows direct correlation between biochemical changes within a tissue and histological features, providing topographically localised biochemical information.

Method

Fresh frozen endometrial samples (benign, cancer) were analysed using DESI-MSI. Peaks of interest were identified from mass spectra, matched with histopathological tissue annotations and clinical data, which was combined to generate a reference database from which principal component analyses (PCA) and maximum margin criterion (MMC) were performed highlighting the biochemical differences between the sample groups analysed.

Results

59 fresh frozen sections were analysed using DESI-MSI, of which 47 (79.7\%) were endometrial tumour tissues and 12 (20.3\%) were benign. Clear distinction of the different tissue types (tumour-associated stroma versus tumour) was identified within each sample. Benign endometrial samples and endometrial cancer samples produced unique spectra which enabled clear separation in PCA-cross validated MMC analyses. Cross-validation resulted in 91.5\% sensitivity and 98.0\% specificity for the correct classification of EC. Phosphatidylinositol, PI (34-0), was more abundant in tumour tissue, and phosphatidylglycerol, PG (44:1), more abundant in benign tissue.

Conclusion

DESI-MSI can discriminate benign endometrial versus tumour tissue by identifying unique lipodomic profiles. Our analysis contributes to knowledge of lipid metabolism in cancer and can identify potential lipid markers. These markers can be useful in identifying patients at risk in whom signalling pathways involved in carcinogenesis are overexpressed.

Aims

Surgical staging, treatment and prognosis of uterine corpus malignancies are highly dependent on disease severity and spread, factors that can be intraoperatively assessed by frozen section (FS). We aimed to determine the accuracy of FS in surgical staging and agreement with permanent section (PS); to evaluate the association between adverse prognostic intraoperative findings with final histopathology.

Method

Retrospective chart analysis from January 2007 to March 2017 of all uterine corpus malignancies diagnosed in a tertiary university hospital. Kappa (K) statistics and proportions of agreement (PA) with 95% confidence intervals were applied. Exclusion criteria were absence of FS, clinically advanced disease, coexisting second malignancy.

Results

A total of 205 cases were identified. Regarding myometrial depth invasion, substantial agreement between FS and PS was found (K=0.63), which was higher for tumours confined to the inner half of myometrium (PA=0.92) and lower for serosa invasion (PA=0.33). The sensitivity and specificity for involvement of the outer half was 74% and 99%. For cervical stromal involvement, a sensitivity and specificity of 65% and 99% was found. Regarding adverse prognostic oncological factors: the rate of adjacent organ invasion was higher in mesenchymal tumours (50%); lymph node involvement was more frequent in serous (45%) and mixed cell adenocarcinoma (40%), followed by mullerian mixed tumours (33%). Positive ascitic fluid was more frequent in mixed (50%) and miscellaneous (33%) categories.

Conclusion

Particularly in low risk disease and epithelial tumours, comprehensive surgical staging with FS seems beneficial. For locally aggressive tumours, preoperative imagiological staging might have a promising role.

CLINICAL DECISION-MAKING BASED ON PREOPERATIVE ENDOMETRIAL SAMPLING IN ENDOMETRIAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Reijnen1, N. Visser1, L. Massuger1, I. Nagtegaal2, J. Bulten2, J. Pijnenborg1

1Radboud University Medical Center Nijmegen, Obstetrics and Gynecology, Nijmegen, The Netherlands
2Radboud University Medical Center Nijmegen, Pathology, Nijmegen, The Netherlands

Aims

To determine the agreement between preoperative endometrial sampling and final diagnosis for tumor grade and subtype.

Method

MEDLINE, EMBASE, ClinicalTrials.gov and the Cochrane library were searched from inception to January 1, 2017, for studies that compared tumor grade and histological subtype in preoperative endometrial samples and hysterectomy specimen. In eligible studies the index test included office endometrial biopsy, hysteroscopic biopsy or dilatation & curettage; the reference standard had to be hysterectomy. Outcome measures included tumor grade, histological subtype or both.

Results

Two independent reviewers assessed the eligibility of the studies. Risk of bias was assessed (QUADAS-2). A total of 45 studies (12,459 patients) met the inclusion criteria. Pooled agreement rate for tumor grade was 0.67 (95% confidence interval [CI] 0.60–0.75) and Cohen’s k was 0.45 (95% CI 0.34–0.55). Agreement between hysteroscopic biopsy and final diagnosis was higher (0.89, 95% CI 0.80–0.98) than for office endometrial biopsy (0.73, 95% CI 0.60–0.86) and dilation and curettage (0.70, 95% CI 0.60–0.79). Lowest agreement rate was found for grade 2 endometrial carcinomas (0.61, 95% CI 0.53–0.69). Downgrading was found in 25% and upgrading was found in 21% of the endometrial samples. Agreement for histological subtypes was 0.95 (95% CI 0.94–0.97) and 0.81 (95% CI 0.74–0.92) for the preoperative endometrioid and non-endometrioid carcinomas respectively.

Conclusion

The moderate agreement between preoperative endometrial sampling and final diagnosis should be taken into account when selecting the most appropriate surgical treatment procedure.

CLINICOPATHOLOGIC CHARACTERISTICS OF ENDOMETRIAL CARCINOMA METASTATIC TO THE OVARY COMPARED TO ENDOMETRIAL CARCINOMA WITH SYNCHRONOUS OVARIAN CARCINOMA

N. Gomez-Hidalgo¹, R. Soslow¹, B. Weigelt¹, V. Sioulas¹, A. Aloisi¹, N. Abu-Rustum¹, J. Mueller¹, V. Makker¹, M. Leitao¹
¹Memorial Sloan Kettering Cancer Center, Department of Surgery, New York, USA

Aims

To characterize the clinicopathologic characteristics and outcomes of sporadic synchronous endometrial and ovarian cancers (SEOC) patients compared to endometrial carcinoma with metastasis to the ovaries.

Method

Cases with carcinoma in the endometrium and ovary who underwent primary surgery at our institution between 06/1993 and 09/2014 were identified. Pathology reports were reviewed to determine the pathologist’s assessment of whether the ovarian carcinomas were likely synchronous or metastatic. Stage IV were excluded.

Results

76 cases were identified. 19 were SEOCs and 57 cases were classified as endometrial carcinoma with ovarian metastasis (ECOM). Median age was 52 (range: 32-71) and 63 (range: 43-89) years, respectively (p=0.4). Non-endometrioid histology was seen in only 21% of SEOC as compared to 58% in ECOM (P=0.006). No myoinvasion was noted in 32% SEOC compared to only 9% ECOM (P=0.01). Endometriosis was noted in 58% SEOC compared to 4% ECOM (P<0.0001). Median follow-up time was 44.2 mo (range: 0.4-201.4) for the entire cohort. The 4-year progression-free survival (PFS) was 82% (SE+/9.5) for SEOC and 51.6% (SE+/7) for ECOM group (p=0.06). 4-year overall survival (OS) was 94.7% (SE+/5.1) for SEOC and 69.8% (SE+/6.2) for ECOM (p=0.046). 4-years PFS for endometrioid histology only cases was 84% (SE+/10.6) for SEOC vs 77.8% (SE+/8.87) for ECOM (p=0.97). 4-years OS for endometrioid histology was 93.3% (SE+/8.4) for SEOC vs 81.9% (SE+/8.2) ECOM (p=0.3).

Conclusion

SEOC was associated with more favorable endometrial factors and endometriosis, these are likely dissemination by retrograde flux. SEOC was associated with better survival outcomes but not when analyzing endometrioid histology alone.
Aims

The risk of endometrial cancer (EC) in BRCA mutation carriers is unclear. Whether risk-reducing surgery should include hysterectomy (TH) at the time of bilateral salpingo-oophorectomy (BSO) is controversial.

Method

We analysed our prospectively maintained clinical database of BRCA mutation carriers >20 years of age. Expected EC rate was calculated using national data standardised by age, year and geographical region from date of BRCA1/2 test report (true prospective group) and from 01/01/1980-31/12/2015 (full dataset). Women were censored at time of death, hysterectomy or date of last follow up. Observed EC cases were verified with the national cancer registry.

Results

There were 2156 women (BRCA1 n=1107, BRCA2 n=1049) and over 51,185 total women years at risk (median: 23.5yrs). Median age at last follow up was 51yrs (IQR 42, 60). In total, 160 underwent risk-reducing TH-BSO (median 42.5yrs, IQR 38, 48) and a further 447 underwent BSO without TH (median age 45yrs, IQR 40, 52) and were followed up for a median 6.2 years. Fourteen women were diagnosed with EC; two had high-grade serous pathology. None were recorded in the BSO group. We found no evidence for an increased risk of EC overall (E: 9.8, O: 14; OR: 1.42 95% CI: 0.78-2.39, p=0.24), nor in the prospective group from mutation report (E: 3.64, O: 2; OR: 0.55 95% CI 0.07-1.98) where there were only two endometrioid cancers in 8724.5 years follow-up.

Conclusion

We found no evidence for an increased risk of EC amongst BRCA mutation carriers, although the cohort is still young.

CLUSTERIN IMMUNOEXPRESSION IS ASSOCIATED WITH EARLY STAGE ENDOMETRIAL CARCINOMAS

K. Sait

'King Abdulaziz University Hospital, gynecology oncology unit, Jeddah, Saudi Arabia

Aims

Clusterin has anti-apoptotic, regeneration and migration stimulating effects on tumor cells. This study investigates the relation between clusterin expression and the clinicopathological parameters in endometrial carcinomas.

Method

Seventy one cases of previously diagnosed endometrial carcinoma (including 59 endometrioid adenocarcinoma, 9 serous adenocarcinoma, 1 clear cell adenocarcinoma, and 2 malignant mixed Mullerian tumor) and 30 tissue samples of non-cancerous endometrium (including 16 proliferative endometrium, 10 secretory endometrium and 4 endometrial polyps) were employed for clusterin detection using tissue microarrays and immunostaining.

Results

A total number of 23 (32.4%) cases were positive for clusterin immunostaining. Brown granular cytoplasmic expression of clusterin was detected in 33.9% of endometrioid adenocarcinomas, 22.2% papillary serous endometrial carcinomas. Three (10%) control cases showed granular cytoplasmic expression. Positive clusterin immunostaining was found more frequent in well differentiated and stage I endometrial carcinomas, showing significant statistical association (p-value = 0.036 and p-value = 0.002 respectively). Significant difference in clusterin expression was observed between tumor cases and control group (P-Value = 0.019), i.e., endometrial carcinomas cases are more than four times likely to show positive clusterin immunostaining (odds ratio 4.313 with 95% confidence interval 1.184–15.701). This study did not find relation between clusterin expression and disease recurrence, survival or any of the other clinicopathological parameters in endometrial tumors. The results of our study confirms the diagnostic values of clusterin in supporting the diagnosis of endometrioid carcinoma.

Conclusion

When clusterin is expressed in endometrial tumors, it is associated with lower stage. The correlation of clusterin with tumor stage suggests involvement of this molecule in endometrial tumor progression.

ROBOT-ASSISTED LAPAROSCOPY VERSUS LAPAROTOMY FOR INFRA-RENAL PARAAORTIC LYMPHADENECTOMY IN WOMEN WITH HIGH-RISK ENDOMETRIAL CANCER: A RANDOMIZED CONTROLLED TRIAL (RASHEC)

S. Salehi1, E. Åvall-Lundqvist2, B. Legerstam1, J.W. Carlson1, H. Falconer1

1Karolinska Institutet/Karolinska University Hospital, Department of Women’s and Children’s Health/Division of Obstetrics and Gynecology, Stockholm, Sweden
2Linköping University, Department of Oncology and Department of Clinical Experimental Medicine, Linköping, Sweden
3Karolinska Institutet/Karolinska University Hospital, Department of Oncology and Pathology/Department of Pathology and Cytology, Stockholm, Sweden

Aims

To investigate if robot-assisted laparoscopic surgery (RALS) was non-inferior to laparotomy (LT) in harvesting infrarenal paraaortic lymph nodes in patients with presumed stage I-II high-risk endometrial cancer.

Method

Patients with histologically proven endometrial cancer, presumed stage I-II with high-risk tumor features, were randomized to hysterectomy, bilateral salpingo-oophorectomy, pelvic and paraaortic lymphadenectomy by either RALS or LT. Primary outcome was paraaortic lymph node count. Secondary outcomes were perioperative events, postoperative complications and total health care cost.

Results

Overall 120 patients were randomized and 96 patients were included in the per protocol analysis. Demographic, clinical and tumor characteristics were evenly distributed between groups. Mean (±SD) paraaortic lymph node count was 20.9 (±9.6) for RALS and 22 (±11, p=0.45) for LT. The difference of means was within the non-inferiority margin (−1.6, 95% CI -5.78, 2.57). Mean pelvic node count was lower after RALS (28±10 vs. 22±8, p<0.001). There was no difference in perioperative complications or readmissions between the groups. Operation time was longer (p<0.001) but total blood loss less (<0.001) and hospital stay shorter (<0.001) in RALS group than LT group. Health care costs for RALS was significantly lower (mean difference $1,568 USD/€1,225 Euro, p<0.05).

Conclusion

Our results demonstrate non-inferiority in paraaortic lymph node count, comparable complication rates, shorter hospital length and lower total cost for robot-assisted laparoscopic surgery over laparotomy. Generalizability of the latter finding requires a high-volume setting and high surgical proficiency. In women with high-risk endometrial cancer confined to the uterus, RALS is a valid treatment modality.

PROGNOSTIC FACTORS AND TREATMENT OUTCOMES IN SURGICALLY-STAGED NON-INVASIVE UTERINE CLEAR CELL CARCINOMA: A TURKISH GYNECOLOGIC ONCOLOGY GROUP STUDY

1Turkish Gynecologic Oncology Group, Gynecologic Oncology, Ankara, Turkey
2Turkish Gynecologic Oncology Group, Gynecologic Oncology, İstanbul, Turkey
3Turkish Gynecologic Oncology Group, Gynecologic Oncology, İzmir, Turkey
4Turkish Gynecologic Oncology Group, Gynecologic Oncology, Antalya, Turkey

Aims

To assess the prognosis of surgically-staged non-invasive clear cell carcinoma (UCCC), and to determine the role of adjuvant therapy.

Method

A multicenter, retrospective department database review was performed to identify patients with UCCC who underwent surgical treatment between 1997 and 2016 at 8 Gynecologic Oncology centers. Demographic, clinicopathological, and survival data were collected.

Results

A total of 232 women with UCCC were identified. Of these, 53 (22.8%) had surgically-staged non-invasive UCCC (UCCC with no myometrial invasion). Twelve patients (22.6%) were upstaged at surgical assessment, including a 5.6% rate of lymphatic dissemination (3/53). Of those, 1 had stage IIIA, 1 had stage IIIC1, 1 had stage IIIC2, and 9 had stage IVB disease. Of the 9 women with stage IVB disease, 5 had isolated omental involvement indicating omentum as the most common metastatic site. UCCC limited only to the endometrium with no extra-uterine disease was confirmed in 41 women (73.3%) after surgical staging. Of those, 13 women (32%) were observed without adjuvant treatment whereas 28 patients (68%) underwent adjuvant therapy. The 5-year disease-free survival rates for patients with and without adjuvant treatment were 100% vs. 74.1%, respectively (p=0.06).

Conclusion

Extra-uterine disease may occur in the absence of myometrial invasion, therefore comprehensive surgical staging including omentectomy should be the standard of care for women with UCCC regardless of the depth of myometrial invasion. Larger cohorts are needed in order to clarify the necessity of adjuvant treatment for women with UCCC truly confined to the endometrium.

A FEASIBILITY STUDY OF SENTINEL LYMPH NODE MAPPING BY CERVICAL INJECTION OF A TRACER IN JAPANESE WOMEN WITH EARLY STAGE ENDOMETRIAL CANCER

Y. Todo¹, H. Kato¹, S. Takeshita¹, M. Yamazaki¹
¹Hokkaido cancer center, gynecologic oncology, sapporo, Japan

Aims

The aim of this study was to investigate the feasibility of sentinel lymph node mapping characterized by a cervical tracer injection in endometrial cancer.

Method

This retrospective study was carried out using data for 57 patients with endometrial carcinoma who had undergone intraoperative sentinel lymph node mapping and subsequent surgical staging. Technetium colloid and/or indocyanine green was injected into the uterine cervix and a gamma-detecting probe and/or photodynamic eye camera system was used intraoperatively to locate hot spots.

Results

Of the 57 patients, 52 (91.2%) had FIGO Stage I disease. Successful unilateral or bilateral mapping occurred in 54 patients (94.7%) and 46 (80.7%), respectively. The median number of sentinel lymph nodes detected was two (range, 0–5). Following sentinel lymph node mapping, 41 patients (71.9%) underwent pelvic lymphadenectomy alone and 16 (28.1%) full lymphadenectomy. The median number of lymph nodes resected was 17 (range, 8–110). Sentinel lymph nodes were involved in four patients (7.0%), two with macrometastasis and two with low-volume metastases. The sensitivity and negative predictive value for detecting lymph node metastasis were both 100%.

Conclusion

Sentinel lymph node mapping with the use of cervical tracer injection is highly feasible in Japanese women with early stage endometrial cancer.
LYMPHOCELE AFTER PELVIC LYMPHADENECTOMY FOR PATIENTS WITH ENDOMETRIAL CANCER

T. Rogovskaya1, A. Sidoruk1,2, N. Mikaya1, N. Bondarev3, E. Ulrikh1, Y. Gavrisht4, I. Berlev1,2, A. Urmancheeva1,4

1Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia
2North-Western State Medical University named after I.I Mechnikov, Gynaecological department, Saint-Petersburg, Russia
3Pavlov First Saint Petersburg State Medical University, Oncological department, Saint-Petersburg, Russia
4North-Western State Medical University named after I.I Mechnikov, Oncological department, Saint-Petersburg, Russia

Aims

To identify the incidence of lymphocele after pelvic lymphadenectomy in patients after laparoscopic and open abdominal surgery for endometrial cancer.

Method

648 endometrial cancer patients underwent hysterectomy and bilateral pelvic lymphadenectomy with laparoscopic and open approach in N.N. Petrov Research Institute of Oncology from 2010 to 2016. The median age of patients at surgery was 59.8 (25–88) years. Median BMI was 32.7 (18.31–60.97) kg/m2. A total of 327 patients after laparoscopic surgery were compared to 321 patients after open surgery group. In both groups the majority of patients were at stage IA and IB (89.3% in the laparoscopic group and 69.7% in the laparotomic group). Metastases in pelvic lymph nodes were detected in 4.89% and 10.9% of patients respectively. Ultrasound examination of the pelvis for all patients after surgery was performed.

Results

The overall incidence of lymphoceles was 320/648 (49.4%): 141/320 (44.06%) after laparoscopy and 179/320 (55.9%) after open surgery (p=0.01). Symptomatic lymphoceles were found in 15 (4.6%) and 21 (6.5%) patients after laparoscopic and open surgery respectively. The mean size (largest diameter) of lymphoceles was 43.7 mm (1–155 mm). There was a significant size difference between asymptomatic (mean size 39.9 mm; 1–114 mm) and symptomatic lymphoceles (mean size 82.3 mm; 32–155 mm) [p=0.02].

Conclusion

The incidence of lymphocele after lymphadenectomy for endometrial cancer is high (49.4%). Most of them are asymptomatic (88.9%). Laparoscopic approach in endometrial cancer surgery is associated with a lower occurrence of both asymptomatic and symptomatic lymphoceles compared to open surgery.
HYPOXIA AND HYPERGLYCAEMIA ARE ASSOCIATED WITH METFORMIN RESISTANCE IN ENDOMETRIAL CANCER
V. Sivalingam1, A. Latif2, S. Kitson1, R. McVey2, H. Kitchener1, I. Stratford4, E.J. Crosbie1

2Division of Pharmacy and Optometry, School of Health Sciences, Manchester, United Kingdom
3Department of Histopathology, Central Manchester University Hospitals Foundation Trust, Manchester, United Kingdom
4Division of Pharmacy and Optometry, School of Health Science, Manchester, United Kingdom

Aims

Obesity and insulin resistance are key drivers in the pathogenesis of endometrial cancer (EC). Metformin reduces tumour proliferation in vitro and following short-term pre-surgical administration in patients with EC. We hypothesised that metformin’s anti-tumour activity is driven by effects on mitochondrial function and affected by glucose and oxygen concentrations.

Method

Ishikawa and HEC1A EC cell lines were used in cell viability, flow cytometry and mitochondrial assays to test the cytostatic and mitochondrial function effects of metformin at varying glucose (0.5-25mM) and oxygen (1%-21%) concentrations. In patients, baseline serum glucose and insulin levels were measured before treatment with metformin in a pre-surgical study. Baseline tumour hypoxia (HIF-1α, CA-9) and change in mitochondrial mass (TOMM-20) was measured by immunohistochemistry in endometrial tumours.

Results

In vitro, metformin’s dose-dependent cytostatic effects (p<0.01) were reduced by high glucose and hypoxia (p<0.05-0.001). These conditions suppressed basal and mitochondrial respiration in mitochondrial assays (p=0.017). In vitro, metformin increased mitochondrial mass (p<0.0001) but decreased mitochondrial function (p<0.001) at low glucose concentrations (p<0.01), while treatment in patients was associated with increased mitochondrial mass (p=0.03). There was no association with baseline glucose or insulin levels but metformin response was reduced in hypoxic tumours (p=0.03).

Conclusion

Supraphysiological concentrations of metformin are required for cytostatic effects in high glucose culture conditions. Metformin response is reduced in low oxygen concentrations, both in vitro and in patients. Metformin targets mitochondrial function, however in high glucose, a switch to glycolysis may contribute to metformin resistance. Understanding these metabolic adaptations can help identify patients likely to benefit from metformin.
ENDOMETRIAL CANCER II

EFFICACY OF ENDOMETRIAL CANCER FOLLOW-UP: AN EXPERIENCE FROM A TERTIARY CARE HOSPITAL IN ITALY

I. Turrini1, F. Sorbi1, A. De Magnis1, D. Pavone1, G. Fantappiè1, F. Petraglia1, I. Noci1, M. Fambrini1

1University of Florence, Department of Experimental and Clinical Biomedical Sciences - Division of Obstetrics and Gynecology, Florence, Italy

Aims

To review the experience of a tertiary university hospital on endometrial cancer follow-up in a 10 year period.

Method

We retrospective review our institutional experience of follow up between September 2006 and September 2016 for patients treated for endometrial carcinoma and critically analyzed how to improve the clinical practice and the quality of life, reducing the public spending. Patients have been examined with a frequency of 4-5 months for the first 2 years, 6-8 months between third and fifth year, every 12 months between fifth and tenth year.

Results

367 patients were enrolled. The recurrence rate was 8.18% with the highest recurrence rate in stage IIIC (36.4%). Only six patients (20%) showed symptoms before the diagnosis with no difference in recurrence free survival between asymptomatic and symptomatic patients. Among the asymptomatic endometrium recurrences, the diagnosis was made with imaging clinical examinations in the 87.5% of cases. Vaginal cytology did not detect any disease recurrence in case of central asymptomatic endometrium recurrences. There were no relapses after the fifth year of follow-up.

Conclusion

Considering the necessity of a spending reduction for the National Health System, we recommend a more careful modulation of the number of examinations and of required tests based on risk factors and on the patient's prognostic. In accordance with literature, the use of vaginal cytology in endometrial cancer follow-up should be reduced. The absence of recurrence after the fifth year of follow-up might suggest to reduce the length of follow-up programme.
ENDOMETRIAL CANCER II

ESGO7-1066

THE INFLUENCE OF SOME CLINICAL FACTORS ON SURVIVAL OF ENDOMETRIAL STROMAL SARCOMA PATIENTS.

V. Sukhin1, O. Sukhina2, V. Kolomatskaja3, N. Fedorenko1

1Grigoriev Institute of medical radiology, Oncogynecology, Kharkov, Ukraine
2Grigoriev Institute of medical radiology, Radiation therapy, Kharkov, Ukraine
3Grigoriev Institute of medical radiology, Clinical oncology, Kharkov, Ukraine

Aims

analyse clinical cases of uterine sarcoma patients, who were diagnosed for the first time and underwent treatment between January 1997 and December 2016 in the clinic of «Grigoriev Institute for Medical Radiology of NAMS of Ukraine».

Method

There was evaluated the treatment results of 42 uterine endometrial stromal sarcoma patients stage IA-IVB (T1-3NxM0-1). All the patients underwent surgery, radiotherapy and/or chemotherapy. The treatment efficacy was assessed by the incidence-rate, recurrence-rate, disease-free and overall survival, site of recurrence and metastasis.

Results

the progression index was 22.2 ± 1.0 % at stage I, 50.1 ± 1.7 % at stage II, 66.7 ± 1.7 % at III stage, and 62.5 ± 1.8 % at stage IV, with the period of observation up to 60 months. The recurrence-rate after combined or complex treatment in ESS patients stage I–IV was 42.9 ± 7.6 %. loco-regional recurrence was detected in 16.7 ± 5.8 % of patients, distant metastases – in 26.2 ± 6.8 %.

Conclusion

The progressive disease in term before 6 months was noted in 80 % of patients with stage II and IV. The 5-year non-progressive survival, without taking into consideration the stage of disease, was 57.1 %. The treatment regimen has no influence on relapse-rate in ESS patients.

RECURRENCE PREDICTION SCORE: DEVELOPMENT AND VALIDATION OF A SYSTEM TO PREDICT BASELINE RISK OF RECURRENCE IN STAGE I-II ENDOMETRIAL CARCINOMA

K. Takahashi1, M. Yunokawa2, I. Kuno1, Y. Yoneoka1, T. Tsukada1, M. Kobayashi1, K. Tate1, H. Shimizu1, T. Uehara1, M. Ishikawa1, S.I. Ikeda1, T. Kato1

1National cancer center hospital, Department of gynecology, Tokyo, Japan
2Cancer institute hospital of JFCR, Medical Oncology Department, Tokyo, Japan

Aims

To develop and validate the 3-year recurrence prediction score (RPS) system for predicting the baseline risk of recurrence in stage I-II endometrial carcinoma.

Method

We reviewed 427 patients with FIGO stage I-II endometrial carcinoma who underwent surgery without any adjuvant therapy at our institution from 2005 to 2013. Multivariate analysis was performed using clinicopathological factors to identify the risk factors for 3-year recurrence-free survival (RFS) in 251 patients treated in odd-numbered years (test cohort). We assigned score points to each risk factor based on Cox regression analyses and the sum of the risk factor score points was defined as the RPS system. The scoring system was applied to 176 patients treated in even-numbered years (validation cohort).

Results

The significant risk factors were age ≥60 years, pathological type II, cervical stromal invasion, and positive peritoneal cytology and Cox regression analysis revealed that the regression coefficients of each factor were almost same, and we defined each score points as 1. Score distribution and the 3-year RFS rate for each RPS are shown in Table 1 and Table 2. The 3-year RFS was significantly higher in the low-RPS group (RPS 0-1) than in the high-RPS group (RPS 2-3) (97.7% vs. 71.1%, p < 0.01) (95.2% vs. 79.9%, p < 0.01) in both test and validation cohort (Figure 1).

Conclusion

The RPS system showed significant reproducibility for predicting the baseline risk of recurrence using multiple risk factors.
A FEASIBILITY OF LAPAROSCOPIC SURGERY WITH PELVIC LYMPHADENECTOMY FOR EARLY-STAGE ENDOMETRIAL CANCER

N. Takahashi1, E. Yoshioka1, A. Mochizuki1, Y. Kasamatsu1, N. Kado1, M. Abe1, M. Takekuma1, Y. Hirashima1
1Shizuoka Cancer Center, Gynecology, Shizuoka, Japan

Aims

To investigate feasibility of laparoscopic surgery with pelvic lymphadenectomy for endometrial cancer.

Method

Laparoscopic surgery for endometrial cancer hadn't been covered by insurance until 2014 in Japan. Since 2015, we have performed laparoscopic surgery (LPS) for 93 endometrial cancer patients. Pelvic lymphadenectomy were performed for 35 of them. We judge the adaptation of lymphadenectomy for endometrial cancer from frozen-section results (Table 1). Insurance allows to perform total laparoscopic hysterectomy (TLH)+bilateral salpingo-oophorectomy (BSO)+pelvic lymphadenectomy, not to perform para-aortic lymphadenectomy. We compared them with 102 patients by laparotomy (LPT) with pelvic lymphadenectomy for endometrial cancer performed 2011-2016 about age, body mass index (BMI), operative time, blood loss, resected lymph nodes, intraoperative and postoperative complications.

* TA H-BSO was performed for all patients.
* TA H: total abdominal hysterectomy
* BSO: bilateral salpingo-oophorectomy
* PL A: pelvic lymphadenectomy
* PAL A: para-aortic lymphadenectomy
* others: carcinoma in situ, clear cell adenocarcinoma, etc.

Results

Patient characteristics were not significantly different between two groups (median age: 58 (39-76) for LPT vs 58 (24-78) for LPS, BMI: 23 (16-36) vs 28 (17-35), respectively). The median operative time was 341 min (225-596), blood loss 12 ml (0-191), resected lymph nodes 45 (18-78) in LPS, and 266 min (163-48), 325 ml (72-1018), 44 (24-82) in LPT. The operative time in LPS was longer (p < 0.01), although blood loss was less than LPT (p < 0.01). And resected lymph nodes were almost equal between the two groups.

The statistic difference on intra and perioperative complications between the two was not significant. (blood transfusion: 6.4% vs 0%; p = 0.08; injuries of other organ: 0% of both groups)

Also, the statistic difference on post-operative complications was not significant as well (surgical site infection 4.9% vs 0%, p = 0.28; pelvic peritonitis 6.9% vs 8.7%, p = 0.78; ileus 0% of both groups).

Conclusion

Laparoscopic surgery with pelvic lymphadenectomy for endometrial cancer was feasible compared with conventional laparotomy.
A PREDICTION MODEL OF SURVIVAL FOR PATIENTS WITH BONE METASTASIS FROM UTERINE CORPUS CANCER
S. Takeshita¹, T. yukiharu¹, K. hidenori¹, S. chisa¹
¹Hokkaido Cancer Center, Gynecology, Sapporo, Japan

Aims

The aim of the study was to establish a predictive model of survival period after bone metastasis from endometrial cancer.

Method

A total of 28 patients with bone metastasis from uterine corpus cancer were included in the study. Data at the time of bone metastasis diagnosis, which included presence of extraskeletal metastasis, performance status, history of any previous radiation/chemotherapy, and the number of bone metastases were collected. Survival data were analyzed using Kaplan–Meier methods and Cox proportional hazards models.

Results

The most common site of bone metastasis was the pelvis (50.0%), followed by lumbar spine (32.1%), thoracic spine (25.0%), and rib bone (17.9%). The median survival period after bone metastasis was 25 weeks. The overall rate of survival after bone metastasis of the entire cohort was 75.0% at 13 weeks, 46.4% at 26 weeks, and 42.9% at 52 weeks. Performance status of 3–4 was confirmed as an independent prognostic factor (HR, 3.5; 95% CI, 1.41–8.70) and multiple bone metastases tended to be associated with poor prognosis (HR, 2.4; 95% CI, 0.95–5.97). A prognostic score was calculated by adding up the number of these two factors. The 26-week survival rates after bone metastasis were 88.9% for those with a score of 0, 45.5% for those with a score of 1, and 0% for those with a score of 2 (p=0.0006).

Conclusion

This scoring system can be used to determine the optimal treatment for patients with bone metastasis from endometrial cancer.
EXPRESSSION OF THE PUTATIVE CANNABINOID RECEPTOR GPR55 IS INCREASED IN ENDOMETRIAL CARCINOMA

T. Ayakannu1,2, T. Anthony3, J. Chatterjee1, P. Ellis1, A. Tailor1, Q. Davies4, M. Esther4, S. Butler-Manuel1, J. Konje2,5

1University of Surrey- Royal Surrey County Hospital, Guildford Gynaecology Oncology Research Department, Guildford, United Kingdom
2University of Leicester, Endocannabinoid Research Group- Reproductive Sciences Section- Department of Cancer Studies and Molecular Medicine, Leicester, United Kingdom
3University of Leicester, Endocannabinoid Research Group- Reproductive Sciences Section- Department of Cancer Studies and Molecular Medicine, Leicester, United Kingdom
4University of Leicester, Department of Gynaecology Oncology, Leicester, United Kingdom
5Sidra Medical and Research Centre, Department of Obstetrics and Gynaecology, Doha- Qatar, Qatar

Aims

The GPR55 receptor is a potential key player in malignant transformation involving human tumours. Aim of this study was to evaluate GPR55 expression in endometrial carcinoma (EC).

Method

A total of 27 endometrial biopsies (21 ECs (15 type 1, six type 2)) and six normal age-matched controls atrophic endometrium were recruited. Samples were divided into two: one for this study and one for histological confirmation of diagnosis. GPR55 transcript levels were measured using Taqman multiplex qRT-PCR. Immunohistochemistry was performed using commercially available GPR55 antibodies. Statistical testing was performed using one-way ANOVA followed by Dunn's ad hoc post-test or Mann-Whitney U-test.

Results

GPR55 transcript levels were significantly raised (p<0.0020) in the EC when compared with atrophic tissues. Sub-analyses revealed that GPR55 transcript level in patients with type 1 disease were significantly elevated compared to control patients (p<0.0007), but were not elevated in patients with type 2 disease (p<0.1320). Furthermore, GPR55 transcript levels in patients with grade 1 and 2 EC type 1 were statistically significantly elevated (p<0.01) and (p<0.05), respectively, but not in grade 3 type 1 EC and type 2 (serous and carcinosarcoma) samples. IHC showed GPR55 immunoreactivity to be markedly increased in EC samples compared to atrophic endometrium, with differential staining intensities; atrophic< type 2 < type 1 EC, mirroring the transcript levels.

Conclusion

This study demonstrates that, GPR55 expression is elevated in EC and may play a role in the aetiopathogenesis of EC. GPR55 could be an invaluable as a diagnostic tool and a potential therapeutic target.

ESGO7-0369

Implications of Para-Aortic Lymph Node Metastasis in Patients with Endometrial Cancer Without Pelvic Lymph Node Metastasis

Y. Todo1, H. Yamazaki1, C. Shimada1, S. Takeshita1, H. Kato1
1Hokkaido Cancer Center, Gynecologic Oncology, Sapporo, Japan

Aims

The aim of this study was to confirm the incidence and implications of a lymphatic spread pattern involving para-aortic lymph node (PAN) metastasis in the absence of pelvic lymph node (PLN) metastasis in patients with endometrial cancer.

Method

We carried out a retrospective chart review of 754 patients with endometrial cancer treated by surgery at Hokkaido Cancer Center between 2003 and 2016. Of these patients, 380 (50.4%) who underwent PLN dissection and PAN dissection were reviewed retrospectively. We determined the probability of PAN metastasis in patients without PLN metastasis and investigated survival outcomes of PLN−PAN+ patients.

Results

The median numbers of PLN and PAN removed at surgery were 41 (range: 11–107) and 16 (range 1–65), respectively. Sixty-four patients (16.8%) had lymph node metastasis, including 39 (10.3%) with PAN metastasis. The most frequent lymphatic spread pattern was PLN+PAN+ (7.9%), followed by PLN+PAN− (6.6%), and PLN−PAN+ (2.4%). The probability of PAN metastasis in patients without PLN metastasis was 2.8% (9/325). The 5-year overall survival rates were 96.5% in PLN−PAN−, 77.6% in PLN+PAN−, 63.4% in PLN+PAN+, and 53.6% in PLN−PAN+ patients.

Conclusion

The likelihood of PAN metastasis in endometrial cancer patients without PLN metastasis is not negligible, and the prognosis of PLN−PAN+ is likely to be poor. The implications of a PLN−PAN+ lymphatic spread pattern should thus be taken into consideration when determining patient management strategies.
NEW ASPECTS IN PREVENTION AND EARLY DIAGNOSTIC OF ENDOMETRIAL CANCER IN A FIRST-DEGREE RELATIVES FROM FAMILIES WITH LYNCH SYNDROME.

I. Tripac
1Institute of Oncology, Gynaecology, Chisinau, Moldova

Aims

Accumulation of malignant neoplasms in families with Lynch syndrome, creates the need for screening for the early diagnosis and prevention of hereditary cancer.

Prevention and early diagnosis of endometrial cancer in families with high cancer risk will reduce the incidence and mortality of women with hereditary predisposition to endometrial cancer.

Method

Material and methods: We retrospectively followed 361 women who were recruited to the National Register of Cancer Families between 2007-2013, including data on 145 families of probands with endometrial cancer (38 cases), ovarian cancer (36), colorectal cancer (CRC) (31 cases), Breast cancer (20 cases) and multiple primary malignant neoplasms (MPMN) (20 cases). As the control, the age-adjusted population frequencies of endometrial cancer were used. The work used clinical, instrumental and laboratory methods of investigation.

Results

Results: A total of 18 endometrial cancer cases with a frequency of 4.9 ± 1.14% were observed. Compared with women without family history, we found an increased risk of endometrial cancer for women from families with Lynch syndrome, which exceeds the population frequency by 490 times. The peak of the maximum incidence of women with endometrial cancer falls at the age of 45-52 years, while the peak incidence of EC in probands falls on the older age of 59-62 years.

Conclusion

Conclusions: A high percentage of accumulation of malignant pathology, including EC, among women from families with Lynch syndrome, underlines the necessary of screening for the early diagnosis and prevention of cancer in these families.
Aims

The EFFECT project is a multi-centric prospective observational registration project evaluating the quality and effectiveness of uterine cancer treatments in Belgium.

Method

41 quality indicators (QI) were selected based on literature and consensus of national experts. Data was collected through an online registration module (optional) developed by the Belgian Cancer Registry. All patients diagnosed with uterine cancer in the 2012-2016 period were eligible. QI descriptive statistics and funnel plots are reported here.

Results

3316 new diagnoses were registered by 58 hospitals. Median age was 69 years and main histology was endometrioid adenocarcinoma (71.7%). 98.1% of cases were discussed at a multidisciplinary team meeting (low variability between hospitals); 86.0% of surgical patients had a pre-operative biopsy (high variability, see figure QI 4); 78.4% of patients with clinical stage I underwent a TH/BSO (high variability); 52.6% of clinical stage I endometrial carcinoma patients had minimally invasive surgery (high variability). 74.4% of stage I grade III patients had lymphadenectomy (high variability). 30-day post-operative mortality was 0.4%.

Figure: Funnel plot showing the proportion of surgical patients who had a pre-operative biopsy (QI 4), showing all hospitals (dots) and Belgian average (86.0%, solid black line).
Conclusion

QoC of uterine cancer is heterogeneous in Belgium, with surgical management being particularly variable. Further analysis will assess whether QoC has improved over the study period.
ENDOMETRIAL CANCER II

ESGO7-1257

THE IMPACT OF GRADE IN ENDOMETRIOID ENDOMETRIAL CANCER INVADING CERVICAL STROMA AFTER HYSTERECTOMY AND BSO.

L. van Lonkhuijzen¹, C. Mom¹, R. Charles¹, G. Fons¹, M. Buist¹, M. Tjong¹, G. Kenter¹, J. van der Velden¹

¹Center for Gynecologic Oncology Amsterdam CGOA- location AMC, Gynaecologic Oncology, Amsterdam, The Netherlands

Aims

To determine the impact of grade on recurrence pattern and survival in endometrial cancer patients with cervical stromal invasion and to analyze the literature to determine the spread pattern, risk on and pattern of recurrence in the same group with grade 1.

Method

A retrospective study was performed where 97 consecutive patients, treated by hysterectomy/BSO and adjuvant radiotherapy (RT) were analyzed with respect to age, grade, type of (adjuvant) treatment, presence of extra uterine disease and outcome. Literature studies, where it was possible to separately analyze grade 1 tumors, were analyzed regarding extra uterine disease, recurrence pattern and survival in relation to type of (adjuvant) treatment.

Results

34 patients (34.7%) had grade 1, 39 (40.3%) grade 2 and 24 (24.0%) grade 3. Extra uterine disease was found in 17%, 38% and 46% of grade 1, 2 and 3 patients respectively. Overall survival was significantly better in grade 1 versus grade 2, 3 patients (82.7% vs 63.2%, p=0.027). Only 1 patient with grade 1 died from disease. One study from literature was found, reporting specifically on 20 grade 1 tumors where only 1 recurrence was reported.

Conclusion

Grade 1 patients with endometrial cancer and cervical stromal invasion have an excellent prognosis. It is debatable if complete staging and/or adjuvant treatment, especially pelvic RT, results in a better outcome for this subgroup. Because all patients had adjuvant RT the role of staging and adjuvant RT remains unclear. The scarce literature confirms the excellent prognosis of the grade 1 subgroup but more detailed data are needed.
ENDOMETRIAL CANCER II

SENTINEL NODE BIOPSY IN ENDOMETRIAL CANCER WITH CERVICAL AND FUNDAL ICG INJECTION

O. Vazquez1, O. Aristegui1, A. Bombin1, K. Goiri1, J. Aguerre1, R. Ruiz1, M. Gorostidi1, I. Jauarena1, A. Lekuona1

1H.U. Donostia, Ginecologia y Obstetricia, San Sebastian, Spain

Aims

To describe a novel sentinel lymph node (SN) tracer injection procedure featuring cervical and fundal green indocyanine (ICG) injection for endometrial cancer.

Method

Between June 26th 2014 and October 31st 2016, 111 patients underwent laparoscopic surgery for endometrial cancer at our Institution. In all cases SN biopsy with dual cervical and fundal ICG injection was performed. All SLN were processed with an ultrastaging technique. 69 patients also underwent total pelvic and paraaortic lymphadenectomy.

Results

The overall SN detection rate was 92.79% (103/111). The overall pelvic SN detection rate was 89.19% (99/111) and the bilateral pelvic SN detection rate was 61.26% (68/111). Paraaortic SN were detected in 59.46% (66/111). Isolated paraaortic SN detection was 4% (4/111). We found macroscopic Lymph Node metastases (LN) 11 patients (9.9%). In another 10 patients microdisease was present in LNs, raising global LN affectation to 18.92. There were 1 false negative case in wich SN was negative with a positive aortic lymphadenectomy, and another positive case in linphadenectomy in wich was not detected the SN. The S was 94.44%, E 100%, VPN 97.83% and LHR(-) 0.06.

| Overall SN Detection Rate | 92.79% | 103/111 |
| Pelvic SN Detection Rate | 89.19% | 99/111 |
| Bilateral Pelvic SN Detection Rate | 61.26% | 68/111 |
| ParaAortic SN Detection Rate | 59.46% | 66/111 |

ESGO7-1325

IMPROVING USAGE AND ADHERENCE BY CONVERTING THE ENDOMETRIAL CANCER GUIDELINE INTO DECISION TREES
M. van der Aa1, S. Verboort2, M. Timmermans3, M. Sieswerda4, W. van Driel5, D. Bolf6, X. Verbeek6
1IKNL, Research, Enschede, The Netherlands
2IKNL, Oncology, Maastricht, The Netherlands
3IKNL, Research, Rotterdam, The Netherlands
4IKNL, ICT, Utrecht, The Netherlands
5NKI-AVL, Gynecologic Oncology, Amsterdam, The Netherlands
6Catharinaziekenhuis Eindhoven, Gynecologic Oncology, Eindhoven, The Netherlands

Aims

Oncological guidelines are often large documents with a huge amount of information on diagnostic procedures and treatment options. Due to this amount of information, inconsistencies are common and the recommendations in the guidelines are difficult to find. When new information based on relevant clinical trials becomes available it is difficult to implement this in these guidelines. Representing guidelines as decision trees is a way to overcome these hurdles. The aim of our study is to examine the feasibility of converting the Dutch multidisciplinary endometrial cancer guideline recommendations into easily accessible decision trees to facilitate guideline usage in daily practice.

Method

We converted the most recent Dutch endometrial cancer guideline into data driven decision trees using a structured method where nodes represent data-items and leaves represent recommendations and/or references to other decision trees.

Results

In total we developed 23 decision trees (www.oncoguide.nl). Currently, the decision trees are updated by professionals involved in treating patients with endometrial cancer. Furthermore, we identified information gaps which we can use in designing new trials and we were able to standardize terminology throughout the recommendations.

Conclusion

Converting guidelines into decision trees is feasible but also challenging. With the decision trees it is now possible to: 1) decide on treatment options easily in daily clinical practice, 2) use this information for shared decision making with the patient, 3) substantiate, document and/or evaluate a treatment advice, 4) use information for discussion at a multidisciplinary tumour board and 5) identify information gaps for which clinical trials could be developed.
LOWER UTERINE SEGMENT INVOLVEMENT AS A PROGNOSTIC FACTOR ON ENDOMETRIAL CANCER

C. Villalain González1, C. Biosques Martinez1, C. Bárcena García1, J.S. Jiménez López1, A. Tejerizo García1, M.D.L.R. Oliver Pérez2

1Hospital Universitario 12 de Octubre, Obstetrics and Gynecology Department, Madrid, Spain
2Hospital Universitario 12 de octubre, Pathology Department, Madrid, Spain
3Hospital Regional Universitario Carlos Haya Málaga, Obstetrics and Gynecology: Chief Of Service, Málaga, Spain
4Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecologic Oncology and Endoscopy, Madrid, Spain
5Hospital Universitario 12 de octubre, Obstetrics and Gynecology: Gynecological Oncology and Endoscopy, Madrid, Spain

Aims

To evaluate the impact of the low uterine segment on both overall survival (OS) and recurrence-free survival (RFS) on patients diagnosed of endometrial cancer

Method

We reviewed 327 consecutive cases of endometrial malignancies diagnosed and treated at our institution between 1/1/2001 and 31/12/2014 with follow-up until January 2016. Patients received as primary treatment hysterectomy and double adnexectomy and on cases of intermediate to advanced risk (ESGO criteria), pelvic and para-aortic lymphadenectomy and/or adjuvant therapy was performed. A univariate Cox regression analysis was established to study both OS and RFS.

Results

87 patients presented with low uterine segment involvement (LUS). A univariate Cox regression model showed that tumors with LUS were 1.47 to 3.76 times more likely to relapse than those without it (p=0.01). Relapse rate for those with LUS was of 34.9% vs 18.6% on the rest of the study population.

RFS were, respectively 65.1% and 81.4%, being these differences statistically significant (p<0.01). Patients with LUS involvement were 1.52 to 4.10 times more likely to die than those without it (p<0.01). Mortality rate was statistically significantly higher on patients with LUS involvement 32.5% vs. 17.3% (p<0.01) and OS was of 67.5% and 82.7% respectively.

Conclusion

Although LUS has not been deeply studied on literature, it was been associated with lymphovascular invasion, RFS and OS. According to our study, LUS is a negative prognostic factor on both RFS and OS on endometrial cancer. Further studies are needed to evaluate its implications on treatment and prognosis on patients diagnosed of endometrial cancer.
HISTEROSONICALLY GUIDED ENDOMETRIAL SAMPLING ON ENDOMETRIAL CARCINOMA: ACCURACY AND IMPLICATIONS

Aims

To determine accuracy of preoperative endometrial sampling guided by histeroscopy.

Method

We reviewed 327 consecutive cases of endometrial malignancies treated at our institution between 1/1/2001 and 31/12/2014. Histology and tumoral grade were compared on preoperative and final reports. Cases where preoperative biopsy was not recorded or tumoral grade not informed were excluded.

Results

Histological and FIGO tumoral grade on preoperative and final reports are shown on Table 1 and 2 respectively.

Concordance on histology was found on 80.2% (256/319) of cases. On tumoral grade it was of 60.8% (144/237) and on 31.6% (75/237) an upgrade was observed on the final report. Global grade-histology concordance between preoperative and postoperative report was of 60.8% (144/237).

Conclusion

Hysteroscopy is still the gold standard technique for preoperative endometrial sampling although it isn’t exempt from inaccuracy on diagnosis.
A CHINESE MULTI-CENTRIC RESEARCH ON FERTILITY-SPARING THERAPY OF ENDOMETRIAL CANCER AND COMPLEX ATYPICAL HYPERPLASIA

Y. Wang, R. Zhou, J. Wang

1Peking University People’s Hospital, Department of Obstetrics and Gynecology, Beijing, China

Aims

This multi-centric retrospective cohort study aims to provide experience for fertility-sparing therapy of endometrial cancer (EC) and complex atypical hyperplasia (CAH).

Method

Patients ≤40, diagnosed with IA (confined to endometrium) G1EC and CAH, plus ER and PgR positive were enrolled and treated according to procedure.

Results

Totally 15 national hospitals 68 patients were enrolled including 37 EC and 31 CA. (1) Oncologic and fertility outcome: Complete remission (CR) rate is 94%. With treatment time prolonged to 12, 15 and 18 months, CR rate increases to 85%, 91% and 94%. Pregnant rate is 46.9% and live birth rate is 40.6%. (2) Recurrence and retreatment: After median follow-up of 48 months, fifteen patients relapse (25.4%). Secondary CR rate is 79%, with the similar CR time as primary treatment (34vs.26 weeks, P=0.604). Secondary relapse rate is 30% after 48 months’ follow up. (3) Analysis of correlated factors: EC (compared to CAH, RR0.23, P=0.015), complicated with diabetes (RR0.06, P=0.017), BMI≥25kg/m2 (RR0.31, P=0.049) are risk factors of CR failure at 6-months treatment. Multivariate analysis shows maintenance therapy significantly decrease recurrence rate (OR0.08, P=0.019). GnRHa combined with progesterone as second-line therapy when mono-agent reacts poorly seems decrease recurrence rate (OR0.013, P=0.143). Assisted reproductive benefits pregnancy rate(54.4%vs.15.6%, P=0.018).

Conclusion

Fertility-preserving therapy for young IAG1 EC and CAH has high CR rate although is easy to relapse. Retreatment has the similar response as primary treatment. Simultaneous GnRHa could be considered as second-line therapy. We recommend maintenance therapy after CR and consider ART to promote conception.
ROBOTIC VERSUS LAPAROSCOPIC TRANSPERITONEAL PARA AORTIC LYMPHADENECTOMY IN GYNECOLOGIC CANCERS: A SINGLE INSTITUTE EXPERIENCE

V. gallotta1, K. Gaballa2, C. Conte1, A. Federico1, A. Biscione1, M.T. giudice1, S. pelligra1, V. Chiantera3, G. vizzielli1, S. Guell Alletti, A. Fagotti1, G. Scambia1, M.G. Ferrandina1

1Università Cattolica del Sacro Cuore, Gynecologic oncology, Roma, Italy
2Oncology Center Mansoura University, Surgical Oncology, Mansoura, Egypt
3University of Palermo, Gynecologic Oncology, Palermo, Italy

Aims

To evaluate the surgical and pathological outcomes of patients underwent transperitoneal para-aortic lymphadenectomy (PAL) for gynecological cancer patients with minimally invasive approach.

Method

Between 2012 and 2016, 184 patients underwent robotic transperitoneal (R-PAL) (n=78) and laparoscopic transperitoneal (L-PAL) (n=106), 43 for cervical cancer (23.3%), 31 for endometrial cancer (16.8%) and 110 (59.7%) for ovarian cancer in Gemelli hospital in Rome. The patients were retrospectively evaluated and compared.

Results

78 patients underwent R-PAL were compared to 106 patients underwent L-PAL. The study showed no significant difference between the 2 groups in terms of age, BMI, and preoperative characteristics. In all series 24 (13%) patients had BMI > 32. The Median operative time for both groups was 237.5 minutes for R-PAL and 220 for L-PAL (p=0.446). Median blood loss was 100 in R-PAL and 80 in L-PAL (p=0.693). Only one patient was converted to open approach in the robotic group. The rate of intraoperative complications in the whole series was 2.7% with no significant difference between the 2 groups (P=0.652). The rate of the postoperative complications in the whole series was 16.8 % with slightly higher rate in robotic group (p=0.045). In all series, the pathological results showed presence of lymph node metastasis in 18 (9.7%) patients, with no difference between the two groups.

Conclusion

The present study showed feasibility, safety of minimally invasive approach for PAL.

ENTEROSORPTION AS A SUPPORTIVE TREATMENT DURING EXTERNAL RADIOTHERAPY IN PATIENTS WITH UTERINE AND CERVICAL CANCER

V. Matkovic1, K. Katic1, A. Corusic1, R. Likic2

1Clinic for Obstetrics and Gynecology- University Hospital Centre Zagreb, Department of gynaecologic oncology, Zagreb, Croatia
2University Hospital Centre Zagreb, Department of Clinical Pharmacology- Zagreb, Croatia

Aims

The most common adverse reactions of external pelvic radiotherapy include: frequent stools, frequent urination, dysuria, tenesmus, abdominal pain and blood count changes. To reduce them, patients should mind their diet, take enough fluids and use medications. One of the possibilities is Enterosgel, a selective enterosorbent.

Method

We administered Enterosgel as a part of a clinical study "The role of Enterosgel in prevention of gastrointestinal adverse reactions of percutaneous radiation". 90 patients with uterine or cervical cancer, treated by external pelvic radiotherapy, were divided into 2 groups: the first group included 46 patients who were given 45 g of Enterosgel per day, and the second group included 44 patients who didn’t take Enterosgel. We monitored the following parameters: ECOG, body weight, diarrhoea, nausea, leukocytes, thrombocytes and erythrocytes count and potassium and sodium levels.

Results

There was no statistically significant difference between the two groups for blood count, electrolytes levels and ECOG. We found a statistically significant difference for body weight, number of diarrheal stools and number of days without nausea. Compared to patients who weren’t taking Enterosgel, patients in Enterosgel group lost 0.49 to 2.17 kg less (p-value = 0.00234), had 0.47 to 6.29 less diarrheal stools (p-value = 0.02325), and had 1.03 to 5.71 less days with nausea (p-value = 0.005588).

Conclusion

Preliminary results indicate that Enterosgel can be recommended as a supportive treatment during pelvic radiation, because it is well tolerated and effectively reduces gastrointestinal problems and weight loss. However, additional studies that will include more patients are needed.

RIVER FLOW INCISION: A MODIFIED INCISION TECHNIQUE FOR DECREASING MORBIDITY OF ILIO-INGUINAL DISSECTION

M.D. Ray¹, A. Mishra¹
¹DR BRA IRCH- All India Institute of Medical Sciences, Surgical Oncology, New Delhi, India

Aims

Ilio-Inguinal LND is an important component of surgical treatment for Ca Penis, Vulva, Primary cutaneous cancer, STS, melanoma etc. Skin flap necrosis is one of the most common complications after IILND with reported frequency up to 65% in published literature. Our experience with a modified surgical approach of River flow incision has been most successful in eliminating flap necrosis.

Method

A modified skin incision was used to perform IILND in 74 prospective patients. Irrespective of primary histology or timing, same technique was used in all cases. Two curvilinear parallel skin incisions were made; each sited about 4 cm above and below inguinal ligament. Flaps were raised below Scarpa's fascia. LND was performed in both inguinal and iliac basin with a standard technique. All patients were followed up prospectively for 30 days after surgery and complications if any, were recorded according to Clavien-Dindo System of reporting surgical complications.

Results

74 patients underwent 104 ILND from July 2012 till Dec 2016. Unilateral dissection was performed in 44 patients and 30 underwent bilateral ILND. There was only one instance of flap necrosis/loss. Complications recorded were Seroma (14.4%), Lymphedema (4.8%), Surgical site infection (4.8%), Deep vein thrombosis (2.7%), partial wound dehiscence (7.9%), partial skin flap loss (2%) all corresponding to Clavien–Dindo Grade 1 & 2.

Conclusion

‘River Flow’ Incision is a simple but effective surgical modification which has enabled us to perform therapeutic ILND safely. Avoidance of flap necrosis, significantly decreased morbidity and almost no learning curve are highlights of this modification of surgical technique.
IDENTIFICATION OF INGUINO-FEMORAL SENTINEL LYMPHNODE IN VULVAL CANCER: SINGLE INSTITUTE EXPERIENCE
B. Ghosh¹, E. Myriokefalitaki¹, C. Robotin¹, M. Datta¹, B. Worsnop¹, M. Smith¹, R. Slade¹, B. Winter-Roach¹
¹The Christie NHS FT UK, Gynaecological Oncology, Manchester, United Kingdom

Aims

to investigate the implications of biopsy taking prior performing identification and excision of inguino-femoral sentinel lymphnode in vulval cancer, according to ESGO guidelines.

Method

Retrospective study of all patients with presumed stage 1 vulval cancer who underwent identification and excision of inguinal sentinel lymph node in our institute, between 1/3/2015 and 31/1/2017. Data collection included patients demographics, tumour location and characteristics, lymphoscintigraphic and histopathological features, and surgical outcomes.

Results

We identified 30 cases of median age 63.1 years (range 34-92 y.o). Preoperative imaging excluded distance disease. Tumour has been previously excised in 46.7% of the cases. Identification of a both hot and blue lymph node was achieved in 93.3% cases. In 2 (6.7%) cases a sentinel lymph node could not be identified by lymphoscintigraphy and therefore a full lymphadenectomy was performed. Both cases were from the subgroup of patients with previously excised primary tumors, with a failure rate of 14.3% vs 0% of those with incisional biopsies, p<0.05. None of them had final positive lymph nodes. 3 out of 28 (10.7%) sentinel lymph nodes were positive. There were no cases (0%) with groin wound healing problems, lymph cyst or lymphoedema. There were no grade 3-4 complications or deaths (0%). There is no groin recurrence in a median of 11 months follow up (range 1-22).

Conclusion

It is important to counsel patients regarding the failure to surgically identify the sentinel lymph node, in case that an excisional biopsy has been performed, and proceed with full lymphadenectomy.
COMBINED RUPIVACAINE PERI-INCISIONAL INJECTION AND INTRAPERITONEAL NEBULIZATION: A NEW EFFECTIVE TOOL IN PAIN CONTROL AFTER LAPAROSCOPIC SURGERY IN GYNECOLOGY: A RANDOMIZED CONTROLLED CLINICAL TRIAL

A. Vitagliano1, M. Noventa1, S. Gizzo1, P.S. Litta1, S. Bergato1, V. Bertoldo1, S. Tosatto1, M. Palumbo1, A.S. Lagana2, S.G. Vitale2, M. Blaganje3, B. Kobal3, D.S. Kristina3, A. Lukanovic3, C. Saccardi1

1University of Padua, Department of Woman and Child Health, Padua, Italy
2University of Messina, Department of Human Pathology in Adulthood and Childhood “G. Barresi”, Messina, Italy
3University Medical Centre Ljubljana, Division of Gynaecology and Obstetrics, Ljubljana, Slovenia

Aims

To evaluate the efficacy of intraoperative topical ropivacaine in the control of post-operative pain in the first 48 h after operative laparoscopy for benign adnexal or uterine pathologies.

Method

We conducted a prospective, randomized, double-blind, placebo-controlled clinical trial. Patients received a standard dose of topical ropivacaine (injected at the three portal sites and atomized in the abdominal cavity) or placebo. We measured the intensity of pain in the first 48 hours using VAS (visual-analogue-scale). Moreover, we evaluated shoulder tip pain, the request for rescue analgesics, time to discharge from recovery room, time to mobilizing on the ward and time to return to daily activities. Patients were divided into two groups (Group_A: benign adnexal pathologies; Group_B: benign uterine diseases) and assigned to Subgroup_1 (ropivacaine) and Subgroup_2 (placebo).

Results

A total of 187 women were included: 93 in Group_A and 94 in Group_B. Forty-seven patients entered Subgroup_A1, 46 Subgroup_A2, 48 Subgroup_B1 and 46 Subgroup_B2. Subgroup_A1 experienced lower post-operative pain at 4 (p=0.008) and 6 h (p=0.001) as well as a faster return to daily activities (p=0.01) in comparison with Subgroup_A2. Both Subgroup_A1 and Subgroup_B1 showed lower shoulder tip pain (respectively, p=0.032 and p=0.001) as well as shorter time to mobilizing on the ward after surgery (respectively, p=0.001 and p=0.01). The remaining variables analysis did not show significant results.

Conclusion

Combined topical analgesia with ropivacaine could represent a new safe and effective tool in the control of post-operative pain in gynecological laparoscopic surgery. Given the greater benefits for adnexal surgery, this strategy may be more suitable for this class of patients.
Aims

Objective. To identify clinical features of women who developed three or more primary malignancies including genital tract (GT) cancers.

Method

Methods. We retrospectively studied women with three or more primary malignancies including GT cancer who were treated since 2001 to 2016.

Results

Results. Of the 16 patients, 15 developed triple cancers and 1 quintuple cancers. The most common GT cancer was endometrial cancer (n=13), and 4 of the patients had synchronous ovarian cancer. Cervical and peritoneal cancer were observed in 2 and 1 patient, respectively. Fifteen patients developed non-GT cancer as their first cancer. The age at diagnosis of first cancer ranged 21-69 years (median, 52 years), and the age at diagnosis of the first GT cancer ranged 46-80 years (median, 65 years). The most common non-GT cancer was breast cancer (n=9), followed by colon (n=5), gastric (n=3) and thyroid cancer (n=3). Subsequent non-GT cancers were observed only in endometrial cancer patients (n=5: gastric, breast, lung, pancreas, and external ear). Six patients had a first-degree relative with gastric or colon cancer, and one had a first-degree relative with breast cancer. Two breast cancer patients treated with tamoxifen developed endometrial cancer. Quintuple cancer (esophagus, tongue, breast, cervix, and low-pharynx) developed in an ex-smoker.

Conclusion

Conclusions. The most common GT cancer in patients with three or more primary malignancies was endometrial cancer. Hereditary factors, tamoxifen, and older age appear to be associated with developing these cancers. Smoking and HPV infection seem to be linked with multiple cancers in a cervical cancer patient.
THE FeASIBILITY OF LAPAROSCOPIC SURGERY AND SAME-DAY DISCHARGE IN GYNECOLOGIC ONCOLOGY FOR OBESE AND VERY OBESE PATIENTS

J. Peng¹, S. Sinasac², K. Pulman², L. Zhang², J. Murphy², T. Feigenberg²
¹University of Toronto, Faculty of Medicine, Toronto, Canada
²Trillium Health Partners, Gynecologic Oncology, Mississauga, Canada

Aims

Surgical interventions are the mainstay of treatment for many gynecological cancers. Minimally invasive surgery offers many potential advantages, including same day discharge. However, performing laparoscopic pelvic surgery in obese patients remains challenging.

Objective: To examine the feasibility and safety of performing laparoscopic gynecologic-oncology procedures with same day discharge in obese and morbidly obese patients.

Method

A retrospective study of patients who underwent laparoscopic surgeries by a gynecologic oncologist from January 2012-June 2016, at a designated cancer centre. Using BMI, patients were categorized as non-obese (BMI<30 kg/m²), obese (BMI30-40kg/m²) and morbidly obese (BMI≥40 kg/m²). Intra and post-operative complications and length of hospital stay were recorded. Group differences were compared with Kruskal-Wallis nonparametric test or Fisher exact test. Univariate and multivariate regressions were done for same day discharge.

Results

Of 497 patients, 288 were non-obese (58%), 162 obese (33%) and 47 morbidly obese (9%). Complex surgical procedures were performed in 58.0% of obese patients and 55.3% of morbidly obese patients. Conversion to laparotomy occurred in less than 9% of all patients with no group differences. Low intra-operative (9-11%) and severe post-operative (2%) complication rates were observed with no group differences. Of 182 (36.7%) patients who had same day discharge, younger age and shorter procedure length increased the likelihood of same day discharge success (p<0.01). Obese patients had a much lower rates of same day discharge compared to non-obese patients (30.2% vs. 69.8%, OR 3.2).

Conclusion

While laparoscopic gynecologic-oncology procedures for obese patients are safe and feasible, much lower success of same day discharge was observed.
ANALYSIS OF EFFICACY AND SAFETY OF OLARATUMAB + DOXORUBICIN OR DOXORUBICIN ALONE IN PATIENTS WITH UTERINE LEIOMYOSARCOMA: RETROSPECTIVE ASSESSMENT OF THE PHASE 1B/2 STUDY JGDG

B.A. Van Tine¹, P. Peterson², A. Shahir³, R. Ilaria Jr.⁴, R.L. Jones²
¹Washington University in St. Louis, Medical Department, St. Louis, USA
²Eli Lilly and Company, Diabetes, Indianapolis, USA
³Eli Lilly and Company, Diabetes, Windlesham, United Kingdom
⁴Royal Marsden Hospital, Sarcoma Unit, London, United Kingdom

Aims

Olaratumab (olara), a recombinant human IgG1 monoclonal antibody that specifically inhibits PDGFRα activation, has demonstrated improvement in median overall survival (mOS) in combination with doxorubicin (dox), compared to doxorubicin alone in a Phase 1b/2 Study. Since leiomyosarcoma (LMS) was the most common soft tissue sarcoma (STS) subtype in the study, we sought to characterize the safety and efficacy of olara+dox in the uterine LMS subpopulation.

Method

A retrospective review was performed on the Phase 2 portion of the study to identify patients with uterine LMS. Kaplan-Meier and Cox methods were used for OS and progression-free survival (PFS). Safety was assessed using CTCAE 4.0.

Results

Fifteen patients with uterine LMS (olara+dox N=8, dox N=7) were identified in the intent to treat population. Median OS was 25.0 (95% CI: 4.9, not estimated [n/e]) and 11.4 (3.6, n/e) months for olara+dox and dox (HR [95% CI] 0.61 [0.175, 2.144]), respectively. Median PFS was 2.7 (95% CI: 1.1, 11.0) and 3.6 (1.0, n/e) months for olara+dox and dox (HR [95% CI] 0.93 [0.245, 3.541]), respectively. The grade≥3 adverse events (AE) observed in 2 or more olara+dox treated uterine or non-uterine LMS patients were: anemia, neutropenia, thrombocytopenia, and fatigue. Grade≥3 febrile neutropenia occurred in 3 patients with uterine and in 1 patient with non-uterine LMS.

Conclusion

Although small cohort size limited definitive conclusions, the clinically meaningful improvement in mOS and safety profile in the uterine LMS population with olara+dox versus dox alone is consistent with that previously reported in the overall STS population.
Aims

To assess safety and efficacy of stereotactic ablative radiotherapy (SABR) for gynaecological cancers in the West of Scotland.

Method

Patients with gynaecological cancers treated with SABR were identified from ARIA database for the period February 2014 to December 2016. Electronic and paper records were scrutinised to record demographic information, indication for treatment, dose and fractionation, toxicities (acute and late), and outcome.

Results

Ten patients were identified, age from 41 to 75 years (median age 52). A total of 12 treatment sites included primary lesions (2 as boost in radical treatment schedule – 1 patient refused brachytherapy, 1 was unfit for Anaesthetic, 1 in metastatic setting for symptom control), central recurrences (2 vaginal, 1 parametrial), and oligometastatic sites (2 pelvic nodes, each treated separately, 1 psoas muscle, 1 abdominal wall lesion, 1 patient with 2 peritoneal deposits, each treated separately). Doses ranged from 1200cGy in 2 fractions (boost in patient who refused a second Brachytherapy insertion) to 3530cGy in 5 fractions.

Four patients had previous radical radiotherapy to Pelvis and SABR was a re-treatment.

Toxicity from this treatment was minimal; there was no G3 toxicity recorded following SABR after a median follow-up of 18 months. Three patients demonstrated excellent clinical or radiological response, 4 demonstrated partial response, and 2 had no response, 4 patients subsequently died, including both where there was no response. Conclusion

Preliminary results demonstrate the feasibility, tolerability and safety of SABR in Gynaecological malignancies, even in those who have previously received full dose Pelvic radiation.
MALNUTRITION AND SARCOPENIA: RISK FACTORS FOR SHORTER SURVIVAL IN PATIENTS TREATED WITH PELVIC EXENTERATION FOR RECURRENT GYNECOLOGICAL MALIGNANCY.

V. Seebacher1, A. Rockall2, M. Nobbenhuis3, R.M. Alvarez Lopez3, A. Sohaib2, T. Knogler4, D. Barton3

1Medical University of Vienna, Gynecology and Gynecologic Oncology, Vienna, Austria
2Royal Marsden Hospital, Radiology, London, United Kingdom
3Royal Marsden Hospital, Gynaecology Unit, London, United Kingdom
4Medical University of Vienna, Radiology, Vienna, Austria

Aims

Pelvic exenteration is a highly morbid procedure performed as the last option for cure in selected patients with recurrent or persistent gynaecological malignancies. Due to a lack of objective factors predicting outcome, patient selection is in part based on subjective criteria. The aim of the present study was to investigate the prognostic value of malnutrition and sarcopenia on the outcome of patients with recurrent gynaecological malignancies treated by pelvic exenteration.

Method

We retrospectively evaluated muscle body composite measurements based on pre-operative CT scans, pre-operatively filled out questionnaires stratifying the risk for malnutrition, and clinical-pathological parameters in 65 consecutive patients with recurrent gynaecological malignancies treated by pelvic exenteration. Selected parameters were investigated for their predictive value for postoperative morbidity by logistic regression analyses. Relevant parameters were included in uni- and multivariate survival analyses.

Results

In 32 and in 34 patients pre-operative CT scans and questionnaires were available for analyses, respectively. We found (1) low muscle attenuation (MA) – an established factor for muscle depletion – and (2) malnutrition, based on a pre-operative questionnaire, to be independently associated with shorter overall survival (p=0.006 and p=0.008, respectively). Interestingly, MA was significantly lower in overweight and obese patients (p=0.04). We did not find any of the investigated factors to be predictive for post-operative morbidity.

Conclusion

The present study suggests, that pre-operative low MA and malnutrition, based on CT scan and questionnaire, are associated with shorter survival in patients with recurrent gynaecological malignancies treated with pelvic exenteration. Further studies are needed to validate these findings in larger cohorts.
IS NERVE-SPARING SURGERY REALLY NERVE SPARING? A VIDEO OF THE PELVIC NERVOUS SYSTEM AFTER LAPAROSCOPIC DISSECTION OF A THIEL-EMBALMED SPECIMEN TREATED BY A NEW PROCEDURE

F. Siegenthaler¹, S. Imboden¹, S. Mohr¹, N. Boemker², V. Djonov², M.D. Mueller¹

¹Inselspital Bern- University of Bern, Department of Obstetrics and Gynecology, Bern, Switzerland
²Institute of Anatomy, University of Bern, Bern, Switzerland

Aims

The inability to visualize the small caliber nerve fibers makes nerve-sparing surgery very difficult. We demonstrate the anatomic path of the pelvic autonomic nerves by laparoscopic dissection of a female cadaver using a technique that allows advanced description of small nerves.

Method

A Thiel-embalmed female cadaver was dissected laparoscopically. After opening of the retroperitoneal space the pelvis was immersed with nitric acid. This facilitated the dissection of the connective tissue and the subsequent preparation was performed only with rinsing and suction. The autonomous nerves were followed up to the visceral organs. The relationships of the nerves to arteries, viscera and ligaments were documented.

Results

The superior hypogastric plexus was situated anteriorly and below the aortic bifurcation. It branched into the left and right hypogastric nerve connecting the superior to the inferior hypogastric plexus. Other afferences of the inferior hypogastric plexus were the sacral and pelvic splanchnic nerves. We detected an impar hypogastric nerve stretching medially to the mesorectum. Furthermore, we identified a delicate network of nerves originating from the hypogastric nerve and stretching medially towards the rectum.

Conclusion

Precise knowledge of the neuroanatomy of the pelvis is important to reduce morbidity after surgery. Thiel fixation and preparation with nitric acid permitted dissection of the nerves up to the intraorganic branches. With our technique, we demonstrate that the area medially below the superior hypogastric plexus – commonly used as an anatomical cleavage point – isn’t devoid of nerves. This suggests that nerve-sparing surgery may not be as nerve sparing as sometimes presumed.
ESTABLISHMENT AND CHARACTERISATION OF PATIENT-DERIVED XENOGRAFT MODELS FOR MALIGNANT GYNECOLOGIC TUMORS

S. Suzuki1, S. Tamauchi1, Y. Shimizu1, M. Yoshihara1, K. Nakamura1, N. Yoshikawa1, H. Kajiyama1, F. Kikkawa1

1Nagoya University Graduate School of Medicine, Obstetrics and Gynecology, Nagoya, Japan

Aims

The patient-derived xenograft (PDX) models have been used in the oncologic field to develop new therapeutic agents, which preserve tumor microenvironment and tumor characteristics, and well reflect patient's histological features. In this study, we attempted to establish PDX models derived from malignant gynecologic tumor patients' surgical specimens implanted into severe immunodeficient mice.

Method

Between April 2016 and March 2017, a total of 15 separate clinical samples (13 malignant ovarian tumors, 1 fallopian tube cancer and 1 uterine carcinosarcoma) were collected and implanted subcutaneously in NSG mice. Surgical tumor tissues were cut into pieces of 2 to 3 mm and transplanted within one day. Three patients had received chemotherapy and/or radiation therapy before surgery.

Results

A total of 8 PDX models (6 malignant ovarian tumors including malignant-transformation of mature cystic teratoma, 1 fallopian tube cancer and 1 uterine carcinosarcoma) were established for a take rate of 53%. The latency time to development of clinically apparent disease from the time of initial implantation varied from 1 to 4 months. Regarding malignant-transformation of mature cystic teratoma, the xenograft tissue was replanted into six nude mice, and after engraftment, two mice were irradiated and other 2 mice were administered cisplatin. Four weeks later, the tumors were sampled and analyzed histologically. Even in nude mice, tumor morphology was maintained. This PDX model's responses to antitumor treatment were similar to those of the patient.

Conclusion

Further evaluation of the PDX models for malignant gynecologic tumors will contribute to the development of treatment strategies.
Aims

Endometriosis-associated malignant transformation in abdominal surgical scar is very rare and aggressive phenomenon. Our review aims to provide a clinical overview, focusing on risk factors affecting survival.

Method

We performed a systematic review based on prior reviews and case reports regarding the phenomenon published as abstracts in English, since 1980 up to 2016. Overall we identified 47 cases, and we included another case from our institution. We analyzed the data, focusing on risk factors that might affect overall survival.

Results

All the patients reported in the literature, had a uterine surgery, mainly caesarean-section (CS). The average time-lag from first surgery to the diagnosis of cancer was about 19-years. Clear-cell carcinoma was the most prevalent histology (67%), followed by endometrioid adenocarcinoma (15%). Most of the patients were treated by extensive surgery and chemotherapy and/or radiation. Overall 5-years survival was about 40%. The median survival was 42 months. Although our review is currently the largest in the literature, we cannot draw any statistical significant results due to the limited number of patients reported. On multiple logistic-regression model and Cox-regression model we found a tendency towards less favorable prognosis with clear-cell histologic type in the first 3 years (p=0.169) and tumor diameter larger than 8 cm in non-clear-cell histology, 18 months post diagnosis (p=0.06).

Conclusion

Endometriosis-associated malignant transformation in abdominal scar is rare and aggressive. It is mostly related to CS scars, and is diagnosed many years post-surgery. Clear-cell histology tends to endure worse prognosis. The treatment is mainly, extensive surgery and adjuvant chemotherapy and/or radiotherapy.
THE BELGIAN REGISTRY FOR GESTATIONAL TROPHOBLASTIC DISEASES: CENTRAL PATHOLOGICAL REVIEW

A. Vandewal1, K. Delbecque2, P. Moerman3, J.C. Noel4, E. Marbaix4, P. Delvenne5, M. Nisolle6, F. Kridelka6, I. Vergote7, F. Goffin6, S. Han7

3University Hospitals Leuven, Department of Pathologic Anatomy, Leuven, Belgium
4Erasmus Hospital, Department of Pathologic Anatomy, Brussels, Belgium
5University Hospital Saint-Luc, Department of Pathologic Anatomy, Brussels, Belgium
6University Hospital of Liège, Department of Obstetrics and Gynaecology, Liège, Belgium
7Leuven Cancer Institute University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium

Aims

We aimed to compare local pathology reports of gestational trophoblastic diseases (GTD) with central pathological reviews.

Method

This prospective observational study used the data of the Belgian register for GTD between July 2012 and January 2017. We compared pathology reports of local pathologists with the central review by the pathologists of the Belgian Registry. Of a total of 332 patients, 2 were excluded (one with suspicion of mole not otherwise specified and one extra-uterine pregnancy with increased hCG level without proven molar pregnancy), 21 data missing and 6 without pathology. Pathology slides of 303 patients were reread by a central pathologist.

Results

Our data showed a disagreement between local and central pathologist in 66 cases (24%). Downgrading (e.g. complete mole to abortion) was observed in 30 cases (46%), upgrading (e.g. complete mole to choriocarcinoma) was observed in 36 cases (55%). After primary diagnosis of a partial mole or complete mole, rate of agreement was 59.5% and 88.5% respectively. The diagnosis of choriocarcinoma (n = 8) was confirmed in 75%. There was one initial diagnosis of invasive mole, which was downgraded to a complete mole. When the local pathologist diagnosed a placental site trophoblastic tumour, the expert agreed in 2 out of 3 cases. The only epithelioid trophoblastic tumour at initial diagnosis was confirmed by the central pathologist.

Conclusion

A review of the pathology report by a central pathologist changed the diagnosis of patients with GTD in 24%. The revised diagnosis had an important impact on the follow-up and treatment of these patients.
THE BELGIAN REGISTRY FOR GESTATIONAL TROPHOBLASTIC DISEASES: CURATIVE EFFECT OF A SECOND CURETTAGE

A. Vandewal1, K. Delbecque2, P. Moerman3, J.C. Noel4, E. Marbaix2, P. Delvenne2, M. Nisolle5, F. Kridelka6, I. Vergote7, F. Goffin6, S. Han1

1University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium
2University Hospital of Liège, Department of Pathologic Anatomy, Liège, Belgium
3University Hospitals Leuven, Department of Pathologic Anatomy, Leuven, Belgium
4Erasmus Hospital, Department of Pathologic Anatomy, Brussels, Belgium
5University Hospital Saint-Luc, Department of Pathologic Anatomy, Brussels, Belgium
6University Hospital of Liège, Department of Obstetrics and Gynaecology, Liège, Belgium
7Leuven Cancer Institute University Hospitals Leuven, Department of Obstetrics and Gynaecology, Leuven, Belgium

Aims

We assessed the curative effect of a second curettage in patients with persistent hCG serum levels after first curettage for a gestational trophoblastic disease (GTD).

Method

This prospective observational study used the data of the Belgian register for GTD between July 2012 and January 2017. We analysed the data of patients who underwent a second curettage. We included 313 patients in the database. Seventeen patients were excluded for various reasons (no pathology report, no information about treatment or lost to follow-up). Primary endpoints were need for second curettage and chemotherapy.

Results

There were 85 partial moles and 147 complete moles diagnosed. Choriocarcinoma and invasive mole was diagnosed in ten and three patients respectively. Placental site trophoblastic tumour and epithelioid trophoblastic tumour was diagnosed each in two patients.

Thirty-seven patients of the study population (12%) underwent a second curettage, 21 patients (57%) needed no further treatment afterwards. Sixteen patients (43%) needed postoperatively further chemotherapy. Of these patients 12 (75%) were cured with single-agent chemotherapy and 4 patients (25%) needed multi-agent chemotherapy. Patients with hCG levels below 5000 IU/L undergoing a second curettage were cured without chemotherapy in 65% versus 45% of patients with hCG level more than 5000 IU/L. Of the ten patients with a hCG level below 1000 IU/L, eight were cured without chemotherapy.

Conclusion

Patients with persistent trophoblastic diseases with persistent hCG level can benefit from a second curettage to avoid chemotherapy, especially when the hCG level is lower than 5000 IU/L and even more if hCG level is below 1000 IU/L.

ESGO7-0115

A NATIONAL, PROSPECTIVE OBSERVATIONAL STUDY OF FIRST RECURRENCE AFTER PRIMARY TREATMENT FOR GYNECOLOGICAL CANCER IN NORWAY

1Sørlandet hospital Kristiansand, Gynecology, Kristiansand, Norway
2Haukeland University Hospital, Department of Obstetrics and Gynecology, Bergen, Norway
3Oslo University Hospital, Department of Gynecologic Oncology, Oslo, Norway
4Stavanger University Hospital, Department of Obstetrics and Gynecology, Stavanger, Norway
5Akershus University Hospital, Department of Obstetrics and Gynecology, Lørenskog, Norway
6Førde Central Hospital, Department of Obstetrics and Gynecology, Førde, Norway
7Vestfold Hospital Trust, Department of Obstetrics and Gynecology, Tønsberg, Norway
8University Hospital of Tromsø, Department of Gynecologic Oncology, Tromsø, Norway
9St. Olav’s University Hospital, Department of Obstetrics and Gynecology, Trondheim, Norway

Aims

Gynecological cancer patients are routinely followed up for 5 years after primary treatment. However, the value of such follow-up has been debated, as retrospective studies indicate that first recurrence is often symptomatic and occurs within 2-3 years of primary treatment. We prospectively investigated time to first recurrence, symptoms at recurrence, diagnostic procedures, and recurrence treatment in gynecological cancer patients after primary curative treatment.

Method

Clinicians from 21 hospitals in Norway interviewed 680 patients with first recurrence of gynecological cancer (409 ovarian, 213 uterine, and 58 cervical cancer patients) between 2012 and 2016. A standardized questionnaire was used to collect information on self-reported and clinical variables.

Results

Within 2 years of primary treatment, 72% of ovarian, 64% of uterine, and 66% of cervical cancer patients were diagnosed with first recurrence, and 54%, 67%, and 72%, respectively, had symptomatic recurrence. 46% of symptomatic patients failed to make an appointment before their next scheduled follow-up visit.

Conclusion

This is the first prospective, nationwide study to systematically record information on gynecological cancer recurrences. Most recurrences occurred within 2 years of primary treatment; the mean annual incidence rate for years 3-5 after primary treatment was <7%. Sixty percent of patients experienced symptomatic recurrence, but 46% of the symptomatic patients failed to make an appointment earlier than scheduled. Hospital-based follow-up is resource-demanding and may lead to delayed diagnosis of recurrence. Our results imply that shorter hospital-based follow-up should be considered, and patient self-management encouraged.

4Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Department of Pathology, Amsterdam, The Netherlands
5VU University Medical Center-Cancer Center Amsterdam, Centre for Gynecologic Oncology Amsterdam CGOA, Amsterdam, The Netherlands
6VU University Medical Center-Cancer Center Amsterdam, Department of Pathology, Amsterdam, The Netherlands

Aims

Usual VIN (uVIN), responsible for 20% of the vulvar cancers, is caused by a persistent human papillomavirus (HPV) infection. A better understanding of the microenvironment in relation to lymph node metastasis is essential for the development of effective immunotherapeutic strategies for these tumors.

Method

In the present study, we investigated the microenvironment of tumor-draining lymph nodes of HPV-related vulvar cancer patients, by comprehensive four-color flow cytometry-based phenotyping and enumeration of different T cell subsets by studying expression levels of activation markers (ICOS and HLA-DR), co-inhibitory markers (CTLA-4 and PD-1), and FoxP3+ regulatory T cells (Tregs) levels in tumor-negative (LN-, n=6) versus tumor-positive lymph nodes (LN+, n=5) obtained after surgery as primary treatment.

Results

We found significantly more double-negative CD4+CD8+ T cells, significantly more FoxP3+ Tregs, and a lower CD8+ T cell/ FoxP3+ Treg ratio in LN+ compared to LN-. Assessment of the expression of the immune checkpoints CTLA-4 and PD-1 on the T cell subsets showed selective up-regulation of CTLA-4+CD4+ T cell rates in LN+ versus LN- (p<0.03).

Conclusion

Higher frequencies of suppressive T cell subsets (CD4+CD8+ and FoxP3+ Tregs) and CTLA-4+CD4+ T cells are present in LN+ compared to LN- from patients with HPV-related vulvar cancer. Undoubtedly, the numbers of included samples in this study will have to be increased to obtain higher statistical power, but our preliminary data clearly point to the potential of (local) CTLA-4 blockade in the treatment of early-stage or locally advanced vulvar carcinoma, in order to counter apparent immune suppression.
COMPARISON OF GENE MUTATIONAL ANALYSES, INCLUDING BRCA1 ALTERATIONS, IN TWO PROSPECTIVE STUDIES IN NEWLY DIAGNOSED VERSUS PLATINUM-RESISTANT OVARIAN CANCER

methods and results

Aims

We compared prevalences of various genomic alterations in patients with epithelial ovarian cancer treated in two prospective clinical trials, ROSiA (single-arm: front-line bevacizumab-containing therapy [Oza 2016; NCT01239732]) and PENELOPE (placebo-controlled phase III: chemotherapy ± pertuzumab for low HER3 mRNA-expressing platinum-resistant disease [Kurzeder 2016; NCT01684878]), to explore genomic profiles predicting for platinum resistance.

Method

Pre-treatment tissue samples were analysed using FoundationOne® (Foundation Medicine). The distribution of mutational load was compared between trials using a bootstrapped Kolmogorov-Smirnov test. Relative prevalences of gene alterations in >5% of patients were compared using Fisher's exact test. Benjamini-Hochberg false-discovery rate (FDR) adjustment for multiplicity was applied using a 10% threshold for statistical significance.

Results

Samples from 141 PENELOPE and 154 ROSiA patients were evaluable. The mean mutational load was 3.64/megabase and 4.48/megabase, respectively; the difference bordered on statistical significance (bootstrapped Kolmogorov-Smirnov test p=0.097). The figure shows mutational profiles by trial. There were marked differences between PENELOPE and ROSiA for alterations in BRCA1 (16/141 [11.3%] vs 34/154 [22.1%], respectively; odds ratio 0.45) and MYC (20/141 [14.2%] vs 38/154 [24.7%]; odds ratio 0.50); neither
remained statistically significant after multiplicity adjustment (both FDR p=0.21).

**Conclusion**

Apparent qualitative and quantitative inter-trial differences in mutational profile, particularly *BRCA1* mutation, from diagnostic/archival samples may be attributable to prognosis and patient selection (poor-prognosis platinum resistant vs unselected newly diagnosed). No significant difference in mutational load was observed. Analyses by histological subtype and combined markers warrant exploration.
PRE-OPERATIVE RADIOIMIC MODELS ANNOTATE EPITHELIAL OVARIAN CANCER PROGNOSTIC PHENOTYPES
H. Lu¹, C. Fotopoulou¹, A. Rockall¹, E. Curry¹, M. Arshad¹, A. Thornton¹, P. Cunnea¹, H. Gabra¹, E. Aboagye¹
¹Imperial college London, Surgery and Cancer, London, United Kingdom

Aims

CT images can be quantitatively analysed to describe intuitive features such as shape and texture. The features generated from such analyses (i.e. texture analysis or radiomic data) have been associated with prognosis and cellular pathways in many cancer types. The non-invasive and cost-effective nature of radiomic data make it a promising biomarker candidate for cancer patients. In this study, we aimed to investigate the clinical value of radiomic data as a potential biomarker in serous ovarian cancer.

Method

Here, we developed texture analysis software in-house and extracted 657 features from each CT scan. We collected radiomic data and comprehensive molecular information including copy number profile, proteomic and molecular subtype for over 200 primary serous ovarian tumours.

Results

We found that radiomic features of primary ovarian tumours closely correlated with ovarian cancer stage, grade and survival. Furthermore, we discovered that a subset of radiomic features correlated with molecular subtypes and PI3K pathways.

Conclusion

In summary, we demonstrated that radiomic data could be a potential diagnostic and prognostic biomarker to guide future therapy.
FDG-PET/CT IN THE PRE-OPERATIVE EVALUATION OF WOMEN WITH OVARIAN CANCER - EXPERIENCES WITH INCIDENTAL FINDINGS

S.E. Sponholtz¹, O. Mogensen², M.G. Hildebrandt³, P.T. Jensen¹
¹Odense University Hospital, Department of Gynecology and Obstetrics, Odense, Denmark
²Karolinska University Hospital, Department of Gynecology and Obstetrics, Stockholm, Sweden
³Odense University Hospital, Department of Nuclear Medicine, Odense, Denmark

Aims

To assess the clinical impact of pre-operative FDG-PET/CT in women with ovarian, fallopian tube, or peritoneal cancer (OC) with special focus on consequences of incidental findings.

Method

Pre-operative FDG-PET/CT scans in the initial staging of women with OC performed from January 2011 - December 2012 were reviewed to evaluate the impact of incidental findings on additional examinations and the delay and change in planned treatment of OC. All incidental findings and decisions regarding further examination were registered at the first succeeding multidisciplinary team conference. Subsequent procedures were tracked via medical records.

Results

Of 209 included women, 44 (21.1%) presented with one or several incidental findings. Further examination was performed in 35 (79.5%). Malignancy was identified in 15/35 (42.9%), revealing metastases from OC (11), a synchronous primary cancer (3) and one recurrence of a previous cancer. The OC metastases were localized in the lungs, uterus, colon, vagina, and breasts. The remaining 20 women with incidental findings had two benign lesions and one pre-malignant lesion identified whereas no abnormality was found in 17 patients. A significant delay in time until treatment of median four days (range 1-83) was found when an incidental finding was further examined (p < 0.004).

Conclusion

In the present setting, with fast track access to additional diagnostics, further examinations of incidental findings by FDG-PET/CT delayed time to treatment of OC by median four days. The clinical implications of this must be balanced against the gain of detecting unrecognized malignancy in 15 of 209 patients (7.2%).
HIGH GRADE SEROUS OVARIAN CARCINOMAS ORIGINATE IN THE FALLOPIAN TUBE

12Penn Ovarian Cancer Research Center- University of Pennsylvania Perelman School of Medicine, Department of Obstetrics and Gynecology, Philadelphia, USA

Aims

High-grade serous ovarian carcinoma (HGSOC) is the most frequent type of ovarian cancer and has a poor outcome. It has been proposed that fallopian tube cancers may be precursors of HGSOC but evolutionary evidence for this hypothesis has been limited. We aimed to provide insights into the origins of HGSOC.

Method

We performed whole-exome sequence and copy number analyses of laser-capture microdissected fallopian tube lesions (p53 signatures, serous tubal intraepithelial carcinomas (STICs), and fallopian tube carcinomas), ovarian cancers, and metastases from nine patients with HGSOC.

Results

The majority of tumor-specific sequence and structural alterations in ovarian cancers were present in STICs, including those affecting TP53, BRCA1, BRCA2 or PTEN genes. An evolutionary analysis revealed that p53 signatures and STICs were the precursors of ovarian carcinoma which in turn gave rise to metastatic lesions. In one patient we identified a second STIC as a metastasis in the fallopian tube opposite from the affected ovary. These analyses revealed a window of seven years between the development of a STIC and the initiation of ovarian carcinomas, with development of metastases following rapidly thereafter.

Conclusion

Our results provide insights into the etiology of ovarian cancer and have implications for the prevention, early detection and therapeutic intervention of this disease.
OVARIAN CANCER II

ESGO7-0780

CLINICAL SIGNIFICANCE OF C-MET AND PHOSPHO-C-MET IN OVARIAN CANCER
L. Lim1, C.C. Wu2, Y.T. Hsu2, C.L. Chang1,2,3
1MacKay Memorial Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan R.O.C.
2MacKay Memorial Hospital, Department of Medical Research, New Taipei City, Taiwan R.O.C.
3MacKay Memorial Hospital, Department of Medicine, New Taipei City, Taiwan R.O.C.

Aims

C-Met is expressed in human ovarian cancer tissues and phosphorylation of c-Met activates signaling cascades that might affect the behavior of cancer cells. C-Met inhibitors are now under investigation. In this project, we evaluate the clinical significance of c-Met and phospho-c-Met in ovarian cancer.

Method

Tissue arrays consist of archived ovarian cancer tissues from 269 patients were stained with anti-Met mAb and anti-phospho-Met (Tyr1234/1235) mAb. The stainings were scored on a scale of 0 to 3+. High expression was defined as over 50% of moderate and intense staining. Patients’ charts were reviewed until April 2017 for analysis.

Results

Patients with late stage had significant increased lower expression in both c-Met and phospho-c-Met (P=0.0016 and 0.0037). Besides, low expression of c-Met also correlated with higher histological grade (P<0.0001). Lower progression-free survival were found in low expression of c-Met and phospho-c-Met (P=0.0024 and 0.0163) despite no significant difference in overall survival (P=0.1308 and P=0.5351).

Conclusion

High expression of c-Met and phospho-c-Met are associated with better progression-free survival.
RETROSPECTIVE ANALYSIS OF THE IMPACT OF PLATINUM DOSE MODIFICATIONS ON THE OUTCOMES OF STAGE I-IV OVARIAN CANCER PATIENTS

S. Liutkauskiene¹, M. Ilekis², K. Jureniene³, S. Grižas⁴, E. Juozaitytė⁵
¹Hospital of Lithuanian University of Health Science, Oncology and hematology department, Kaunas, Lithuania

³Lithuanian University of Health Sciences, Institute of Biomedical Sciences, Kaunas, Lithuania
⁴Affiliate of Lithuanian University of Health Sciences Kaunas Oncology Hospital, Surgery department, Kaunas, Lithuania
⁵Lithuanian University of Health Sciences, Oncology and hematology department, Kaunas, Lithuania

Aims

The objective of this study was to evaluate the impact of platinum dose reduction and delays on progression free survival (PFS) and overall survival (OS) in patients with stage I-IV ovarian cancer.

Method

Medical records of patients with FIGO stage I-IV ovarian cancer were reviewed. PFS was calculated as the time from surgery until the date of progression or death, OS from surgery until the date of death. Last follow up was on 2016-05-30.

Results

Patients were divided into four platinum response status groups: 1) platinum refractory (N=19), OS 17 months (95% CI: 2.4-31.5); 2) platinum resistant (N=26) OS 20 months (95% CI: 15.1-24.8); 3) partially platinum sensitive (N=16 patients), OS 33 months (95% CI: 19.8-46.1); 4) platinum sensitive (N=39), OS not reached (Figure 1), P <0.0001.

Patients were divide into four chemotherapy delay/platinum reduction groups. 38 patients experienced no dose delay or reductions, OS was 40 months (95% CI: 23.8-56.1); 12 patients had a dose reduction, OS was 21 months (95% CI: 15.6-26.3); 38 patients had a delay, OS was 45 months (95% CI: 17.5-72.4); 12 patients had both schedule and dose modifications, OS was 33 months (95% CI: 29.8-36.2), P>0.05 (Figure 2). The main reason of chemotherapy modification was neutropenia (52%) (Figure 3).

Conclusion

There were no statistically significant OS differences the the four groups of chemotherapy modifications. Neutropenia is the mos common side effect affecting dose modifications.

2Netherlands Cancer Institute / Antoni van Leeuwenhoek hospital, Surgery, Amsterdam, The Netherlands
3Netherlands Cancer Institute / Antoni van Leeuwenhoek hospital, Pathology, Amsterdam, The Netherlands
4Netherlands Cancer Institute / Antoni van Leeuwenhoek hospital, Gastroenterology, Amsterdam, The Netherlands

Aims

Primary mucinous ovarian tumours and mucinous ovarian metastases of the gastrointestinal(GI)-tract can be difficult to differentiate, especially in the presence of pseudomyxoma peritonei (PMP). We evaluated whether this differentiation is relevant for treatment and chance of recurrence.

Method

In this single-centre, retrospective study, 94 patients diagnosed with a mucinous ovarian tumour with or without PMP between January 2000 and February 2017 were reviewed. Demographics, clinical data, histological data and follow-up data were collected and analysed.

Results

Sixty-six (70%) mucinous tumours originated in the ovary, 23 (25%) were metastases from the GI-tract and 5 (5%) had an unknown origin. PMP occurred significantly more often in patients with metastases (70%) compared to patients with primary ovarian tumours (17%, p<0.05). Results of immunostaining, serum tumour marker measurements and treatment are shown in Table 1. There was no significance difference in the incident of recurrence between patients with primary ovarian tumours (33%) and patients with metastases (32%, p=0.930) and between patients with PMP (22%) and patients without PMP (39%, p=0.150). Follow up ranged from 3 months–12 years.

Conclusion

No serum tumour marker or immunostaining can differentiate with certainty between primary ovarian tumours and metastases from the GI-tract. The incidence of recurrence is independent of the origin and the presence of PMP, suggesting that both origins have similar biological behaviour and require similar diagnostic work up and treatment protocols.

ROLE OF TUMOR MARKERS IN CLINICAL RESPONSE TO THERAPY IN PATIENTS WITH EPITHELIAL OVARIAN CANCER (EOC)

C. Macchi†, F. Calavita†, P. Danna†, M. Mitidieri†, D. De Ruvo†, E. Male†, P. Zola†
†S. Anna Hospital, Obstetrics and Gynecology - Department of Surgical Sciences - University of Turin, Turin, Italy

Aims

Overall survival at 5 years of epithelial ovarian cancer (EOC) is 41% and most of EOC recur several time, so it’s important to have a tool to predict the response to chemotherapy. The aim of the study is to evaluate the role of biomarkers as predictive factors for the patients with EOC, treated with chemotherapy.

Method

CA-125 and HE4 values were determined for each cycle of chemotherapy in 41 patients aged ≥18 with EOC and ≥3 cycles. The average value, the slope of the straight line passing through the values of the first and third cycle (point 1 and point 3) and the half-life of the markers were analyzed through univariate analysis and correlated with response according to RECIST criteria. To calculate p values, T student test was used. For the analysis of the curves a generalized linear model was used for repeated measures.

Results

The curves plotted with average of HE4 and CA-125 show a statistically significant difference between responders (RR) and non-responders (NN) groups (CA-125: p=0.008; HE4: p=0.005). Comparing HE4 (RR=46.5 die, NN=79.3 die; p=0.005) and CA-125 (RR=28.8 die, NN=53.8 die; p=0.004) half-lives, these results are independent predictors for response to chemotherapy. The slope of the curve passing through the points 1 and 3 is different for CA-125 (RR=-132.175; NN=-53.14) and HE4 (RR=-141.625; NN=-3.5).

Conclusion

In conclusion, serum levels of CA-125 and HE4 and their half-lives can predict the clinical response to chemotherapy, in patients treated for EOC.
Aims

Epithelial ovarian cancer (EOC) is the 2nd common gynaecological cancer and is the commonest cause of death. Standard treatment of EOC is combination of cytoreductive surgery and chemotherapy.

Recent studies (EORTC 55971 and CHORUS) suggest that complete cytoreduction should remain the objective when surgery undertaken.

The primary aim of this study is to evaluate if the use of the PlasmaJet (PJ) device enables increased cytoreduction rates in comparison to standard surgical technique (SST).

Secondary aims include morbidity and mortality data, Quality of life (QoL) and survival.

Method

Following ethics approval and clinical trials registration (NCT02376231 & ISRCTN26261491), patients recruited when discussing surgery after consent obtained, patient blinded randomised controlled trial, Baseline QoL and at various timepoints collected, Randomisation performed in theatre and patient blinded, Operative details and post op data collected.

Results

110 patients recruited with nearly half in each arm. 8 adverse events. Results suggest decreased bowel resection rate in PJ arm (p<0.05), reduced stoma rates despite higher cytoreduction rate (p,0.05) and higher diaphragm stripping (p<0.05) rates.

LOS was generally lower in PJ arm compared with SST. Analysis of QoL scores suggests significant improvement in QoL scores in the PJ arm.

Conclusion

This is the first RCT of PlasmaJet™ suggesting it may play a role in improving debulking rates while reducing morbidity. A larger multicentre RCT is being recruited to for further evaluation of the reduced stoma rates. Translational work is ongoing with the samples collected at the time of surgery to evaluate reasons behind the response in the PJ arm.
Aims

The PARP inhibitor olaparib is approved in the EU for maintenance therapy of BRCA-mutated (BRCAm+) platinum-sensitive relapsed ovarian cancer patients who are in response to their most recent platinum-based chemotherapy. So far, only limited data on real-world olaparib treatment are available.

Method

The German prospective, non-interventional study C-PATROL (NCT02503436) collects real-world clinical and patient-reported outcome data in BRCAm+ platinum-sensitive relapsed ovarian cancer patients treated with olaparib according to label. This first preplanned interim analysis (cut-off date: 06 April, 2017) provides data on safety and dosing under real-life conditions. Data were analyzed by descriptive statistics.

Results

This interim analysis comprises the first 75 patients (median age 61 [45 to 80] years; ECOG ≤1: 93.3%; patients with ≥2 relapses: 49.3%, patients with ≥3 prior platinum-based chemotherapeutic regimens: 53.3%) with ≥3 months observation after start of olaparib therapy. Patients started with a median daily dose of 800 [300 to 800] mg olaparib. For 70.7% of patients no dose reduction was reported. For 29.3% of patients dose interruptions (median duration 10.0 [2 to 51] days) were documented. Olaparib therapy was permanently stopped due to an adverse event in 3 patients. Treatment-emergent adverse events (all grades) were documented for 85.3% of patients. Anemia (34.7% of all patients), nausea (29.3%) and fatigue (26.7%) were the most common ones.

Conclusion

The current interim analysis indicates that under routine conditions olaparib is well tolerated with a manageable toxicity profile. The toxicity profile is in line with the results of the clinical trial program of olaparib.
MOVING BEYOND THE MICROSCOPE AND INTO PRECISION MEDICINE: ESTABLISHING PROOF-OF-PRINCIPLE FOR A “MOLECULAR” SECOND LOOK SURGERY IN OVARIAN CANCER

J. Martignetti¹, M. Schwartz², O. Camacho-Vanegas¹, A. Wood¹, M. Dashkoff², C. Whitelock¹, T. Harkins³, A.M. Beddoe², P. Dottino²

¹Icahn School of Medicine at Mount Sinai, Genetics & Genomic Sciences, New York, USA
²Icahn School of Medicine at Mount Sinai, Obstetrics- Gynecology- and Reproductive Sciences, New York, USA
³Swift Biosciences, Ann Arbor, MI, USA

Aims

Ovarian cancer (OvCa) survival has not improved over 4 decades nor has our ability to identify true treatment responders. We hypothesized that coupling ultra-deep sequencing technology to the theoretically powerful technique of second-look surgery (SLS) could transform a relatively low resolution cytopathology-based technique into a precision medicine tool of extreme sensitivity and specificity. The simultaneous goals would be to identify potentially drug targetable mutations at the start of treatment and then response to that treatment.

Method

We identified 10 patients with advanced-stage, high-grade serous OvCa who had previously undergone traditional SLS. Targeted next-generation panel sequencing (NGS) interrogating 56 cancer-relevant genes was used for ultra-deep sequencing primary and recurrent tumor specimens, blood, ascites fluid and peritoneal washes. All NGS-identified mutations were validated using an orthogonal technology, digital droplet PCR (ddPCR) or Sanger sequencing.

Results

26 tumor-specific mutations were identified including TP53 mutations in all patients. All five patients who originally had positive cytopathology from SLS were also positive by “molecular” SLS. Notably, mutations present in primary tumor were identified in both SLS and even tumor recurrences 2 years after initial presentation. Three of the five SL patients with negative cytopathology were re-diagnosed as molecular positive. Importantly, these mutations were detected in tumor recurrences 3 years later.

Conclusion

For the first time, we establish through targeted ultra-deep DNA sequencing that tumor-specific mutations present in a patient’s primary and recurrent tumors are detectable at the time of SLS. The clinical value of this enhanced molecular diagnostic approach will need to be defined in future studies.
Aims

Analyse how well untrained examiners – without experience in the use of International Ovarian Tumor Analysis (IOTA) terminology or simple ultrasound-based rules (simple rules) – are able to apply IOTA terminology and simple rules. And to assess the level of agreement between non-experts and an expert.

Method

This prospective multicentre cohort study enrolled women with ovarian masses. Ultrasound was performed by non-expert examiners and an expert. Ultrasound features were recorded using IOTA nomenclature, and used for classifying the mass by simple rules. Interobserver agreement was evaluated with Fleiss’s kappa and percentage agreement between observers.

Results

Fifty consecutive women were included. We observed 46 discrepancies in the description of ovarian masses when non-experts utilized IOTA terminology. Tumour type was misclassified often (n=22), resulting in poor interobserver agreement between the non-experts and expert (kappa=0.39, 95% CI 0.244-0.529, percentage of agreement =52.0%).

Misinterpretation of simple rules by non-experts was observed 57 times, resulting in an erroneous diagnosis in 15 patients (30%). The agreement for classifying the mass as benign, malignant or inconclusive by simple rules was only moderate between the non-experts and expert (kappa=0.50, 95% CI 0.300-0.704, percentage of agreement =70.0%). The level of agreement for all 10 simple rules features varied greatly (kappa index range: 0.08-0.74, percentage of agreement 66-94%).

Conclusion

Although simple rules are useful to distinguish benign from malignant adnexal masses, they are not that simple for untrained examiners. Training with both IOTA terminology and simple rules is necessary before simple rules can be introduced into guidelines and daily clinical practice.
PELVIC NODAL METASTASIS IN PRIMARY MALIGNANT SEX-CORD STROMAL TUMOURS OF THE OVARY: A SINGLE INSTITUTION EXPERIENCE

R. Modi, M. Mankad, P. Dave, A. Desai, S. Patel

1Gujarat Cancer & Research Institute, Department of Gynaecological Oncology, Ahmedabad, India

Aims

To evaluate the incidence of pelvic nodal metastasis in patients with primary malignant sex-cord stromal tumours (SCSTs) of the ovary and add to the limited data available on nodal metastasis in ovarian SCSTs.

Method

A retrospective 5-year single institution review of patients with primary malignant ovarian SCSTs at The Gujarat Cancer and Research Institute (GCRI) between 2009 and 2014 was done. Information was collected regarding patient and tumour characteristics from pathology and medical records.

Results

A total of 48 patients were reviewed, 36 (75%) had granulosa cell tumour followed by fibroma-thecoma group (14.6%). All the nodal tissues examined in these patients were negative. Stage I (85.4%) was most common at presentation.

Conclusion

Our study supports the recommendation of recent published data regarding lack of lymph node metastasis in SCSTs and abandonment of lymphadenectomy for staging procedures of these tumours in primary upfront surgeries.
OVARIAN CANCER II

ESGO7-1222

IMPACT OF RIGHT UPPER QUADRANT CYTOREDUCTIVE TECHNIQUES FOR ADVANCED OVARIAN CANCER ON POSTOPERATIVE HEPATIC FUNCTION AND LIVER FAILURE

S. Nasser1, K. Lathouras1, J. Campbell2, L. Jiao1, C. Fotopoulou1

1West London Gynaecological Cancer Centre-Imperial College NHS Trust, Department of Surgery and Cancer, London, United Kingdom
2Hammersmith Hospitals-Imperial College NHS Trust, Department of Anaesthesia, London, United Kingdom
3Hammersmith Hospitals-Imperial College NHS Trust, Department of Hepatobiliary and Pancreatic Surgery, London, United Kingdom

Aims

The study evaluates postoperative hepatic function and risk of liver failure in patients with advanced ovarian cancer who underwent extensive right upper-abdominal cytoreductive surgery in the primary, relapsed or interval setting.

Method

Medical records were retrospectively reviewed for all women with primary or relapsed ovarian cancer (OC) between 01/2016-12/2016. All patients who underwent liver and/or right diaphragmatic cytoreduction were included in the present study.

Postoperative liver enzyme function (LFTs), as evaluated by alanine transaminase (ALT), alkaline phosphatase (ALP) and bilirubin (Bil), was reviewed and correlated with postoperative complications.

Results

A total of 39 patients were identified. 28 (72%) with primary OC had undergone upfront, 8 (21%) interval and 11 (28%) secondary/tertiary cytoreduction.

Thirty-one cases were high grade serous at FIGO IIIC (22/39). The surgical procedures were full-thickness diaphragmatic resection (n=26; 67%), right partial pleural resection (n=in 3; 12%), cardiophrenic lymph-node resection (n=2; 8%), liver capsule stripping with subcapsular tumor resection (n=22; 56%) and porta-hepatis tumor resection (2; 5%). All patients (39/39) had normal preoperative LFTs.

In 2 (56%) patients LFTs increased immediately and peaked on the 1st postoperative day. Mean value of the highest ALT across all patients was 89 (range: 6-244), ALP 56 (24-210) and Bilirubin 13 (4-27).

In 33 (85%) cases elevated LFTs normalized by 5th postoperative day with no major changes in bilirubin. No immediate complications were directly linked to right upper-quadrant cytoreduction. Two patients developed pulmonary oedema and atrial flutter that resolved with conservative management.

Conclusion

Right upper-abdominal debulking for OC is associated with a transient 50-100% increase (of upper normal limit) in liver-enzymes postoperatively, with little clinical implications. Due to the existing, albeit rare, risk of liver failure patients should be monitored carefully.

4University Clinic of Oncology and Radiotherapy- Skopje, Biochemical Laboratory, Skopje, FYR Macedonia
5University Clinic of Obstetrics and Gynecology- Clinical Center- Nis, Gynecological Oncology, Nis, Serbia

Aims

Comparison of the diagnostic performance of HE4 with the Risk of Malignancy Index (RMI) and Morphology Index (MI) in differentiation of ovarian endometriosis from epithelial ovarian cancers (EOC) in premenopausal women.

Method

Prospective, comparative study was conducted at the University Clinic of Obstetrics and Gynecology in Skopje. 164 premenopausal women were consecutively recruited and analyzed in three study groups: ovarian endometriosis-ASRM stage III and IV (37 cases), “other benign pelvic masses” (57 cases), EOC (11 cases) and one control group (59 healthy women). Morphology Index was calculated as a sum of the scores for tumor’s structure and tumor’s volume according to the Ueland’s criteria. RMI was calculated according to the Jacobs’ criteria. After ultrasonography, all subjects were blood sampled for HE4 and CA125. Surgery and histology verification of the material was performed. Group classification done according to the histologic results. Cut-offs for HE4, RMI and MI as follows: ≥70pmol, ≥25 and ≥5, respectively.

Results

Sensitivity, specificity, positive and negative predictive values and accuracy for ovarian endometriosis vs. EOC, for each of the tested markers are given accordingly: HE4 (81.82%; 100%; 100%; 94.87%; 95.83%); RMI (90.91%; 35.14%; 29.41%; 92.86%; 47.92%) and MI (100%; 75.68%; 55%; 100%; 81.25%).

Conclusion

HE4 performs best in discrimination of ovarian endometriosis from EOC in premenopausal women, but ultrasonography through MI is most sensitive method, detecting all cancer cases. Both HE4 and MI should be done for optimal management in a patient with pelvic mass.

DESCRIBING INTRA-TUMOURAL HETEROGENEITY IN HIGH GRADE SEROUS OVARIAN CANCER

K. Nixon, P. Cunnea, R. Wulandari, E. Curry, C. Albert-Morera, N. Rama, D. Bowtell, H. Gabra, E. Stronach, C. Fotopoulou

1 Imperial College London, Surgery and Cancer, London, United Kingdom
2 Peter MacCallum Cancer Centre, Cancer Genomics and Genetics Program, Melbourne, Australia
3 West London Gynaecological Cancer Centre - Imperial College NHS trust, Surgery and Cancer, London, United Kingdom

Aims

High Grade Serous Ovarian Cancer (HGSOC) remains the leading cause of death among gynaecologic malignancies despite advances in surgical techniques and novel targeted regimens. Disparity in response to treatment is partially due to the vast spatial and temporal intra-tumoural heterogeneity (ITH) observed, making the development of longer term effective therapeutic approaches challenging. We aim to characterise this ITH to understand the molecular mechanisms behind peritoneal dissemination and to define the link between heterogeneity and patient outcome.

Method

Tumour deposits from multiple anatomical sites were collected from advanced (FIGO III/IV) HGSOC patients during maximal effort upfront debulking at a single institution. Tumour cells were extracted, cultured short-term in-vitro, treated with cisplatin and apoptosis and cell viability measured. Patients are tracked for relapse and relapse samples collected where possible.

Results

Thirty-eight patients (mean age: 60 years; range 32-91) were anatomically mapped. Mean number of tumour deposits collected was 8 (range: 4-16) across the entire peritoneal cavity and paracardiac lymph nodes. Phenotypic apoptosis assays showed vast heterogeneity in platinum response across different tumour deposits and individual patients in 64% of patients sampled to date (>2 standard deviation (SD) score of in-vitro cisplatin sensitivity). Correlation with clinical response showed a trend of low heterogeneity (low SD score) with higher probability of future development of platinum-resistant relapse.

Conclusion

Data from phenotypic assays demonstrate a spatial and temporal functional tumour heterogeneity in advanced HGSOC. This functional data coupled with parallel proteomic and genomic analysis will provide a definitive description of ITH and clonally evolved chemo-resistance in HGSOC.
DOES OVARIAN CANCER HAVE A DIFFERENT BEHAVIOR IN THE ELDERLY?

S. Olbrecht1,2, T. Baert1,3, A. Laenen4, I. Vergote1,2,3, A. Coosemans1,3
1 University Hospital Leuven, Department of Gynecology and Obstetrics, Leuven, Belgium
2 KU Leuven, Department of Oncology - Laboratory of Gynecologic Oncology - ImmunOvar Research Group - KU Leuven - Leuven Cancer Institute, Leuven, Belgium
3 KU Leuven, Department of Oncology - Laboratory of Tumor Immunology and Immunotherapy - ImmunOvar Research Group - KU Leuven - Leuven Cancer Institute, Leuven, Belgium
4 KU Leuven, Biostatistics and Statistical Bioinformatics Center of Leuven, Leuven, Belgium

Aims

The mean age at diagnosis of ovarian cancer (OC) is 66.7 years (yrs). However, a substantial proportion is above 75. Since increasing evidence arises that the immune system behaves differently in elderly, considering age in treatment might be relevant. This study provides an overview of OC patients aged above 75 to map histopathology, survival and treatment tolerance.

Method

Women with OC, diagnosed between 2005 and 2015, were included into two groups (above 75yrs (+75yrs) or below 75yrs (-75yrs)). Groups were matched for stage, year of diagnosis and histopathology.

Results

We included 129 patients +75yrs and 88 patients -75yrs. In the +75yrs, 17.05% refused initial treatment. In 69.77% chemotherapy was indicated, of which 3 patients underwent surgery but refused chemotherapy. The difference in delay in chemotherapy administration was non-significant between groups. Thrombocytopenia was more common in +75yrs receiving Carboplatin-Paclitaxel (TC) (p=0.012). For anemia and neutropenia no significant differences were found. A trend was seen to more neutropenic fever in the -75yrs who received Carboplatin (p=0.08). Recurrence occurred in 73.56% +75yrs who underwent the state-of-the-art treatment from which 15 patients chose palliation in second line, compared to 68.12% -75yrs from which only 5 chose palliation. There was no statistical age related difference in progression free survival (PFS) when patients received optimal treatment. The overall survival after 12 months was better in the -75yrs (p=0.0132).

Conclusion

The toxicity profile of TC or Carboplatin in the elderly is comparable to toxicity in younger patients. When elderly patients are treated with the state-of-the-art treatment PFS is similar to -75yrs.
OVARIAN CANCER INCIDENCE CORRECTED FOR OOPHORECTOMY

E. Pavlik, L. Baldwin

University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

Current reported incidence rates for ovarian cancer may significantly underestimate the true rate because of the inclusion of women in the calculations who are not at risk for ovarian cancer due to prior benign salpingo-oophorectomy (SO). We have considered prior SO to influence risk estimates for ovarian cancer and here report the effect of SO on population risk.

Method

Kentucky Health Claims Data, International Classification of Disease 9 (ICD-9) codes, Current Procedure Terminology (CPT) codes, and Kentucky Behavioral Risk Factor Surveillance System (BRFSS) Data were used to identify women who have undergone SO in Kentucky, and these women were removed from the at-risk pool in order to re-assess incidence rates. All age-adjusted rates were calculated based on the standard 2000 US population. The protective effect of SO on the population was determined on an annual basis for ages 5–80+ using data from the years 2009–2013. Analyses were done using SAS Statistical software version 9.4. and for programs calculating the complete prevalence rates from the KHCD data. Statistical tests were two sided with a p-value ≤ 0.05 for statistical significance.

Results

The corrected age-adjusted rates of ovarian cancer that considered SO ranged from 33% to 67% higher than age-adjusted rates from the standard population. Correction of incidence rates for ovarian cancer by accounting for women with prior SO gives a better understanding of risk for this disease faced by women.

Conclusion

The calculated rates of ovarian cancer were substantially higher when SO was taken into consideration than those obtained from estimates for the standard population.
PAIN PERSISTING AFTER THE RESOLUTION OF OVARIAN ABNORMALITIES

E. Pavlik¹, R. Ore¹, E. Ueland¹, B. Headley¹, M. Altman¹, H. Palalay¹, L. Haggenjos¹, L. baldwin¹, R. Miller¹, C. DeSimone¹, S. Johnson¹, T. Fredericks¹, F. Ueland¹, J. van Nagell¹
¹University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To determine whether pain continues when ovarian abnormalities spontaneously resolve.

Method

Ovarian abnormalities were identified in a population of 44,475 individuals that had received 270,302 ovarian screens by transvaginal ultrasonography. Participants reported the presence or absence of abdominal pain using a detailed questionnaire (CLINICAL OBSTETRICS GYNECOLOGY 55,36–42, 2012). Chi square testing was used for all comparisons.

Results

8067 women with 20303 ovarian abnormalities completed questionnaires with 2737 reporting symptoms of abdominal pain. Ovarian abnormalities included: cysts (n=5033), cysts with septations (n=1931), cysts with solid areas (n=900) or solid ovarian structures (n=203). Abnormalities were followed through 31627 sonographic exams (average=3.9 exams). The majority of women (96.2%, 2634/2737) reported resolution of pain when the ovarian abnormality spontaneously resolved. There were no differences in frequency of pain with regard to type of ovarian abnormality (P=.28153, table). For those reporting pain versus no pain after resolution, there were differences observed in BMI (P=.056) and volume of the abnormality prior to resolution (P<.0001), but not patient age (P=.19730). After the ovarian abnormality was no longer visualized, women were less likely to report pain with BMI <25 or when the abnormality had been small (<20mL).

<td>65 (3.6%)</td>
<td>30 (3.9%)</td>
<td>5 (1.7%)</td>
<td>3 (4.8%)</td>
</tr>
</tbody>
</table>

Conclusion

One third of women monitored by serial transvaginal sonography will have pain associated with their ovarian abnormality. When the abnormality is followed to resolution, associated abdominal pain will disappear in 96% of cases. The frequency of pain resolution does not appear to be related to the type of ovarian cyst, but may be associated with the volume of the ovarian abnormality.

ULTRASOUND SURVEILLANCE OF OVARIAN ABNORMALITIES CHARACTERIZED BY STABLE MORPHOLOGY OR MORPHOLOGIES CHANGING BETWEEN CYSTS, SEPTATED CYSTS, CYSTS WITH SOLID STRUCTURE OR SOLID STRUCTURES

E. Pavlik1, S. Johnson1, E. Ritter1, B. Headley1, M. Altman1, H. Palalay1, L. Haggenjos1, E. Ueland1, E. Harvey1, R. Ore1, T. Fredericks1, L. Baldwin1, C. DeSimone1, R. Miller1, F. Ueland1, R. Kryscio1, J. van Nagell1

1University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To determine time to resolution of ovarian abnormalities that demonstrated either stable or changing morphologies.

Method

44,475 individuals received 270,302 ovarian screens by transvaginal ultrasonography. Ovarian abnormalities that demonstrated changes in morphology and resolved (n=1117) were compared to ovarian abnormalities with stable morphology that resolved (n=1800). Significance was determined by Chi square and t-testing.

Results

1117 resolving ovarian abnormalities, characterized by changes in structure, were examined: (cysts=503, cysts with septation(s)=396, cysts with solid areas=180, solid abnormalities=38). Resolving abnormalities received a total of 5658 scans by transvaginal sonography for an averaged 5.1 scans, see table. Resolution times of abnormalities with changing morphology paralleled those with a stable morphology (shown in parenthesis). Half of the cysts & cysts with septations that changed morphology resolved in ~24 months while over 75% resolved in 4+ years and the remainder took more than 5 years. Half of the unstable cysts with solid areas resolved in 8 months. Half of the unstable solid structures resolved in 18 months. Resolution time increased by 10 months with cysts and cysts with septations that had changes in morphology compared to those with unchanging morphology.

</tbody>
</table>

* P<0.05; **not significantly different changing vs unchanging.

Conclusion

When the morphology of an ovarian abnormality is changing, time to resolution increases for cysts and cysts with septations. Half will resolve within 24 months regardless of complexity. Half of the remainder will resolve under a four year surveillance plan. The remainder will persist for more than 5 years before resolving and should be subject to continuing surveillance.
SYMPTOMS RELEVANT TO SURVEILLANCE FOR OVARIAN CANCER

E. Pavlik, R. Ore

University of Kentucky, Obstetrics & Gynecology, Lexington, USA

Aims

To examine how frequently and confidently healthy women report symptoms during surveillance for ovarian cancer.

Method

A symptoms questionnaire was administered to 24,526 women over multiple visits accounting for 70,734 reports. A query of reported confidence was included as a confidence score (CS). Chi square, McNemars test, ANOVA and multivariate analyses were performed.

Results

17,623 women completed the symptoms questionnaire more than one time and >9500 women completed it more than one four times for >43,000 serially completed questionnaires. Frequency of reported symptoms is in Table 1. Reporting ovarian cancer symptoms was ~245 higher than ovarian cancer incidence. The positive predictive value (0.073%) for identifying ovarian cancer based on symptoms alone would predict one malignancy for 1368 cases taken to surgery due to reported symptoms. Confidence on the first questionnaire (83.3%) decreased to 74% when more than five questionnaires were completed. Age-related decreases in confidence were significant (p < 0.0001). Women reporting at least one symptom expressed more confidence (41,984/52,379 = 80.2%) than women reporting no symptoms (11,882/18,355 = 64.7%), p < 0.0001. Confidence was unrelated to history of hormone replacement therapy or abnormal ultrasound findings (p = 0.30 and 0.89).

UTERINE LAVAGE: AN OFFICE PROCEDURE WITH A PROMISING POTENTIAL FOR DIAGNOSING EARLY-STAGE OVARIAN CANCER THROUGH LIQUID BIOPSY

T. Perri1, K. Levanon2, K. Bahar-Shany2, M. Beiner1, B. Brandt1, E. Friedman3, Y. Hants1, J. Korach1

1Sheba medical center, Gynecologic Oncology, Ramat Gan, Israel
2Sheba medical center, Oncology, Ramat Gan, Israel
3Sheba medical center, The Suzanne Levy-Gertner Oncogenetics Unit, Ramat Gan, Israel

Aims

To date, no screening strategy exists for early diagnosis of high-grade ovarian carcinomas (HGOC). In-line with the increasing evidence that HGOC originate from the fallopian tube, it is potentially possible to obtain tumor cells or tumor-associated biological molecules from a liquid-biopsy through uterine lavage. We aimed to develop the technique into a feasible test for early-HGOC detection in high-risk populations.

Method

Eligible patients were BRCA-mutation non-pregnant carriers, who have not undergone risk-reducing salpingo-oophorectomy. An intrauterine insemination-catheter (Insemi™-Cath, 3.5Frq13cm, Cook Inc. USA) was inserted into the cervical canals during routine office-visit. No anesthetic or analgesic was administered and no cervical dilatation/manipulation was used. Ten mL saline were infused into the uterine cavity and immediately retrieved. The liquid was analyzed for proteins, DNA and RNA biomarkers. Proteomic-profiling of microvesicles to characterize early “cancer signature” in biopsies are being developed.

Results

To date, we performed the lavage procedure on 18 patients who provided informed consent, some repeatedly during two consecutive follow-up visits. Time consumption was 1-2 minutes. Most patients reported no-or-minimal discomfort or pain. One lavage procedure was stopped due to pain, and two patients reported mild spontaneously-resolving abdominal pain. In all cases, enough fluid (average 4-5ml) was retrieved for further analysis, enabling the characterization of 2500 different proteins in a sample and providing enough DNA and mRNA to allow PCR and next-generation sequencing.

Conclusion

Our uterine lavage technique is an easy, low-burden, minimal-complication office-procedure, providing a potential method for obtaining liquid-biopsy for early detection of HGOC.
OVARIAN CANCER II

ESGO7-0683

BEVACIZUMAB- CONTAINING FIRST LINE CHEMOTHERAPY MIGHT REDUCE PROGRESSION-FREE SURVIVAL AFTER RECURRENCE IN ADVANCED EPITHELIAL OVARIAN CANCER

T. Perri1, Y. Bar1, M. Beiner1, B. Brandt1, L. Helpmann1, G. Ben-Baruch1, J. Korach1
1Sheba medical center, Gynecologic Oncology, Ramat Gan, Israel
2Meir Medical Center, Gynecologic Oncology, Kfar-Saba, Israel

Aims

Recently, the VEGF inhibitor Bevacizumab was added to the standard front-line therapy of high-grade epithelial ovarian carcinoma (HGEOC). Large randomized trials have shown Bevacizumab benefit, with both progression-free and overall survival. Yet, it was shown that tumor vessels can rapidly regrow after cessation of Bevacizumab, and tumor burden can then increase. We aimed to describe changes in progression free survival after recurrence (PFS2) in advanced stage HGEOC patients treated with and without Bevacizumab at first line.

Method

Included in this cohort study were all consecutive HGEOC patients who have had a debulking surgery between 2011-2015, with either stage 4 or stage IIIc with any residual disease. Sixty-seven patients were treated with carboplatin-paclitaxel. Forty-one patients who were diagnosed after 2013 were treated with carboplatin-paclitaxel-Bevacizumab as it was then approved in our country. Their clinical data was compared.

Results

The groups did not differ in either age at diagnosis, stage, rate of BRCA-mutation carriers or neoadjuvant chemotherapy use. Median follow up was 29 and 32 months in the patients treated with and without Bevacizumab respectively. Progression free survival (PFS) was longer in the Bevacizumab group (14.5 Vs. 10.5 months). Although response rate to second line was comparable, PFS2 in those who received Bevacizumab at first line was significantly shorter (5.9 vs.8.8 months).

Conclusion

According to our cohort, bevacizumab prolongs progression-free survival after first line in stages IIIc with residual disease and stage 4 HGEOC patients, yet it might interfere with PFS2.
NEGATIVE PARP IMMUNOHISTOCHEMISTRY AS A PREDICTOR OF PLATINUM SENSITIVITY IN OVARIAN CANCER

R. Poka¹, S. MOLNÁR¹, L. BARÁTH¹, J. LUKÁCS¹, L. RUDOLF², Z. KRASZNAI¹, Z. HERNÁDI¹, G. MEHES¹

¹University of Debrecen - Faculty of Medicine, Unit.Gynaecol.Oncol.-Dept.ObGyn., Debrecen, Hungary
²University of Debrecen - Faculty of Medicine, Dept.Pathology, Debrecen, Hungary
³University of Debrecen - Faculty of Medicine, Dept.Pathology, Debrecen, Hungary

Aims

We analysed PARP immunohistochemistry results and clinical data of 65 advanced (stage III and IV) ovarian cancer cases to clarify prognostic relevance of PARP expression.

Method

PARP protein expression was determined by immunostaining using a Leica Bond MAX Immunostainer (Leica Microsystems, Wetzlar, Germany) with rabbit polyclonal anti-PARP antibody (ab6079 330, Abcam, Cambridge, UK). Intensity and distribution of immunostaining was assessed by light microscopy (Leica DM2500 microscope, DFC 420 camera and Leica Application Suite V3 software; Leica) and evaluated with a four grade (0-3+) system. Mean progression-free survivals were generated for each groups of PARP expression.

Results

Thirty-five cases (53.8%) were chemotherapy naive and 27 of them (77%) showed no PARP expression. PARP expression among 30 cases following at least one prior line of chemotherapy was negative in 20 cases (67%). Mean PFS after first-line chemotherapy was 17.5 months. PFS of PARP 0, 1+, 2+ and 3+ cases were 18.4, 20.3, 7.8 and 7.4 months, respectively. Mean PFS after second-line chemotherapy was 11.8 months. Among PARP 0, 1+, 2+ and 3+ cases PFSs were 10.4, 12.8, 8.7 and 22.6 months, respectively. Restricting analysis to the population dichotomized by „any” or „no” PARP expression resulted in a significant difference in PFS achieved by first-line taxol-carboplatin chemotherapy (9.9 vs 19.2 months, respectively, p=0.0067). PFS achieved by the second-line chemotherapy also showed survival advantage for PARP negative cases (22.7 vs 13.8 months), however this difference was not statistically significant (p=0.4770).

Conclusion

PARP expression assessed by immunohistochemistry may predict platinum-sensitivity in ovarian cancer.
OPTICAL IMAGING FOR PERITONEAL METASTASES DETECTION IN OVARIAN CANCER: A PILOT STUDY

P.C. Pop¹, I. Veys¹, S. Vankerckhove², R. Barbieux², M. Gomez Caldón³, M. Moreau⁴, D. Larsimont³, V. Donckier¹, P. Bourgeois², G. Liberale¹

¹Jules Bordet Institute, Surgery, Brussel, Belgium
²Jules Bordet Institute, Nuclear Medicine and Clinic-Unit of Lymphology, Brussel, Belgium
³Jules Bordet Institute, Pathology, Brussel, Belgium
⁴Jules Bordet Institute, Data Centre and Statistic, Brussel, Belgium

Aims

Cytoreductive surgery (CS) is limited by the vision of the surgeon. Furthermore, no tools exist for the detection of tumoral cells in post neoadjuvant chemotherapy (NAC) residual scars (RS).

The aims of this study are to evaluate the role of ICG-Fluorescence Imaging (FI) for the detection of peritoneal metastasis and tumoral cells in RS (post NAC).

Method

Patients admitted for primary or interval CS with stage III/IVa from September 2013 to August 2016 were elected for the study. Free ICG (0.25 mg/kg) was IV injected intraoperatively before CS. Fluorescence intensity and tumor to background ratio (TBR) was calculated for all peritoneal nodules (PN) and RS.

Results

Twenty patients including 17 seropapillary adenocarcinoma, and 3 others type of tumors were included. A total of 108 PN and 25 RS were imaged, resected and analysed by histopathology. Amongst PN, 73 were malignant (67.6%) and 35 benign (32.4%). The mean of the TBR (ex vivo) was 1.8 (SD 1.3) in malignant nodules and 1.0 (SD 0.79) in benign nodules (p = 0.007). With a TBR cut-off of 1.3, sensitivity and specificity are respectively 72.6% (53/73) and 45.7% (16/35). Amongst the 25 RS, the mean TBR (in vivo) was 2.06 (SD 1.15) in malignant (n=2) and 1.21 (SD 0.50) in benign nodules (n=23). The positive predictive value of ICG-FI to detect tumoral cells in scars was 57.1%.

Conclusion

ICG-FI is able to discriminate between benign and malignant PN, but not sufficient specific for the detection of tumoral cells in RS post NAC.
AHIF, A HYPOXIA-INDUCED LONG NONCODING RNA, ENHANCES HYPOXIA EPITHELIAL OVARIAN CANCER PROLIFERATION BY INHIBITING APOPTOSIS

J. Qiu¹, H. Keqin¹
¹Obstetrics and Gynecology Hospital of Fudan University, Obstetrics and Gynecology, Shanghai, China

Aims

Hypoxia is a common characteristic of solid tumor, and is a key stress that triggers apoptosis in many cancer types, including epithelial ovarian cancer (EOC). Previous studies discovered a hypoxia-upregulated long non-coding RNA (lncRNA), named “a natural antisense transcript of hypoxia-inducible factor 1 (aHIF)” in some tumors. However, the contributions of aHIF to EOC remain unknown. In this study, we aimed to investigate the expression, function and underlying mechanisms of aHIF under hypoxia conditions in EOC progression.

Method

Expression of aHIF in EOC tissues and its correlation with clinicopathological factors were examined. A series of in vitro and in vivo assays were performed to determine the function and mechanism of aHIF in hypoxia-induced EOC progression.

Results

Clinically, aHIF was overexpressed in EOC tissues relative to normal controls, and the overexpression correlated with advanced International Federation of Gynecologists and Obstetricians stage and high histological grade. In vitro, aHIF was upregulated by hypoxia in EOC cells. Under hypoxia conditions, aHIF knockdown inhibited cell proliferation and accelerated apoptosis. In vivo, aHIF knockdown inhibited tumorigenesis of EOC cells. Mechanically, Dysregulation of mitochondrial apoptosis pathway-associated genes including Caspase-9, Caspase-7, Bax and Bcl-2 by aHIF may partially explain aHIF-induced EOC progression under hypoxia conditions.

Conclusion

Our data offers convincing evidence for the first time that aHIF could enhance EOC proliferation by inhibiting apoptosis through aHIF-mitochondrial apoptosis pathway under hypoxia conditions. These results can help to understand hypoxia-induced EOC progression from the perspective of lncRNA.
ELNCRNA1, A LONG NONCODING RNA TRANSCRIPTIONALLY INDUCED BY OESTROGEN, PROMOTES EPITHELIAL OVARIAN CANCER CELL PROLIFERATION

J. Qiu¹, H. Keqin¹
¹Obstetrics and Gynecology Hospital of Fudan University, Obstetrics and Gynecology, Shanghai, China

Aims

We previously identified a novel oestrogen (E2)-upregulated IncRNA, TC0101441, via microarray analysis. However, the detailed mechanism by which E2 upregulates TC0101441 and the role of TC0101441 in epithelial ovarian cancer (EOC) progression have not been elucidated. In the present study, we further analysed TC0101441, which we designated oestrogen-induced long non-coding RNA-1 (ElncRNA1), and investigate the function and underlying mechanisms of ElncRNA1 in E2-dependant EOC progression.

Method

A serial of assays were performed to determine the mechanism by which E2 upregulates ElncRNA1. ElncRNA1 expression in EOC tissues was examined. In vitro and in vivo functional assays were performed to elucidate the role of ElncRNA1 in E2-dependant EOC progression.

Results

E2 transcriptionally upregulates ElncRNA1 through the oestrogen receptor α (ERα)-oestrogen response element (ERE) pathway using RNA stability assays, bioinformatics-based searches for ERE binding sites, chromatin immunoprecipitation (ChIP) assays and dual luciferase reporter assays. Clinically, ElncRNA1 levels are significantly higher in EOC tissues than in normal ovarian surface epithelium. In vitro and in vivo loss-of-function assays revealed that ElncRNA1 promotes EOC cell proliferation. This pro-proliferation effect of ElncRNA1 was partially mediated by the regulation of Cyclin D1/CDK4/CDK6 pathway.

Conclusion

These findings provide the first evidence that E2 upregulates ElncRNA1 at the transcriptional level through the ERα-ERE pathway and that this novel E2-upregulated IncRNA has an oncogenic role in EOC growth. The placement of ElncRNA1 in the E2-ERα-ERE-Cyclin D1/CDK4/6 signalling pathway may provide greater insight into the effects of oestrogen on EOC progression from the perspective of IncRNA.

C-REACTIVE PROTEIN AS A PREOPERATIVE DIFFERENTIAL DIAGNOSTIC MARKER IN PATIENTS WITH ADNEXAL MASSES

E. Reiser1, S. Aust1, H. von Mersi1, A. Reinthaller1, S. Polterauer1, C. Grimm1

1Department of Gynecology & Gynecologic Oncology, Medizinische Universität Wien, Vienna, Austria

Aims

Various serum tumor markers have been investigated as a preoperative differential diagnostic marker in women with adnexal masses. Serum C-reactive protein (CRP) is a widely used biomarker for inflammatory processes and was shown to be a valid prognostic biomarker in patients with epithelial ovarian cancer (EOC).

Method

CRP serum levels of 3234 patients with adnexal masses and subsequent surgery were investigated (patients with benign ovarian tumors: n= 2719; borderline tumor of the ovary [BTO]: n = 125; EOC: n = 390).

Results

Mean (standard deviation) serum CRP in patients with benign ovarian tumors, BTO, and EOC were 0.9 (2.5) mg/dL, 1.2 (2.5) mg/dL, and 3.7 (4.7) mg/dL, respectively (p < 0.001). Sensitivity and specificity for the combination of CRP and CA 125 was 80.1% and 90.8%, respectively. NPV (negative predictive value) and PPV (positive predictive value) was 92.2% and 76.9%, respectively. In univariate and multivariate analysis, CRP serum levels were independently associated with the diagnosis of BTO and EOC (HR 6.7 [5.2-8.5], p<0.001 and HR 2.2 [1.4-3.3], p < 0.001). The combination of CRP and CA-125 serum levels resulted in number needed to treat (NNT) of 1.5 (suspicious ultrasound and normal CRP and CA-125 serum levels compared to suspicious ultrasound and elevated CRP and CA-125 serum levels) to detect one additional case of EOC/BTO.

Conclusion

CRP serum levels independently predicted the presence of BTO and EOC in patients with adnexal masses. Particularly in combination with CA-125, CRP serum levels seem to be of additional value in the preoperative differential diagnosis of adnexal masses.

ASSESSMENT OF THE RISK OF RELAPSE OF NEOPLASM OVARI (ARRNO): A NEW APPLICATION FOR CLINICAL PRACTICE

A. Savinoval¹, I. Gataullin²

¹Regional Clinical Oncological Center of Tatarstan, Department N4, Kazan, Russia
²Kazan State Medical Academy, Department of Oncology - Radiology and Palliative Care, Kazan, Russia

Aims

The aim of the present study was to develop an algorithm of the assessment of the individual risk of ovarian cancer relapse after accomplishment of the first line therapy.

Method

A retrospective analysis of the data of 1103 patients (01.01.2010-01.01.2015) with ovarian cancer, who received primary cytoreductive surgery with combination of platinum-based chemotherapy in their first line of treatment was performed. The prognostic role of the following 12 parameters was studied: age, stage, tumour status (T), grade, hystotype, results of ultrasound and CT after first line chemotherapy, CA 125pre (before start of combined therapy) and CA 125post (after accomplishment of first line chemotherapy), HE 4pre (before start of combined therapy) and HE 4post (after accomplishment of the first line therapy), the level of cytoreduction (optimal, suboptimal and radical).

Results

After binary regression analysis we defined best data set: stage, hystotype, grade, pelvic ultrasound examination, CA 125pre and HE 4post. Based on the developed algorithm we designed an ARRNO score with AUC (area under the curve) was 0.761 (95%CI: 0.733-0.789). After ROC-analysis we defined as well 3 intervals, corresponding to the low (0-0.39), moderate (0.40-0.85) and high (0.86-1.0) risk of relapse. At the final step the ARRNO score was integrated into application for personal computers, which, in case of integration into internal network of hospitals, provides the possibility to assess the risk of relapse at the moment of accomplishment of the first line therapy.

Conclusion

ARRNO score provides oncologists with a new tool for the more sophisticated follow-up of patients with ovarian cancer.
LOW GRADE SEROUS OVARIAN CARCINOMA: AN EVALUATION OF PRACTICE PATTERNS

J. Siemon, M. Guillermo, D. Gershenson, B. Slomovitz, M. Schlumberger

1University of Miami Sylvester Comprehensive Cancer Center, Gynecologic Oncology, Miami, USA
2University of Texas MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston, USA

Aims

Low Grade Serous Carcinoma (LGSC) is a rare subtype of ovarian cancer with a typically indolent and chemoresistant course. Optimal treatment strategies are unknown. Our objective was to identify differences in practice patterns amongst physicians who treat LGSC.

Method

A de novo survey was distributed to members of the Society of Gynecologic Oncology. Questions about demographics, management of primary and recurrent disease, and use of consolidation were included. Statistical analyses was performed using Chi-square and logistic regression.

Results

There were 235 respondents. 48% had completed fellowship within the last 10 years, 83% recommended somatic testing during treatment, and 67% always send patients for genetic counseling. Treatment preferences for primary disease varied by debulking status (Figure 1). 47% of practitioners use hormone antagonism as consolidation after primary treatment. Physician experience with LGSC did not influence the decision to use consolidation (OR 1.09 [0.60-1.97], p=0.78). In contrast to patients with platinum resistant disease, secondary cytoreduction was preferred for patients with long disease-free intervals following primary treatment (p<0.001). Hormone antagonism was the preferred treatment for platinum resistant disease (52.3%), with 18% of physician utilizing targeted agents in the recurrent setting.

Conclusion

There is significant variation in the management of LGSC among practitioners. Further efforts to improve knowledge and disseminate information about the optimal management of this disease should be encouraged.

ESGO7-1046

COMPARISON OF OVERALL SURVIVAL AND PROGNOSTIC FACTORS IN HIGH AND LOW GRADE OVARIAN SEROUS ADENOCARCINOMAS

T. H. Schnack¹, S. Mejer Sørensen, H. Claus¹
¹Rigshospitalet - University hospital Copenhagen, Gynecological Clinic, Copenhagen Ø, Denmark

Aims

Low grade serous tumors are characterized by young age at diagnosis a slow growth pattern and despite a high level of chemoresistance a better prognosis as compared to high grade serous adenocarcinoma. We aim to examine overall survival in early and advanced stage low and high grade ovarian serous adenocarcinomas.

Method

Methods: Population based prospectively collected data on ovarian low grade serous adenocarcinomas (n=327) and high grade serous adenocarcinomas (n=2488) was obtained from the Danish Gynecological Cancer Database. Univariate Kaplan Meier and multivariate Cox-regression were used. Statistical test were 2-sided. P-values of <0.05 were considered statistically significant.

Results

Results: The overall survival was higher among low grade than in high grade ovarian adenocarcinomas in univariate (log rank < 0.0001) and multivariate cox analysis (HR 1.4 95% CI: 1.1-1.7). This association was strengthened in sub-analysis limited to stage Ib-IIb with no residual tumor (HR 2.2. 95% CI: 1.5-3.7), whereas no significant difference was observed in stage Ib-IIb with residual tumor or stage IIIc-IV (HR 0.8 95% CI: 0.5-1.6 and HR 1.2 95% CI 0.9-1.6, respectively). The cox analyses were adjusted for age at diagnosis, residual tumor (yes vs. no), stage and performance status, which were significant prognostic factors in all analyses.

Conclusion

Low grade ovarian serous adenocarcinoma have a better overall survival when diagnosed in early stages with no residual tumor, whereas no survival benefit was observed in cases with residual tumor or advanced stage disease as compared to high grade serous adenocarcinomas in analyses adjusted for age, residual tumor, stage and performance score.
Aims

To evaluate the effect of the "time to chemotherapy" (TTC) interval after debulking surgery on survival in patients with advanced ovarian cancer.

Method

We retrospectively studied data from 276 patients with International Federation of Gynecology and Obstetrics stage III or IV ovarian cancer who were consecutively treated between January 2006 and 2013. TTC was analysed and correlated with outcome.

Results

Median age at diagnosis was 54 years (range, 20–80 years), and 258 patients received postoperative platinum-based chemotherapy. The 25%, 50%, and 75% quartiles of intervals from surgery to start of chemotherapy were 18, 22, and 28 days, respectively. TTC [≤28 days versus >28 days; hazard ratio (HR) 1.578 (95% CI 1.057–2.355), P = 0.026], complete debulking with no gross residual disease [HR 0.419 (95% CI 0.274–0.640), P <0.05], and preoperative albumin level [HR 0.549 (95% CI 0.382–0.791, P=0.001] were significant prognostic factors for progression-free survival in multivariate analysis. While delayed TTC (>28 days) did not possess prognostic significance in patients without postoperative residual disease (n = 94), it significantly correlated with progression-free survival in patients with postoperative residual disease [n = 164, HR 1.893 (95% confidence interval 1.209–2.962), P = 0.005].

Conclusion

Our findings suggest that delayed initiation of chemotherapy might compromise progression-free survival in patients with advanced serous ovarian cancer, especially in case of gross residual disease. A prospective study randomizing patients to different time intervals could clarify the definitive relevance of the time between surgery and chemotherapy.

PFKFB3 AND PLA2G3 KNOCKDOWN LEADS TO THE GENERATION OF LIPID LADEN GRANULAR OSMOPHILIC DEPOSITS AND MULTILAMELLAR BODIES IN OVARIAN CANCER

1Mayo Clinic, Experimental Pathology, Rochester, USA
2Mayo Clinic, Obstetrics and Gynecology, Rochester, USA

Aims

The Aims of the study is to determine the effect of glycolysis inhibitor PFK-158 in ovarian cancer (OC). Among different regulators of this pathway, 6-PhosphoFructo-2-Kinase/Fructose-2,6-Bisphosphatases 3 (PFKFB3) a glycolytic enzyme that generates fructose-2,6-bisphosphate (F2,6BP) is recognized as an important control point in glycolysis.

Method

Using molecular techniques, we show that the active form of PFKFB3 (p-PFKFB3ser461) is overexpressed in chemo-resistant OC cell lines and resistant patient derived xenograft (PDX) models compared to chemo-sensitive cell lines. Treatment with PFK158 (PFKI), a specific inhibitor of PFKFB3 activity reduced glucose uptake, ATP and lactate production in addition to inhibiting colony forming ability in both carboplatin (Carb-Pt) and paclitaxel (PTX) resistant OC cell lines in vitro and significantly reduced tumor weight, ascites and metastasis compared to single drug treatments alone in vivo in the highly resistant HEYA8MDR xenografts.

Results

We show for the first time that PFKI promotes cell death by targeting the crosstalk between glycolysis and lipogenesis-two pathways active in OC by inducing autophagy resulting in the depletion of lipid droplets (LDs) in chemoresistant cells. PFKI downregulated the expression of both p-PFKFB3 and PLA2G3, involved in the biogenesis of LDs in several OC cell lines. TEM analysis revealed that genetic downregulation of PFKFB3 and or PLA2G3 resulted in the generation of granular osmiophilic deposits (GROD) and cholesterol rich multilamellar bodies (MLBs) respectively in the lysosomes, recapitulating lysosomal storage disorder phenotypes.

Conclusion

The functional consequence of this phenotype and the clinical implication of these results in the treatment of OC are currently under investigation.

MYASTHENIA GRAVIS IN AN OVARIAN CANCER PATIENT: A POSSIBLE PARANEOPlastic MANIFESTATION CASE
M. Simonsen1, M. Minamoto Miyabe1, H. Toshio Ouki1, A. Cezar Ribeiro Galvão1, D. Leite1, B. Alencar Rolim Murayama1, F. Martins Laginha1, M. Tosello Laloni2, G. Paiva da Silva Lima2, I. Correa Barboza1, M. Penna Antonio1, E. Falacci Matheus1, M. Samora1
1Hospital 9 de Julho, Gynecologic Oncology, São Paulo, Brazil
2Biogen, Research, Boston, USA

Aims

Gynecologic cancer rarely courses with neurological paraneoplastic symptoms. We describe one case of myasthenia gravis as a possible paraneoplastic manifestation of ovarian cancer preceding the neoplasm symptoms.

Method

Case Report

Results

A 61 years old patient with no comorbidities presented bilateral ptosis. Electromyography was suggestive of neuromuscular junction blockade. Dosage of anti-acetylcholine receptor antibody was greater than 20 nmol/L and other anti-neuronal antibodies were negative. She had no thymic image alterations and the use of pyridostigmine resulted in no clinical benefit response. After 30 days, the patient is hospitalized due to abdominal distension, dysphagia and progressive dyspnea. Abdominal tomography showed massive ascites and peritoneal thickening with greater pelvic component; CA-125 was 9561.8 U/mL and biopsy diagnosed an ovarian serous papillary adenocarcinoma. She had respiratory worsening and orotracheal intubation was necessary for 23 days. Plasmapheresis sessions and pulse therapy with methylprednisolone were implemented without clinical improvement. After the introduction of immunoglobulin and cyclophosphamide, ventilator parameters finally improved and CA-125 dropped to 899U/ml. According to tumor board decision, chemotherapy regimen was changed to carboplatin and paclitaxel. In the third cycle patient had no more myasthenic symptoms as well no medications were necessary for myasthenia. Cytoreduction surgery with R0 resection was performed and then 3 more cycles of chemotherapy. In the 6th month of follow-up she had complete resolution of the myasthenic condition, CA125 <35U/mL and normal abdomen images.

Conclusion

Until we know, this is probably the first reported case of possible causality between new diagnosis of ovarian neoplasm and myasthenia gravis as a paraneoplastic syndrome.

THE PROGNOSTIC IMPACT OF NANOG EXPRESSION IN OVARIAN SEROUS CARCINOMA

N. KENDA ŠUSTER1, S. Smrčolj1, I. VIRANT-KLUN2, S. FRKOVIC GRAZIO3

1University Medical Centre Ljubljana, Department of Obstetrics and Gynecology, Ljubljana, Slovenia
2University Medical Centre Ljubljana, Department of Obstetrics and Gynecology- Reproductive unit, Ljubljana, Slovenia
3University Medical Centre Ljubljana, Department of Obstetrics and Gynecology- Department of Pathology, Ljubljana, Slovenia

Aims

The ongoing research about cancer stem cells opened a new perspective on pathogenesis, diagnosis and treatment of ovarian cancer. The objective of this study was to assess the expression of cancer stem cell related marker NANOG (NANOG) in ovarian serous carcinoma and to evaluate its prognostic significance.

Method

The expression of NANOG was evaluated in ovarian tissues from 109 patients with ovarian serous carcinomas. NANOG expression was measured immunohistochemically in a tissue microarray. According to a sum of signal intensity and proportion we divided samples into four NANOG groups: negative, slightly positive, moderate positive and strongly positive. We analyzed the correlation between the clinical data and results from immunohistochemistry.

Results

The positive reaction of the NANOG was shown as yellow-brown particles located in the cytoplasm and sometimes in nucleus. In ovarian serous carcinoma 69.7% cases were NANOG positive. There was no difference in clinical manifestation, response to therapy or survival between the four NANOG groups. At several places especially in the vicinity of small putative stem cells we also observed changes on epithelial cells similar to epithelial-mesenchymal transition.

Conclusion

NANOG was significantly expression in ovarian serous carcinoma. In our study there was no correlation between the intensity of NANOG expression and prognosis of ovarian serous carcinoma. Presence of NANOG predominantly in cytoplasm might be explained by translocation of NANOG protein from nucleus to cytoplasm as cancer progresses. The epithelial-mesenchymal transition, a mechanism that might play an important role in the manifestation of ovarian cancer, should be further investigated.

MOLECULAR PROFILING OF ENDOMETRIOSIS AND ENDOMETRIOSIS-ASSOCIATED OVARIAN CANCER (EAOC)

G.S. Sohn¹, Y.M. Park¹, H.J. Kwon¹, H.Y. Shin¹, E.J. Lee¹, W.K. Yang¹, H.B. Cho¹, D.B. Chay¹, J.H. Kim¹, J.K. Gong¹
¹Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Endometriosis appears to be associated with some specific histologic subtypes of epithelial ovarian cancer, especially clear cell and endometrioid adenocarcinoma. However, the pathogenesis of ovarian cancer development from endometriosis is not well understood. The purpose of this study is to investigate the molecular association of endometriosis and endometriosis associated ovarian cancer (EAOC).

Method

RNA was extracted from 36 paraffin tissue blocks comprising of endometriosis (n=8), atypical endometriosis (n=6) and endometriosis associated ovarian cancer (n=22). Lesion of endometriosis or cancer from whole paraffin-embedded tissue sections were obtained by Laser capture microdissection and differentially expressed genes were analyzed using RNA sequencing technology.

Results

Comparison of gene expression among endometriosis, atypical endometriosis and EAOC revealed different expression patterns by heatmap. 2,923 genes in EAOC and 125 genes in atypical endometriosis were differently expressed compared to endometriosis. 364 genes were up regulated and 296 genes were down regulated in EOAC compared to atypical endometriosis. Comparison merge revealed 6 percent of differently expressed genes were commonly upregulated in all three categories. Pathway analysis revealed that nine genes involving cell proliferation were positively regulated.

Conclusion

This study revealed gene alteration involving endometriosis and endometriosis associated ovarian cancer. These findings may be an important resource for studying the pathogenesis of ovarian cancer developing from endometriosis.
ESTABLISHMENT AND CHARACTERIZATION OF IMMORTALIZED HUMAN OVARIAN SURFACE EPITHELIAL CELLS USING LENTIVIRAL SYSTEM.

G.S. Sohn1, Y.M. Park1, H.J. Kwon1, H.Y. Shin1, E.J. Lee1, W.K. Yang1, H.B. Cho1, D.B. Chay1, J.H. Kim1, J.K. Gong1

1Gangnam Severance Hospital- Yonsei University College of Medicine, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

Immortalization is a key difference that distinguishes cancer cell from normal cell. In cell line studies, normal cells like human ovarian surface epithelial cells (HOSE) are difficult to culture and limited due to the senescence nature of normal cell. The aim of this study is to establish normal ovary epithelial cell lines for the counterpart to research ovarian cancer.

Method

Immortalized human ovarian surface epithelial cells (IHOSE) were established by transfecting HPV E6/E7 and SV40 T antigen to short cultured HOSE using the lentiviral system. Cells were grown in Dulbecco’s Modified Eagle Medium in the presence of 10% fetal bovine serum and were cultured in 5% CO2 balanced air at 37°C. Thereafter, IHOSE were extracted genomic DNA and total RNA for DNA fingerprinting and RNA sequencing.

Results

Five IHOSEs that were arrived ten passages were established using the lentiviral system. Five IHOSEs were confirmed newly establishment using STR profiling. RNA sequencing was performed to identify IHOSEs characteristics, and gene expression changes were compared with HOSEs and ovarian cancer cell lines. IHOSEs have confirmed that the genes related to the cell cycle and DNA repair signal has changed more than HOSEs.

Conclusion

Newly established IHOSEs can be important research resources for the counterpart against molecular alternation of ovarian cancer.

THE ROLE OF APPENDECTOMY IN MUCINOUS BORDERLINE OVARIAN TUMORS

T. Song¹, M.K. Kim²

¹KangBuk Samsung Hospital - Sungkyunkwan University School of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Samsung Changwon Hospital- Sungkyunkwan University School of Medicine-Changwon-Republic of Korea, Department of Obstetrics & Gynecology, Changwon, Republic of Korea

Aims

To determine the frequency of appendiceal involvement in patients undergoing surgery for mucinous borderline ovarian tumors (mBOTs), and to evaluate the associated morbidity, and the recurrence risk and survival after appendectomy.

Method

The hospital databases were searched for women who underwent adnexal surgery at the Department of Obstetrics and Gynecology of four Korean academic hospitals, and whose final or frozen diagnosis was mBOTs. A literature search was performed, using electronic database (MEDLINE and EMBASE), to assess the available evidence on performing an appendectomy in patients with mBOTs.

Results

Of the 473 included patients with mBOTs, 201 (42.5%) underwent appendectomy, 247 (52.2%) did not undergo appendectomy at the time of initial surgery, and 25 (5.3%) had previously undergone appendectomy. Among the 201 patients who underwent appendectomy, primary and metastatic appendiceal mucinous neoplasms were occurred in 1 patient each (0.5%), who showed a macroscopically abnormal appendix. Appendectomy itself was not associated with operative complications ($P = 0.082$), recurrence risk ($P = 0.964$), or survival ($P = 0.219$). Consistent with our findings, a comprehensive search of the literature revealed that the frequency of appendiceal involvement in mBOTs was less than 1% in either primary or metastatic appendiceal neoplasms.

Conclusion

If the appendix is grossly normal, an appendectomy seems unnecessary in patients with mBOTs.
OVARIAN CANCER II

ESGO7-0148

THE CLINICAL SIGNIFICANCE OF ELEVATED PREOPERATIVE CA125 OR CA19-9 IN BORDERLINE OVARIAN TUMORS

T. Song¹, M. Kim²

¹KangBuk Samsung Hospital - Sungkyunkwan University School of Medicine, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
²Samsung Changwon Hospital - Sungkyunkwan University School of Medicine - Changwon- Republic of Korea, Department of Obstetrics & Gynecology, Changwon, Republic of Korea

Aims

To investigate whether elevated CA125 (≥35 U/mL) and CA19-9 (≥37 U/mL) suggest advanced-stage disease (defined as stage II or higher) or poor prognosis in patients with borderline ovarian tumors (BOTs).

Method

We retrospectively identified 591 patients with BOTs. Multivariate logistic regressions and Cox proportional hazard regressions were used to determine the clinicopathologic factors associated with the presence of advanced-stage disease and the prognostic factors associated with recurrence free-survival.

Results

CA125 was elevated more often in serous than in mucinous tumors (50.6% vs. 35.5%; P=0.003), whereas CA19-9 was elevated more often in mucinous than serous tumors (33.6% vs. 15.3%; P = 0.001). An elevated CA125 level was independently associated with the presence of advanced-stage disease in serous (P=0.005) and in mucinous BOTs (P=0.015). However, preoperative elevation of CA19-9, unlike CA-125, was not associated with advanced-stage disease. Elevated preoperative CA125 level (P=0.037) was an independent prognostic factor for recurrence-free survival in patients with serous BOTs. However, neither CA125 nor CA19-9 had prognostic significance in mucinous BOTs.

Conclusion

Elevated preoperative CA125, unlike CA19-9, is a diagnostic and prognostic biomarker associated with the presence of advanced-stage disease and risk of relapse in patients with serous BOTs.

THE PROGNOSTIC ROLE OF PREOPERATIVE HYPONATREMIA IN PATIENTS WITH ADVANCED EPITHELIAL OVARIAN CANCER (EOC)

M. Sporkmann1, P. Harter1, F. Heitz1, B. Ataseven1, S. Schneider1, S. Prader1, A. Kahl1, A. Traut1, A. du Bois1

1Kliniken Essen Mitte, Gyn + Gyn Oncology, Essen, Germany

Aims

To determine the impact of preoperative hyponatremia with regard to pre-, intra- and postoperative characteristics in patients with advanced primary epithelial ovarian cancer (EOC).

Method

All consecutive patients with EOC (FIGO stage III-IV) between 01/2011 and 12/2015 were prospectively included in the analysis. All data were collected in a prospectively maintained database. Hyponatremia was defined as serum sodium (Na) <135 mmol/l. Statistical analysis were mean and standard deviation or median (range) compared by the student’s t-test.

Results

In total, 390 patients (normal Na: n=363 (93.1%) and hyponatremia: n=27 (6.9%)) were analyzed. Patients with hyponatremia had significantly lower serum albumin (39 g/l vs. 42 g/l), higher age-adjusted charlson comorbidity score >2 (58.1% vs. 92.6%), and more often ascites >500ml (38.6% vs. 70.4%), respectively. Furthermore, complete resection rate was significantly lower in patients with hyponatremia (65.0% vs. 29.6%, p=0.001). We found no differences in postoperative characteristics like length of stay on intensive care unit, hospital stay, or the complications according to the Clavien-Dindo classification and 30-days mortality. But there was a significant difference in 60- (4.4% vs. 14.8%) and 90-days mortality (5% vs. 14.8%), p=0.018 and p=0.032 respectively.

Conclusion

Preoperative hyponatremia is associated with more ascites, lower rates of complete resection and higher 60- and 90-day mortality. The serum sodium might be useful for risk stratification in patients with advanced EOC.
OVARIAN CANCER

ESGO7-0634

THE PROGNOSTIC ROLE OF AB0 BLOODGROUP AND RHESUS FACTOR IN PATIENTS WITH ADVANCED EPITHELIAL OVARIAN CANCER (EOC)

M. Sporkmann¹, F. Heitz¹, P. Harter¹, S. Schneider¹, S. Prader¹, B. Ataseven¹, A. Hengsbach¹, A. Traut¹, A. du Bois¹

¹Kliniken Essen Mitte, Gyn + Gyn. Oncology, Essen, Germany

Objectives
Recently published data on patients with gastric cancer or with ovarian cancer showed an impact of the AB0 blood groups (BG) on the outcome. The aim of this study was to evaluate the prognostic value of AB0 BG and Rhesus factor (Rf) in patients with advanced primary epithelial ovarian cancer (EOC).

Methods
All consecutive patients with EOC (FIGO stage III-IV) treated between 01/2011 and 02/2017 were included in the analysis. All data were collected in a prospectively maintained database. Each BG was compared to each other, as well as a combined analysis with Rf.

Results
In total, 557 patients (BG A: n=267; BG 0: n=192; BG B: n=66; BG AB: n=32) were analyzed. The distribution of Rf positive patients in all groups showed no significant difference. There were no differences between patients' characteristics nor between intra- or postoperative parameters, like FIGO-stage, residual disease or need of blood transfusion, between all BGs. Patients with BG AB had significantly less high-grade serous histology compared to non-BG AB (68.8% vs. 85.9%). Overall survival (OS) was not different between distinct AB0 BG. Progression free survival (PFS) in BG AB was significantly better compared to BG B (32 months vs. 20 months; p=0.026), compared to BG A it did not reach significance (32 months vs. 21 months; p=0.056). Analysis of Rf negative patients (n=480 (86.2%)) showed a significant difference in PFS (33 months vs. 22 months) but not in OS (58 months vs. 54 months), p=0.016 and p=0.577 respectively.

Conclusions
With regard to PFS, BG AB had a prognostic impact in patients with EOC compared to BG B. Rf positive patients had an impaired PFS compared to patients with Rf negative.
A SYSTEMATIC REVIEW ON COST-EFFECTIVENESS OF EARLY DETECTION AND PREVENTION STRATEGIES FOR OVARIAN CANCER

G. Sroczynski¹, A. Gogollari¹, F. Kühe¹, N. Pashayan², M. Widschwendter², U. Siebert¹,²,³,⁴,⁵,⁶

¹UMIT - University for Health Sciences- Medical Informatics and Technology- Inst.

⁵Harvard T.H. Chan School of Public Health, Center for Health Decision Science- Department of Health Policy and Management, Boston, USA
⁶Harvard Medical School, Institute for Technology Assessment and Department of Radiology, Boston, USA

Aims

We conducted a systematic review on cost-effectiveness studies evaluating early detection and prevention strategies for ovarian cancer in various populations.

Method

We systematically searched relevant databases (Medline/Embase/Cochrane Library/CRD/EconLit) for decision-analytic modelling studies assessing the cost-effectiveness of early detection and/or prevention strategies for ovarian cancer. We summarized study characteristics and results including quality-adjusted life-years (QALY), life-years gained (LYG), and incremental cost-effectiveness ratios (ICER; in cost/QALY or LYG) in standardized evidence tables. Economic results were converted to 2015 Euros using GDP-PPP and CPI.

Results

Twenty studies varying in terms of target population, discount rate, perspective and evaluated strategies were included. Ovarian cancer screening in women age 45+ yielded ICERs from 12,000 Euro/LYG in population with 5% prevalence of high-risk women to 68,000 Euro/LYG in average-risk women. A recent study reported 10,000 Euro/QALY for multimodal screening with a risk-adapted algorithm. Risk-reducing surgery in mutation carriers yielded ICERs from cost-saving to 4,000 Euro/LYG (2,000-16,000 Euro/QALY). In premenopausal women, risk-reducing interventions yielded ICERs ranging from 700 Euro/LYG in women with 10% lifetime cancer risk to 47,500 Euro/LYG in women with 2% lifetime risk (6,000-52,000 Euro/QALY). In postmenopausal women, respective ICERs were 2,000-47,000 Euro/LYG (2,000-757,000 Euro/QALY). Genetic testing in women at increased risk followed by risk-reducing interventions in mutation carriers yielded ICERs of 10,000-32,000 Euro/LYG (8,000-9,000 Euro/QALY).

Conclusion

Based on our findings, both screening and preventive surgery in women at increased or high risk for ovarian cancer can be considered effective and cost effective. Results were sensitive with regard to test accuracy, test costs, and the screening frequency.

HYPERTHERMIA AND CISPLATIN INCREASE HEAT SHOCK PROTEIN HEME OXYGENASE-1 EXPRESSION IN OVCAR-3 CELLS

S. Arturas1, V. Cesna2, J. Aldona3, M. Gedgaudaite1, G. Barauskas2, R.J. Nadisauskiene1, Z. Dambrauskas3, S. Paskauskas1, A. Gulbinas3

1Lithuanian University of Health Sciences, Department of Obstetrics and Gynecology, Kaunas, Lithuania
2Lithuanian University of Health Sciences, Department of Surgery, Kaunas, Lithuania
3Lithuanian University of Health Sciences, Institute for Digestive Research, Kaunas, Lithuania

Aims

To evaluate the impact of different temperature and cisplatin combinations to the expression of heat shock protein heme-oxygenase-1 (HO-1) and the cells viability in OVCAR-3 cells.

Method

Imitating the typical clinical conditions of HIPEC, OVCAR-3 cells were exposed to different hyperthermia and cisplatin concentrations for one hour. Afterward the MTT viability test, flow cytometer analysis, isobologram analysis and quantitative reverse transcription polymerase chain reaction was performed and analysed.

Results

The rising temperature from 37°C to 42°C alone and in combination with half of the maximal inhibitory concentration of cisplatin (IC50) had insignificant effect on OVCAR-3 cells viability and apoptosis. The combination of hyperthermia up to 42°C and IC50 dose of cisplatin significantly increased the expression of heat shock protein HO-1 in OVCAR-3 cells. Cisplatin alone decreased cell viability in a linear pattern. The antagonistic effect of hyperthermia and cisplatin was revealed by the isobologram method.

Conclusion

Hyperthermia usable in clinical practise and cisplatin increase the expression of heat shock protein HO-1 in OVCAR-3 cells. Further research is essential regarding modulation of the HO-1 expression as a new therapeutic option to improve the results of HIPEC.

EVALUATION OF APPENDAGES' TUMORS IN IOTA SYSTEM IN REFERENCE TO HISTOPATHOLOGICAL RESULTS

M. Szubert¹, S. Malwina², N. Anna², M. Martyna³, L. Mokros³, J. Suzin¹

¹Medical University of Lodz, I Department of Gynecology and Obstetrics- Clinic for Operative and Oncological Gynecology, Lodz, Poland
²Medical University of Lodz, I Department of Gynecology and Obstetrics- Clinic for Operative and Oncological Gynecology- Students’ Scientific Society, Lodz, Poland
³Medical University of Lodz, Department of Clinical Pharmacology, Lodz, Poland

Aims

Ovarian cancer is one of the most common women cancers after menopause. The aim of the study was to evaluate how IOTA (International Ovarian Tumor Analysis) Simple Rules used in ultrasound examination modifies probability of occurrence malignant and benign ovarian tumor in tested population.

Method

The study group consisted of 426 patients with ovarian tumors operated in the years 2014-2015. Changes of appendages were rated according to IOTA Simple Rules. Results of this study were compared with the final histopathology reports. Statistical analysis was performed in STATISTICA 13 PL with Medical Pack.

Results

Malignant tumour patients (n=43) were statistically significantly older (mean age 61.0 ±11.6 vs 43.6±16.2, p<0.001), had higher BMI (mean 27.3±7.0 vs 25.2±5.2, p<0.05), more pregnancies (median 2 vs 1, p=0.001) and higher Ca125 level (median 251.5 vs 18.5, p<0.001) than patients with benign tumour (n=346). Also, they more often suffered from diabetes mellitus and arterial hypertension. For determining malignant tumour IOTA Rule 1 reached sensitivity of 83%, specificity 88%, positive predictive value (PPV) of 51% and negative PV 97%. IOTA Rules were better in prediction malignancy than Ca125 value alone (sensitivity of 71%, specificity 92%, positive predictive value (PV) of 56% and negative PV 96%).

Conclusion

In our study, performance of IOTA in predicting or ruling out malignant tumour was highly satisfying. IOTA Rules and Ca125 may be complementary and used to assess risk of malignant vs benign ovarian neoplasm, yet context of other clinical variables may also be important.

IN VITRO CHEMOSENSITIVITY IN OVARIAN CARCINOMA – COMPARISON OF THREE LEADING ASSAYS

B. Tatar¹, B. Gokhan², Ilker S.³, K.D. Alper⁴, Alp U.⁵, T. Zafer Selcuk²

¹Department of Gynecologic Oncology, Suleyman Demirel University School of Medicine, Isparta, Turkey
²Department of Gynecologic Oncology, Hacettepe University School of Medicine, Ankara, Turkey
³Department of Gynecologic Oncology, Zekai Tahir Burak Maternity and Teaching Hospital, Ankara, Turkey
⁴Onkosel Biotechnology, Hacettepe University Technopolis, Ankara, Turkey
⁵Department of Pathology, Hacettepe University School of Medicine, Ankara, Turkey

Aims

All the patients with ovarian carcinoma may not have equal response to the standard chemotherapeutic regimen although they have the same histologic type of tumor. An alternative approach to current therapy of ovarian carcinoma is individualization of the treatment by determination of sensitivity of tumoral tissue to chemotherapeutic agents before the initiation of chemotherapy. The study is designed to determine the efficacy of in vitro chemosensitivity assays in ovarian carcinoma and to measure the correlation of three leading assays with each-other.

Method

Fresh tumoral tissue samples of 26 newly diagnosed primary ovarian cancer patients were studied with MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide], ATP-TCA (Adenosine Triphosphate Tumor Chemosensitivity Assay) and DISC (Differential Staining Cytotoxicity) assays. Chemosensitivity of tumors were studied for paclitaxel, carboplatin, docetaxel, topotecan, gemcitabine and doxorubicin with each of the three assays. Subgroup analysis was done for stage, grade and histologic type.

Results

The in vitro chemosensitivity results of MTT, ATP and DISC assays were found to be similar. The subgroups that in vitro assays would be more useful are encountered for patients with advanced stage and serous histology ovarian carcinoma.

Conclusion

In vitro chemosensitivity can be determined in ovarian carcinoma with ATP, MTT or DISC assays before initiation of chemotherapy. These three assays correlate well with each other and they are especially useful for serous and advanced cancers. Large prospective studies comparing standard versus assay directed therapy with an end-point of overall survival are needed before routine clinical utilization of these assays.
PRELIMINARY SAFETY AND EFFICACY OF TUMOR TREATING FIELDS (200 KHZ) WITH WEEKLY PACLITAXEL FOR RECURRENT OVARIAN CANCER – PHASE II INNOVATE STUDY

I. Vergote1, R. von Moos2, L. Manso3, C. Sessa4

1Kantonsspital Graubünden, Medical Oncology, Chur, Switzerland
2Hospital 12 de Octubre, Medical Oncology, Madrid, Spain
3IOSI Oncology Institute of Southern Switzerland, Medical Oncology, Bellinzona, Switzerland

Aims

Tumor Treating Fields (TTFields), a non-invasive, regional treatment is approved for recurrent and newly diagnosed glioblastoma by the FDA. TTFields deliver intermediate-frequency alternating electric fields to the tumor by disrupting the mitotic spindle formation. INNOVATE is the first trial testing TTFields (200kHz) in ovarian cancer.

Method

Thirty-one recurrent platinum-resistant ovarian cancer patients were treated with TTFields plus weekly paclitaxel. Patients had unresectable tumors, ECOG performance 0-1, and measurable disease per RECIST. The primary endpoint was incidence and severity of treatment-emergent adverse events. Secondary endpoints included progression free and overall survival and radiological response rate.

Results

The median age was 60 (45-77 years), 77% had serous histology, 52% had ECOG score of 0. All patients were platinum-resistant. Ten (32%) patients had serious adverse events (SAEs) during the study, unrelated to TTFields: 31% related to gastrointestinal disorders (ileus, jaundice and ascites) and 31% to respiratory events (dyspnea, pleural effusion and pulmonary embolism). One tumor-related SAE led to permanent discontinuation of the device. Most patients reported mild-moderate TTFields-related skin irritation; only two patients (6.4%) had severe-grade events. The median PFS was 8.9 months (95% CI 4.7, NA). Of evaluable tumors, 25% had partial response and 46.4% had stable disease – a clinical benefit of 71.4%. Six patients (19.4%) had a CA125 response: decrease of 50% or more in serum levels. The median OS was not reached.

Conclusion

Data show that TTFields plus weekly paclitaxel are tolerable and safe in heavily pre-treated platinum-resistant ovarian cancer patients. Further testing of TTFields with chemotherapy in ovarian cancer is warranted.
BORDERLINE OVARIAN TUMORS: A NATIONWIDE OVERVIEW OF INCIDENCE, SURVIVAL AND RISK OF SUBSEQUENT INVASIVE OVARIAN TUMORS

M. Schuurman\(^1\), M. Timmermans\(^1\), K. Van de Vijver\(^2\), T. van Gorp\(^3\), R. Kruitwagen\(^4\), M. van der Aa\(^4\), V. Lemmens\(^5,6\)

\(^2\)The Netherlands Cancer Institute, Divisions of Diagnostic Oncology and Molecular Pathology, Amsterdam, The Netherlands
\(^3\)Maastricht University Medical Centre, Department of Obstetrics and Gynecology, Maastricht, The Netherlands
\(^4\)Comprehensive Cancer Organisation the Netherlands IKNL, Research, Utrecht, The Netherlands
\(^5\)Comprehensive Cancer Organisation the Netherlands IKNL, Department of Research, Utrecht, The Netherlands
\(^6\)Erasmus MC, Department of Public Health, Rotterdam, The Netherlands

Aims

Population-based studies on borderline ovarian tumours (BOTs) are rare as data collection is mostly limited to invasive ovarian tumours. In this nationwide study, we provide an overview of trends in incidence and survival of BOTs and establish the risk of a subsequent invasive ovarian tumour.

Method

All patients diagnosed with BOTs between 1993 and 2015 (n=6,706) were selected from the Netherlands Cancer Registry (NCR). Age-adjusted incidence rates and relative survival ratios were calculated. Patients with a subsequent invasive ovarian tumour were identified by the NCR.

Results

Incidence of BOTs doubled between 1993 and 2011, after 2011 incidence declined (see Figure). Five-year relative survival increased from 91% in 1993-1997 to 98% in 2010-2015. The proportion of bilateral tumours decreased from 16% to 11% during the same time periods. Of all patients, 0.9% developed a subsequent invasive ovarian tumour during a median follow-up time of 8 years.

Conclusion

Incidence of BOTs increased over time, but declined since 2011. The decline might be due to changes in the classification of gynecological tumours. The risk of a subsequent invasive tumour is low. Survival is high and has improved since 1993. An earlier detection through improvements in ultrasound or improved distinction between BOTs and metastases of gastrointestinal tumors may have contributed to the increased survival. Further analyses are going on to gain more insight into those changes.
ASSOCIATIONS BETWEEN MOLECULAR SUBTYPES AND POSTOPERATIVE COMPLICATIONS AFTER PRIMARY CYTOREDUCTIVE SURGERY FOR ADVANCED STAGE HIGH-GRADE SEROUS OVARIAN CANCER

D. Torres1, A. Kumar1, J. Bakkum-Gamez1, C. Langstraat1, E. Goode2, W. Cliby1, C. Wang2

1Mayo Clinic, Gynecologic Surgery, Rochester- MN, USA
2Mayo Clinic, Health Sciences Research, Rochester- MN, USA

Aims

Individualized treatment approaches to maximize oncologic outcomes and minimize perioperative morbidity in high-grade serous ovarian cancer (HGSOC) are lacking. Given the relationship between TCGA (The Cancer Genome Atlas) molecular subtypes, survival outcomes, residual disease (RD), and intraperitoneal disease spread, we seek to evaluate the association of molecular subtype with 30-day postoperative complications and 90-day mortality after primary cytoreductive surgery (PCS) in advanced stage HGSOC.

Method

TCGA subtypes were derived from Agilent 4x44k tumor mRNA expression profiles of 279 women with HGSOC undergoing PCS from 1994-2009. RD status was categorized as 0, 0.1-0.5, 0.6-1.0, or > 1cm. Surgical complexity (SC) scores were calculated as high, intermediate, or low. Complications were graded according to the modified Accordion classification 0-4 scale. Fisher’s exact test was used to assess categorical associations.

Results

TCGA molecular subtype distribution is listed in Table 1. MES was more likely to have preoperative albumin levels ≤ 3.5g/dL (33%, P<0.05). Despite higher rates of RD > 1cm (19%, N=14), lower rates of RD0 (12%, N=9) and similar SC scores (P=0.27), grade 3-4 complications were twice as likely in MES (29%, P=0.06) vs. any other subtype. No difference in 90-day mortality was noted (P=0.65).

</table>

Table 1. TCGA molecular subtypes by demographics and perioperative characteristics.

Conclusion

MES subtype of HGSOC is more likely to have grade 3-4 morbidity after PCS and lower preoperative albumin levels. Given the fine balance between RD and morbidity and mortality after PCS, preoperative molecular subtyping may assist in tailoring individualized treatment of HGSOC.
BRCA1/2 mRNA EXPRESSION AS A PROGNOSTIC FACTOR IN OVARIAN CANCER

I. Tsibulak1, A. Berger1, S. Abdel Azim1, G. Shivalingaiah2, S. Wenzel1, A. Wiedemair1, H. Fiegl1, C. Marth1, A.G. Zeimet1

1Innsbruck Medical University, Department of Obstetrics and Gynaecology, Innsbruck, Austria
2Innsbruck Medical University, Division of Human Genetics, Innsbruck, Austria

Aims

Mutations in cancer susceptibility genes BRCA1/2 are considered to be associated with better survival possibly due to a better response to platinum-based chemotherapy and PARP inhibitors. We wondered whether the expression of BRCA1/2 measured at the transcriptome level could also be indicative for platinum response and thus predict clinical outcome in ovarian cancer.

Method

We analyzed BRCA1 and 2 mRNA expression in 201 fresh-frozen ovarian cancer samples and in 12 healthy fallopian tubes using quantitative real-time PCR. BRCA mutations detection was performed by next generation sequencing. Associations between BRCA expression and clinicopathologic parameters were evaluated using Mann-Whitney-U and Kruskal-Wallis tests. OS and PFS were estimated using Kaplan-Meier plots and multivariate Cox-Regression. Optimal cut-off points were defined using Youden index.

Results

We found higher BRCA1 and 2 expression in ovarian cancer tissues in comparison with control tissues (p=0.011; p<0.001, respectively). BRCA1 expression was higher in older patients (p=0.036) and in advanced FIGO stages (p=0.036). Higher BRCA2 expression was found in cases with residual tumor after primary debulking (p=0.032) and in high-grade tumors (p<0.001). Univariate survival analysis showed high BRCA2 expression to be associated with poor PFS (p=0.002) and both high BRCA1 and 2 expression levels associated with poor OS (p=0.012, p=0.001; respectively). Multivariable survival analysis confirmed poor PFS in patients with high BRCA2 expression (p=0.028) and poor OS in patients with high BRCA1 expression (p=0.033).

Conclusion

Higher expression of BRCA1 and 2 predicts poor survival in patients with ovarian cancer possibly due to improved homologous DNA damage repair, which may lead to reduced platinum sensitivity.

BOWEL RESECTION IN ADVANCED OVARIAN CANCER: A SINGLE CENTER EXPERIENCE

D. Tsolakidis1, A. Papanikolaou1, S. Pitis1, D. Zouzoulas1, P. Lymeriadi1, L. Zepeiridis1, G. Grimbizis1, B. Tarlatzis1

1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloníki, Greece

Aims

Bowel resection is often required in advanced ovarian cancer patients with high tumor dissemination in order to achieve complete cytoreduction. The purpose of this study was to evaluate the benefit of these patients from radical surgery.

Method

We conducted a retrospective review of medical records of 66 patients with ovarian cancer, who underwent bowel resection between January 2004 and December 2016. Complications, cytoreductive and oncological outcomes were reported.

Results

44 (66.7%) patients underwent bowel resection during primary, 13 (19.7%) during interval and 9 (13.6%) during secondary debulking surgery. Intestinal surgeries included: 41 patients underwent rectosigmoid resection, 7 had colectomy and 5 had colectomy plus rectosigmoid resection. From the rest patients 7 underwent small bowel resections and 6 multiple enterectomies. Complete and optimal (<1cm) debulking was achieved in 34 (51.5%) and 20 (30.3%), respectively. Median hospitalization was 11 days. Median perioperative blood loss was 700cc and postoperative blood transfusion was mandatory in 39 patients. Median resuscitation time was 4 hours and 22 (33.3%) patients required ICU admission after surgery. Postoperative complications such as pelvic abscess formation were observed in two patients and fistula in one of them. Median disease-free and overall survival was 22 and 41 months, respectively. Perioperative mortality was 4.5%.

Conclusion

Bowel resection is the most frequent additional procedure in order to achieve complete or optimal cytoreduction in advanced ovarian cancer. It has acceptable perioperative morbidity, mortality and increased survival rates.

DIAPHRAGMATIC SURGERY IN DEBULKING SURGERY FOR ADVANCED OVARIAN CANCER: A SINGLE CENTER 12 YEARS EXPERIENCE

D. Tsolakidis¹, A. Papanikolaou¹, D. Zouzoulas¹, S. Pitis¹, D. Aivazi¹, T. Theodoridis¹, A. Vatopoulou¹, B. Tarlatzis¹

¹Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

The aim of this study is to describe the role of diaphragmatic surgery during primary and interval cytoreduction in advanced ovarian cancer.

Method

We conducted a retrospective review of medical records of 62 patients with advanced ovarian cancer, who underwent diaphragmatic surgery during primary and interval debulking surgery between January 2004 and December 2016. Disease free survival, overall survival, cytoreductive outcome, intra and postoperative complications related to diaphragmatic surgery were analyzed.

Results

5 (8%) patients had FIGO stage IIIB, 39 (63%) stage IIIC and 18 (29%) stage IV. 46 (74%) underwent primary and 16 (26%) interval debulking surgery. In 22 patients the diaphragmatic peritoneum was stripped, in 11 patients was resected with the adjacent infiltrated part of diaphragmatic muscle and the adjacent pleura, in 17 patients was coagulated and in 12 a combination of these techniques was applied. Median disease-free survival and overall survival were 20 and 52 months, respectively. No residual disease or less than 1cm was achieved in 28 (45.2%) and 29 (46.8%) patients, respectively. The most frequent complication related to diaphragmatic surgery was pleural effusions in 38 (61.3%) patients. Chest tube placement was necessary in 13 (21%) and thoracocentesis in 5 (8%) patients. The median time of chest tube stay was 7 days.

Conclusion

Diaphragmatic surgery is an integral part of upper abdominal cytoreductive procedures during primary and interval debulking with an acceptable and manageable morbidity rate.
EVALUATION OF ULTRASOUND MODELS IN THE DIAGNOSIS OF ADNEXAL MASSES; A COST-EFFECTIVENESS ANALYSIS

E. Meys¹, L. Jeelof², B. Ramaekers², C. Dirkse², L. Kooreman³, B. Slangen¹, R. Kruitwagen¹, T. Van Gorp¹
¹Maastricht University Medical Center+ MUMC+, Obstetrics and Gynaecology, Maastricht, The Netherlands
²Maastricht University Medical Center+ MUMC+, Clinical Epidemiology and Medical Technology Assessment KEMTA, Maastricht, The Netherlands
³Maastricht University Medical Center+ MUMC+, Pathology, Maastricht, The Netherlands

Aims

To determine the cost-effectiveness of recently introduced ultrasound models in the diagnosis of adnexal masses compared to the Risk of Malignancy Index (RMI):

- Subjective assessment (SA);
- Simple rules added by subjective assessment (SR+SA);
- Simple rules with inconclusive results diagnosed as malignant (SR+Mal);
- Logistic regression model 2 (LR2); and
- Assessment of Different NEoplasias in the adneXa model (ADNEX).

Method

Potential cost-effectiveness was explored using an economic model, which was limited to short term costs. The comparative sensitivity, specificity and costs of the diagnostic strategies including surgical management and recovery, were explicitly incorporated in the model. The analysis took a hospital perspective including all costs from detection of the mass up to recovery following surgery. Incremental cost-effectiveness was expressed as the costs per correct diagnosis (i.e. either true positive/negative test results).

Results

Although effectiveness was highest for SA, cost of SR+SA were lowest (figure 1). The outcome of the cost-effectiveness analyses was most influenced by specificity. The probability of being the most cost-effective was the highest for the strategy of SR+SA for a wide range of willingness-to-pay thresholds (≤€39,817). RMI had low cost-effectiveness probabilities (<1%).

Conclusion

Although SA is the best diagnostic strategy in terms of diagnostic accuracy, SR+SA is the preferred method from a cost-effectiveness perspective.
OPPORTUNISTIC TUBECTOMY IS SAFE IN WOMEN UNDERGOING HYSTERECTOMY FOR BENIGN GYNAECOLOGICAL CONDITIONS; RESULTS FROM THE HYSTUB-TRIAL

L. van Lieshout¹, B. Pijlman², C. Vos³, M. de Groot⁴, S. Houterman⁵, S. Coppus⁶, M. Harmsen⁶, I. van den Put¹, J. Piek¹
¹Catharina Hospital Eindhoven, Obstetrics and Gynaecology, Eindhoven, The Netherlands

⁴Elisabeth-Tweesteden Hospital, Clinical Chemistry and Haematology, Tilburg, The Netherlands
⁵Catharina Hospital Eindhoven, Education and Research, Eindhoven, The Netherlands
⁶Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands

Aims

The Fallopian tube is most likely the organ of origin of high grade serous “ovarian” carcinomas. Therefore, opportunistic removal of this organ might lead to a lower incidence. Since this procedure has an opportunistic nature, it should not have adverse effects. To determine whether opportunistic tubectomy in premenopausal women undergoing hysterectomy for benign indications is both hormonally and surgically safe, we conducted this trial. The primary outcome was change in serum Anti-Müllerian Hormone (AMH) concentrations measured preoperative, and 6 months postoperative. Secondary outcomes were surgical parameters such as operative time, blood loss and complication rate.

Method

This multicentre randomised controlled trial was conducted in four hospitals in the Netherlands. A total of 104 premenopausal women, aged 30 to 55 years, were randomly assigned either hysterectomy with opportunistic bilateral tubectomy (N=52) or standard care hysterectomy with preservation of the Fallopian tubes (N=52).

Results

There were no significant differences between the two groups in baseline characteristics and preoperative AMH concentrations (2.21 pmol/L in the intervention group versus 1.24 pmol/L in the control group, P=0.19). Most importantly, postoperative AMH concentrations (2.11 pmol/L in the intervention group versus 1.43 pmol/L in the control group, P=0.35) did not differ significantly. Furthermore, addition of tubectomy to hysterectomy did not lead to poorer surgical outcomes.

Conclusion

Opportunistic bilateral tubectomy in addition to hysterectomy does not lead to a greater decline in ovarian function or poorer surgical outcomes when compared to hysterectomy alone. Therefore, tubectomy is a safe procedure in premenopausal women undergoing hysterectomy for benign indications.
OVARIAN CANCER II

ESGO7-0874

PATHOLOGIC DISTRIBUTION OF DISEASE DURING INTERVAL DEBULKING VERSUS PRIMARY TUMOR REDUCTION IN PRIMARY PERITONEAL, OVARIAN, OR FALLOPIAN TUBE CARCINOMA

R. Previs1, C. Bailey1, B. Fellman2, T. Zaid1, M. Huang1, A. Brown1, E. Ahmed1, B. Nyla1, R. Broaddus3, D. Bodurka1, A. Sood1, S. Westin1

1The University of Texas MD Anderson Cancer Center, Department of Gynecologic Oncology & Reproductive Medicine, Houston, USA
2The University of Texas MD Anderson Cancer Center, Department of Biostatistics, Houston, USA
3The University of Texas MD Anderson Cancer Center, Department of Pathology, Houston, USA

Aims

The surgical approach for primary tumor reductive surgery (PTRS) for primary peritoneal, ovarian or fallopian tube carcinoma has been used to extrapolate the technique for interval debulking after neoadjuvant chemotherapy (NACT). Few studies have evaluated whether procedures such as hysterectomy contribute to comparable removal of macroscopic disease after NACT. Our study compared pathologic distribution of disease after NACT versus PTRS.

Method

Patients who underwent NACT or PTRS were identified from 1995-2016. Involvement of organs at surgery was categorized as either macroscopic, microscopic, or no tumor. Statistical analyses included Mann-Whitney and chi-squared or Fisher’s exact tests.

Results

Of the 1000 patients identified, 374 (37.7%) received NACT and 618 (62.3%) underwent PTRS. Uterine involvement was significantly different in the NACT group compared to PTRS; the majority of uterine specimens from the NACT group were free of disease (macroscopic 30 % vs 49%, no tumor 52% v. 39 %, p <0.001). There was no difference in the amount of residual tumor in cervical specimens in the NACT group compared to PTRS (macroscopic 7.2% v. 6.6%, no tumor 90% v. 91.4%). Macroscopic large bowel involvement was 63.6% in NACT versus 84.7% in the PTRS versus (p < 0.001). There were statistically significant differences in the pathologic characteristics of disease in the ovaries/tubes, omentum, and bowel.

Conclusion

Pathologic disease distribution after NACT is significantly different than at PTRS. NACT appears to reduce macroscopic disease in surgical specimens. Hysterectomy including removal of the cervix may not be mandatory after NACT to achieve no gross residual disease.
SIGNIFICANCE OF PD-1 AND PD-L1 EXPRESSION IN OVARIAN CANCER BIOLOGY

V. Wieser¹, I. Gaugg¹, M. Fleischer¹, S. Gindhart², S. Wenzel³, S. Sprung³, S. Lax³, A. Zeimet¹, H. Fiegl¹, C. Marth¹
¹Medical University Innsbruck, Department of Obstetrics and Gynecology, Innsbruck, Austria
²Medical University Innsbruck, Division of Human Genetics, Innsbruck, Austria
³Medical University Innsbruck, Institute of Pathology, Innsbruck, Austria
⁴Academic Teaching Hospital of the Medical University Graz, Department of Pathology, Innsbruck, Austria

Aims

Induction of checkpoint molecules such as programmed cell death protein (PD-1) and its ligand PD-L1 is an essential step in tumor immune escape which may be regulated by interferon gamma (IFNγ, encoded by IFNG). Therapeutically, antibodies against PD-1 or PD-L1 restore T-cell immunogenicity and suppress tumor progression. Here, we investigate the role of intra-tumoral PD-1 and PD-L1 mRNA expression in ovarian cancer (OC) and explore its relation to IFNγ

Method

We analyzed the mRNA expression of PD-1, PD-L1 and IFNg determined by quantitative real-time PCR in tissue of 171 patients with low grade serous (LGSOC; n=11), high grade serous (HGSOC; n=107), endometrioid (n=43) and clear cell (n=10) OC and compared it to each 14 normal ovaries and fallopian tubes.

Results

We observed an induction of the PD-1 pathway in OC tissue compared to healthy controls. Further, a significant correlation between PD-1, PD-L1 and IFNg expression was detected. PD-1 and PD-L1 mRNA expressions increased with tumor grade. However, only high PD-L1 mRNA expression was inversely associated with age. Notably, we further found that TP53 mutated tumors exhibited high PD-L1 levels and BRCA1/2 mutations were associated with both high PD-1 and PD-L1 levels. In the cohort of FIGO stage III/IV HGSOC, which represents the major subgroup, high PD-1 and high PD-L1 was associated with an adverse progression-free and overall survival, respectively.

Conclusion

Our study suggests that the PD-1 pathway is controlled by IFNγ in OC and is especially involved in immune biology of poorly differentiated, BRCA1/2 or TP53 mutated cancers.
ERCC1-EXPRESSING CIRCULATING TUMOR CELLS AS A POTENTIAL DIAGNOSTIC TOOL FOR MONITORING PLATINUM-BASED CHEMOTHERAPY AND FOR PREDICTING OUTCOME OF OVARIAN CANCER

P. Wimberger1, I. Chebouti2, J.D. Kuhlmann3, P. Buderath2, S. Weber2, Y. Bokeloh2, S. Hauch2, R. Kimmig2, S. Kasimir-Bauer2

1Carl-Gustav-Carus University Dresden- TU Dresden, Gynecology and Obstetrics, Dresden, Germany

3Carl-Gustav-Carus University Dresden- TU Dresden, Gynecology and Obstetrics, Dresden, Germany
4Acomed Statistik, Acomed Statistik, Leipzig, Germany
5Qiagen, Qiagen, Hilden, Germany

Aims

We recently showed that the presence of ERCC1+CTCs (defined as positive for at least one of the AdnaTest markers and ERCC1-positivity), is an independent predictive biomarker for primary platinum-resistance and poor prognosis of ovarian cancer. The aim of our study was to determine, whether the additional assessment of ERCC1-transcripts increases the overall CTC-detection rate. Moreover, we analyzed clinical relevance of ERCC1+CTCs after adjuvant chemotherapy.

Method

65 paired blood samples of primary ovarian cancer patients at primary diagnosis and after adjuvant chemotherapy were studied for CTCs with the AdnaTest OvarianCancer (QIAGEN, Germany). We analyzed the tumor-associated transcripts EpCAM, Muc-1 and CA-125. ERCC1-transcripts were investigated in a separate approach by singleplex RT-PCR.

Results

Besides Adnatest+CTCs, the additional assessment of ERCC1 allows the detection of CTCs, which are negative for Adnatest markers and exclusively positive for ERCC1-transcripts (Adnatest+/ERCC1+CTCs). This results in an increased overall CTC-detection rate from 23% to 40% before surgery and from 20% to 38% after chemotherapy. However, CTCs with combined positivity for at least one Adnatest marker and ERCC1-positivity (ERCC1+/CTCs) showed the most relevant prognostic information and correlated with platinum-resistance (p=0.01) and reduced PFS (p=0.029) and OS (p=0.0008). Moreover, the persistence of ERCC1+CTCs after adjuvant chemotherapy indicated poor prognosis (PFS: p=0.005; OS: p=0.006).

Conclusion

The combined detection of Adnatest+/ERCC1+CTCs and Adnatest+/ERCC1+CTCs increases the overall detection rate of CTCs in ovarian cancer patients. Specifically, we suggest that ERCC1+CTCs could be used as blood-based biomarker for monitoring platinum-based chemotherapy and for identifying ovarian cancer patients with poor prognosis.

7Roche Pharma AG, Biostatistics and Epidemiology, Grenzach-Wyhlen, Germany
8Roche Pharma AG, Medical Affairs, Grenzach-Wyhlen, Germany
9St. Vincentius-Kliniken, Department of Gynecology, Karlsruhe, Germany

Aims

Phase III trials demonstrated the efficacy and safety of front-line bevacizumab-containing therapy for ovarian cancer. Previous interim analyses of the single-arm OTILIA study (NCT01697488) evaluating front-line bevacizumab-containing therapy in German clinical practice showed a 21.7-month median progression-free survival (PFS) and similar outcomes irrespective of age. Post hoc analyses explored factors potentially predicting premature treatment discontinuation and PFS.

Method

Patients with newly diagnosed FIGO stage IIIB–IV ovarian cancer received the EU-approved bevacizumab-containing regimen. Co-primary endpoints were safety and PFS. A logistic regression model including age, diabetes mellitus, cardiovascular comorbidities, ascites, ECOG performance status and FIGO stage assessed factors associated with treatment discontinuation for reasons other than disease progression, death or documentation completion. Potential prognostic factors for PFS were explored using Cox regression analysis.

Results

By 31/01/2017, 433 of 808 patients had discontinued therapy. The most common reasons for treatment discontinuation were disease progression (12%), end of documentation (10%), treatment-related toxicity (8%) and non-toxicity-related patient request (6%). Factors suggesting increased risk of treatment discontinuation were age ≥70 versus <70 years (odds ratio 1.67 [95% CI 1.18–2.38]; p=0.004) and diabetes mellitus (odds ratio 1.79 [95% CI 1.06–3.03]; p=0.030). Cox regression analysis suggested worse PFS in patients with post-operative residual tumour ≥1cm or ascites >500mL; age and comorbidities were not associated with PFS.

Conclusion

In post hoc analyses, premature bevacizumab discontinuation seemed more likely in older or diabetic patients. However, neither age nor comorbidities was associated with worse PFS. Patient education and counselling are essential to ensure maximal duration of effective therapy.
AN OBSERVATIONAL, MULTICENTER, PROSPECTIVE STUDY OF TRABECTEDIN PLUS PEGYLATED LIPOSOMAL DOXORUBICIN (PLD) IN PATIENTS WITH PLATINUM-SENSITIVE RECURRENT OVARIAN CANCER (PSROC)

D. Reichert1, P. Wimberger2, U. Ringsdorf3, M. Krohn4, M. Kuther5, I. Runnebaum6, J. Sehouli7

1Medizinische Studiengesellschaft NORD-WEST GmbH- Gemeinschaftspraxis für Onkologie, Onkologie, Westerstede, Germany
2Universitätsklinikum Carl Gustav Carus- TU Dresden, Onkologie, Dresden, Germany
3Lahn-Dill-Kliniken GmbH- Gynäkologie und Geburtshilfe, Onkologie, Wetzlar, Germany
4Agaplesion Diakonieklinikum Rotenburg GmbH- Frauenklinik - Gynäkologie und gynäkologische Onkologie- Geburtshilfe und Perinatologie, Onkologie, Rotenburg, Germany
5Städtisches Krankenhaus Kiel GmbH, Medical oncology, Kiel, Germany
6Klinikum der Friedrich-Schiller-Universität Jena - Klinik für Frauenheilkunde, Onkologie, Jena, Germany
7Charité Universitätsmedizin Berlin, Medical oncology, Berlin, Germany

Aims

The prospective, non-interventional phase IV OVA-YOND study evaluated trabectedin+PLD in real-life clinical practice to assess the toxicity and efficacy of the combination.

Method

Data from patients with PSROC treated with PLD 30 mg/m² followed by trabectedin 1.1 mg/m² 3-h i.v. infusion every three weeks have been collected.

Results

From 02/2013-12/2016, 77 enrolled patients from 31 sites across Germany and treated with ≥1 cycle of trabectedin+PLD were evaluated. All patients had PSROC with a median platinum-free interval of 12 months (range: 6-86 months). Median age of patients was 66 years (range: 40-78) and 80.5% had ECOG performance status 0/1. Median number of trabectedin+PLD cycles received per patient was 6 up to a maximum of 21 cycles. Median treatment duration was 4.24 months, mostly on an outpatient basis (≥66.7). Five patients (6.5%) had a complete response and 19 patients (24.7%) achieved a partial response for an ORR of 31.2% with a median duration of 6.25 months. Additionally, 16 patients (20.8%) had disease stabilization for a disease control rate of 51.9%. With 64 PFS events recorded, median PFS was 6.3 months (CI95%: 5.1-7.3), whereas median OS was 16.4 months (CI95%: 11.3-19.3). Most common grade 3/4 trabectedin-related adverse events (TRAЕ) were leukopenia (18.2% of patients), neutropenia (15.6%), thrombocytopenia (9.1%), ALT (7.8%)/AST (6.5%) increase, and nausea/vomiting (5.2% each). No grade 5 or unexpected TRAE occurred.

Conclusion

Trabectedin+PLD confer clinically meaningful benefit to patients with PSROC, being either comparable or better to those observed in selected populations from clinical trials or other real-life studies, with a manageable safety profile.
ARID1A MUTATION WITH LOSS OF PROTEIN EXPRESSION OF BAF250A MAY ACT AS AN EARLY EVENT IN THE TRANSFORMATION OF ENDOMETRIOSIS INTO OVARIAN CANCER

C.H. Wu¹, H. Lin¹, Y.C. Ou¹, C.C. Huang²
¹Kaohsiung Chang Gung Memorial Hospital, Obstetrics and Gynecology, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Chang Gung Memorial Hospital, Pathology, Kaohsiung, Taiwan R.O.C.

Aims

Ovarian clear cell carcinoma (CCC) and endometrioid adenocarcinoma (EMC), regarded as endometriosis-associated ovarian cancer, are the second most frequent types of epithelial ovarian cancer (EOC) accounting for 35~40% of EOC in Asia. Mutation of ARID1A (the AT-rich interactive domain 1A (SWI-like) gene) resulting in inactivation of its encoding nuclear protein, BAF250a, has been frequently identified in these tumors. The timing of loss of ARID1A protein expression during the development of endometriosis-related ovarian cancer would be investigated in this study.

Method

We retrospectively collected the cases diagnosed as CCC or EMC from 2001 to 2012 and further analyzed the expression of protein BAF250a from tumor blocks containing benign endometriosis, CCC or EMC by immunohistochemical study.

Results

During 2001 and 2012, 94 CCC and 136 EMC were collected and loss of ARID1A expression was found in 47 (50.6%) cases in CCC and 26 (18.9%) cases in EMC, respectively. 22 (23.4%) of CCC and 14 (10.3%) of EMC were disclosed having concurrent endometriosis in tumor side, and 82% (17 of 22) in CCC and 100% (5 of 5) in EMC of atypical endometriosis, adjacent to those ARID1A-deficient carcinoma were also found to be ARID1A deficient, comparing to none of the endometriotic epithelium not adjacent to the tumor (distant endometriosis foci).

Conclusion

In our study, it indicated that loss of expression of ARID1A might already present in a portion of atypical endometriosis, which possibly has undergone genetic alteration, indicating a risk of malignant transformation from benign endometriosis to CCC and EMC.
THERAPEUTIC SIGNIFICANCE OF FULL LYMPHADENECTOMY IN EARLY-STAGE OVARIAN CLEAR CELL CARCINOMA

H. Yamazaki*, Y. Todo*, H. Kato*
*HOKKAIDO CANCER CENTER, Gynecology, Sapporo, Japan

Aims

The aim of this study was to evaluate a therapeutic significance of full lymphadenectomy in early-stage ovarian clear cell carcinoma (OCCC).

Method

We retrospectively reviewed records of 127 consecutive OCCC patients with pT1/pT2 and M0 disease between January 1995 and December 2015. Survival outcome was compared with or without para-aortic lymph node dissection (PAND). Statistical analysis for selec were analyzed with Cox proportional hazard models.

Results

Of the 127 patients, 36 (28%) patients did not undergo lymphadenectomy and 12 (10%) patients underwent pelvic lymph node dissection (PLND) alone. Seventy-nine (62%) patients underwent PLND and PAND. Of the 91 patients with lymphadenectomy, ten (11%) had lymph node metastasis. There was no significant difference in age and distribution of positive peritoneal cytology, pT status, capsule rupture, peritoneal involvement, and combined chemotherapy between the PAND- group and the PAND+ group. Cox regression multivariate analysis confirmed that older age (HR, 2.5; 95% CI, 1.2–5.3), lymph node metastasis (HR, 5.4; 95% CI, 1.7–17.2), and positive peritoneal cytology (HR, 5.1; 95% CI, 2.0–13.2) were significantly and independently related to poor overall survival (OS), but implementation of both PLND and PAND (HR, 0.4; 95% CI, 0.2–0.9) were significantly and independently related to improved OS.

Conclusion

Although few in number, there are some patients with early-stage OCCC who can benefit from full lymphadenectomy. Its therapeutic role should be continuously investigated in OCCC patients at potential risk of lymph node metastasis.
OVARIAN CANCER II

ESGO7-0487

ESTABLISHMENT AND CHARACTERIZATION OF A HUMAN OVARIAN CLEAR CELL CARCINOMA CELL LINE (FDOV1) DERIVED FROM A CHINESE PATIENT

W. Jiang¹, S. Ye¹, L. Xiang¹, W. Yang², T. He¹, X. Pei¹, H. Yang¹

¹Fudan University Shanghai Cancer Center, Department of Gynecologic Oncology, Shanghai, China
²Fudan University Shanghai Cancer Center, Department of Pathology, Shanghai, China

Aims

Ovarian clear cell carcinoma (OCCC) is a distinct histologic subtype with grave survival. The underlying molecular mechanism is not fully elucidated. Cell lines are useful experimental tools for research. We describe the establishment and characterization of a new OCCC cell line from a Chinese patient.

Method

FDOV1 was derived from an ovarian tumor from a 67-year-old woman. The morphology, growth pattern and karyotype were analyzed. Xenografts were established and characterized by histology and immunohistochemistry. Subsequently, whole-exome sequencing (WES) on both FDOV1 and patient’s formalin-fixed paraffin-embedded tissue block was performed to investigate the molecular profile.

Results

FDOV1 has been subcultured for more than 50 generations. Monolayer cultured cells are polygonal in shape, showing a transparent cytoplasm full of vacuoles (Fig 1.A). The number of chromosomes ranges from 45 to 90 (Fig 1.B). FDOV1 cells produce CA-125, but not CA-199. The cells could be transplanted (Fig 1.C) and produced tumors mimicking the donor tumor morphologically and immunohistochemically (Fig 1.D). WES showed both FDOV1 and tissue block harbored PIK3CA H1047R mutation and ARID1A

Conclusion

Only 13 patient-derived OCCC cell lines have been reported in the literature. FDOV1 is the very first one from a Mainland Chinese patient and has co-existing PIK3CA and ARID1A mutations, which would probably be a good model for exploring the molecular mechanism of OCCC.
OVARIAN CANCER II

ESGO7-0515

ALTERATION OF THE TUMOR MICROENVIRONMENT BY NOTCH SIGNALING ENHANCES THE MUTUAL ASSOCIATION WITH EPITHELIAL OVARIAN CANCER AND MESOTHELIAL CALLS

M. Yoshihara1, H. Kajiyama1, M. Sugiyama1, F. Kikkawa1
1Nagoya University, Obstetrics and Gynecology, Nagoya, Japan

Aims

Peritoneal mesothelial cells (PMCs) are the primary components of the tumor microenvironment for epithelial ovarian cancer (EOC) cells. The Notch signaling-mediated alteration of the tumor microenvironment can play a crucial role in tumor progression; however, the exact role of Notch signaling between EOC and PMCs remains uncertain. The aim of this study was to assess changes of PMCs in the association with EOC, focusing on Notch pathways.

Method

We examined the effects of TGF-β1 treated PMCs on EOC progression via Notch signaling inhibition and analyzing how PMCs promote EOC cells attachment and proliferation, and induced chemoresistance.

Results

Level of TGF-β1 is higher in malignant ovarian tumor compared with benign ones. With TGF-β1 stimulation, expression of Notch 3 and Jagged 2 were increased in PMCs in immune-blotting analysis. We also confirmed elevation of HES1, a target gene of Notch signaling in TGF-β1 stimulated PMCs. We investigated the effects of TGF-β1 treated PMCs on EOC, using FACS systems, and revealed that EOC cells co-cultured with TGF-β1 stimulated PMCs showed higher chemo-resistance than with control PMCs. In the EOC cells with TGF-β1 stimulated PMCs, Jagged 1, Notch3, and HES1 were elevated compared with control.

Conclusion

PMCs stimulated with TGF-β1 induced heterogeneity of EOC cells via Notch signals. Our results suggested that alteration of the tumor microenvironment by Notch signaling were effectively enhanced in the mutual association with chemoresistant EOC and PMCs.
OVARIAN CANCER II

ESGO7-1366

INTERACTION OF GANETESPIB WITH CYTOTOXIC DRUGS IN OVARIAN CANCER CELL LINE MODELS

1Medical University of Vienna, Department of Obstetrics and Gynecology, Vienna, Austria
2Medical University of Vienna, Department of Surgery, Vienna, Austria
3Charité University Hospital- European Competence Center for Ovarian Cancer Berlin, Department of Gynecology, Berlin, Germany
4Innsbruck Medical University, Department of Gynecology and Obstetrics, Innsbruck, Austria

Aims

High-grade serous ovarian cancer (HGSOC) has a high mortality rate because patients are generally detected in an advanced stage and show resistant relapses. Primary cell lines of relapsed patients were established and tested for a possible synergy of the HSP90 inhibitor ganetespib with paclitaxel and platinum drugs. HSP90 stabilizes mutated oncogenes and inhibits their proteasomic degradation.

Method

Primary ovarian cell lines were established from ascitic fluid or pleural effusions (GANNET53: Ganetespib in Metastatic, p53-mutant, Platinum-resistant Ovarian Cancer) and chemosensitivity tested in MTT assays. Soluble carbonic anhydrase IX (sCAIX) was measured by ELISA.

Results

Primary ovarian cells grow adherent or as spheroids with prolonged doubling times and showed low sensitivity to ganetespib alone. Combination of ganetespib with paclitaxel proved to be antagonistic employing primary and established ovarian cancer cell lines whereas the combination of this HSP90 inhibitor with platinum drugs (cisplatin, carboplatin, oxoplatin) yielded synergistic effects. Furthermore, the primary cell lines of resistant patients revealed sensitivity to platinum drugs in vitro. Ascitic fluid is partially hypoxic and showed high levels of sCAIX which is associated with tumor aggressiveness and a poor prognosis. Expression of sCAIX was found to be sensitive to inhibition with ganetespib.

Conclusion

Cell lines established from recurrences of resistant ovarian cancer patients were resistant to paclitaxel but sensitive to platinum drugs. The cytotoxicity of platinum drugs could be enhanced in combination with ganetespib. Drug resistance seems to be associated with low proliferation, formation of spheroids and hypoxic conditions with expression of sCAIX and increased tumor aggressiveness.
Aims

This study aimed to evaluate the expression of programmed death ligand-1 and its correlation with clinicopathologic features in ovarian clear cell carcinoma (OCCC).

Method

The PD-L1 expression was measured by tissue-microarray-based immuno-histochemistry from 123 patients diagnosed with OCCC. The associations of clinicopathologic features with PFS and OS were analyzed by Kaplan-Meier method and multivariate analysis was further performed by Cox regression model.

Results

Overall, high PD-L1 expression was observed in 44.7% (55/123) of OCCC patients, and was strongly associated with advanced stages (p = 0.026), positive ascitic fluid (p = 0.016), platinum-resistant disease (p = 0.045) and recurrence (p = 0.038). Moreover, patients with high PD-L1 expression were associated with poorer OS (Hazard ratio [HR], 2.877; p = 0.001) and PFS (HR, 1.843; p = 0.021) than those with low PD-L1 expression. In subgroup analysis, PD-L1 high patients experienced a poorer PFS (HR,1.926; p = 0.044) and OS (HR,2.492; p = 0.021) than PD-L1 low cases among advanced stages (III-IV), but this difference was not observed in stage I-II patients. Meanwhile, PD-L1high was associated with poorer prognosis than PD-L1low in platinum-resistant patients (OS, HR: 2.253, p = 0.037; PFS, HR: 1.448, p = 0.233). Multivariate analysis revealed that PD-L1 high and advanced stages (III-IV) were adverse independent prognosticators for both PFS (HR_{PD-L1}, 2.0, p_{PD-L1} = 0.038; HR_{stage}, 10.2, p_{stage} < 0.001) and OS (HR_{PD-L1}, 3.0, p_{PD-L1} = 0.011; HR_{stage}, 14.3, p_{stage} < 0.001).

Conclusion

High PD-L1 expression might be a risk factor for PFS and OS in patients with OCCC. Immunotherapy targeting PD-L1 pathway could be used in OCCC.
VEGFR RECEPTORS, AS MOLECULAR MARKERS OF ANGIOGENESIS AND LYMPHANGIOGENESIS IN OVARIAN CANCER.
P. Ziober-Malinowska¹, M. Mazurek-Kociubowska¹, R. Tarkowski¹, M. Sobstyl¹, K. Kutak¹, W. Bednarek¹
¹Medical University of Lublin, 1st Chair and Department of Oncological Gynaecology, Lublin, Poland

Aims

Vascular endothelial growth factor VEGF is one of the cytokines responsible for multi-step process angiogenesis in tumors. Aim: To evaluate the expression of VEGF receptor immunohistochemistry in ovarian cancer in relation to the histological tumor grade, disease stage FIGO, the level of CA125 in the blood serum of patients, the female sex hormone concentration and histopathological.

Method

The study was performed on a group of 61 patients with ovarian carcinoma. Immunohistochemistry expression of VEGF receptors correlated with the histological tumor grade, disease stage FIGO, the level of CA125 in the blood serum of patients, the female sex hormone concentration and histopathological.

Results

63.93% of patients detected the expression of VEGFR3, especially in tumors with an average degree of histological differentiation. VEGF1 expression was more common in endometrial cancer, ovarian cancer, compared to serum. Statistical significance was proved expression of VEGF2 in patients with ovarian and CA125 values within normal limits.

Conclusion

The receptors VEGFR can be found in the future, used in the diagnosis and treatment of patients with ovarian cancer, can be considered as molecular markers of lymphocytes and angiogenesis. Their increased expression does not affect the clinical stage of the disease FIGO, and increased expression correlates with more frequent VEGF3 lymphatic metastases.
APPLICATION OF LEARNING SKILL “TEACHING ON THE RUN” TO POST-GRADUATE FIRST-YEAR RESIDENTS FOR IMPROVEMENT IN THE QUALITY OF PAPANICOLAOU SMEAR

Aims

Papanicolaou smear (Pap smear) with cervical cytology could reduce incidence and mortality rate of cervical cancer. However, poor quality of Pap smear decreases screening efficacy. The aim of our study was to evaluate whether “Teaching On The Run (TOTR)” training program could help junior residents to improve skill and quality of Pap smear.

Method

Since May through December 2015, a total of 40 post-graduate first-year (PGY1) residents were randomly divided into two groups. The with-TOTR group (n=22) received the protocol-driven TOTR training program composed of plan learning, learn, appraise/assess, feedback and outcome evaluation. The without-TOTR group (n=18) received traditional big-class teaching instead. The rate of unidentifiable Pap smear and causes of unsatisfactory Pap smear were analyzed between the two groups.

Results

The results showed that TOTR training program significantly reduced the rate of unsatisfactory Pap smear quality from 34.1% to 24.1% (p<0.0001). In addition, the rate of unidentifiable Pap smear was significantly lower in the with-TOTR than without-TOTR group (2.16% vs. 5.81%, p=0.018), and was similar to that performed by gynecologists (2.16% vs. 2.34%, p=0.425). Furthermore, we identified the most two significantly improved items through TOTR training were less scarce cells (12.8% to 8.2%) and overlapping cells or contained blood (5.8% to 3.6%) (both p-values <0.005).

Conclusion

TOTR training program effectively helps PGY1 residents to improve their skills on accuracy and quality of Pap smear within a short-term training period.
INCREASED RISK OF CANCERS AMONG BRCA1 CARRIERS WITH LOW BLOOD SELENIUM LEVELS

J. Lubinski1, W. Marciniak1, R. Derkacz2, P. Baszuk1, M. Muszyńska1, M. Kuświk1, T. Huzarski2, J. Gronwald3, S.A. Narod4, A. Jakubowska2

1Read-Gene SA, Dobra, Poland
2Pomeranian Medical University in Szczecin, Department of Genetics and Pathology, Szczecin, Poland
3Women’s College Research Institute, Toronto, Canada

Aims

Prospective evaluation of relationship between selenium and cancer among women with BRCA1 constitutional mutations.

Method

We performed a nested case-control study of baseline blood selenium levels and cancer risk using data and biological samples from 4276 BRCA1 carriers that were participants in a biobanking initiative between 2010 and 2017. Cases included women with any incident breast/ovarian cancer (n=48) and controls (n=92) were women with no cancer at baseline or follow up. Blood from cases was collected at least 6 months before cancer diagnosis. Cases and controls were matched for year of birth, adnexectomy status and smoking. Blood selenium was quantified using mass spectroscopy.

Results

Women with blood selenium level <110 µg/l had a higher than 3-fold increased risk of cancer (logistic regression OR 3.12; CI 1.17-9.89; p = 0.033).

Conclusion

The optimum level of blood selenium in BRCA1 carriers living in Poland can not be lower than 110 µg/l.

Supported by grant of the National Centre for Research and Development (NCBiR) no INNOMED/I/16/NCBR/2014.
WOMEN'S ATTITUDES TO AUSTRALIAN CERVICAL SCREENING PROGRAM CHANGES AS EXPRESSED IN AN ONLINE PETITION

H.M. Obermair1, R.H. Dodd1, C. Bonner1, J. Jansen1, S. Carter1, K. McCaffrey1
1University of Sydney, School of Public Health, Sydney, Australia

Aims

The Australian Cervical Cancer Screening Program, which has halved the incidence and mortality of cervical cancers in Australia since 1991, will change in 2017 from currently two-yearly Pap smears from age 18 to 69 to five-yearly HPV DNA testing from ages 25 to 74. An opposing petition on the website “Change.org” received 70,000 signatures and 20,000 comments. This study aimed to identify reasons for opposition to the revised cervical cancer screening program, expressed in the open-ended comments.

Method

Of 19,633 comments posted between 16th February and 19th March 2017, a random 2000 comments were analysed by two researchers.

Results

33% of statements highlighted that commenters placed high value on women’s health. 17% were concerned about the five-yearly screening interval. Women with a personal experience of cervical cancer or pre-cancerous lesions expressed opposition to the changes (15%). Support for disease prevention/early detection (14%), belief that the changes were a cost-cutting measure (14%), and a belief that men should not make decisions about women’s health (8%) were other central themes. Concern about increased age of first invitation was voiced in 9% of comments, and concern about HPV testing itself was expressed in only 3% of comments.

Conclusion

Many women expressed concerns that the screening program changes may adversely impact women’s health, indicating a need for health education in this area. The primary concern of commenters specific to the program was potentially missing cases of cervical cancer due to later age of first invitation and increased screening interval, with a perception this was a cost-cutting measure.
RISK FACTORS ASSOCIATED WITH ENDOMETRIAL CANCER: AN UMBRELLA REVIEW

1Institute of Reproductive and Developmental Biology, Surgery and Cancer, Imperial College London, London, United Kingdom
2Queen Charlotte’s and Chelsea Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom
3Department of Hygiene and Epidemiology, University of Ioannina School of Medicine, Ioannina, Greece
4Section of Nutrition and Metabolism, International Agency for Research on Cancer IARC, Lyon, France
5Department of Obstetrics and Gynaecology, University of Ioannina, Ioannina, Greece
6Department Gynaecologic Oncology, Lancashire Teaching Hospitals, Preston, United Kingdom
7Department of Biophysics, University of Lancaster, Lancaster, United Kingdom

Aims

Endometrial cancer is the most common gynaecological cancer among European women. Many modifiable risk factors have been associated with endometrial cancer, although the associations may be affected by inherent bias. We evaluated the strength and validity of the available evidence on modifiable risk factors for endometrial cancer (EC).

Method

We conducted an umbrella review of meta-analyses investigating modifiable risk factors for endometrial cancer. The primary analysis focused on cohort studies, with evidence graded as strong, highly suggestive, suggestive or weak based on random effects summary estimate, largest study per meta-analysis, number of cases, between-study heterogeneity, 95% prediction intervals, small study effects, excess significance bias and sensitivity analysis with credibility ceilings.

Results

We identified 144 meta-analyses investigating associations between 9 categories of risk factors for endometrial cancer (93 cohort studies). Only three (7%) risk factors demonstrated strong evidence without hints of bias for association with EC: rise in body mass index in premenopausal women and increase in waist-to-hip ratio (increased risk), and multiparous women (reduced risk of EC).

Conclusion

Of the many identified risk factors for endometrial cancer, only three were found to have strong association without hint of bias. Other claimed associations may also be valid, but further evidence is required. Our findings re-emphasise the importance of targeting the increasing number of obese and overweight women at high risk of endometrial cancer with weight-loss strategies. Future research efforts should explore the effect of obesity on metabolic dysregulation and metabolic pathways which, when altered, may promote endometrial cancer.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER II

QUALITY OF LIFE AFTER ENDOMETRIAL CANCER SURGERY WITH AND WITHOUT LYMPHADENECTOMY: A SINGLE INSTITUTION RETROSPECTIVE COHORT STUDY

E. Lajtman1, M. Mlynček1, M. Matejka1, T. Kapusta1
1Faculty Hospital Nitra and Constantine the Philosopher University in Nitra, Department of obstetrics and gynecology, Nitra, Slovak Republic

Aims

To compare the quality of life of endometrial cancer patients treated with surgery with and without lymphadenectomy.

Method

Quality of life of the endometrial cancer (FIGO stages I and II) patients treated with surgery between 2012 and 2016 was analyzed. The patients were divided into two groups: Group A consisted of 102 patients who had hysterectomy and bilateral salpingo-oophorectomy without lymphadenectomy (HBSO); Group B consisted of 53 patients who had hysterectomy and bilateral salpingo-oophorectomy with lymphadenectomy (HBSO+LYA). The EORTC Quality of Life Questionnaire Endometrial Cancer Module (QLQ-EN24) and Quality of Life Questionnaire Cancer Module (QLQ-C30) were administered to the selected patients. The data were analyzed using the manual of the EORTC Group.

Results

According to QLQ-C30 fatigue showed statistically significant difference between Group A and Group B (3.033 ± 8.05 vs. 16.99 ± 22.35, p=0.045). As to the symptom scales according to QLQ-EN24 lymphedema showed a statistically significant difference between two groups with a score of 11.74 ± 16.63 in Group A and 21.94 ± 23.63 in Group B (p=0.0279).

Conclusion

Our study showed that fatigue and lymphedema decrease the quality of life in the patients with endometrial cancer treated with lymphadenectomy. Systematic pelvic and paraaortic lymphadenectomy should be accomplished only in the high risk endometrial cancer group to select the adjuvant treatment after surgery.

6Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain

Aims

Study of the influence of surgical and histopathological risks factors on the abnormal healing in patients operated of gynecological cancers and the response to the topical treatment with olivoleina.

Method

Prospective cohorts study in 100 patients, randomised and comparative, between January 2014 and July 2016. Groups of patients were defined whether the studied risk factor was present or not. In a randomly way, olivoleina was prescribed in 66 patients. The monitoring was carried in 3, 6 and 12 months. The scars were assessed according to the Vancouver, Manchester and Posas Scales.

Results

64 patients received lymphadenectomy. The average of surgical time was 188.06 minutes, of blood loss was 761.90 cc and of monitoring was 10.13 months. When the lymphadectomy was made, the patients used to have difficulty to the healing in a significant way from the beginning until 6 months later (p<0.01). The subgroup of patients with treatment showed an improvement from the 6th month (p<0.05) and from the 12 months (p<0.01). The high average blood loss during the surgical intervention and the surgical time hindered in the initial healing and 3 months later (p<0.01). The treatment proved a significant improvement in the final result (p<0.01). Dermatologic effects and the tolerance perceived were good-very good in 95.2% and 96.9% of the cases respectively.

Conclusion

The quality of the healing after the topical treatment with olivoleina was significantly better in the patients who received lymphadenectomy. It can be recommended to patients after they have undergone gynecological cancer surgery.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER II

ESGO7-0861

QUALITY OF LIFE ASSESSMENT IN OVARIAN CANCER PATIENTS RECEIVING CHEMOTHERAPY: A PILOT STUDY

A. V. Silva¹, L. Bel¹, C. Faria², M. Silva³, L. Antunes³, A. Petiz², D. Pereira³, J. Savva-Bordalo³

¹Instituto Português de Oncologia do Porto, Medical Oncology, Porto, Portugal
²Instituto Português de Oncologia do Porto, Gynecology, Porto, Portugal
³Instituto Português de Oncologia do Porto, Epidemiology, Porto, Portugal

Aims

Assessment of Quality of Life (QoL) of patients with ovarian cancer admitted in our institution undergoing chemotherapy. Identification of areas and variables associated with worse results in view of possible future intervention.

Method

A prospective longitudinal observational study was performed for 12 months. After obtaining an informed consent, patients completed EORTC QLQ-C30 and ovarian cancer-specific QLQ-OV28 questionnaires at diagnosis, after 3 and 6 cycles of treatment. Association between QoL scores and clinical variables was assessed using Mann-Whitney or Kruskal-Wallis tests, as applicable.

Results

Twenty-one patients were recruited, 62% (n=13) had ECOG PS 0. Median age was 55 years old (range 27-73). During the study only one patient died and 102 questionnaires were completed. The mean global QoL score was 49.6 ± 20.15 at diagnosis, 51.11 ± 23.75 after 3 cycles and 62.5 ± 26.7 after 6 cycles of therapy. At baseline, scales with worst results were emotional functioning (within functional scales), constipation, fatigue, appetite loss (within symptom scales) and attitude to disease/treatment. Except for the last one, all of them have had an improvement at third evaluation. There was an impairment of mean score in cognitive functioning, body image, sexuality, hair loss and neuropathy. Age above 50 years old and post-menopausal status at diagnosis were associated with worst QoL (p< 0.05).

Conclusion

This prospective study reinforce the importance of quality of life assessment in ovarian cancer patients ongoing chemotherapy, as a potential tool for therapeutic and management decisions, in order to benefit of our patients care.
SEXUAL FUNCTIONING AND QUALITY OF LIFE AFTER VULVAR RECONSTRUCTION WITH THE LOTUS PETAL FLAP

N.C. te Grootenhuis¹, J. Hellinga², P.M. Werker², A.G. van der Zee¹, M.H. Oonk¹, M.W. Stenekes²
¹University Medical Center Groningen, Obstetrics and Gynaecology, Groningen, The Netherlands
²University Medical Center Groningen, Plastic Surgery, Groningen, The Netherlands

Aims

Resection of (pre) malignant lesions in the vulvoperineal area may result in large defects that cannot be closed primarily. In these cases reconstruction is needed. In the vulvoperineal area the lotus petal flap technique is widely used. The aim of this study was to evaluate both sexual functioning and quality of life of patients who underwent reconstructive surgery with a lotus petal flap in the vulvoperineal area, since no data are available on this topic.

Method

A cross-sectional study was performed on all patients undergoing a reconstruction with a lotus petal flap from 2005-2016 in the University Medical Center Groningen. The Female Sexual Function Index (FSFI), European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-C30 (EORTC QLQ-C30) and Body Image Scale (BIS) were used.

Results

Twenty-six (68%) patients responded to the questionnaires. The mean age was 65.5 years (SD 16.3) and median follow-up time was 38.5 months (range 15.8-141.4). Quality of life scores were slightly decreased compared to healthy females aged 60-69 years. The total median FSFI score was 13.4 out of 36.0 (SD 8.2) and 53% reported to be sexually active. The mean score on the BIS was 9.6 out of 30.0 (SD 7.3).

Conclusion

Quality of life after vulvoperineal reconstructive surgery with a lotus petal flap is slightly decreased compared to healthy females and vulvar cancer patients. Sexual functioning and body image are decreased after reconstruction of a vulvoperineal defect with a lotus petal flap. Our results should be used for pre-operative counseling and follow-up of these patients.
QUALITY OF LIFE AFTER TREATMENT OF GYNAECOLOGIC CANCER II

ESGO7-0077

PATIENTS’ AND GENERAL PRACTITIONERS’ VIEWS OF FOLLOW-UP AFTER TREATMENT OF GYNECOLOGICAL CANCER

Vistad1, H. Fidjeland1, M. Brekke2
1Sørlandet hospital Kristiansand, Gynecology, Kristiansand, Norway
2Institute of Health and Society, Department of General Practice, Oslo, Norway

Aims

Greater involvement by general practitioners (GPs) in cancer follow-up has been suggested. We aimed to explore gynecological cancer survivors’ attitudes toward follow-up by GPs and whether time in the surveillance program influences their opinions. We also aimed to assess GPs views of increased responsibility for gynecological cancer survivors.

Method

A questionnaire on expectations and attitudes to follow-up after gynecological cancer treatment was distributed to women after end of treatment (new) and >1 year in the surveillance program (experienced). Further, a questionnaire was mailed to GPs regarding their attitudes toward follow-up of gynecological cancer.

Results

239 patients (100 new, 139 experienced) and 317 GPs responded. 36% of new patients were willing to be followed-up by their GP compared to 17% of experienced patients, p=0.02. 42% of the GPs were willing to assume exclusive responsibility within three years after treatment. A patient-specific letter from the specialist and expedited routes of re-referral were important conditions to help them provide follow-up care. Both survivors and GPs thought that detection of recurrence was the most important reason for follow-up. 90% of GPs believed that they were better suited than hospital specialists at providing psychosocial support, but the survivors preferred to talk to the gynecologist about psychological and physical late effects after cancer treatment.

Conclusion

Our results suggest that patients change their attitude of who should be responsible for follow-up after they have started in the surveillance program. Before alternative follow-up regimens are implemented, patients’ and GPs’ attitudes to follow-up should be taken into account.
Aims

MicroRNAs (miRNAs, miR-) regulate gene expression and modulate several cell pathways associated with tumor malignancy. Of the various miRNAs associated with cancers, miR-944 has been associated with cervical cancer tumorigenesis from the previous studies. The aim of this study was to investigate the clinical prognostic value of miR-944 expression in FFPE sample of cervical cancer.

Method

A total of 68 FFPE cervical cancer tissues were obtained and to check the validity of this biomarker, normal FFPE samples from 50 patients who underwent a hysterectomy for non cervical, benign gynecological diseases were included together. Using quantitative reverse transcriptase PCR (RT-qPCR) to measure miR-944 expression levels in both FFPE samples and simultaneously had electrical medical record assessment of enrolled cervical cancer patients to review their clinical prognostic factors.

Results

Expression levels of miR-944 in cervical cancer tissues were significantly higher than those in normal tissues ($P < 0.0001$). Increased expression of miR-944 was also markedly associated with tumor size ($P = 0.049$), FIGO stage ($P = 0.027$), and lymph node metastasis ($P = 0.007$). Furthermore, Kaplan Meier analysis suggested that cervical cancer patients with high miR-944 expression had shorter overall survival time than those with low miR-944 expression ($P = 0.004$). Multivariate Cox proportional hazards model analysis of miR-944 showed that high expression of miR-944 was independent prognostic factors for overall survival.

Conclusion

In conclusion, up-regulation of miR-944 is a meaningful biomarker that has association with poor clinical prognosis in cervical cancer patients.
SINGLE-STRAND-ANNEALING RATHER THAN NON-HOMOLOGOUS-END-JOINING PREDICT HEREDITARY OVARIAN CARCINOMA

M. Deniz1, L. Prof. Dr. Wiesmüller1, T. Dr. Romashova1, T. PD Dr. Friedl1, W. Prof. Dr. Janni1
1Universitätsklinikum Ulm, Frauenklinik, Ulm, Germany

Aims

Deficiency in DNA double-strand break repair especially in homologous recombination (HR) is associated with an increased risk for developing ovarian cancer. It is suggested that up to 25 % of ovarian cancer patients have inherited mutations and up to 7 % somatic mutations resulting in HR defects. HR deficiency opens new options for targeted therapies; the PARP inhibitor Olaparib is approved for BRCA-mutated ovarian cancers. Great efforts have been made to carve out prognostic markers and patient characteristics detecting cancer susceptibility and therapeutic responsiveness. In this work, we performed functional analyses in peripheral blood lymphocytes (PBLs) using a case-control design.

Method

We examined 38 women with defined familial history of breast and/or ovarian cancer, 40 women with primary ovarian cancer, and 35 healthy women without previous cancer or family history. Using a GFP-based test we analyzed error-prone DSB repair mechanisms which are known to compensate HR defects and to generate chromosomal instabilities.

Results

While non-homologous end-joining (NHEJ) did not discriminate between cases and controls, we found increases of single-strand annealing (SSA) in women with familial risk vs. controls (P=0.016) and patients with ovarian cancer vs. controls (P=0.002). Consistent with compromised HR we also detected increased sensitivities to carboplatin in PBLs from high risk individuals (P=0.019) as well as in patients with early-onset ovarian cancer (P=0.046) in comparison to cells from healthy controls.

Conclusion

These findings underscore the great potential of detecting distinct DSB repair activities in PBLs as method to estimate ovarian cancer susceptibility and associated treatment responses beyond the limitations of genotyping.
ASCITES DERIVED TUMOR ASSOCIATED MACROPHAGE ALTERS CHEMOSENSITIVITY IN OVARIAN CANCER CELLS
S. Jeon1, H. Jeon1
1Soonchunhyang university Cheonan hospital, OB & Gyn, Cheonan, Republic of Korea

Aims

Macrophages are the dominant myeloid cells found in tumor microenvironment. Tumor associated macrophage (TAM) has been proved to promote tumor growth, metastasis and chemoresistance. In this study we generated macrophage cell line from the ascites of ovarian cancer model of ID8 injected mouse, determined it’s phenotype and investigated carboplatin chemosensitivity on ovarian cancer cell line in the presence of Macrophage cell line by transwell assay.

Method

To generate macrophage cell line we performed cell harvest, sorting, and immortalizing macrophage, and to determine phenotype of macrophage we perform flow cytometry, Quantitative real time polymerase chain reaction, immunofluorescence and LDL uptake assay. And to investigate carboplatin response of ovarian cancer cell cocultured with macrophages, we used transwell assay and cell viability assay.

Results

TAMs from ascites of mouse ovarian cancer model had mixed phenotype with M1 and M2. In vitro transwell assay, ovarian cancer cells which were cocultured with TAMs had more chemoresistant than control group upon carboplatin treatment.

Conclusion

Our data suggest that soluble factors from ascites derived TAMs may alter carboplatin chemosensitivity in ovarian cancer cells. Blockade of these function of TAMs might increase the clinical effect of platinum-based chemotherapy.

UTERINE LAVAGE-DERIVED MICROVESICLE PROTEOMICS AS A NOVEL APPROACH FOR OVARIAN CANCER DETECTION

1Tel Aviv University, Human Molecular Genetics and Biochemistry, Ramat Aviv, Israel
2Sheba Medical Center, Cancer Research Center, Ramat Gan, Israel
3Meir Medical Center, Gynecologic Oncology Unit, Kfar Saba, Israel
4Meir Medical Center, Obstetrics and Gynecology, Kfar Saba, Israel

7Sheba Medical Center, Obstetrics and Gynecology, Ramat Gan, Israel
8Rabin Medical Center, Gynecologic Oncology, Petah Tikva, Israel
9Sheba Medical Center, Institute of Pathology, Ramat Gan, Israel

Aims

Screening tests for high-grade ovarian carcinoma (HGOC), including serum CA125 and vaginal ultrasonography, fail to reduce disease-specific mortality, hence the universal recommendation for high-risk populations (e.g., BRCA1/2 mutation carriers) remains risk-reducing bilateral salpingo-oophorectomy (RRBSO) around the age of 40. As most HGOC arise from the fallopian tube epithelium (FTE), a 'liquid biopsy' may be obtained through washing of the uterine and tubal cavity, a procedure termed uterine lavage (UtL). We developed a diagnostic proteomic signature for detection of HGOC, based on microvesicles from UtL samples.

Method

Overall, 121 samples from 39 HGOC patients and 82 controls were analyzed by mass-spectrometry. Samples were divided into a discovery set (n=54) used to define the diagnostic signature, and an independent, blinded validation set (n=67).

Results

UtL microvesicle proteomics identified on average 2500 proteins per sample and more than 7000 proteins in the entire cohort. Using support vector machine algorithms, we extracted a 21-protein classifier with a high level of specificity and sensitivity, as represented in the Receiver Operating Characteristics (ROC) curve with an AUC of 0.90. Validation on an independent cohort showed an AUC of 0.74. Moreover, the signature was able to correctly diagnose all 4 early-stage lesions. RT-PCR and immunohistochemistry were able to confirm differential expression of signature proteins.

Conclusion

This proof-of-principle work demonstrates the technical feasibility of UtL, and the ability to obtain a predictive signature for HGOC, based on UtL microvesicle proteomics. Further work is required to implement this approach for early detection in high risk populations.
PTEN STATUS AND CIRCULATING AND ENDOMETRIAL MARKERS OF INSULIN SIGNALLING IN MORBIDLY OBESE WOMEN UNDERGOING BARIATRIC SURGERY

**Aims**

Obesity is strongly associated with endometrial cancer (EC). There is extensive interaction between the sex hormone and insulin/IGF axes which both converge on the PI3K/AKT pathway. We assessed the effects of obesity and weight loss on endometrial proliferation, PTEN status and circulating and endometrial biomarkers of insulin signalling.

**Method**

Morbidly obese women undergoing bariatric surgery were recruited to a prospective cohort study and underwent blood and endometrial sampling at baseline, two and 12 months post surgery. Endometrial proliferation (Ki-67, pAKT), insulin receptor (IR), Insulin-like Growth Factor-Binding Protein 1 (IGFBP1) and PTEN status were assessed using immunohistochemistry.

**Results**

Seventy two women with median BMI 52.2kg/m² (IQR 47, 57) underwent bariatric surgery. Significant reduction in endometrial proliferation (Ki-67) and downregulation of the PI3K/AKT pathway (pAKT) were observed at 2 and 12 months post surgery. At baseline, endometrial glands were PTEN wild type in 31/35 with sufficient tissue for interpretation. Four were PTEN null at baseline; three of these had incidental atypical hyperplasia (AH) or EC. Glandular PTEN staining reappeared with weight loss in 3 of 4 cases. Endometrial IGFBP1 expression was significantly increased 2 months post-bariatric surgery. Serum IGF1 was significantly increased and endometrial IR expression significantly decreased 12 months post-bariatric surgery.

**Conclusion**

PTEN loss may be a reversible feature of early endometrial carcinogenesis. Increased expression of IGFBP1 2 months post weight loss can be explained by falling circulating insulin levels. As circulating IGF1 increased after bariatric surgery the decrease in proliferation may be due to elevated IGF binding proteins.
CIRCULATING TUMOR CELLS: POTENTIAL MARKERS OF MINIMAL RESIDUAL DISEASE IN OVARIAN CANCER? - A STUDY OF THE OVCAD CONSORTIUM

E. Obermayr1, N. Bednarz-Knoll2, B. Orsetti3, H.U. Weier4, S. Lambrechts5, D. Cacsire Castillo-Tong1, A. Reinthaller1, E. Braicu6, S. Mahner7, J. Sehouli6, I. Vergote5, C. Theillet3, R. Zeillinger1, B. Brandt8

7University Medical Center Eppendorf, Gynecology and Gynecologic Oncology, Hamburg, Germany
8University Medical Center Schleswig-Holstein, Clinical Chemistry, Kiel, Germany

Aims

In 75% of ovarian cancer patients the tumor mass is completely eradicated by established surgical and cytotoxic treatment; however, the majority of the tumors recur within 24 months. Here we investigated the role of circulating tumor cells (CTCs) indicating occult tumor load, which remains inaccessible by established diagnostics.

Method

Blood was taken at diagnosis (baseline samples, n=102) and six months after completion of adjuvant first-line chemotherapy (follow-up samples; n=78). CTCs were enriched by density gradient centrifugation. A multi-marker immunostaining was established and further complemented by FISH on CTCs and tumor/metastasis tissues using probes for stem-cell like fusion genes MECOM and HHLA1.

Results

CTCs were observed in 26.5% baseline and 7.7% follow-up blood samples. Baseline CTCs indicated a higher risk of death in R0 patients with complete gross resection (univariate: HR 2.158, 95% CI 1.111-4.191, p=0.023; multivariate: HR 2.720, 95% CI 1.340-5.522, p=0.006). Despite the drop down of CTC counts during treatment (from mean 12 to 1 CTCs per ml blood), non-responders were more likely to retain CTCs (p<0.05). Chromosomal gains at MECOM and HHLA1 loci suggest that the observed cells were cancer cells and reflect pathophysiological decisive chromosomal aberrations of the primary and metastatic tumors.

Conclusion

Our data suggest that CTCs detected by the multi-marker protein panel and/or MECOM/HHLA1 FISH represent minimal residual disease in optimally debulked ovarian cancer patients. The role of CTCs cells especially for clinical therapy stratification of the patients has to be validated in consecutive larger studies applying standardized treatment schemes.

Aims

Defective DNA repair by homologous recombination (HR) is a feature of approximately 50% of high-grade serous ovarian cancers (HGSOC). Quantifying various forms of genomic damage has emerged as a biomarker for underlying DNA repair deficiencies. However, little is known on the temporal stability of these measures and whether genomic scar dynamics have predictive clinical value.

Method

Matched primary and (first) recurrent HGSOC tumor samples from 42 patients were analyzed with SNP-array profiling and (for a subset of 29) paired whole-exome sequencing. Tumor ploidy was estimated and large-scale transitions (chromosomal breaks between adjacent regions of at least 10 Mb) were quantified using validated ploidy-specific cut-offs to identify HR-deficient (HRD) cases. Mutational load was calculated as the number of single-nucleotide (exonic) variants.

Results

HRD was detected in 24/42 (57.1%) primary and recurrence samples. 22 patients remained HR-deficient at progression, whereas 2 patients switched from HR-deficient to HR-proficient and vice versa. Overall, HRD status at primary diagnosis was a significant predictor for HRD status at first recurrence \(p<0.001\). Deleterious somatic BRCA1/2 mutations were detected in 7/29 patients (24.1%), all in patients with a primary HR-deficient tumor. One BRCA1-mutated patient switched to HR-proficiency at relapse, but no frameshift reversion event could be documented. Median somatic mutational load was 354 at primary diagnosis and 335 at first recurrence \(p=0.732\) and did not differ according to HRD status at both timepoints \(p=0.546\) and \(p=0.989\).

Conclusion

Genomic scars demonstrate a stable pattern through tumor progression, which may limit their predictive value at relapse.
VAGINAL AND VULVAR CANCER II

NEOADJUVANT ELECTROCHEMOTHERAPY IN SQUAMOUS VULVAR CANCER: PRELIMINARY RESULTS OF A PHASE II TRIAL

G. Borghese¹, A.N. Della Gatta¹, M. Ferioli², M. Procaccini², G. Dondi², A. Livi³, M. Tesei³, B. Corti³, A. Galuppi², A.G. Morganti², A.M. Perrone¹, P. De Iaco¹

¹ S. Orsola-Malpighi Hospital, Unit of Oncologic Gynaecology, Bologna, Italy
² S. Orsola-Malpighi Hospital, Radiotherapy Unit, Bologna, Italy
³ S. Orsola-Malpighi Hospital, Pathology Unit, Bologna, Italy

Aims

In previous studies electrochemotherapy (ECT) showed a local control of 80% in patients affected by relapse of squamous cell vulvar cancer (V-SCC). These results encouraged the use of ECT as neoadjuvant treatment in V-SCC. Aim of the study is to evaluate the effectiveness of ECT in reducing lesions in primary V-SCC and the possibility to decrease surgical aggressiveness and complication rate.

Method

The sample size was calculated based on the two-stage optimal design by Simon. The first step was planned to include 9 patients. In case of detection of at least one clinical PR, the study would enroll 8 additional patients. We enrolled patients with histological diagnosis of primary V-SCC and eligible for surgery. Accurate mapping of all lesions and ECT were performed. One month after ECT clinical response was evaluated according to RECIST criteria and the type of surgery was confirmed or modified. Surgery and pathological evaluation of surgical specimens were performed. Adjuvant therapies were prescribed based on pathological evaluation.

Results

We report the results of the first step of the trial. The average age of population was 67±10 years (mean±SD). Clinical response after therapy was observed in 7 patients (77.8%) with 1 CR and 6 PR. No peri-operative complications were recorded. Tumor downsizing led to more conservative surgery in 6 patients. With a median follow-up of 14±11 months (mean±SD) all patients are alive without disease.

Conclusion

Our preliminary analysis suggests that ECT is a suitable neoadjuvant treatment in patients with primary V-SCC. ECT may reduce tumor size and surgical aggressiveness.
SENTEINEL LYMPH NODE MAPPING IN EARLY STAGE VULVAR CANCER

T. Pichlík¹, H. Robová¹, L. Rob³, M.J. Halaška¹, M. Hruda¹, P. Škapa²
¹Faculty Hospital Kralovské Vinohrady, Dept. of Obstetrics and Gynaecology, Praha 10, Czech Republic
²Faculty Hospital Motol, Department of Pathology, Praha 5, Czech Republic

Aims

To evaluate the oncogynaecological outcome in women with vulvar cancer up to 4 cm in the greatest diameter undergoing extirpation of groin sentinel lymph node instead of inguinofemoral lymphadenectomy.

Method

Our prospective study included 80 women with vulvar cancer stage 1B. We excluded patients with suspicion of invasion of groin lymphatic nodes, patients with multifocal tumour and patients that had been treated for other malignancy. Sentinel lymph nodes were detected according to one-day protocol. 20 MBq of radiocoloid Tc99 and 2ml of patent blau were injected intra-dermally peritumourously at different time at the day of surgery. Lymphoscintigraphy was performed. Sentinel lymph node was extirpated and sent for perioperative histopathological examination. The groin lymphatic dissection was performed in patients with positive sentinel lymph nodes.

Results

Out of 80 patients we had to excluded 3 due to the suspicion of groin lymph nodes involvement. There were identified 149 lymph nodes in 115 groins, i.e. 1.3 sentinel lymph node per one groin. 12 women had positive lymph nodes (15.6%), all of them had positive only sentinel lymph nodes with negative other lymph nodes. 6 patients had local or groin recurrence with primary negative lymph nodes, 2 patients with primary positive lymph nodes had groin recurrence.

Conclusion

Sentinel lymph node detection in vulvar tumour smaller than 4 cm decreases morbidity without any negative impact on oncogynaecological outcome.

³First Faculty of Medicine- Charles University and General University Hospital, Department of Pathology, Prague, Czech Republic

Aims

To evaluate the sonographic characteristics of inguinal lymph nodes in patients with vulvar cancer.

Method

All consecutive patients with vulvar cancer planned for surgical staging of lymph nodes (LNs) at a Gynecologic oncology center were enrolled in the study. LNs were sonographically assessed using a predefined evaluation form that included topography, size, morphology and vessel architecture. The LNs were classified as not infiltrated, suspicious of metastatic involvement, and certainly metastatic. The definitive histopathology was used as a standard reference.

Results

Between 2009 and 2016, of the 75 patients included in the study, data from 131 groins were analyzed. The sensitivity and specificity of ultrasound for the detection of metastatic lymph nodes reached 86.0% and 93.2%. Ultrasound findings revealed typical findings of non-infiltrated lymph nodes as an oval shape (p<0.001), presence of hilum sign (p<0.001), and homogeneity (p<0.001). Infiltrated lymph nodes were described as having cortex asymmetry (p<0.001) or rounded shape (p<0.001), absence of hilum sign (p<0.001), heterogeneous structure (p<0.001), the presence of necrosis (p<0.001), and infiltration of the capsule (p<0.001). Regarding size, the results showed that the larger nodes (p<0.001) were related to infiltrated lymph nodes with the largest/shortest (L/S) ratio≤2.0 (p=0.044). In contrast to infiltrated LNs, non-infiltrated LNs were avascular or showed only hilar perfusion (p>0.001).

Conclusion

The typical features of an infiltrated inguinal lymph node are cortex asymmetry in early stage of metastasizing (intranodal metastases) or a rounded shape in late stage with complete node infiltration, loss of hilum sign, a heterogeneous structure with necrosis, and infiltration of the capsule.

8Catharina Hospital, Obstetrics and Gynaecology, Eindhoven, The Netherlands
9Leiden University Medical Center, Obstetrics and Gynaecology, Leiden, The Netherlands

Aims

Inguinofemoral lymphadenectomy for patients with vulvar squamous cell carcinoma is associated with significant morbidity. Inguinal drain management might influence the incidence of complications. The aim of this nation-wide prospective study (MAMBO: Morbidity And Measurement of the BOdy) was to assess the feasibility and the incidence of complications of volume-controlled versus short drainage of the groin.

Method

The MAMBO study consisted of two observational studies in all eight oncology centers in the Netherlands between 2012 and 2016. In the first study, the drain was removed when the production was <30 ml/24 hours except from the first 48 hours and for a maximum of 28 days (MAMBO-IA). In the second study the drain was removed five days postoperatively regardless the production (MAMBO-IB). Complications within eight weeks after surgery were assessed and the incidence of complications was compared.

Results

We included 141 patients (251 groins); 77 patients (139 groins) for volume-controlled drainage and 64 patients (112 groins) for short drainage. Volume-controlled drainage was associated with less lymphocele formation (10% versus 52% respectively, p<0.001). There was no difference in wound infection or primary wound breakdown. The incidence of one or more complications was 41% per groin after volume-controlled drainage versus 72% after short drainage, p=0.005.

Conclusion

This prospective study shows that volume-controlled drainage is associated with significantly less complications compared to short drainage. We advise volume-controlled drainage after inguinofemoral lymphadenectomy in patients with vulvar squamous cell carcinoma.
INTER-OBSERVER AGREEMENT FOR ASSESSING THE DEPTH OF INVASION IN VULVAR SQUAMOUS CELL CARCINOMA

A.W. Pouwer1, I. Otte2, M. van den Brand3, J. van der Horst4, L.J.V. Harterink2, K.K. van de Vijver4, E. Guerra5, J. Bulten2, J.A. de Hullu1

1Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
2Radboud university medical center, Pathology, Nijmegen, The Netherlands
3Rijnstate hospital, Pathology, Arnhem, The Netherlands
4The Netherlands Cancer Institute, Pathology, Amsterdam, The Netherlands
5Hospital Universitari de Bellvitge, Pathology, Barcelona, Spain

Aims

The depth of invasion (DOI) is an important prognostic factor for patients with vulvar squamous cell carcinoma (SCC). Two different methods are used to assess the DOI: the conservative (recommended by The International Federation of Gynecology and Obstetrics) and the alternative method. See Figure 1. As the DOI guides the mode of treatment, there should be an uniform measurement method which best reflects clinical outcomes.

The aim of this study is to assess the inter-observer agreement between pathologists using the conventional versus the alternative method.

Method

Fifty-one slides of vulvar SCC were selected, these slides represent daily practice. Five pathologists (including one resident) independently assessed all slides. Pathologists were requested to measure the DOI using both the conservative and the alternative method. The DOI was categorized into ≤1 mm and > 1 mm and Light’s kappa for multi-rater agreement was calculated.

Results

Preliminary results: Kappa was 0.73 using the conservative method versus 0.61 using the alternative method. Pathologists were more sure about their measurement using the alternative method. Three pathologists scored the ease of use equally for both methods, two pathologists scored the conservative method more easy.

Conclusion

Pathologists reach substantial agreement in determining the DOI using both the conservative and the alternative method. Pathologists were more sure about their measurement using the alternative method. The number of participating pathologists will be increased.

THE IMPACT OF WRITTEN INFORMATION AND COUNSELING (WOMAN-PRO II PROGRAM) ON SYMPTOM OUTCOMES IN WOMEN WITH VULVAR NEOPLASIA: A MULTICENTER RANDOMIZED CONTROLLED PHASE II STUDY

S. Raphaelis1, H. Mayer1, B. Senn2

1University of Vienna, Department of Nursing Science, Vienna, Austria
2University of Applied Sciences FHS St. Gallen, Institute for Applied Nursing Sciences, St. Gallen, Switzerland

Aims

To determine if written information and/or counseling based on the WOMAN-PRO II Program decreases symptom prevalence in women with vulvar neoplasia by a clinically relevant degree and to explore differences between the 2 interventions in symptom prevalence, symptom distress prevalence, and symptom experience.

Method

A multicenter randomized controlled parallel-group phase II trial with 2 interventions provided to patients after the initial diagnosis was performed in Austria and Switzerland. Women randomized to written information received a predefined set of leaflets concerning wound care and available healthcare services. Women allocated to counseling were provided additionally with 5 consultations by an Advanced Practice Nurse (APN) between the initial diagnosis and 6-months post-surgery focusing on symptom management, utilization of healthcare services, and health-related decision making. Symptom outcomes were measured 5 times simultaneously to the counseling time points.

Results

A total of 49 women with vulvar neoplasia participated in the study. Symptom prevalence decreased in women with counseling by a clinically relevant degree, but not in women with written information. Sporadically, significant differences between the 2 interventions could be observed in individual items, but not in the total scales or subscales of the symptom outcomes.

Conclusion

The results indicate that counseling may improve symptom prevalence in women with vulvar neoplasia by a clinically relevant extent. The observed group differences between the 2 interventions favor counseling slightly over written information. The results justify testing the benefit of counseling thoroughly in a comparative phase III trial.

ICG-NIR FOR DETECTING THE SENTINEL LYMPH NODE IN EARLY STAGE VULVA CANCER: A CASE SERIES FROM A UK CENTRE

S. Rundle1, N. Bizzarri1, S. Natsis1, N. Ratnavelu1, R. O’Donnell1, A. Kucukmetin1, A. Fisher1, C. Ang1, R. Naik1

1Northern Gynaecological Oncology Centre, Queen Elizabeth Hospital, Gateshead, United Kingdom

Aims

Standard techniques for sentinel lymph node (SLN) biopsy in vulva cancer use a combination of blue dye (BD) and radio-labelled nanocolloid (Tc-99m) as the lymphatic tracers to enable pre and intra-operative localisation of SLNs. Indocyanine green-near infrared (ICG-NIR) fluorescence for SLN biopsy has been widely reported in cancers of the endometrium and cervix. To date, limited data on the use of ICG-NIR for SLN biopsy in early stage vulva cancer is available. Here we present updated data from a UK centre using ICG-NIR for SLN biopsy in patients with vulva cancer.

Method

Patients presenting with unifocal squamous cell cancers of the vulva of less than 4cm diameter were included. Exclusion criteria included bulky lymphadenopathy on CT or clinical examination. ICG-NIR fluorescence imaging was performed in addition to the standard combined technique for SLN detection. If sentinel lymph node detection failed, side specific lymphadenectomy was performed in accordance with the patients pre-operative counselling and consent.

Results

18 patients underwent the SLN procedure using BD/TC-99m and ICG-NIR. Of the SLN successfully detected, 96% were positive for ICG fluorescence compared to 80% for BD

Conclusion

ICG-NIR is a valid and safe technique for the detection of SLN in patients with early stage vulva cancer. ICG-NIR appears superior to BD for the intra-operative visualisation of the SLN.
HUMAN PAPILLOMAVIRUS IN VULVAR INTRAEPITHELIAL NEOPLASIA

Y.H. Tang1,2, H.J. Huang1,2, L.Y. Yang1, R.C. Wu1, A. Chao1,2, C.H. Lai1,2
1Chang Gung Memorial Hospital, Obstetrics and Gynecology, Taoyuan, Taiwan R.O.C.
2Chang Gung Memorial Hospital, Gynecologic Cancer Research Center, Taoyuan, Taiwan R.O.C.
3Chang Gung Memorial Hospital, Clinical Trial Center, Taoyuan, Taiwan R.O.C.
4Chang Gung Memorial Hospital, Pathology, Taoyuan, Taiwan R.O.C.

Aims

Vulvar intraepithelial neoplasia (VIN) is a precursor lesion of vulvar cancer. Human papillomavirus (HPV) is causative for part of VIN lesions. We aimed to analyze the distribution of HPV in VIN and its relation to treatment outcomes.

Method

We retrospectively analyzed patients who diagnosed as VIN between 1990 and 2014 in our institution. HPV DNA was extracted from formalin-fixed and paraffin-embedded samples. SPF1/GP6+ polymerase chain reaction (PCR) followed by HPV Blot and E6 type-specific PCR were performed.

Results

Of the 113 VINs (31.0% with VIN1, 18.6% with VIN2, and 50.4% with VIN3), 85.0% were positive for HPV. Patients with positive HPV was diagnosed younger than those with negative results (44.1 vs. 63.4 years, \(P = 0.008\)). HPV-positivity was significantly higher in VIN3 (94.7%) compared with VIN2 (76.2%) and VIN1 (74.3%) \(P = 0.013\). The most prevalent type was HPV16 (60.4%), followed by HPV6 (14.6%), and HPV11 (11.5%). Of the 20 patients with recurrent VIN (n = 13) or progression to vulvar cancer (n = 7), 19 had positive HPV. HPV16 was related to VIN3 \(P < 0.001\) and higher recurrent/progression rate \(P = 0.004\). All seven VINs with progression to cancer were HPV positive, six with HPV16 (one was initially VIN1 at 21 years old) and one with HPV58.

Conclusion

HPV-positivity was related to younger age in VIN. HPV16 was most prevalent genotype and significantly related to recurrence/progression. We should closely follow up VIN patients with positive HPV16, and perform biopsies for suspicious lesions despite young age.

RECONSTRUCTIVE PLASTIC SURGERY IN THE TREATMENT OF VULVAR CARCINOMAS

D. Tsolakidis1, A. Papanikolaou1, I. Theodoulidis1, V. Theodoulidis1, S. Pitis1, P. Pappas1, B. Tarlatzis1

1Papageorgiou Hospital, 1st Dept Obstetrics & Gynaecology, Thessaloniki, Greece

Aims

Vulvar reconstruction can be challenging for the gynecologist and multidisciplinary approach is necessary for better wound healing, adequate function, and acceptable appearance. The purpose of this study was to present our experience in reconstructive plastic surgery by using skin/musculocutaneous flaps after extirpation of primary or recurrent vulvar cancer in our clinic.

Method

From January 2006 to December 2016, 109 women with vulvar malignancies underwent radical vulvectomy. Thirteen of them resulted in large perineal defects and vulvar reconstruction was assisted by a plastic surgeon, including lotus flap (7 patients, average age 68.4 years), V-Y flap (5 patients, average age 67.8 years), vertical rectus abdominis musculocutaneous flap (1 patient, age 72 years). The disruption rate and length of hospital stay were evaluated and compared among those techniques.

Results

Although V-Y flaps had the highest rate of disruption (2/5), their hospitalization was the lowest (20.2 days) with 196.7 average operative duration. Lotus flaps resulted in the highest length of hospital stay (24.4 days) with 168 average operative duration. The technique with the lower rate of disruption was vertical rectus abdominis musculocutaneous flap (0%) with 300 average operative duration.

Conclusion

Study outcomes suggest that vulvar reconstructive surgery exerts benefits in patients with vulvar cancer. Multidisciplinary approach with plastic surgeon, in larger vulvar tumors is associated with a favorable oncological outcome as well as acceptable cosmetic results in vulvar cancer patients.
THE IMMUNE MICROENVIRONMENT IN NON-INVASIVE VULVAR PAGET DISEASE

Aims
Non-invasive Vulvar Paget disease (VPD) is a rare skin disorder that mainly affects elderly women. Recently, cases of patients with VPD that responded to topical 5% imiquimod cream, an immune modulator, are reported. However, knowledge about the immune microenvironment of VPD is lacking. The aim of this study was to investigate the basic composition of the immune infiltrate in VPD.

Method
The immune infiltrates in 10 VPD patients were compared to those seen in either healthy controls (n=30), and the premalignancy with known response to imiquimod: vulvar high grade squamous cell intraepithelial lesions (n=43). Additional immunohistochemistry for CD4, CD8, CD14, CD20, CD56 and FoxP3 was performed.

Results
On H&E a lichenoid immune infiltrate with little interface reaction was observed in submucosal stroma of most VPD samples. Immunophenotyping showed that this stromal infiltrate mainly consisted of a variety of T-cells. B-cells, NK-cells and macrophages were also present. We noticed a great variety in the amount of cells per sample within one patient.

In the intraepithelial compartment VPD contained significantly less CD4+ and CD8+ compared to vulvar HSIL and healthy controls, and significantly less FoxP3+ cells than in HSIL cases. In contrast, the dermal compartment in VPD contained significantly more CD4+, CD8+, CD14+ and FoxP3+ cells than in healthy controls, but significantly less FoxP3+ cells in comparison to the dermal compartment of HSIL cases.

Conclusion
VPD is characterised by the presence of a dense lichenoid infiltrate, with a mixed cell population in the dermal immune infiltrate, whereas the epithelium is immunosuppressed.

GROIN TREATMENT IN VULVAR CANCER: IS SENTINEL LYMPH NODE DETECTION BASED ON LYMPHOSCINTIGRAPHY ENOUGH?

V. Veiga¹, L. Correia², J. Lopes¹, M. Bernardino², A.R. Sofia², I. Santana², A.F.J. Jorge²

¹Centro Hospitalar de Leiria, Gynecology, Leiria, Portugal
²Instituto Português de Oncologia de Lisboa, Gynecology, Lisboa, Portugal
³Centro Hospitalar Lisboa Norte, Gynecology, Lisboa, Portugal

Aims

To evaluate if the sentinel lymph node detection (SLND) based on lymphoscintigraphy is predictive of groin nodes status, depending on tumor location.

Method

SLND performed in vulvar cancers, in Portuguese Institute of Oncology of Lisbon, between 2005 and 2016.

Ninety six unifocal invasive squamous cell carcinomas of the vulva of less than 4 cm, without suspicious groin nodes, were included.

Tumor location in relation to the midline was classified as lateral [>1 cm from midline (n=46; 48%)], lateral ambiguous [medial border <1 cm from midline but not involving it (n=21; 22%)] and midline (n=29; 30%).

Preoperative lymphoscintigraphy drainage pattern was evaluated and development of node metastasis in groins without initial drainage was calculated.

Results

From lateral tumors, 84.4% (n=38) had ipsilateral, 11.1% (n=5) bilateral and 4.4% (n=2) contralateral drainage. In one case SLN was not found. One patient (2%), with initial ipsilateral drainage, developed metastasis in contralateral groin.

From lateral ambiguous tumors, 71.4% (n=15) had ipsilateral and 28.6% (n=6) bilateral drainage. From those with ipsilateral drainage, no contralateral groin metastasis were identified in follow-up.

From midline tumors, bilateral drainage occurred in 52% (n=15) and unilateral in 48% (n=14). Three cases (10%), from unilateral drainage group, developed groin metastasis at the side of no drainage.

Conclusion

In our study, lymphoscintigraphy predicted groin nodes status in 96% of the cases. In midline tumors, as recommended by literature, but not in lateral ambiguous, both groins must be evaluated, as 21% (3/14) of the cases with unilateral drainage developed contralateral groin metastasis.
VAGINAL AND VULVAR CANCER II

ESGO-0741

GROIN RECURRENCE IN VULVAR CANCERS WITH NEGATIVE SENTINEL LYMPH NODE BIOPSY

V. Veiga1, L. Correia2, M. Rocha3, A. Coelho2, A. Gomes2, A.F. Jorge2
1Centro Hospitalar de Leiria, Gynecology, Leiria, Portugal
2Instituto Português de Oncologia de Lisboa, Gynecology, Lisboa, Portugal
3Instituto Português de Oncologia de Lisboa, Lisboa, Portugal

Aims

To evaluate the rate and characteristics of groin recurrences after negative sentinel lymph node (SLN) biopsy in vulvar cancer.

Method

Ninety six unifocal invasive squamous cell carcinomas of less than 4 cm, without suspicious groin nodes, submitted to SLN detection in Portuguese Institute of Oncology of Lisbon, between 2005 and 2016, were included. In all cases a combination of preoperative Tc-99m nanocolloid and intraoperative blue dye was used.

Those cases with negative SLN biopsy were divided in two groups: Group 1 – with groin recurrence and Group 2 – without it.

Patients age, body mass index, menopausal status, number of SLN, tumor pathological characteristics, local recurrence rate and indication for postoperative vulvar radiotherapy were compared between groups using non parametric tests. Significant differences were considered when p-values <0.05.

Results

The SLN detection rate was 99%.

Of the 95 SLN detected 66.3% (n=63) were negatives. From those, 8 (12.7%) groin recurrences were identified in a median time of 7(4-47) months.

Comparing both groups, there were no statistical significant differences between them according all the characteristics analyzed.

Conclusion

In our experience, groin recurrence rate after negative SLN biopsy was 12.7% but no predictive factors were identified.
CORRELATION OF ISOTOPE COUNT WITH SENTINEL POSITIVITY IN VULVAR CANCER

L. Woelber1, S. Joosse2, D. Grimm1, S. Mathey1, S. Mahner3, E. Burandt1, S. Klutmann5, B. Schmalfeldt1, K. Prieske1

1 University Medical Center Hamburg-Eppendorf, Department of Gynecology, Hamburg, Germany
2 University Medical Center Hamburg-Eppendorf, Institute of Tumorbiology, Hamburg, Germany
3 University of Munich, Department of Gynecology, Hamburg, Germany
4 University Medical Center Hamburg-Eppendorf, Institute of Pathology, Hamburg, Germany
5 University Medical Center Hamburg-Eppendorf, Department of Nuclear Medicine, Hamburg, Germany

Aims

Sentinel node biopsy (SNB) has become standard of care in vulvar cancer. Often several active nodes are excised per groin, as the correlation of isotope count with the presence of metastases remains unclear. This can result in increased morbidity despite of SNB. The current analysis investigates, whether resection of the hottest node could be sufficient to detect sentinel lymph node (SNL) metastasis.

Method

All patients with primary vulvar cancer receiving a SNB with radioactive tracer at the University Medical Center Hamburg-Eppendorf between 2008 and 2015 were evaluated. The day before surgery, patients received four peritumoral intradermal deposits with an overall mean dosage of 85±12MBq

\[^{99m}\text{Tc}\]

Intraoperatively, a handheld gamma counter was used to identify the SNL.

Results

145 patients with 289 groins were analysed. A median of 2 (range 1-7) SNL per groin were removed. From 94/289 (32.5%) groins more than 2 SNL were excised. In 50 groins, a positive SNL was detected. The median number of positive SNL per groin was 1 (range 1-4).

The SNL with the highest isotope count carried metastases in 36/46 groins (78.3%; in 4 cases highest count unknown). In 10/46 (21.7%) positive groins, the SNL with the highest count was not the metastatic SNL. Median count of these 12 SNL was 60% of the highest count with a range from 11.0% to 74.0%.

Conclusion

The highest isotope count does not reliably detect the positive SNL in vulvar cancer. To prevent groin recurrence, all SNL accumulating relevant radioactive tracer over 10% background activity should be removed.
PALLIATIVE CARE

ESGO7-0472

IS THERE TIMELY INTERVENTION OF PALLIATIVE CARE IN GYNAECOLOGICAL CANCER PATIENTS AT THE END OF LIFE?

N. Rahim1, S. Kaushik2

1Brighton and Sussex University Hospitals NHS Trust, Brighton and Sussex Medical School, Brighton, United Kingdom
2Brighton and Sussex University Hospitals NHS Trust, Gynaecology, Brighton, United Kingdom

Aims

Palliative care is a crucial element of care plans for gynaecological cancer patients. It maximises comfort and quality of life and addresses patient wishes to ensure a dignified death. This retrospective study aims to examine aspects of end of life care of gynaecological cancer patients who died during 2015 within the Brighton and Sussex University Hospitals Trust.

Method

31 women were suitable for inclusion in the study. Variables under study included last hospital admission and last active treatment before death, MDT discussions, palliative care input, DNAR form completion and discussions regarding preferred place of death.

Results

Within the last week of life, 23% (7/31) of women had their final admission and 8% (2/31) had active treatment. 32% (10/31) were last discussed at an MDT meeting more than 4 months before death. 81% (25/31) of the women had palliative care input with 39% (9/31) having an initial assessment during the week approaching death. 74% (23/31) had a signed DNAR form and 68% (21/31) had their preferred location of death documented, however only 29% (6/31) achieved this.

Conclusion

A number of components of end of life care need addressing to improve care for gynaecological cancer patients within the trust, specifically provision of palliative care, DNAR form completion and discussions regarding location of death. Implementation of advanced care plans for all women would ensure that these areas are adequately addressed in order to allow patients the most dignified death possible.
PALLIATIVE CARE

ESGO7-0136

THE RELATIONSHIP BETWEEN SYMPTOM BURDEN, BODY IMAGE AND QUALITY OF LIFE IN ASIAN GYNAECOLOGICAL CANCER PATIENTS

K. Tewani1, Y. Lim2, I. Teo3

1K K Women’s and Children’s Hospital - Singapore, Palliative Consultant in Department of Gynecological Oncology, Singapore, Singapore
2K K Women’s and Children’s Hospital - Singapore, Department of Gynecological Oncology, Singapore, Singapore
3Lien Centre, Clinical Psychologist, Singapore, Singapore

Aims

This study examines symptom burden and body image disturbance in patients with gynaecological cancers, and the extent they are related to quality of life.

Method

A cross-sectional study in which patients diagnosed with gynaecological malignancies were recruited from a tertiary hospital in Singapore (n = 104). They were assessed using self-report assessments of symptom burden, quality of life (using the Functional Assessment of Cancer Therapy-General form), and body image dissatisfaction (using the Body Image Scale). Clinical factors were abstracted from patient medical records.

Results

Approximately 1 out of 4 patients reported feeling less physically attractive and dissatisfied with their body. Symptom burden alone predicted physical well-being, \( p < .001 \) and functional well-being, \( p < .001 \). Body image dissatisfaction significantly predicted emotional well-being \( p = .01 \) and symptom burden no longer predicted emotional well-being once body image dissatisfaction was entered into the model.

Patients with cervical cancer reported significantly higher body image dissatisfaction, \( p = .01 \), and younger age was found to be a significant risk factor for clinically-relevant score of body image distress, \( p = .02 \).

Conclusion

Symptom burden and body image dissatisfaction were associated to patient's quality of life. Body image dissatisfaction explained the relationship between symptom burden and emotional well-being, and may be a potential target for intervention. Particular attention should be paid to patients who are younger and diagnosed with cervical cancer as they are more susceptible to body image disturbance.
SYNTHESIS OF A THERANOSTIC AGENT: RADIOIODINATED PEGYLATED PLGA-INDOCYANINE CAPSULES AND IN VITRO DETERMINATION OF THEIR BIOAFFINITY ON OVARIAN, CERVICAL AND BREAST CANCER CELLS

L. Akman¹, F.Z. Biber Muftuler², A. Bilgi¹, A. Yurt Kilcar¹, S.G. Gokulu¹, E.I. Medine², M.C. Terek¹
¹EGE UNIVERSITY FACULTY OF MEDICINE, OBSTETRICS AND GYNECOLOGY, IZMIR, Turkey
²Institute of Nuclear Sciences- Ege University, Department of Nuclear Applications, IZMIR, Turkey

Aims

The aim of current study is to synthesize atheranostic (multi-functional) agent, which is targeted on ovary, cervical and breast cancer types with diagnosis and treatment potential and to determine its bioaffinity by using in vitro methods.

Method

Indocyanine (ICG) was preferred as the first modality of our agent due to its fluorescence properties. Then, ICG was encapsulated with PEGylated PLGA (IPP). Additionally, Paclitaxel (PAC) was conjugated with IPP (IPPP) to target the agent to reproductive organs like ovary, cervix and breast. Lastly, IPPP was radiolabeled with 131I as the second modality of developed theranostic agent. In vitro incorporation and cytotoxicity assays, and fluorescent imaging assays were performed.

Results

Incorporation values of 131I-ICG and 131I-IPP were similar on all cell lines during study period. 131I-IPPP has higher incorporation values than 131I-PAC on MCF-7, MDAH-2774 and HeLa cells at all-time points. The highest uptake values are observed for 131I-PAC and 131I-IPPP at 240 min on MDAH-2774 cells as 18.88 ± 2.24 and 22.05 ± 2.85, respectively. The incorporation values of 131I-IPPP at 30 min on MCF-7 and MDAH-2774 cells were higher 1.70 and 1.62 times than 131I-PAC. The cellular uptake study confirmed the high binding efficiency of 131IIPPP with MDAH-227 cells. Fluorescence microscopy demonstrated that both ICG and IPPP successfully bound target cancer cells.

Conclusion

The designed compound(IPPP), which has fluorescence capability (from Indocyanine), encapsulated structure (with PEGylated PLGA), included an anticancer drug (Paclitaxel) for targeting and radionuclidic tracer (131I) content for tracing, has bioaffinity and promise for diagnosis and therapy on ovarian, cervical and breast cancer cell lines.
A NEW DIAGNOSTIC ALGORITHM FOR THE MANAGEMENT OF UTERINE MASSES: THE UMG (UTERINE MASS MAGNA GRAECIA) RISK SCORE

A. Di Cello¹, M. Borelli², M.L. Marra³, F. Marco⁴, R. Venturella⁵, F. Zullo⁵

¹University Magna Graecia, Unit of Obstetrics and Gynecology - Department of Experimental and Clinical Medicine - University “Magna Graecia” of Catanzaro - Italy, Catanzaro, Italy
²University Magna Graecia ok Catanzaro, PhD School of PhD Programmes Life Sciences and technologies - Catanzaro, Italy
³University Magna Graecia oggi Catanzaro, Unit of Obstetrics and Gynecology - Department of Experimental and Clinical Medicine - Catanzaro, Italy
⁴University of Trieste, Department of Life Sciences, Trieste, Italy
⁵University “Magna Graecia” of Catanzaro - Italy, Unit of Obstetrics and Gynecology - Department of Experimental and Clinical Medicine, Catanzaro, Italy

Aims

To identify a reliable non-invasive predictive tool to classify uterine masses according to the risk of malignancy.

Method

The charts of 3107 patients who underwent surgical treatment for uterine masses at our institution between 2004 and 2016 were retrospectively reviewed. Clinical, biochemical, imaging, surgical and pathological data of 2750 women with uterine fibroids and 43 patients with uterine sarcomas were analysed. The statistical relationships between relevant characteristics and the final pathology were analysed.

Results

In univariate analyses, a small set of possible predictors (age; CA125, LDH-1% and LDH-3% isoenzyme serum levels; central and peripheral vascularization of the uterine mass) was identified (p<0.005). Regression tree analysis and model selection revealed that the best predictive score [herein called the “uterine mass Magna Graecia (UMG) score”] was associated with LDH-1% and LDH-3% isoenzyme serum levels. Moreover, considering the presence or absence of central vascularization in women with a “UMG score”>29, it was possible to classify patients into three different risk categories, coded for mnemonic reasons as green (≤29), yellow (>29 without the presence of central vascularization) and red (>29 with the presence of central vascularization). With an area under the ROC curve of 99.9%, 99.6% specificity, 100% sensitivity and a negative predictive value of 100%, the UMG score represents an accurate tool for excluding oncologic risk in uterine masses.

Conclusion

We have identified an easy and inexpensive score we used to reliably classify more than 2750 patients with uterine masses with a negative predictive value in excluding the risk of sarcoma of 100%.
**Aims**

It has been demonstrated that human papillomavirus (HPV) is one of the causes of vulvar invasive squamous cell carcinoma (VSCC), being identified in about 30-50% of those cases. However, evidence is lacking on the influence of HPV-status on the prognosis of this malignancy. This study aims to determine the influence of HPV-status on the prognosis of patients diagnosed with vulvar SCC.

**Method**

We analyzed, retrospectively, the clinical files of every patient diagnosed with primary vulvar SCC submitted to surgery at our institution, from 2008 to 2014, that had a HPV genotype analysis in the surgical sample. We evaluated and compared both groups (HPV-positive vs HPV-negative) in a three year follow-up for the following data: demographic and clinical data, first-line therapy and its clinical response, recurrence rate, disease-free interval, overall and cancer related mortality rates.

Student t test and chi-square were used for statistical analysis of the continuous and categorical variables, respectively.

**Results**

62 patients were included, 21 (34%) were HPV-positive and 41(66%) HPV-negative. There were no statistically significant differences between the two groups in demographic and clinical variables. Response to first-line therapy (95% vs 96%), recurrence rate (32% vs 38%), disease-free interval (25 vs 22 months), overall (43% vs 41%) and cancer related mortality (28% vs 29%) were also similar in both HPV-positive and HPV-negative patients, respectively.

**Conclusion**

The prevalence of HPV in VSCC patients was similar to that described in published literature. In our study, at a three year follow-up, the HPV status did not influence the prognosis of disease in patients who underwent surgery.
OSTEOMIMICISM INDUCED BY CDCA IS INTERFERED BY LITHOCHOLIC ACID IN BREAST CANCER

L. Absil\textsuperscript{1}, F. Journé\textsuperscript{2}, D. Nonclercq\textsuperscript{1}
\textsuperscript{1}UMONS, Department of Histology, Mons, Belgium
\textsuperscript{2}UMONS, Department of Human Anatomy and Experimental Oncology, Mons, Belgium

Aims

We have investigated the involvement of farnesoid X receptor (FXR) in breast cancer cells to determine [1] a possible relationship between its expression and proliferation of cells; and [2] the role of FXR in osteomimetism of breast cancer.

Method

We evaluated [1] by immunofluorescence the FXR, the RUNX2 and some bone proteins (OPN, OC, BSP, OPG) expression; and [2] the cells proliferation by crystal violet staining in MCF-7 and MDA-MB-231 cell lines, after different treatments (chenodeoxycholic acid (CDCA), lithocholic acid, z-guggulsterone, ibandronate).

Results

We observed an activation of cell proliferation in MCF-7 but not in MDA-MB-231 after a CDCA treatment. This stimulating effect is interfered by lithocholic acid in MCF-7. Z-guggulsterone decreased cell proliferation in both cell lines. FXR expression increased after a CDCA treatment and decreased with ibandronate in both cell lines. CDCA induced an increase of RUNX2 and bone proteins expression and this expression is interfered by lithocholic acid (in both cell lines) and by z-guggulsterone in MDA-MB-231 cells.

Conclusion

Z-guggulsterone decreased bone proteins expression in MDA-MB-231 cells but not in MCF-7, caused by the ER implication in these cells. Lithocholic acid is a competitive inhibitor of FXR and indirectly of cells proliferation and bone proteins expression when it is used in combination with CDCA. Altogether, experimental data highly support a relationship between FXR, ER (in MCF-7) and RUNX2 expression, and the propensity of the tumor cells to develop osteomimetism, involving an increase of RUNX2 expression after CDCA treatment and a subsequent promotion of bone-related protein synthesis.
Aims

This study aims to determine the proportion of pregnancy and breastfeeding subsequent to breast cancer (BC) diagnosis in women of reproductive age and their impact on cancer relapse.

Method

This study is an observational retrospective cohort study of 105 female Omani patients within the reproductive age (15-49 yrs) diagnosed with BC and maintained follow up between 2007 to 2015 at Sultan Qaboos University Hospital (SQUH), a tertiary teaching Hospital in Oman. Only living patients were selected in order to minimize any missing data. The data was collected from the BC database at SQUH and from the electronic medical records of the patients. SPSS was used to obtain frequencies and percentages of pregnancy and breastfeeding. RR of cancer relapse associated with pregnancy and breastfeeding were calculated by binary logistic regression analysis.

Results

The proportion of pregnancies subsequent to BC was 13%. Among pregnant patients, 77% of them breastfed. There was a statistical non-significant reduction in the risk of relapse when pregnancy was within two years of BC diagnosis 0.42(95% CI: 0.05- 2.97) and beyond two years 0.21(95% CI: 0.01- 3.78). The RR associated with breastfeeding was 0.67(95% CI: 0.14- 3.02)

Conclusion

In Oman the percentage of pregnancy after BC was slightly higher than the reported literature and more women breastfed in Oman compared to the Western countries. The risk of BC recurrence was low with pregnancy and breastfeeding.
PREMATURE MENOPAUSE SYMPTOMS AND PREVALENCE IN REPRODUCTIVE AGED WOMEN DIAGNOSED WITH BREAST CANCER

M. Al Khaduri, A. Al-Ma’adi, Y. Al Farsi
1Sultan Qaboos University, Obstetrics and Gynecology, Muscat, Oman
2Sultan Qaboos University, Obstetrics and Gynecology, Muscat, Oman
3Sultan Qaboos University, Family Medicine and Public Health, Muscat, Oman

Aims

The aim of this study is to detect the prevalence of premature menopause in Omani women with breast cancer (BC).

Method

A retrospective cohort study was conducted. It included Omani women who were diagnosed with breast cancer from 2007 to 2015. Only those diagnosed with BC in their reproductive age (19-49), still alive and followed up at Sultan Qaboos University Hospital (SQUH) were included. The sample size was calculated and 105 patients fulfilled the inclusion criteria. Clinical characteristics included age of diagnosis, chemotherapy and hormonal therapy, FSH level, changes in period after the treatment and the GnRH agonists use. Menopause was diagnosed if there was amenorrhea for 12 months and FSH more than 40 after cessation of chemotherapy treatment. SPSS was used for analysis.

Results

Breast cancer women were seen to experience changes in their menstrual period. 29.5% of them suffered from menopausal symptoms and 25.7% became menopausal. Two risk factors were assessed in this study that were accelerating the occurrence of premature menopause (age >40 years and cyclophosphamide). They contribute to 59.3% and 25.8% respectively in causing premature menopause. For the purpose of protecting fertility, the GnRH agonist was prescribed for some patients and we found no significant association between the two as the p value was 0.388.

Conclusion

The chance for each premenopausal BC woman to be menopausal after chemotherapy is about 25.7% and this increased in older BC women (>40) compared to younger women. In order to avoid all these outcomes, fertility preservation options prior to BC treatment should be considered.

BRAIN METASTASIS: IS THE END COMING?

S. ALVES¹, J. LOBO², F. PEREIRA¹, C. LEAL², R. COUTO¹, S. SOUSA¹, D. PEREIRA¹
¹IPO PORTO, MEDICAL ONCOLOGY, OPORTO, Portugal
²IPO PORTO, PATHOLOGICAL ANATOMY, OPORTO, Portugal

Aims

Breast cancer brain metastasis are not uncommon, and 15-30% of patients with metastatic disease will develop brain metastasis. The subtype where it it occurs most frequently, is basal-like, followed by HER2-positive tumors. Developing brain metastasis is associated with a significant worsening of the prognosis and with neurological dysfunction. Only a few patients live beyond 12 months.

32 years-old woman submitted to a right radical mastectomy (with sentinel lymph node biopsy) on November 2005. Histological examination: invasive ductal carcinoma (4,1 cm), grade 3, with an extensive ductal carcinoma in situ. 1 sentinel lymph node metastasized. No expression of oestrogen and progesterone hormone receptors. It was staged as pT2N1M0. She received chemotherapy, with FAC regimen (5-Flourouracil/Doxorubicin/Cyclophosphamide, until April 2006) and adjuvant radiotherapy. On May 2006 started dizziness and imbalance. A magnetic resonance imaging (MRI) study was performed: 5 mm nodular lesion in the right parieto-occipital region (metastasis versus granuloma). It was decided to repeat the exam in 3 months. She performed a new MRI on August 2006: the nodular lesion presented 2 cm of larger dimension, being compatible with a metastasis. She underwent surgery with total excision of the tumor lesion on September 2006. She performed palliative brain radiotherapy and received chemotherapy with CMF regimen (Cyclophosphamide/Methotrexate/5-Flourouracil). Since then she has remained on surveillance with a good performance status.

The authors intend to emphasize the long survival of this patient; nowadays, it would be crucial to test HER2 status for the availability of targeted therapies.

CORRELATION AND OUTCOME PREDICTION OF BIOMARKERS IN EARLY, ESTROGEN RECEPTOR-POSITIVE AND HER2-NEGATIVE BREAST CANCER: COMPARISON OF ENDPREDICT, UPA/PAI-1 AND KI67

S.I. Anders¹, J. Ettl¹, E. Klein¹, A. Noske², M. Kiechle¹

¹Klinikum rechts der Isar Technische Universität München, Department of Gynecology and Obstetrics, Munich, Germany
²Klinikum rechts der Isar, Department for Pathology, Munich, Germany

Aims

Due to the molecular tumor heterogeneity of breast cancer, novel multigene assays have been developed helping to stratify patients according to their individual risk of distant recurrence. Especially for patients at intermediate risk a new dimension of risk estimation and therefore change in decision making has been achieved.

Method

321 patients with estrogen-receptor (ER)-positive and Her2-negative breast cancer at intermediate risk were included in this monocentric prospective study from 2011-2015. Classical clinic-pathological markers, ki-67, uPA/PAI-1 and EndoPredict (EP) were assessed for all patients. Concordance of these predictive markers and patient follow up, including the compliance to advised CTX, RTX and hormone therapy, was analysed.

Results

Overall survival, distant and local recurrence of all patients, as well as therapy compliance was assessed (min 21 months and max 5 year follow up).

Conclusion

Concordance of ki-67, PgR status and other pathology-based surrogates, uPA/PAI-1 and Epclin classification could be assessed. In this prospective comparison of EndoPredict, uPA/PAI-1, ki-67 and progesterone receptor we found, that EP is superior to all other biomarkers with respect to feasibility and decision impact. This leads to substantial avoidance of adjuvant chemotherapy in this patient collective.
Aims

To illustrate the importance of preoperative MRI in the surgical treatment decision in patients with invasive breast cancer.

Method

We reviewed retrospectively the preoperative MRI (3 Tesla) of 169 patients operated at Hôtel-Dieu de France for invasive breast cancer. The sequences of 85 patients who underwent a radical treatment (mastectomy) were compared to those of 84 patients who benefited from conservative surgery. We estimated the tumor volume (TV) and breast volume (BV) on enhanced MRI and then we compared the tumor volume to breast volume ratio (TV/BV) in both groups.

Results

When compared to pathologic reports, the MRI seemed to slightly increase the estimation of tumor size. The mean of tumor to breast volume ratio was 9.5% in the mastectomy group vs. 1.7% in the conservative treatment group (p = 0.000). Using a threshold of 4, a tumor to breast volume ratio less than 4% seemed to favor the adoption of the conservative option in the surgical treatment decision in patients with invasive breast cancer (p = 0.000). MRI had also helped the assessment of multifocality and multicentricity of tumor which were noted respectively in 57.4% and 54.4% of cases treated with mastectomy vs. 15.5% and 3.6% of cases treated conservatively (p = 0.000).

Conclusion

Our data suggest that preoperative MRI can aid the surgical treatment decision in patients with invasive breast cancer by assessing the tumor to breast volume ratio as well as by providing a full mapping of multifocal and multicentric lesions in the breast tissue.

MRI-BASED PREDICTIVE FACTORS OF AXILLARY LYMPH NODE METASTASES IN BREAST CANCER

D. Atallah¹, M. Moubarak¹, W. Arab², N. EL Kassis¹, G. Chahine³, M. Ghossain⁴, C. Salem⁴

¹, Beirut, Lebanon
², Saint Joseph University, Beirut, Lebanon
³, Oncology, Beirut, Lebanon
⁴, Radiology, Beirut, Lebanon

Aims

To determine the accuracy of MRI in detecting axillary lymph nodes (ALNs) metastases preoperatively and to define predictive characteristics of ALN involvement in patients with invasive breast cancer.

Method

Breast MR (3 Tesla) examinations of 169 patients with invasive breast cancer were reviewed at Hôtel-Dieu de France Hospital. Morphological parameters in addition to apparent diffusion coefficient (ADC) value were compared with pathological nodal status.

Results

The sensitivity and specificity of MRI in detecting ALN involvement were 87.5% and 55.6% respectively. The negative and positive predictive value of MRI was 81.64% and 66.34% respectively. The mean size of metastatic ALN was larger than that of negative ALN (13.9 mm vs. 10.9 mm, p = 0.000). ALNs larger than 12 mm were associated with higher risk of metastases (p = 0.000). The asymmetry of size between ipsilateral and contralateral ALNs was more significant in positive ALNs on pathology (p= 0.008 vs. 0.043). In a univariate analysis, the round shape of ALN, loss of fatty hilum, irregular contours and hypo-intensity/heterogeneous intensity on T2-weighted sequence were significantly predictive of lymph node metastasis (p = 0.000 for the four characteristics). In a multivariate analysis, only the round shape of lymph node and the hypo-intensity/heterogeneous intensity on T2-weighted sequence were significantly associated with lymph node metastasis (p=0.01 and p=0.018 respectively). The ADC value of ALN did not aid the differentiation between benign and metastatic lymph nodes (p= 0.862).

Conclusion

Conventional MRI using the ALN shape and the signal intensity in T2-weighted sequences can evaluate the axilla with high sensitivity.
CASE REPORT: METACHRONOUS OVARIAN CARCINOMA AFTER A BREAST CANCER HER2+++  

Z.B. benlahrech¹

CLINICAL CHARACTERISTICS OF THE PATIENTS WHO EXPERIENCED EARLY RECURRENCE AFTER CURATIVE SURGERY FOR BREAST CANCER

J. Cha1, S. Kim1
1Yonsei University Wonju College of Medicine, Radiation Oncology, Wonju, Republic of Korea

Aims

To identify the patients with high risk of early recurrence who need to be evaluated during chemotherapy or radiotherapy after curative surgery.

Method

Seven hundred and seventy-four patients who underwent curative surgery and radiotherapy between January 2010 and December 2016 were reviewed retrospectively. Among them, recurrence was detected in two patients (0.3%) during the interval between the surgery and the completion of RT. Their tumor characteristics, treatment details, and follow up information were reviewed.

Suspicious mass was detected on simulation computer tomography (sCT) of patient 1. Total mastectomy was performed and it revealed 7.5cm-sized recurrence. She completed radiotherapy of total dose 54 Gy followed by 6 cycles of Cyclophosphamide/Methotrexate/Fluorouracil. Operation bed seroma was showed on sCT of patient 2 and she complained its growing. Wide excision revealed 3.1cm-sized metaplastic carcinoma. A month later multiple metastases developed in liver and bones.

Conclusion

In patients with risk factors such as negative hormone receptor and nodal metastasis, paying attention to sCT findings might be helpful to detect early recurrence. Considering rarity of the early recurrence, further study engaging large number of patients is required.

2Arbor Vitae Center- Clinica Nuova Villa Claudia, Endoscopic Gynecology, Rome, Italy
3National Cancer Institute “Regina Elena”, Department of Experimental Clinical Oncology, Rome, Italy
4University of Rome Tor Vergata, Department of Biomedicine and Prevention, Rome, Italy
5Catholic University of the Sacred Heart, Department of Women’s and Children’s Health, Rome, Italy

Aims

Current literature showed that breast cancer patients using tamoxifen have an increased risk of endometrial pathology. To investigate the different incidence of histological alteration of endometrium and their possible correlation with the following adjuvant treatment: tamoxifen (TAM), non-steroidal aromatase inhibitors (AIs) or no treatment (NT).

Method

We reviewed retrospectively 970 breast cancer women who were referred to the Hysteroscopic Service of three Italian Centers (University of Messina, Gynecological Center “Nuova Villa Claudia” of Rome, “Regina Elena” National Cancer Institute of Rome) for vaginal bleeding or ultrasound indications.

Results

Hysteroscopic and histological findings in the TAM, AIs and NT groups, respectively, included: atrophic/physiological endometrium in 48, 52 and 33.3% of cases; endometrial polyp in 40.4, 38 and 49.1% of cases; submucous myoma in 4, 3 and 5.2% of cases; simple hyperplasia in 5, 3 and 7.1% of cases; complex hyperplasia in 0.3% in TAM patients and 0.4% in NT cases, no case in AIs group; dysplasia in 0.3% of TAM patients and 0.4% of NT patients, no case in AIs group; and endometrial cancer in 2, 4 and 4.1% of cases; one case (0.4%) of endometrial metastasis from the breast cancer was registered in the NT group (Table 1).

Conclusion

Our preliminary data analysis suggests that TAM is not likely to be associated with endometrial pathology in breast cancer patients. In conclusion, we suggest a gynecological follow-up for all breast cancer patients, regardless of the adjuvant treatment; in addition, we solicit future studies to confirm the TAM safety profile in breast cancer patients.

USE OF COMPLEMENTARY THERAPIES IN BREAST AND GYNAECOLOGICAL CANCER PATIENTS DURING SYSTEMIC THERAPY

L. Drozdoff\(^1\), E. Klein\(^1\), L. Gantner\(^1\), M. Kiechle\(^1\), D. Paepke\(^1\)

\(^1\)TU München, Frauenklinik Klinikum Rechts der Isar, München, Germany

Aims

Recent studies state that approximately 10 to 70\% of breast and gynaecological cancer patients use complementary medicine (CAM) during systemic therapy. The aim of this study was to verify the number of CAM users at our certified cancer center.

Method

Between February and April 2017 a self-administered questionnaire was given to all breast and gynaecological cancer patients undergoing systemic cancer therapy at the certified cancer center of the Klinikum Rechts der Isar. Completed questionnaires (85\%, \( n = 202/238 \)) were analyzed by age, cancer diagnosis, therapy status and CAM treatments.

Results

81\% of the responding patients use complementary therapy methods. These include:

- 68\% vitamins and minerals
- 38\% phytotherapeutics
- 31\% mistletoe treatment
- 37\% homoeopathics
- 61\% medicinal teas
- 2\% others

CAM use is correlated with younger age (61 y vs. 66 y) and primary non metastatic cancer diagnosis (94\%). No difference in breast cancer patients or patients with gynaecologic malignancy, as well as systemic therapy status could be analyzed.

Conclusion

Our data demonstrates high use of CAM by cancer patients undergoing systemic therapy. It is indispensable to implement counselling and evidence-based complementary treatments into clinical routine of cancer centers. A counselling service for integrative medicine concepts and outpatient program (ZIGG) was therefore implemented in our cancer center in 2005.
HIGHLY INCREASED CONCENTRATION OF ANTIBODIES AGAINST THE RED MEAT DERIVED SILIC ACID, NEU5GC, IN WOMEN WITH BREAST CANCER UNDER CHEMOTHERAPY

\textsuperscript{6}Theagenion anti-cancer Institute of Thessaloniki- Greece, Department of Gynecology-Oncology, Thessaloniki, Greece

Aims

N-glycoly neuraminic acid (Neu5Gc) is a sialic acid synthesized by animals, but not humans and birds. However, it can be incorporated in human cells and trigger immune response. Neu5Gc has been found on the surface of many cancer cells including breast cancer. Development of anti-Neu5Gc antibodies in cancer patients is thought to induce cancer progress by triggering inflammatory reaction. In the present study, anti-Neu5Gc antibodies were measured in 40 samples of healthy women and in 40 patients with breast cancer.

Method

Anti-Neu5Gc antibodies were measured using ELISA method. Different concentrations of human IgG (Sigma) were used to produce a standard curve for the expression of relative antibody concentrations in μg/ml.

Results

The patients with breast cancer exhibited a mean concentration of 89.6 μg/ml (median=57.4 μg/ml, max.=378 μg/ml), much higher than that healthy individuals (mean 6.6 μg/ml, SD 6.7 μg/ml, median=4.0 μg/ml)(p<0.000). The average and maximum concentration of anti-Neu5Gc antibodies detected in women with breast cancer were much higher than that detected by our team in patients with lung cancer (average 20.6 μg/ml–23.6 μg/ml, depending on the type) and ovarian cancer (average 30.2 μg/ml). Higher concentrations did not correlate with metastasis occurrence.

Conclusion

Highly increased concentrations of anti-Neu5Gc antibodies were found in patients with breast cancer. Future results may elucidate if it could be used as an indicator for the prognosis of the disease.

LIPOSARCOMA OF THE BREAST
I. Sassi¹, S. Gadria¹, M. Slimane¹, I. Ben Safta¹, A. Chabchoub¹, O. Addouni², A. Gammoudi², J. Ben Hassouna¹, K. Rahal¹
¹Salah Azaiz Institute, Surgical Oncology department, Tunis, Tunisia
²Salah Azaiz Institute, Pathology Department, Tunis, Tunisia

Aims

Liposarcoma of the breast (LSB) is a rare disease that was first described by Neumann in 1862. It represents 0.3% of all mammary sarcomas, and 0.1% of all malignant breast tumors. LSB is characterized by slow growth and presents itself as an asymptomatic mass.

Method

We report the case of a liposarcoma of the breast treated at the Salah Azaiz Institute of Tunisia.

Results

An 80 years old man with a positive family history of breast cancer, presented for a left sided breast lump evolving since 6 months. Clinical exams found a painless, soft to the touch, and movable 40 mm retro areolar lump, associated to an ipsilateral axillary lymph node. Mammogram described a 50 mm well-circumscribed radiolucent mass. After excision biopsy, histopathologic finding showed lipoblasts and cells of pleomorphic look with a multinucleate nucleus and a richly vascularized myxoid stroma. The immunohistochemical staining showed that the tumor cells express the antibodies anti-MDM2 and anti-PS100. Concluding to a 60 mm pleomorphic grade I LSB according to FNCLCC. Chest-abdomen-pelvis CT scan didn’t show distant metastasis. Treatment consisted on a left mastectomy with axillary node biopsy associated to a 50 Gy chest wall radiation therapy. Regular follow up didn’t show any loco-regional or distant metastasis.

Conclusion

LSB is a malignant tumor consisting chiefly of immature, anaplastic lipoblasts of different sizes. Surgery is the treatment of choice, varying from a simple excision to a total mastectomy. Depending on the size, the differentiation degree, and the metastasis, radio and/or chemo therapy can be associated.
THE ROLE OF TOPOISOMERASE II-A (TOPO IIA) AS A PREDICTIVE FACTOR FOR RESPONSE TO NEOADJUVANT ANTHRACYCLINES BASED CHEMOTHERAPY IN LOCALLY ADVANCED BREAST CANCER

M. Gamea

†Aswan University Hospital, Clinical Oncology, Tanta, Egypt

Aims

Topoisomerase II-α is a molecular target of anthracyclines; several studies have suggested that topoisomerase II-α expression is related to response to anthracycline treatment. The objective of this study was to evaluate if topoisomerase II-α overexpression predicts response to anthracycline treatment in locally advanced breast cancer patients.

Method

This prospective study included 50 patients with primary non metastatic locally advanced breast cancer according to American Joint Committee For Cancer Staging (T3-4;N0-3) were treated between January 2012 and January 2012 at Clinical Oncology Department, Tanta University Hospital.

Topoisomerase II-α, HER2, estrogen receptor (ER), progesterone receptor (PR) expression and KI-67 were evaluated by immunohistochemistry in formalin-fixed, paraffin-embedded breast tumors from 50 patients presenting with locally advanced breast cancer.

Results

Tumors from 50 patients, 45 (90%) showed topoisomerase II-α overexpression, patients 34 (68%) for ER positive, 32 (64%) for PR positive and 10 (20%) for HER2 overexpression and 16 (32%) for high KI-67.

Significant correlation between clinical and pathological response with topo IIA, HER2 and KI-67. p value ≤0.001, 0.005 and 0.015 respectively.

1-Responders :

v Clinical (CR): 3 patients had co-expression of topo II and HER2, hormonal receptor negative and high KI-67.

v Clinical (PR): 43 patients majority of them had topo II A overexpression .fig(9-10)

2-Non responders :

4(8%) patients all had negative (TOPOII/HER2), low KI-67 and 2 had hormonal receptor positive and another 2 had hormonal receptor negative.

Conclusion

Our data support a correlation between topoisomerase II-α expression in locally advanced breast cancer patients and improved clinical benefit with neoadjuvant anthracyclines based therapy.
ERIBULIN MESYLATE IN ADVANCED BREAST CANCER: RETROSPECTIVE REVIEW OF A SINGLE INSTITUTE EXPERIENCE.

A. Garcia-Arias¹, R. DiCicilia¹, L. Baldi¹, A. Damato¹, E. Gervasi¹, G. Stridi¹, A. Berselli¹, C. Pinto¹

¹Azienda Ospedaliera Arcispedale Santa Maria Nuova – IRCCS, Oncology Unit, Reggio Emilia, Italy

Aims

Eribulin is a non-taxane microtubule inhibitor, which can be used after anthracycline and taxane in patients with metastatic breast cancer (MBC). The purpose of this study was to investigate the efficacy and safety of eribulin in heavily pretreated MBC.

Method

This was a single institution retrospective analysis of MBC patients treated with eribulin from August 2012 to May 2016.

Results

We included forty-four consecutive MBC patients who received at least one cycle of eribulin. Median patient age was 58 years (range 43-76). All patients were pretreated with anthracyclines, taxanes and 72% with capecitabine. Brain metastases were present in 9 (20%) patients at the time of initial eribulin administration. Most patients were heavily pretreated with a median of 3 (range 2-7) previous chemotherapy lines prior to eribulin and had significant visceral involvement (median 3 organs). A median of 5 cycles of eribulin was delivered. There were no complete responses; partial responses were 20% (9/44) and disease control rate was 54.5% (25/44), progressive disease was seen in 44.5% (19/44) patients. Median progression free survival was 4.5 months (95% CI 2.8-6.2) and median overall survival was 12 months (95% CI 7.8-16.4). 15% of the patients required a dose reduction due to toxicity. Only one patient experienced grade 3 neurotoxicity. Three patients (6.8%) stopped eribulin due to fatigue grade 3. No hypersensitivity reactions and no toxic deaths were observed.

Conclusion

Eribulin monotherapy is an effective and safe regimen for MBC patients. In our experience, eribulin maintains its activity out of clinical trials, without unexpected toxicities.

MUCINOUS CYSTADENOCARCINOMA OF THE BREAST. A RARE ENTITY AND A PATHOLOGICAL CHALLENGE

C. Goudeli¹, N. Koufopoulos², E. Terzakis³, K. Kapatou², D. Dimas³, A. Tzortzopoulou³

¹Hellenic Anticancer Hospital “St.Savvas”, Gynecologic, ATHENS, Greece
²Hellenic Anticancer Hospital “St.Savvas”, Pathology, ATHENS, Greece
³Hellenic Anticancer Hospital “St.Savvas”, Surgical, ATHENS, Greece

Aims

We report a case of mucinous cystadenocarcinoma (MCA), an extremely rare variant of primary breast tumor that is histologically similar to mucinous cystadenocarcinoma of the ovary and pancreas.

Method

A 63 year old woman was admitted in our hospital due to palpable mass to her left axilla. After clinical examination a FNA was performed on her axillary mass and the diagnosis was “positive for malignancy”. Ultrasound examination revealed a 16 mm mass in the left upper quadrant. The patient had a lumpectomy, a wider excision and axillary lymph node dissection.

Results

Histologically the tumor consisted of multiple cystic spaces filled with mucin with several papillary proliferations with epithelial tufting. The cysts were lined by columnar cells with moderate to severe atypia with some areas having a squamoid appearance. Mitotic count was high and necrosis was found. The palpable mass in the left axilla was a lymph node block with a maximum diameter of 47 mm. additional metastases was found in two of thirteen lymph nodes. Tumor cells were positive for CK-7 and negative for CK-20. The neoplasm was ER, PR and C-erb-2 negative and positive for both CK5/6 and EGFR. The patient received adjuvant chemotherapy and radiotherapy. After a 48-month period she has shown no evidence of recurrence or metastasis.

Conclusion

MCA has unique morphology among breast carcinomas as well as a very good prognosis unrelated to the size of the tumor, lymph node metastasis or the molecular subtype.

INTRACYSTIC TRIPLE NEGATIVE BREAST CANCER: UNUSUAL ENTITY

S. Haddad¹, I. Zemni¹, M. Rezgani¹, M. Bouhani¹, H. Henchiri¹, O. Adouni², M. hechiche¹, J. Ben Hassouna¹, K. Ben Rahal¹
¹Salah Azaiez Institute, Surgery, Tunis, Tunisia
²Salah Azaiez Institute, Anatomy and Pathology, Tunis, Tunisia

Aims

Intracystic (encapsulated) papillary carcinoma of breast is a rare variant of breast cancer. It is usually a low-grade tumor showing estrogen, progesterone positivity.

Triple-negative breast cancer is a subtype of breast cancer which has a more aggressive clinical course than other forms of breast cancer, and is associated with aggressive histology and poor clinical outcomes. Rare cases of intracystic triple negative breast carcinoma have been reported in literature. Such cases need to be reported in order to avoid any overtreatment despite being high grade and triple negative.

Method

Among the triple negative breast cancer group of salah azaiez institution, we found two cases of intracystic papillary breast cancer.

Results

Our patients were postmenopausal aged 52 and 63 years old. The mammography showed well-circumscribed mass. Excisional biopsy revealed papillary intracystic papillary carcinoma. The patient underwent surgical treatment with mastectomy and axillary node dissection. The histological findings confirmed the diagnosis of intracystic triple negative immunostaining, high nuclear grade and negative axillary lymph nodes. Our patients underwent chemotherapy and radiation therapy. On post-treatment follow-up, the patient are disease free to date.

Conclusion

Our cases support the view that intracystic papillary breast carcinomas is correlated with a good prognosis, even if it has triple negative phenotype. Hence, the awareness of this clinicopathologic entity is important.
SYNCHRONOUS ASSOCIATION OF A BREAST CANCER AND A UTERINE CHORIOCARCINOMIST IN CONNECTION WITH A CASE AND REVIEW OF THE LITERATURE

F. Hadjarab1, A. TAIBI1
1center pierre marie curie algiers, medical oncology, algiers, Algeria

Aims

it is to bring back a rare case of synchronous association of two cancer (breast and uterine choriocarcinomist)

Method

we used the clinical data of the file of the patient treated in our structure
The breast cancer is the 1st cancer of the woman, The primitive uterine choriocarcinomist is rare pathology

according to the data of the literature this cancer is synchronous generally has other cancers (ovary, uterine, colonist) association with the trophoblastic is exceptional

A search for similar cases in literature with did not find a case similar

Results

the patient is 36 years old, consulted of the appearance of a left adenopathy axillaire and a retraction mamelonnaire A made mammography return in favour of a tumoral process of the bifocal left breast, classified ACR5, a micro biopsy is carried the histology return in favour of a canal carcinoma infiltrating; the patient presented métrorragies, βHCG make return very high 9000 UI, a MRI pelvic and a curetting made diagnoses it of a uterine choriocarcinomist.

The patient receives an néo- auxiliary chemotherapy for choriocarcinomist AE, until total negativation des βHCG, then a surgery on the pelvis

hysterectomy + annexectomy, a left mastectomy, clearing out axillaire homolatéral, after auxiliary chemotherapy for the breast cancer is made with a complement a radiotherapy.

The patient is in complete remission for these 2 néoplasies with a 12 months passing. Conclusion

we conclude that the association of two cancers is rare but it is always necessary to think of diagnosis in front of the appearance of the métrorragies
NO EVIDENCE OF HUMAN PAPILLOMAVIRUS (HPV) INFECTION ON BREAST CANCER IN INDIAN WOMEN

S. Hedau

1National Institute of Cancer Prevention and Research, Molecular Oncology, Noida, India

Aims

Two high-risk HPV types 16 and 18 associated with development of cervical carcinoma and also reported to be present in many other carcinomas. Presence of HPV has been reported in breast carcinoma which is the second most common cancer in India. The two early genes E6 and E7 of HPV type 16 have been shown to immortalize breast epithelial cells in vitro, but the role of HPV infection in breast carcinogenesis is highly controversial. To analyze prevalence of HPV infection in both breast tissues and blood from a large number of women with breast cancer from different regions.

Method

High-risk HPV 16 and 18 DNA was detected by two PCR methods - conventional PCR using consensus primers (MY09/11, or GP5+/GP6+) or HPV16 E6/E7 primers and (ii) highly sensitive Real-Time PCR. A total of 228 biopsies and corresponding 142 blood samples collected from 252 patients from four different regions of India with significant socio-cultural, ethnic and demographic variations were tested.

Results

All biopsies and blood samples of breast cancer patients tested by PCR methods did not show positivity for HPV DNA sequences in conventional PCRs either by MY09/11 or by GP5+/GP6+/HPV16 E6/E7 primers. Further testing of these samples by real time PCR also failed to detect HPV DNA sequences.

Conclusion

Lack of detection of HPV DNA either in the tumor or in the blood DNA of breast cancer patients by both conventional and real time PCR does not support a role of genital HPV in the pathogenesis of breast cancer in Indian women.

BREAST CANCER IN TUNISIAN YOUNG WOMEN
L. Naija¹, B. Laamouri¹, H. Henchiri¹, S. Sakhri¹, O. Jaidane¹, M. Chemlali¹, J. Ben Hassouna¹, M. Hechiche¹, K. Rahal¹
¹Salah Azaiez, Surgical Oncology, Tunis, Tunisia

Aims

Breast cancer occurrence in young women accounts for 9-10% in Tunisia. Tumor characteristics may be more aggressive.

The aim of our study was to describe characteristics in young Tunisian patients with breast carcinoma.

Method

This was a retrospective study about 348 young women aged less than 35 years treated for breast cancer at Salah Azaiez Institute from 2000 to 2008.

Results

The mean age was 31 years. A family history of breast cancer was reported in 28 patients (8%) and pregnancy was associated to breast cancer in 25 patients. The mean tumor size was 39mm. Tumour was bilateral in 2,3% cases. Stage T2 was frequent (39,6%) followed by T4 stage (24%). Patients were metastatic at diagnosis in 11,2% cases. Ductal breast carcinoma was the most common histological subtype (90,2%). Axillary lymph node involvement was found in 61,4% of cases and Hormone receptors were positive in 194 patients (61,4%). Surgery was performed in 90,2% of cases. Radiotherapy was delivered in 75% of cases and chemotherapy was administered in 330 patients (94,8%). Hormonotherapy by Tamoxifen was adjuvant in 176 patients and ovarian suppression was performed in 155. Overall survival and disease free survival at 5 years were 71,6% and 53,9%. Prognostic factors were TNM stage, tumour size, SBR grade, lymph node involvement and capsular rupture, surgery, radiotherapy, adjuvant chemotherapy, hormonotherapy and ovarian suppression.

Conclusion

Despite therapeutic advances, the survival rates remain worse in young women. Further investigations are needed to develop awareness campaigns to improve early detection.
BREAST CANCER IN TUNISIA: ABOUT 730 PATIENTS
L. Achouri¹, H. Bouzaiene¹, H. Henchiri¹, L. Naija¹, S. Sakhri¹, O. Jaidane¹, K. Rahal¹
¹Salah Azaiz, Surgical Oncology, Tunis, Tunisia

Aims

Breast cancer represents a major public health problem in Tunisia. Few recent studies have exhaustively investigated the special features of Tunisian patients. The aim of this study was to identify the epidemiological, clinical, histological and therapeutic characteristics of breast cancer in Tunisia.

Method

It was a retrospective study of 730 patients with breast cancer diagnosed in 2012 and treated in Salah Azaiz Institute.

Results

Our series included 730 patients. Two percent were male. The median age was 50 years. The median clinical tumor size was 35 mm. The median radiological tumor size was 25 mm. Stage T2 was predominantly observed (41.6%). A clinical nodal involvement was present in 69.8% of cases. Metastatic localization was observed in 12.5% of patients. The infiltrating ductal carcinoma was the most common histological type. The median histological size was 25 mm. Hormone receptors were positive in 75.3% of cases. Receptors Her2 were overexpressed in 21% of cases. The most common molecular subtype was the Luminal B. The nodes were positive in 57.4% of cases. Surgery was performed in 89.7% of cases. Radiotherapy was performed in 76.1% of cases. Chemotherapy was administrated to 77.9% of patients. Hormonotherapy was administered to 89.4% of patients. Castration was performed for 61.2% of patients. The Herceptin was administered to 45.3% of cases.

Conclusion

The epidemiological characteristics of breast cancer in Tunisia are mainly the young age and the large tumor size at diagnosis.

SENTINEL LYMPH NODE BIOPSY IN BREAST CANCER AFTER NEOADJUVANT CHEMOTHERAPY
M. Hadidane1, M. Slimane1, H. Henchiri1, S. Sakhri1, B. Laamouri1, H. Bouzaïene1, J. Ben Hassouna1, K. Rahal1
1Salah Azaïz, Surgical Oncology, Tunis, Tunisia

Aims

Sentinel node biopsy (SNB) is largely recommended in breast cancer. However it is still debatable whether this procedure can accurately predict lymph node status after neoadjuvant chemotherapy (NAC). The aim of this study was to determine the detection rate and the false negative rate of SNB after NAC in advance breast cancer.

Method

In this transversal monocentric study, 53 patients were enrolled in Salah Azaïz Institute from June 2012 to August 2016. After neoadjuvant chemotherapy for breast cancer, all patients had sentinel node biopsy.

Results

The median age was 48 years. The median clinical tumor size was 44.96mm. Tumors were cN0 in 34 cases and cN1 in 19 cases. The most common molecular subtype was the luminal B in 23 cases. Lymphoscintigraphy was realised in 32 patients. Detection rate of this method was 83.3%. Patent blu was injected to 47 patients and the detection rate of this method was 95%. The detection rate of the combined method was 96%. The overall SNB detection was 94%. Axillary lymph node dissection was done to all patients. A complete pathologic response was obtained in 13.2% of cases. Immunohistochemical study was performed to the three SNB and was negative. Thus, false negative rate was 16%. Negative predictive value of this technique was 91%.

Conclusion

Detection and false negative rate of SNB were successively 94% and 16%, similarly to results of many prospectives studies dealt with SNB in breast cancer after chemotherapy. Because SNB after chemotherapy is still not worldwide approved, more randomised studies are required.
Aims

Ductal carcinoma in situ (DCIS) of the male breast is an uncommon disease, accounting for approximately 7% of all male breast carcinomas. Compared with invasive carcinomas of the breast, the prognosis associated with DCIS in men is excellent; however, clinical features, pathology, and treatment of this disease are not well defined in the literature. Our aim is to try to update on the various aspects of this disease.

Method

We report two new cases of ductal carcinoma in situ of the male breast treated in Salah Azaiez institute.

Results

It was 2 men aged 58 and 85 years; presented with a typically nodular, retroareolar, partially cystic mass associated with a nipple discharge. The duration of symptoms was 1 month. The size of the lesions was 20 and 25 mm. The pathologic subtype was papillary in one patient, associated with cribriform and comedocarcinoma in the other. Radical mastectomy was performed with axillary dissection in one case and sentinel node method in the other. No lymph node metastases were found. Paget’s disease of the nipple was found in the older man. Patients were alive without disease at 12 months of follow-up.

Conclusion

DCIS in the male patient is best treated by total mastectomy without axillary dissection. We caution the pathologist about the possibility of misdiagnosing this relatively uncommon disease and emphasize that reports of benign papilloma in the male patient should be investigated carefully.
CHOROIDAL METASTASIS OF A BREAST CARCINOMA

H. Henchiri, O. Jaidane, L. Naija, S. Sakhri, H. Salhi, J. Ben Hassouna, K. Rahal

1Salah Azaiez, Surgical Oncology, Tunis, Tunisia

Aims

Choroidal metastases are relatively rare in the course of breast cancer and are mostly asymptomatic. Diagnosis is often late and made at an advanced stage.

We aim through three case reports to illustrate the management of a breast cancer metastatic to the eye.

Method

We report 3 cases of choroidal metastases of a breast carcinoma.

Results

Our patients were aged respectively 32, 48 and 61 years. They were two women and one man. All patients underwent modified radical mastectomy for breast carcinoma earlier. It was an infiltrating ductal carcinoma in all cases. Hormone receptors were positive in two cases. All patients had chemotherapy associated with adjuvant radiotherapy. Two patients had hormonal therapy by Tamoxifen. The mean time to onset of choroidal metastasis was 54 months (6-84 months). The common sign was the sudden decrease in visual acuity and exophthalmos (1 patient). All patients had orbital MRI, and the biopsy confirmed the diagnosis of choroidal metastasis in all cases. All patients had external beam radiation therapy with a complete regression of the metastasis, and a better visual acuity was recovered. One patient had systemic chemotherapy associated with radiotherapy. Two patients were metastatic to the bone and to the lung. All patients were lost on progression.

Conclusion

Choroidal metastasis of the breast cancer is a significant and under-recognized clinical problem for the oncologist. The ocular fundus exam can be useful in follow up in order to act as early as possible. Radiotherapy is the cornerstone of management and will allow the majority of patients to maintain useful vision.

BREAST CANCER IN PREGNANCY AT SALAH AZAIEZ INSTITUTE
1Salah Azaiez, Surgical Oncology, Tunis, Tunisia

Aims

Pregnancy-associated breast cancer is a challenging clinical situation.

The aim of our study was to describe characteristics of breast cancer associated with pregnancy in Tunisian patients.

Method

This was a retrospective study about 25 pregnant young women treated for breast cancer at Salah Azaiez Institute.

Results

The mean age was 30 years. A family history of breast cancer was reported in 3 cases. Breast cancer diagnosis was established during the first trimester for 10 patients, during the 2nd for 4 patients and during the 3rd trimester for 11. A therapeutic interruption of pregnancy was performed in 13 cases. The mean tumor size was 52 mm, tumour was bilateral in 1 case. Stage T2 was frequent (41.7%) followed by T4 stage (25%). The mean radiological size was 31 mm. Patients were metastatic at diagnosis in 3 cases. Ductal breast carcinoma was the most common histological subtype (92%). Axillary lymph node involvement was found in 61.9% of cases and Hormone receptors were positive in 13 patients (59.1%). Breast surgery was performed in 21 cases. Radiotherapy was delivered in 64% of cases and chemotherapy was administered in 22 patients (88%). Hormonotherapy by Tamoxifen was given to 10 patients and ovarian suppression was performed for 9. Overall survival and disease free survival at 5 years were 47.9% and 40.6% respectively.

Conclusion

Pregnancy does not clearly influence the outcome of an established breast cancer. Treatment must be organised by a multidisciplinary team.

BILATERAL ANGIOSARCOMA AFTER BREAST-CONSERVING THERAPY
H. Henchiri1, O. Adouni2, I. Bettaieb2, S. Sakhr1, N. Tounsi1, A. Goucha2, H. Salhi1, H. Bouzaiene1, K. Rahal1, O. Gammoudi2
1Salah Azaiz, Surgical Oncology, Tunis, Tunisia
2Salah Azaiz, Pathology, Tunis, Tunisia

Aims

Angiosarcoma of the breast is rare. It may occur as a complication of radiation therapy after breast conservation. Oncologists will be faced with difficult management decisions for this aggressive tumor. Our aim is to try to update on the various aspects of this disease.

Method

we report a patient with a history of breast carcinoma treated by surgery and radiation, who developed bilateral angiosarcoma.

Results

A 48-year-old female, with a history of right lumpectomy performed eight year ago for breast carcinoma followed by radiation therapy, presented with a painful, bluish and nodular mass occupying the interne quadrants of the right breast. On examination, the lesion measured 4 cm. An excisional biopsy was performed. Histopathological examination revealed a vascular tumor proliferation. A right mastectomy was performed. One year ago, the patient presented with a lump of left breast. MRI showed a malignant lesion. An excisional biopsy of the left axillary lymphadenopathy was performed. Histopathological examination revealed an axillary localization of an angiosarcoma. A left radical mastectomy was performed. Histopathological examination revealed a grade-II angiosarcoma measuring 5 cm. Margins of resection were tumor-free. Five nodes were metastatic from nine. Four nodes had a capsular rupture. Chemotherapy was prescribed. Radiotherapy of the left chest wall was indicated.

Conclusion

Angiosarcoma developing after breast conserving therapy for carcinoma is a rare event. Pathologists should keep this diagnosis in mind when dealing with a breast skin lesion in a patient with a previous history of breast cancer and radiation therapy.
CLEAR CELL CARCINOMA OF THE BREAST: A RARE BREAST CANCER SUBTYPE

H. Henchiri¹, O. Jaidane¹, O. Adouni², L. Achouri¹, S. Sakhri¹, M. Hadidane¹, J. Ben Hassouna¹, O. Gammoudi², K. Rahal¹

¹Salah Azaiez, Carcinological Surgery, Tunis, Tunisia
²Salah Azaiez, Pathology, Tunis, Tunisia

Aims

Clear cell breast carcinoma CCBC is a rare histological breast cancer subtype. Its prognosis may vary depending on specific clinical and pathological characteristics and early diagnosis. Our aim is to discuss the evolutionary characteristics of this entity.

Method

We report two cases of CCBC treated in Salah Azaiez institute.

Results

It was 2 women aged respectively 36 and 67 years. The duration of symptoms was 2 months. The common complaint was a tumor in the right breast. The size of the lesion was 25 mm. Radiological evaluation showed a malignant tumor. Conservative surgery was performed in the first case. The other patient underwent radical mastectomy with axillary lymphadenectomy. No lymph node metastases were found in the first case, we found 5 positive lymph nodes in the second one. Histology concluded to a CCBC SBR III, Luminal B in one case and triple negative in the other. Adjuvant radiation and chemotherapy was planned for one patient. Two months later, both patients developed sub-cutaneous lesions. The biopsy revealed a recurrence of the original tumor. One patient underwent completed excision of lesions, the other underwent radical mastectomy and histology concluded to a multifocal residual tumor; adjuvant radiation therapy, chemo and hormonotherapy was planned for this patient. Two months later, she developed permeation nodes in the right axilla and brain metastasis.

Conclusion

Particular attention should be given to CCBC by pathologists and clinicians to avoid misdiagnosis and delayed treatment, because it has a potentially aggressive clinical course.
AN UNUSUAL METASTASIS TO THE BREAST
H. Henchiri¹, O. Adouni², L. Naja³, S. Sakhri¹, I. Bettaieb², A. Goucha², H. Bouzaïene¹, K. Rahal¹, O. Gammoudi²
¹Salah Azaïz, Surgical Oncology, Tunis, Tunisia
²Salah Azaïz, Pathology, Tunis, Tunisia

Aims

Breast metastases are rare. They represent 0.4 to 6% of all breast cancers. Diagnosis and management of these metastases is an uncommon clinical problem but one that can present difficulties to the oncologist and pathologist. Immunohistochemistry is an important tool for a conclusive diagnosis. We present this case in the aim of trying to update on the various aspects of this entity in order to avoid unnecessary mutilating surgery.

Method

We report a case of a flank fibrosarcoma metastatic on the breast in a young woman.

Results

It was a 33-year-old female patient, single, operated a year ago for sarcoma of the right flank. The surgery was followed by radiotherapy at the dose of 54Gy. Our patient presented 6 months later with a right breast nodule. On the clinical examination an upper external nodule of 15 mm in diameter was found. It was firm, poorly limited and mobile. The echography showed a malignant tumor. Radiologic exam showed a liver metastasis with a suspicious bone lesion. The excision of the mass was performed. Histology and immunohistochemical study confirmed the diagnosis of a mammary metastasis of the previously diagnosed fibrosarcoma. The patient was metastatic in the breast, liver and bone. She had chemotherapy with a stability of the lesions on the control CT scan and then she was lost of sight.

Conclusion

Metastases to the breast must be distinguished from primary breast cancers whose treatment and outcome are different. A confrontation of clinical and pathological data is recommended for an accurate diagnosis.
DEPRESSION AND ANXIETY AFTER MASTECTOMY FOR BREAST CANCER

S. Husić1

1Primary health care, Gynecology, Lukavac, Bosnia - Herzegovina

Aims

The aim of the study was to define the effects of daily hospice team’s activities on depression and anxiety in breast cancer patients having undergone mastectomy after three-month therapy.

Method

This prospective study included 35 patients that underwent mastectomy for breast cancer, followed by 3-month treatment at daily hospice, Tuzla University Clinical Center. Control group consisted of 35 mastectomized patients that did not visit daily hospice. Depression and anxiety were estimated by use of Zung’s scale. Patients were tested initially and retested at 12 weeks.

Results

On initial testing, the mean value of depression was 59.85±6.97 in the study group and 55.65±7.91 in the control group. On three-month retesting, the level of depression was lower in the study group, with a mean value of 48.57±7.06 (P<0.0001) (steam T-test and Wilcoxon’s test) and higher in the control group, with a mean value of 60.45±7.47 (P=0.0001) (steam T-test and Wilcoxon’s test). On initial testing, the mean value of anxiety was 54.97±6.35 and 52.20±6.03 in the study and control group, respectively. On three-month retesting, the level of anxiety was lower in the study group, with a mean value of 43.43±5.97 (P<0.0001), showing improvement from initial testing, but was higher in the control group, with a mean value of 55.68±7.47 (P=0.0002).

Conclusion

In conclusion, daily hospice team’s treatment had favorable effects on lowering the levels of depression and anxiety in patients undergoing mastectomy for breast cancer.

ESGO7-0111

TREATMENT AT A DAY-CARE HOSPICE OF PATIENTS AFTER MASTECTOMY FOR BREAST CANCER IMPROVES THEIR PHYSICAL AND MENTAL HEALTH

S. Husić1
1Primary health care, Gynecology, Lukavac, Bosnia - Herzegovina

Aims

The aim of this research was to establish whether three-month treatment by a multidisciplinary team at a daycare hospice improves the physical and mental health (PMH) of patients after mastectomy for breast tumours and after the completion of oncological therapy.

Method

By a prospective study undertaken on the palliative care ward of the University Clinical Centre in Tuzla, Bosnia and Herzegovina from May 2006 to May 2007, 35 patients were surveyed who had undergone mastectomy for breast tumours and had completed specific oncological therapy. The treatment by the team at the day-care hospice lasted three months. For an assessment of PMH a SF-36 scale was used. In the statistics we used the even T-test and the Wilcox test. The difference was seen to be significant at p < 0.05.

Results

The overall physical health of the patients examined after treatment at the daycare hospice was taken to be 0.55 (0.31 – 0.86) points and was statistically significantly better than the test before treatment at 0.42 (0.27 - 0.83; p < 0.0001). Improvement was achieved in the sub-scales of general health and physical function. Treatment in the day-care hospice of the patients examined also led to improvement of their overall mental health, especially on the sub-scale of social functioning and mental health.

Conclusion

The research established the improvement of all aspects of mental health and most aspects of physical health in the patients after three months’ treatment by a multidisciplinary team at the day-care hospice.
MALE BREAST CANCER IN TUNISIA: EPIDEMIOLOGICAL AND CLINICAL FEATURES & PROGNOSIS FACTORS

O. Kaabia1, G. Amine2, A. NaweF, H. Feteni1, B. Afraa3

1CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia
2CHU Farhat Hached, General surgery, Sousse, Tunisia
3CHU Farhat Hached, Anestheasia and resuscitation, Sousse, Tunisia

Aims

This retrospective study has been realized to determine the epidemiological profile and clinico-pathological aspects of male breast cancer in the center of Tunisia and to analyze its therapeutic results and its prognostic factors.

Method

We analyzed all male breast cancers with a pathological proof of malignancy diagnosed in the departments of gynecology and obstetrics and general surgery of Farhat Hached hospital Sousse Tunisia, between 1997 and 2016. Survival was done with the Kaplan-Meier method.

Results

Forty four new cases of male breast cancer have been diagnosed. The average patient age was 54 years (extremes 28 and 92 years). According to the TNM classification, 6.8% were classified T1 and 43.1% T4; 18.2% were M1. Cancer was bilateral in 9%. 13.7% of the tumors were in-situ carcinomas and 86.4% ductal infiltrating carcinomas. Hormonal receptors were expressed in 45.5%. Triple negative cases represented 36.4%. Chemotherapy was indicated in 68.2% of the patients and loco regional radiation was performed in 86.4% of the cases. Hormonotherapy was prescribed in all cases of positive hormonal receptors. Overall survival rate at 5 years after diagnosis was 26% in all cases and about 55% in patients stage T1N0M0. After univariate analysis, the clinical stages T4, M1 and the pathological stage pN+ affected survival.

Conclusion

The male breast cancer in our area remains relatively less frequent than in women but its prognosis remains alarming even with gold standard treatments. To get better prognosis it is important to increase information among the population and general practitioners and to promote early detection.
Aims

The infiltrating mucinous adenocarcinoma (IMC) is a rare and challenging entity. The aim of our study is to evaluate epidemiologic, clinical and imaging characteristics of pure infiltrating mucinous adenocarcinoma (IMC) and its prognostic factors.

Method

We report a retrospective analysis including 36 female patients with pure IMC treated at the department of gynecology and obstetrics at Farhat Hached Hospital Sousse Tunisia between 2000 and 2016.

Results

The mean age was 53 years. The tumor was classified as T1 in 2 cases, T2 in 18 and T3 in 16 cases. Axillary nodes were staged as N0 in 3 patients, N1 in 12 and N2 in 11. Bone metastases were diagnosed in 2 patients. The sensitivity of mammography and sonography for pure IMC were 66% and 92%, respectively. Breast-conserving surgery was performed in 6. The mean histological tumor size was 42.5 mm. Patients were more likely to have low grade tumors (66%) and positive hormonal receptors (89%). Adjuvant chemotherapy was administrated for 31 patients. After a mean follow-up of 70 months, 4 patients developed local recurrence and 5 distant metastases (bone). The overall survival at 5 years was 71% for all patients and 83% for non metastatic ones. On univariate analysis, clinical stage T, neoadjuvant chemotherapy and lymph node involvement were the most significant prognostic factors for overall survival.

Conclusion

Women presenting with breast symptoms should be examined carefully and evaluated with an appropriate diagnostic work-up because some patients with IMC may present radiologically benign-like lesions.

INTRACYSTIC PAPILLARY CARCINOMA OF THE BREAST : CLINICAL, IMAGING ADN PATHOLOGICAL FEATURES

O. Kaabia¹, F. Hacheni¹, M. Bibi¹, S. hidar¹, H. Zaghouani²

¹CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia
²CHU Farhat Hached, Medical Imaging, Sousse, Tunisia

Aims

Intracystic papillary carcinoma (ICPC) of the breast is a rare entity, with an incidence of 0.5% of all malignant breast tumors. The aim of this study is to characterize the specific iconographic features of this entity to over pass the difficulties to distinguish between benign tumors and this malignant intracystic lesion.

Method

We retrospectively report 12 cases of ICPC of the breast diagnosed and treated in women at the department of gynecology and obstetrics at Farhat Hached Hospital Sousse Tunisia between January 2000 and April 2017.

Results

The mean age at diagnosis was 54 years old (29-73). Eight patient presented with breast pain and the tumor was diagnosed at the ultrasonography. The other 4 patients presented with a painless breast lump. The mean tumor size was 24mm (10-33). On mammography, the mass had circumscribed margins in 7 cases and indistinct margins in 5 cases. Ultrasnography showed complex cystic and solid masses in all patients, with posterior acoustic shadowing in 5 cases and posterior acoustic enhancement in 2 cases. Histopathological examination revealed an intra-cystic papillary carcinoma, associated with foci of ductal carcinoma in situ in 10 cases and micro-invasive carcinoma in 2 cases. All axillary lymph node were not invaded. After a mean follow-up of 32 months, 3 patient developed local recurrence treated by surgery, radiotherapy and hormonotherapy and chemotherapy.

Conclusion

ICPC of the breast is characterized by a more benign behavior and a subsequent better prognosis. The place of extempo pathological examination and sentinel lymph node detection are to be evaluated.
ANEMIA AND LOW PLATELETS REVEALING A SPLENIC METASTASIS OF A PRIMARY BREAST ANGIOSARCOMA

O. Kaabia¹, A. Massoudi¹, F. hacheni¹, A. Brahim²
¹CHU Farhat Hached, Gynecology and Obstetrics, Sousse, Tunisia
²CHU Farhat Hached, Anesthesia and resuscitation, Sousse, Tunisia

Aims

The aim of this case report is to emphasize the poor prognosis of the primitive angiosarcoma of the breast. Breast angiosarcomas mostly affect adolescent and young adult females.

Method

We report the case of a 35-year-old female with high grade primary breast angiosarcoma treated with a mastectomy and a lymph node dissection followed by an adjuvant chemotherapy and radiotherapy at the department of gynecology and obstetrics at Farhat Hached Hospital Sousse Tunisia from November 2016 to April 2017.

Results

The patient presented severe anemia and low platelets. She experienced severe non immunological hemolysis with no other abnormalities, 3 months after surgery and during radiotherapy. A computed tomography showed splenic metastasis. Despite transfusions and corticotherapy, the patient died a month after the diagnosis of the splenic metastasis.

Conclusion

Splenic metastasis are rare but dramatic complications of breast cancer especially the primitive angiosarcoma of the breast.
Aims

Cell proliferation measurement is believed to be an important predictive factor for the success of neoadjuvant chemotherapy (NACT) in breast cancer, but its use is still controversial. The aim of the study was to determine the cut-off value of Ki-67 in breast cancer patients and evaluate its predictive potential.

Method

74 patients with locally advanced breast cancer undergoing NACT were analysed. Response to NACT was measured by pathological complete response (pCR) rate and neoadjuvant response index (NRI). All patients underwent centralized Ki-67 evaluation among other tumor characteristics. Optimal cut-off value of Ki-67 was determined using receiver operating characteristics curve while its predictive potential was confirmed using univariate and multivariate analyses.

Results

Ki-67 cut-off value of 50% was optimal for predicting both pCR rate and NRI. Patients with high Ki-67 (> 50%) achieved NRI 0.49 versus 0.32 in patients with Ki-67 < 50% (p < 0.01). Similar was shown for pCR rate (5.3% in Ki-67 > 50% group vs. 19.4% in Ki-67 < 50% group) yet pCR rate difference did not reach statistical significance (p = 0.06). Independent predictive value of Ki-67 cut-off value was confirmed using multivariate analysis.

Conclusion

Cell proliferation measured by Ki-67 is an important predictor of NACT response. Cut-off value of 50% could be used to identify patients with favorable NACT outcome and higher probability of achieving pCR.
Aims

Low-dose metronomic chemotherapy (LDMC) is increasingly used in metastatic breast cancer (MBC). In the current investigation we examined the therapeutic response of LDMC in MBC.

Method

In this retrospective analysis we focus on patients with MBC receiving LDMC with oral cyclophosphamide (CTX) (50mg daily) and methotrexate (MTX) (2.5mg every other day). Patients were treated between 2009 and 2015. Primary endpoint was disease control rate (DCR) ≥ 24 weeks after start of LDMC. DCR included complete remission (CR), partial remission (PR) and stable disease (SD). Secondary endpoints were duration of progression free survival (PFS) and rates of discontinuation due to progression and side effects.

Results

35 patients entered the study. 11 (31%) patients achieved DCR. 1 (3%) patient had CR, 6 (17%) PR and 4 (11%) showed SD, respectively. The patients had received a median of 2 (range: 1-8) lines of chemotherapy. DCR was achieved in 8/24 (33%) hormone-positive patients and 3/11 (27%) hormone-negative patients. The median PFS was 12 (range: 6-86) weeks. 3 (9%) patients dropped out because of adverse events.

Conclusion

The DCR of 31% is in line with the results of previous phase-II-studies. This orally administered LDMC regimen has a favourable therapeutic index for advanced breast cancer patients without need for rapid response.

5Max Superspeciality Hospital New Delhi, Histopathology Department, Delhi, India
6Max Superspeciality Hospital New Delhi, Max Cancer Centre, Delhi, India
7Amity University Noida, Amity Institute of Molecular Medicine and Stem Cell Research, Noida, India

Aims

Triple negative (ER-/PR-/Her2-) breast cancers are most frequent aggressive tumors in younger women, and are associated with early relapse and poor prognosis. Epigenetic silencing of specific tumor suppressor genes plays an important role in breast cancer initiation and progression but till date no epigenetic biomarker(s) is linked with triple negative breast cancers. In this study, five tumor suppressor genes, BRCA1, p16, GSTP1, HIC1 and CDH1 have been investigated to see if the methylation pattern could serve as a reliable indicator for early detection/progression and/or prognosis of triple negative breast cancer.

Method

Genomic DNA isolated from 124 primary breast tumor biopsies employed for sodium bisulfite conversion of genomic DNA was performed for analysis of promoter methylation by methylation specific polymerase chain reaction (MSP) and the results obtained correlated with the level of the expression of the genes, stage/grade of the disease and clinicopathological parameters.

Results

Out of five specific tumor suppressor genes, GSTP1, HIC1 and CDH1 showed significantly a higher level of methylation in early stage triple negative breast cancer; GSTP1 promoter was hypermethylated in 100% of cases leading to loss of expression in 50% of the TNBCs while HIC1 and CDH1 were hypermethylated in 88.88% tumors with a loss of expression in 37.5% and 25% respectively in early stage triple negative breast cancer.

Conclusion

The results suggest that hypermethylation of these genes may serve as a potential predictive biomarker for early identification and progression of aggressive triple negative breast cancer.
STROMAL B7-H3 AND B7-H4 EXPRESSION CORRELATIONS WITH TUMOR PROGRESSION AND T-CELL INFILTRATION IN PHYLLODES TUMOR OF THE BREAST

J.S. Lee¹, N.I. Kim¹, G.E. Kim¹
¹Chonnam National University Hwasun Hospital, Pathology, Hwasun, Republic of Korea

Aims

The aberrant expression of co-inhibitory B7 molecules, B7-H3 and B7-H4, in the tumor microenvironment has been attributed to reduced anti-tumor immunity and immune evasion, prompting the development of immunotherapeutic approaches. This study was undertaken to detect the expression of B7-H3 and B7-H4 in phyllodes tumors (PTs) and its association with the grade and clinical behavior of PTs. In addition, the association of B7-H3 and B7-H4 with the CD3 and CD8+ T lymphocytes was also assessed to investigate their roles in the regulation of tumor immune surveillance.

Method

Immunohistochemistry was applied to examine the expressions of B7-H3, B7-H4, CD3, and CD8 in 60 benign, 26 borderline, and 15 malignant PTs.

Results

Stromal high B7-H3 and B7-H4 expression was noted in 31 (51.7 %) and 0 (0 %) of 60 benign PTs, 20 (76.9 %) and 2 (7.7 %) of 26 borderline PTs, and 13 (86.7 %) and 9 (20.0 %) of 15 malignant PTs, respectively. Stromal B7-H3 and B7-H4 expression increased continuously as PTs progress from benign through borderline to malignant PTs, respectively (P = 0.003 and P = 0.001). The recurrence rate was higher in the stromal high B7-H3 or B7-H4 expression group than in the low expression group but this difference was not statistically significant. B7-H3 expression inversely correlated with the intensity of CD3 and CD8+ T cells (P = 0.001 and P = 0.027, respectively).

Conclusion

B7-H3 and B7-H4 are involved in the progression of PTs and B7-H3 may play a role in immune surveillance mechanisms of PTs.
**Aims**

We conducted a 1:1 age-matched case-control study to investigate the risk for breast cancer (BC) in relation to self-reported use of underarm cosmetic products (UCPs) containing aluminium salts. Our study for the first time also included analysis of aluminium concentrations in a big series of breast tissues.

**Method**

Structured BC risk interviews were conducted. History of UCP use was compared between 209 BC patients (cases) and 209 age-matched healthy women (controls). Aluminium concentration was analysed in breast tissues of 100 cases and 52 controls who underwent mastectomy for BC or reduction mammoplasty for non-cancer reasons, respectively. Multivariable conditional logistic regression analysis was performed to determine relative risks, estimated as odds ratios (ORs) with 95% confidence intervals (CIs), adjusting for established BC risk factors.

**Results**

Case-control comparisons confirmed established risk factors for BC. Self-reported use of UCP was significantly associated with an increased risk of BC (p=0.036). BC risk increased by an OR of 3.88 (95% CI 1.03-14.66) in women who reported using UCPs more than once daily starting at an age <30. Aluminium in breast tissue was significantly associated to self-reported UCP use (p=0.003) in both cases and controls. Median (interquartile) aluminium concentration was significantly higher (p<0.001) in cases than in controls (5.8, 2.3-13.1 versus 3.8, 2.5-5.8 nmol/g).

**Conclusion**

Frequent use of UCPs may lead to accumulation of aluminium in breast tissue. Extensive use of UCPs particularly at young age was associated with increased risk of BC. Of note, we herein report on pure correlation analyses and not on causal links.

T. Link, K. Kast, P. Wimberger, C. Sadowski

Medizinische Fakultät Carl Gustav Carus an der TU Dresden, Gynecology, Dresden, Germany

Aims

Diagnosis of leptomeningeal metastasis (LM) has become increasingly common because of longer survival of patients by better systemic control. However, treatment options are very limited and their appearance implies a very poor prognosis. Treatment options are intrathecal and systemic chemotherapy, radiotherapy. This report of our single center experience investigates clinical features and determines prognostic factors in a cohort of patients with breast cancer.

Method

Single center data from 43 patients with breast cancer and LM between 2009 and 2016 were retrospectively analyzed with focus on characteristics, clinical outcome and treatment.

Results

Mean interval between diagnosis of breast cancer and diagnosis of LM was 17.5 month (range 0-149 months). LM was diagnosed by MRI and cerebrospinal fluid cytology (CSF) 69.8%, MRI alone 25.6% or CSF 4.7% alone. Treatment included intrathecal therapy alone 48.8%, radiotherapy alone 20.9% or the combination of both 14%. 42% patients had triple negative (TNBC) breast cancer, 9.3 % were Her2-positive (HER2+) and 48.8 % had a hormone receptor positive and Her2-negative disease (HR+/HER2-). Median survival was 1.6 month for TNBC, 13.3 months for HER2+ and 7.4 months for HR+/HER2- disease. 58.1% died due to progression of LM und 23.3% due to systemic progression. 1 patient (Her2+) is still alive 18 months after diagnosis of LM.

Conclusion

Despite the improvement of treatment options for breast cancer within the last years, appearance of LM is still associated with a poor survival. Survival differs between subtypes. More research needs to be done to identify factors for possibly new systemic therapies that improve survival.

THE LUMINAL A BREAST CANCER METASTATIC BEHAVIOUR BETWEEN PERITUMORAL LYMPHANGIOSIS CARCINOMATOSA AND AXILLAR LYMPH NODES

G. Macicasan¹, S. Falk², L. Egon³

¹Praxis Dr. Gabriel Macicasan, Gynäkologie und Geburtshilfe, Frankfurt am Main, Germany
²Institut für Pathologie, Pathologie, Frankfurt am Main, Germany
³Hospital zum Heiligen Geist, Gynäkologie, Frankfurt am Main, Germany

Aims

Based on the central role of biomarkers in planning the mammary cancer therapy, we investigated 412 cases, randomly selected, to emphasize the relationship between peritumoral lymphangiosis carcinomatosa in molecular subtypes in breast cancer and axillary lymph node metastasis.

Method

We have selected cases that are ordered under the four molecular subtypes of breast cancer. We noticed that the majority of mammary carcinoma are part of the Luminal A subtype. For this subtype we analyzed the behaviour between peritumoral carcinomatosa lymphangiosis and axillary lymph nodes.

Results

L1 status has a HIGH RISK of nodule METASTASIS (HRM)
L0 status has a LOW RISK of nodule METASTASIS (LRM) allowing that the size and biology of the tumor have favorable criteria.

Conclusion

Peritumoral lymphangiosis carcinomatosa can be used as a prediction factor in a high or low risk metastasis of axillary lymph nodes, as well as a prognostic factor.

The presence of peritumoral lymphangiosis implies a direct relationship with the metastasis of lymph nodes and their increase in number.

In case of a Luminal A L0 situation we expect few axillary nodes metastasis, which makes possible to even forego the axillary dissection.

ESGO7-0629

ORBITAL METASTASIS OF BREAST CARCINOMA: ABOUT THREE CASES

M. Bouhani¹, M. Slimene¹, S. Sakhri¹, S. Haddad¹, I. Zemni¹, M. Hachiche¹, J. Ben Hassouna¹, K. Rahal¹

¹Institut Salah Azeiz of Oncology, Oncologic Surgery, Tunis, Tunisia

Aims

Breast cancer can metastasize to many sites, but the orbit is an infrequent location and a comparatively rare site of distribution among the ocular area structures, with only 3-10% of all ocular metastases.

Method

All patients diagnosed with orbital metastasis of breast carcinoma at Salah Azaiez institute, Tunis, Tunisia, in the period from 2016 to 2017, from retrospective chart review and histologic analysis.

Results

A total of 3 patients were included. The patients had respectively 63, 50, 51 years old at the time of diagnosis of orbital metastasis. Two patient with a history of a grade 2, hormone receptor-positive, HER2-negative ductal adenocarcinoma (DAC) of the left breast, and one with triple negative DAC. Signs were local pain, diplopia, slight ptosis and proptosis. MRI revealed a mass of the extraocular muscle, in one case, infiltration of extraorbital muscle, and choroid metastasis in the two others cases. The CT body scan did showed any other metastatic site. A navigation-assisted intraorbital biopsy from the orbital roof, performed in one patient, revealed a metastasis of breast cancer. As further treatment they received systemic palliative chemotherapy in addition.

Conclusion

The metastatic involvement of the orbit in malignant tumors is a rarely diagnosed condition. Breast cancer accounts for the majority of these cases.

In patients with a previous history of breast cancer who complain even of mild ophthalmologic symptoms such as local pain, periorbital edema, it is important to consider ocular or orbital metastatic disease. Adequate 3D-Imaging followed by a biopsy will usually confirm the diagnosis.
Malignant melanoma is the most rapidly increasing cancer in the world. Metastatic disease occurs in 20% of patients. Metastases to the breast are rare. Melanoma is, however, among the most commonly reported primary tumors to metastasize to the breast.

Method

A retrospective case review of melanoma registry at Salah Azaiez institute, Tunis, Tunisia, in the period from 2005 to 2016 to find all patients with melanoma metastatic to the breast.

Results

five patients were found to have breast metastases from melanoma during this period. Four patients were premenopausal females with a mean age of 44 years. Two patients had primary lesions on the heel, one the axillary area, one on the head and one in vagina. The median interval between diagnosis of the primary and breast involvement was 19.8 month. One patient had bilateral breast involvement, and all had other sites of metastases. The median survival after diagnosis of breast metastases was 4 months.

Conclusion

Metastasis to the breast must be considered in any patient with a known primary malignant tumor history who presents with a breast lump. Careful triple assessment and multidisciplinary decision making are vital in developing the management plan.
Sclerosing epithelioid fibrosarcoma (SEF) is a rare variant of fibrosarcomas, characterized by epithelioid tumor cells arranged in strands, nests, cords, or sheets embedded within a sclerotic collagenous matrix. It was recently identified as a separate entity due to specific histologic and immunohistochemistry features and its poor prognosis, with only fewer than 100 cases reported in English literature.

Metastatic spread is usually late in the natural course of the disease. **Method**

We report the case of a premenopausal woman who was diagnosed with a metastatic SEF in her breast in Salah Azaiez institute, Tunis, Tunisia, in 2013.

**Results**

We report the case of a 33-year-old woman with a right breast nodule. She was previously known for sclerosing epithelioid fibrosarcoma (SEF) of the right flank, having a wide resection for local recurrence with free margins. A solid periuret mass was surgically excised 3 years later, yielding the diagnosis of metastatic SEF. To our knowledge, this is the first documented metastasis of SEF to the breast, providing a review of literature.

**Conclusion**

These sarcomas have proven difficult to treat, with high recurrence rates despite a multimodal approach.
PRIMARY ECTOPIC AXILLARY BREAST CARCINOMA: ABOUT SIX CASES

M. Bouhani1, I. Zemni1, S. Sakhr1, O. Adouni2, M. Slimene1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

The presence of ectopic breast tissue is reported in 2-6% of the general population with most cases being located in the axillary region. Primary carcinoma of ectopic breast tissue has been reported only in a small number of cases. The aim of this study is to investigate the clinical features, treatments, and prognosis of primary ectopic axillary carcinoma (PEAC).

Method

A retrospective cases review of breast cancer registry at Salah Azaiez institute, Tunis, Tunisia, in the period from 2000 to 2006 to find all patients with PEAC.

Results

A total of 6 patients were included. The average age at the time of diagnosis was 51 years. The five-year survival in this study was 83%. Histologic feature showed: four cases of ductal infiltrated carcinoma, one case of lobular infiltrated carcinoma and one ductal in situ carcinoma. Four patients with positive hormonal receptors and negative HER2 and two patients had a triple negative carcinoma. Five patients underwent surgery as primary treatment, one patient underwent neoadjuvant chemotherapy followed by surgery. Five patient underwent adjuvant radiotherapy. During follow up, five patients is doing well, with no evidence of local recurrences or distant metastases, one patient had hepatic metastasis and she had palliative chemotherapy.

Conclusion

Accessory breasts are not uncommon and are subjected to various pathologies including carcinoma. The management of accessory breast carcinoma parallels that of a normally situated breast carcinoma. Although early detection of accessory breast carcinoma may be difficult, this is a potentially treatable and curable condition.

ULTRASOUND-GUIDED ONCOPLASTIC SURGERY IN NON-PALPABLE BREAST LESIONS
C. Gianella¹, D. Martínez Campo², H. García Briz¹, G. Costa Martínez¹, R. Barriga¹, P. Garbayo Sesma², L. González Gea², I. Pérez Martín², L. Rabadán², B. Santacruz Martín²
¹Hospital Universitario de Torrejón, Unidad de mama, Madrid, Spain
²Hospital Universitario de Torrejón, Ginecología Oncológica, Madrid, Spain

Aims

To evaluate the rate of malignant margins in the oncoplastic surgery of non-palpable ultrasound-guided breast lesions.

Method

- Observational, descriptive and retrospective study. All patients diagnosed with non-palpable malignant breast lesions from October 2011 to May 2015 were included in the study. Patients with neoadjuvant therapy were also included as long as the tumor was not palpable at the time of surgery.

Results

114 patients were included. 66.6% corresponded to infiltrating ductal carcinoma, 22.8% to ductal carcinoma in situ and 10.6% to all other lesions (special and lobular carcinomas). The oncoplastic techniques used were Fisher-type tumorectomy and remodeling (52.6%), circular mammoplasty (16.6%), vertical mammoplasty (14.9%). The malignant margins rate was 7.01% (8 patients).

Conclusion

Reviewing the literature, there is still insufficient evidence to conclude that intraoperative ultrasonography in nonpalpable lesion surgery is a superior technique. Lack of randomized clinical trials are available. There is evidence to conclude that it is a simple, reproducible technique with a short learning curve and that does not generate pain to the patient. The published localization rates are around 100%. Studies should be performed comparing currently available techniques.
MEDULLARY BREAST CANCER

E. Martinez Lamela1, J. Molero Vilchez2, S. Sancho Garcia3, E. Bancalari Rojinca4, S. Peco Adrover5, R. Fuentes Mateos6

1Nuestra Señora del Rosario Hospital/ Infanta Leonor University Hospital, oncological gynecology, Madrid, Spain
2Ntra. Sra. del Rosario Hospital- Toco-Gyn Gynecologic Center, Oncological Gynecology, Madrid, Spain
3Ramón y Cajal Universitary Hospital, Radiatyon Oncology, Madrid, Spain
4Jimenez Ayala Institute, Pathological Anatomy, Madrid, Spain
5Ntra. Sra. del Rosario Hospital, Gynecology and Obstetrics, Madrid, Spain
6Advance Tecniques Cancer Center, Medical Oncology, Madrid, Spain

Aims

Breast medullary carcinoma is a favourable prognose tumor despite its high nuclear grade and miotic index.

It represents 3% of breast cancer, reaching 13% in women with BRAC/1 gene mutation.

It is present in young women as a dense well-defined lesion which seems to be encapsulated, and it can be taken for benign lesion when using imaging techniques.

Sincitial growth pattern with stressed nuclear atypia and a diffuse lymphoplasmocitary infiltrate are its main characteristics.

The incidence of lymph node metastasic disease is 27% reaching up to 94% of survial rate.

Method

Case Report

Results

A 35 years old woman coming to clinics due a new well defined 3cm nodule in left breast. Echography: solid 32x12 mm nodule with quistic degenerated areas. Mammography: solid 22x21x12mm solid nodule in CSE with regular contour, without microcalcifications. BIRADS 4.Core biopsy: solid pattern G3 carcinoma poorly differentiated. Negative extension study.

Augmented tumorectomy is performed under echographic control of countour with BSGC (Sentinel Node biopsy) and oncomamoplasty techniques. Intraoperatoriy biopsis: free margins and two lymph nodes without metastasic evidence.Definitive anatomy: infiltrating carcinoma with medular signs of 2.7cm with free G3 margins. ER+PR+HER 2 neu negative and Ki 67: 90% pT2n N0(0/2)M0 stage.Genetic analysis with negative results.

After presenting case at Tumor Committee, complementary chemotherapy 4 adriamycin/ cyclophosphamide + 12 paclitaxel with postsurgical radiotherapy and posterior hormonal treatment is received.

Conclusion

Medullary breast carcinoma is a favourable histologic type despiste its elevated nuclear grade, with higher disease-free survival rate and global survival rate than those from patients with infiltrating ductal carcinoma of the same stage.
MAJOR HISTOCOMPATIBILITY COMPLEX CLASS I-RELATED CHAIN A (MICA) EXPRESSION AS A MARKER FOR BREAST EPITHELIAL PRECANCEROUS AND CANCEROUS LESIONS

P. Masadah¹, N. Nurkhairaty¹, J.M. Kandouw¹, S. Rau²
¹Hasanuddin University, Pathology Anatomy, Makassar, Indonesia
²Hasanuddin University, Obstetric and Gynecology, Makassar, Indonesia

Aims

To analyse the expression of MICA in various breast epithelial lesion in order to support the diagnosis of precancerous and cancerous lesions, and to gain the knowledge of breast cancer pathogenesis and the role of immune system in cancer.

Method

One hundred and six of paraffin blocks tissue samples was analysed by immunohistochemistry using monoclonal MICA antibody. Samples have been categorized histopathologically as atypical duct hyperplasia, ductal carcinoma insitu, ductal carcinoma invasive (low, moderate, and highly differentiated).

Results

there was a significant differentiation of MICA expression between atypical duct hyperplasia and invasive ductal carcinoma moderate and highly differentiated of the breast. There was as significant differentiation of MICA expression between ductal carcinoma insitu and invasive ductal carcinoma moderate and highly differentiated of breast (p < 0.05).

Conclusion

MICA expression could be used to differentiate precancerous and cancerous lesions of breast.
THE ROLE OF RADIOLOGIC EVALUATION FOR DETECTION OF AXILLARY LYMPH NODE METASTASIS IN EARLY BREAST CANCER

T. Mehmood1
1Shaukat Khanum Memorial Cancer Hospital and Research Centre, Radiation Oncology, Lahore, Pakistan

Aims

Axillary lymph node metastasis (ALNM) is a key prognostic factor of breast cancer, thus, diagnostically accurate methods for determining ALNM are very important. The purpose of this study was to evaluate the availability of preoperative breast ultrasonography (US), magnetic resonance imaging (MRI), and positron emission tomography-computed tomography (PET-CT) for detection of ALNM in early breast cancer (tumor size ≤ 5cm).

Method

We retrospectively analyzed 105 patients with breast cancer who underwent sentinel lymph node biopsy (SLNB) or axillary lymph node dissection (ALND) after preoperative breast US, MRI and PET-CT between January 1, 2013 and December 31, 2014. Positive predictive value (PPV), negative predictive value (NPV), sensitivity and specificity of each radiologic modality was observed.

Results

Of 105 patients with early breast cancer underwent axillary surgery, 71 patients evaluated all radiologic modalities preoperatively. The mean age of patients was 50.7±11.0 years (range 30-80 years). 55 patients underwent planned SLNB and 16 patients underwent planned ALND. 8 patients underwent SLNB needed additional ALND after frozen biopsy. 28.2% (20/71) of patients exhibited ALNM on pathologic report. The PPV was 52.2%, 61.9%, and 92.3%, and the NPV was 83.3%, 86.0%, and 86.2%, respectively. The sensitivity was 60.0%, 65.0%, and 60.0%, and specificity was 78.4%, 84.3%, and 98.0%, respectively.

Conclusion

There are no definitive modalities for detecting ALNM in early breast cancers to replace SLNB. However, PET-CT seems to be a predictive radiologic modality for detection of ALNM considering higher PPV and specificity. If ALNM is suspected based on PET-CT, ALND without SLNB might be a better option.

ADDITIONAL CAVITY SHAVES MARGINS IN BREAST CANCER

L. Achouri1, H. Bouzaine1, N. Tounsi1, B. Lamourri1, H. Henchiri1, R. Doghri2, M. Hechiche1, J. Ben Hassouna1, R. Khaled1

1Salah Azaize, Department of Surgery Carcinologique, Tunis, Tunisia
2Salah Azaize, Department of Pathology, Tunis, Tunisia

Aims

The aim of our study is to evaluate our management strategy for tumor shave in anatomopathological examination after breast-conserving surgery and discuss the role of additional re-excision margin.

Method

We undertook a retrospective review, throughout 2012, of 319 women who underwent lumpectomy with shaving margins for stage 0-III breast cancer.

At our institution, patients who had breast conservation had a lumpectomy with routine CSM with extemporaneous anatomopathological study at the time of initial surgery, associated with an axillary lymph node dissection. If CSM was tumor, the radical surgery was realized. No additional re-excision margin was performed.

Results

The median age was 50 years old. The median clinical tumor size was 30 mm. The median histological size was 20 mm. The infiltrating ductal carcinoma was the most common histological type.

All our patients underwent a lumpectomy with systematic cavity shaving. Tumor in shavings was revealed in 106 (33.2%) patients. It was discovered in extemporaneous examination in 63 (59.5%) cases. In 43(40.5%), it was revealed in the definitive anatomopathological examination and additional mastectomy was necessary. Among these patients who had radical mastectomy, the final histological examination concluded to a residual cancer in 58 (54.7%) cases.

Conclusion

Taking additional CSM at the time of lumpectomy is advocated by some as a way to decrease re-excision rates. Despite these findings, a minority of surgeons have adopted this practice.

PREOPERATIVE AXILLARY LYMPH NODE STAGING IN BREAST CANCER
L. Achouri\textsuperscript{1}, H. Bouzaine\textsuperscript{1}, S. Kacem\textsuperscript{1}, N. Tounsi\textsuperscript{1}, I. Zemni\textsuperscript{1}, H. Hantousse\textsuperscript{1}, M. Hechiche\textsuperscript{1}, J. Ben Hassouna\textsuperscript{1}, K. Rahel\textsuperscript{1}
\textsuperscript{1}Salah Azaize, Department of Surgery Carcinologique, Tunis, Tunisia

Aims

To evaluate the reliability of physical examination in predicting the axillary lymph node involvement in breast cancer, study the factors that may interfere with it and ask about the benefits of means other than the physical examination to have an accurate lymph node status.

Method

A retrospective review was performed of 730 consecutive patients diagnosed with breast carcinoma between January 2012 and December 2012 who had physical examination of the axilla. Definitive histopathological evaluation of lymph nodes has been performed for 654 patients.

Results

A total of 377 (57\%) patients had one or more positive lymph nodes, 80.2\% of whom were identified preoperatively by physical examination. The sensitivity of physical examination in evaluating the axillary node involvement was 80.2\%. Its specificity was 46\%. An underestimation was noticed for T0 and an overestimation for T1, T2, T3 and T4 tumors.

Conclusion

Physical examination is useful for preoperative axillary staging and treatment planning. Nonetheless, it is an inadequate definitive predictor of axillary lymph node involvement, especially that the examiner is not blinded to the breast tumor size which will inexorably influence his assessment.

BILATERAL ORBITAL METASTASES OF INVASIVE CARCINOMA OF BREAST: A CASE REPORT

N. Tounsi1, M. Slimane1, N. Abdelwahed1, I. Zemni1, H. Henchiri1, R. Doghrir2, H. bouazize1, M. Hechiche1, J. Ben Hassouna1, K. Rahel1

1Salah Azaize, Department of Surgery Carcinologique, Tunis, Tunisia

2Salah Azaize, Department of Pathology, Tunis, Tunisia

Aims

Orbital metastases of breast cancer are rare with only 2-11% of all orbital tumors. Orbital metastases predominantly involve the choroid. Metastasis to the extraocular muscles is very infrequent.

Method

We report a case of bilateral orbital metastases of invasive carcinoma of breast and describe a clinical presentation and multimodal treatment.

Results

The patient had been diagnosed with breast cancer 6 years before. Her present complaint was local pain, ptosis, and blurred vision of the right orbit. Magnetic resonance imaging (MRI) of the orbits showed bilateral soft tissue masses of the orbits involving extra-ocular muscles. Orbital biopsy was performed which confirmed metastatic breast carcinoma. Bone scintigraphy demonstrated metastatic spread to the skeleton. She received systemic palliative. Chemotherapy, bisphosphonates with local radiotherapy. She still alive two years after.

Conclusion

Orbital metastases from breast cancer have a poor prognostic, with an average in such cases of 22 to 31 months. Once diagnosis is confirmed treatment for patients with orbital metastases is multidisciplinary.
CHAMOMILE CAN REDUCE THE METASTATIC PROPERTIES OF HUMAN BREAST CANCER CELL LINE THROUGH IMPACT ON VEGF AND MMP ENZYMES ACTIVITY

M. Nikseresht¹, R. Mahmoudi¹, A. Sabet Eghlidi¹, F. Sane²
¹Yasuj University of Medical Sciences, Cellular and Molecular Research Center, Yasuj, Iran
²Kazerun Azad University, Medical Faculty, Kazerun, Iran

Aims

Today there is a special focus on traditional medicine for preventing and treatment of diseases. Herbal medicine has the central role in the traditional medicine and there are different kinds of medicinal plants, which use for this purpose. One of these plants is chamomile. Various studies have reported the anticancer effects of this plant. In this study, the effects of hydroalcoholic extract of chamomile on angiogenic factor, VEGF, and MMP enzymes activities were investigated in human breast cancer cell lines.

Method

MCF-7 and MDA-MB-468 cell lines were cultured and treated with hydroalcoholic extract of chamomile. Cell viability were evaluated by using MTT assay. VEGF gene expression were analysed by Real Time PCR. Enzyme activity of MMP-2 and MMP-9 evaluated by zymography assay. Data were analyzed by one-way ANOVA in SPSS software.

Results

MTT assay on MCF-7 and MDA-MB-468 showed IC50 at 1000 and 1400 μg/ml respectively. At the IC50 doses, VEGF expression and secretion is reduced compared to the control by the cell lines. Treatment of MDA-MB-468 cell line with 1400 μg/ml of chamomile extract caused depletion of MMP-9 and MMP-2 enzyme activity in the cell culture medium.

Conclusion

The results show hydroalcoholic extract of chamomile can reduce the expression of VEGF gene and MMP enzyme activity and so inhibit the angiogenesis progression by these cells. This study was in vitro study and must be tested in vivo by clinical approaches but the use of such these plants in daily diet may be useful for preventing and increase viability in breast cancer.

**EFFECTIVENESS OF BREAST CANCER AWARENESS PROGRAMME IN CHANGING KNOWLEDGE, ATTITUDE AND PRACTICES AMONG EDUCATED WOMEN IN RAIPUR**

A. Pal\(^1\), S. singh\(^2\), P. thakur\(^3\), N. shrivastava\(^2\)

\(^1\)All India Institutes of Medical Sciences, Community and Family Medicine, Raipur, India
\(^2\)All India Institutes of Medical Sciences, General Surgery, Raipur, India
\(^3\)All India Institutes of Medical Sciences, Obstetrics and Gynaecology, Raipur, India

**Aims**

to evaluate the effectiveness of structured awareness programme on knowledge, attitude and practices regarding early detection and treatment of breast cancer among educated women in Raipur

**Method**

The study subjects were 5000 women studying in various educational institutions of Raipur District. Information on their current knowledge, attitude and practices regarding breast cancer was collected by pretest questionnaire. Then the awareness programme was conducted in which information was given on breast cancer, its signs and symptoms, misconceptions, screening methods, preventive measures and treatment modalities and the correct technique of breast self examination. Then post test questionnaire was administered.

**Results**

Significant improvement was noted in the knowledge, attitude and practices score of participants after administration of structured awareness programme regarding early detection and treatment of breast cancer.

**Conclusion**

There is need to spread awareness among the women about the early detection and treatment of breast cancer in the community
Aims
Breast cancer is the most prevalent known women malignancy in the worldwide; lack of awareness of symptoms and delay on diagnosis of breast cancer are the main causes of mortality among women. This study has conducted with the purpose of assessing the effect of educational consulting of breast self-examination based on the health belief model on the knowledge and performance of women over 40 years attending to the health care centers in Hamadan, Iran.

Method
This research was a quasi-experimental study. Eligible women admitted to health centers in Hamadan city in 2015 randomly assigned to intervention and control groups (n = 75 in each group). The intervention group received 4 weekly sessions of breast cancer screening consulting based on Health Belief Model (HBM). Control group received only routine care. Knowledge, HBM constructs, and breast self-examination (BSE) practice compared in both groups before, after and three months after the consultation.

Results
Before the intervention, no significant differences were observed in knowledge, health belief and practice between two groups. While after intervention a significant difference was observed between two groups in mean scores of perceived benefits, perceived barriers, self-efficacy and the health motivations (p <0.05). The significant difference between the two groups was observed in terms of knowledge and BSE practice (p <0.01).

Conclusion
The results indicate the importance of consultation in knowledge and beliefs in improve BSE performance and prevention of breast cancer in women.

DERMATOFIBROSARCOMA PROTUBERANS OF THE BREAST
K. Pohlodek	extsuperscript{1}, I. Mečiarová	extsuperscript{2}, P. Grossmann	extsuperscript{3}, Z. Kinkor	extsuperscript{4}

	extsuperscript{1}Comenius University of Bratislava, 2nd Department of Gynecology and Obstetrics, Bratislava, Slovak Republic
	extsuperscript{2}Alpha medical- Ltd., Department of Pathology, Bratislava, Slovak Republic
	extsuperscript{3}Bioptic Laboratory- Ltd., Department of Molecular Genetics, Plzeň, Czech Republic
	extsuperscript{4}Bioptic Laboratory- Ltd., Department of Pathology, Plzeň, Czech Republic

Aims

Dermatofibrosarcoma protuberans (DFSP) is a rare, slow-growing, low-grade tumor of putative dermal fibroblastic origin. It usually involves the trunk and extremities. The incidence rate is reported to be \( \approx 5 \) per 1 million persons annually. The literature reveals a roughly equal sex distribution, with a slight female predominance. The appearance of the tumor depends on the stage of the disease, since the tumor progresses slowly over a long period before entering a rapid growth phase. It is characterized by a reciprocal translocation \( t(17;22)(q22;q13) \) or more often as a supernumerary ring chromosome involving chromosomes 17 and 22. Herein we present a case report of a woman with locally advanced DFSP of the breast.

Method

Immunohistochemistry of the tumor with CD34 and CD10 antibodies, with anticytokeratins CKAE1/3, CK7, CK8/18 and CK19, S100, desmin filament, epithelial membrane antigen, estrogen and progesterone receptors antibodies, and cytoplasmic staining with h-caldesmon, Bcl-2 and p53 protein expression as well as cell surface glycoprotein CD99, cell adhesion molecule CD31, and stem cell factor receptor CD117. The cytogenetic detection of \( t(17;22)(q22;q13) \) in paraffin-embedded tissue samples using gene specific break apart probes COL1A1, PDGFB and dual fusion probe COL1A1/PDGFB by fluorescence in situ hybridization (FISH).

Results

Histopathological and cytogenetic examinations confirmed the diagnosis of DFSP.

Conclusion

DFSP breast involvement is rare. Complete surgical resection is accepted as the optimal local treatment for DFSP. DFSP is considered to be radiosensitive, although the role of adjuvant radiotherapy remains uncertain. The use of tyrosine kinase inhibitors could be effective, but should not be considered curative.

ESGO7-1086

DESMOID-TYPE FIBROMATOSIS OF THE BREAST

K. Pohlodek¹, I. Mečiarová², R. Benej³

¹Comenius University of Bratislava, 2nd Department of Gynecology and Obstetrics, Bratislava, Slovak Republic
²Alpha medical Ltd., Department of Pathology, Bratislava, Slovak Republic
³University Hospital of Bratislava, Department of Thoracic Surgery, Bratislava, Slovak Republic

Aims

Fibromatosis usually occurs in the abdominal wall and superficial muscular-aponeurotic tissues of the extremities. Mammary fibromatosis is a rare and locally aggressive benign tumor of the breast. The etiology of mammary fibromatosis is unknown. Breast imaging examinations are not specific for fibromatosis and often imitate breast cancer. The authors present two case reports of women with breast fibromatosis, one of them with a locally advanced aggressive form of the disease, where breast surgery and en bloc resection of the underlying parts of thoracic wall were needed.

Method

The first patient underwent a right partial mastectomy, with en bloc resection of the underlying musculature and en bloc resection of the underlying chest wall structures. Repeated frozen section examinations during surgery were needed for confirmation / exclusion of chest wall infiltration. The right chest wall defect was then closed with a polypropylene flat sheet mesh. The second patient underwent breast saving surgery with a partial resection of the underlying musculature. Preoperative diagnosis of fibromatosis through core needle biopsy was provided in both cases. A definitive diagnosis of breast desmoid-type fibromatosis was established from serial paraffin sectioning and immunohistochemistry.

Results

The patients are now 10 and 8 months post-surgery and remains disease free.

Conclusion

Breast imaging examinations are not specific for fibromatosis and often imitate breast cancer. CT and/or MRI can help to define the infiltration into adjacent tissue. Immunohistochemical staining for β-catenin is helpful in establishing a diagnosis, but there are no specific immunomarkers for breast fibromatosis. Standard treatment is a wide surgical resection.

COMPLEMENTARY BREAST MAGNETIC RESONANCE IMAGING FOR TUMOR SIZE ASSESSMENT AND SURGICAL PLANNING IN WOMEN WITH EARLY BREAST CANCER

F.C. Pop¹, C. Stanciu Pop², M. Radermeker³, C. Vandemerckt³, D. Noterman¹, M. Moreau⁴, D. Larsimont⁵, J.M. Nogaret¹, I. Veys¹
¹Jules Bordet Institute, Surgery, Brussels, Belgium
²CHU UCL Namur- Université catholique de Louvain- Belgium, Pathology, Yvoir, Belgium
³Jules Bordet Institute, Radiology, Brussels, Belgium
⁴Jules Bordet Institute, Statistic, Brussels, Belgium
⁵Jules Bordet Institute, Pathology, Brussels, Belgium

Aims

The size and the focality of the primary tumor in breast cancer (BC) influence therapeutic decisions. The purpose of this study is to evaluate if preoperative breast magnetic resonance imaging (MRI) is helpful for the assessment of tumor size and for surgical planning in early BC.

Method

We performed a retrospective review of a prospectively collected database of 174 women with invasive BC who had a complete documentation of the tumor size from mammography (MMG), ultrasonography (US), and MRI.

Results

A total of 186 breast tumors were analyzed. The mean tumor size was different by imagistic method: 14.7 mm by MMG, 13.8 mm by US and 17.9 mm by MRI. The concordance between tumor size in breast imaging techniques (BIT) and pathology size with a cut-off +/- 2 mm was 34.8% for MRI, 32.1% for US and 27.2% for MMG. The concordance was the same in premenopausal women for MRI and US at 35%, in postmenopausal women it was higher with MRI. Correlation between size of BIT and histopathological size remain best with MRI (0.59), than US (0.56) or MMG (0.42). MRI examination revealed additional lesions in 13.8% of patients, with 69% malignancy in those lesions. MRI has change the surgical planning in 15 patients (8.6%) with increased mastectomy rate of 6.6%.

Conclusion

MRI can estimate BC size more accurately, but a significant overestimation exists. Complementary MRI examination could improve the concordance for tumor size between BIT and histopathological size with 16.5% and allowed a more appropriate treatment for 8% of patients.
Aims

Aim: The main aim of the present study is to look for some Biomarkers for the diagnosis of Breast Cancer by exploring the Anthropometric, Biochemical and Cytogenetic Techniques.

Method

Method: The study consists of three parameters for which informed consent were taken from each individual. First for the Anthropometric Analysis, "angle of triradius" (atd) of around 100 Breast Cancer patients (age group 18-70 years) along with age matched 100 Healthy Control females were taken (Harold Cummins, 1960). For the Biochemical Analysis, plasma samples of both the groups were studied by running them in cellulose acetate membrane in an Electrophoretic chamber (Robyt, John F, 1990) and any altered plasma protein patterns that were specific for Breast Cancer patients were observed. For the Cytogenetic Analysis, peripheral blood of the same group of individuals were subjected to lymphocyte culture by standard protocol of Moorehead et al., (1964) and chromosomal aberrations were observed by karyotyping.

Results

Result: In the Anthropometric Analysis, Breast Cancer patients were found to be having wider angles (mean 'atd' of 48°) than their healthy counterparts (mean 'atd' of 39°). In the Biochemical Analysis, most patients were found to be having a raised alpha 2 proteins and a gamma globulin pattern of polyclonal origin, while healthy females showed normal protein pattern and in the Cytogenetic Analysis, patients showed a much higher frequency of numerical as well as structural aberrations than the healthy females.

Conclusion

Conclusion: These parameters in combination have a potential to be used as Biomarkers for the diagnosis of breast cancer.

PAPILLARY CARCINOMA OF MALE BREAST: AN UNCOMMON PATHOLOGY OF BREAST CANCER
M. Rezgani¹, O. Adouni², O. Jaidane¹, I. Bettaieb², H. Salhi¹, M. Ghalleb¹, H. Bouaziz¹, H. Bouzaene¹, T. Dhib¹, J. Ben Hassouna¹, O. Gamoudi², K. Rahal¹
¹Institut Salah Azaiez, Departement of oncological surgery, Tunis, Tunisia
²Institut Salah Azaiez, Department of pathological anatomy, Tunis, Tunisia

Aims

Male breast cancers constitute less than 1% of all the breast cancers. Papillary carcinoma is a very rare tumour of the male breast accounting for between 5 and 7.5% in men versus 0.5 and 2.4% in women.

The aim of this study is to investigate the clinico-pathological features and the treatments of papillary carcinoma of the breast in male.

Method

We retrospectively reviewed in this study eleven cases of papillary carcinoma of the male breast treated between 1994 and 2011 at Salah Azaiez institute.

Results

The median age at diagnostic was 65 years. The median tumor size was 45 mm. Ten patients underwent total mastectomy and one has a simple mastectomy because he was initially metastatic (lungs). Only two patients had positive lymph nodes.

Hormonal receptors were positive in five cases.

Four patients were lost of sight during chemotherapy. Five patients completed adjuvant treatment involving local radiation and chemotherapy. Five had hormonal therapy. One patient had a synchrone adenosquamous carcinoma of the papilla of Vater and hepatocellular carcinoma. He was lost of sight after the abdominal surgery.

For the six remaining patients, they had a median follow up of 64 months (range 24 to 150). One developed regional recurrence, three developed metastases and one had adenocarcinoma of the stomach five years after the first cancer.

Conclusion

Papillary carcinomas have an indolent clinical course. The mainstay of treatment in these carcinomas is surgical excision. Furthermore, novel gene panels may serve as a potential decision tool in this rare entity especially in male population.

BREAST LIPOSARCOMA: A REPORT OF FIVE CASES

M. Rezgani1, O. Adouni2, O. Jaidane1, I. Bettaieb2, H. Salhi1, S. Hadded1, M. Chemlali1, H. Bouzaïene1, T. Dhib1, J. Ben Hassouna1, O. Gamoudi2, K. Rahal1

1Institut Salah Azaïz, Department of oncological surgery, Tunis, Tunisia
2Institut Salah Azaïz, Department of Pathological Anatomy, Tunis, Tunisia

Aims

Liposarcoma of the breast constitutes less than 1% of all malignant breast tumours. It may arise within a cystosarcoma or independently from mammary adipose tissue.

The aim of this study is to investigate the clinico-pathological features and the treatments of breast liposarcoma.

Method

We retrospectively reviewed five cases of breast liposarcoma treated in our institution.

Results

The clinical findings are summarized in table 1. The mean age at the time of the biopsy was 56.2 years. Changes in the overlying skin occurred in three patients. Mammography was realized for all patients associated with echography in four cases. They showed a suspicious tumour but no specific signs. Only three patients were regularly seen. Their clinical follow-up mean period is 8.3 years.

MALE BREAST PAGET’S DISEASE: CLINICAL FINDINGS AND MANAGEMENT IN FOUR PATIENTS

M. Rezgani1, O. Adouni2, O. Jaidane1, H. Salhi1, I. Bettaieb2, S. Haddad2, M. Chemlali1, H. Bouzaiane1, T. Dhieb1, J. Ben Hassouna1, O. Gamoudi2, K. Rahal1

1Institut Salah Azaiz, Departement of oncological surgery, Tunis, Tunisia
2Institut Salah Azaiz, Department of pathological anatomy, Tunis, Tunisia

Aims

Mammary Paget’s disease (PD) is an uncommon form of primary breast cancer involving the skin of the nipple and the areola, associated with an underlying in situ or invasive breast carcinoma in most cases. PD in men is extremely rare.

The aim of this study is to investigate the clinical, pathological features and the treatments of PD in male.

Method

We retrospectively reviewed the medical records of four male patients with histologically confirmed PD, treated at “Salah-Azaiz” Institute.

Results

The mean age of our patients is 65.75 years. All patients consulted for a retroareolar breast mass. The median tumour size was 36.25 mm. The nipple was clinically invaded in all cases. All patients underwent total mastectomy. The histology showed an invasive ductal carcinoma associated with Paget disease in all cases. The axillary nodes were metastatic in all patients.

A multicentric tumour was found in two patients. The hormone receptors were positive in all patients. They all had adjuvant treatment including radiotherapy, chemotherapy and hormonal therapy. After a median follow-up of 81 months, two patients presented bone metastasis.

Conclusion

Paget disease is at high risk of multifocal/multicentric underlying tumours. The presence of palpable mass is almost pathognomonic of invasive neoplasm. Because of the relative scarcity of cases in men, no studies have objectively compared treatment techniques in this population. Prognosis is mainly determined by an eventual underlying breast tumour. Additional research is required to further understand the overall pathogenesis and molecular profile of PD to provide improved insight for personalized, precision-based therapeutic options.
Neurofibromatosis type 1, also known as Von Recklinghausen’s disease, is a rare neuroectodermal disease affecting approximately 1 in 3000 of the world population.

Patients with NF1 run a high risk of developing various types of cancers, especially tumors derived from the embryogenic neural crest.

The aim of this study is to investigate the clinical, pathological features of patients associating neurofibromatosis and breast cancer (BC).

Method

We report three cases of North African women diagnosed with neurofibromatosis type 1, who sought treatment at our center for BC.

Results

The clinical findings are summarized below.

<table>
<thead>
<tr>
<th>Patient</th>
<th>Age</th>
<th>Medical history</th>

<td>Mother diagnosed with BC</td>
<td>Mammography screening</td>
<td>T0N0M0</td>
<td>Invasive ductal carcinoma Luminal A N-</td>
<td>Breast-conserving surgery + Radiation therapy + tamoxifen</td>
<td>Absence of local-regional or distant metastasis</td>
</tr>
<tr>
<td>2</td>
<td>38</td>
<td>Right breast lump</td>
<td>T4bN1M0</td>
<td>Invasive ductal carcinoma N+</td>
<td>Neoadjuvant chemotherapy + mastectomy+ axillary lymph node dissection (LND)+ Radiation therapy</td>
<td>Pleural metastasis 6 months post-surgery</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>45</td>
<td>Paternal aunt diagnosed with BC</td>
<td>Right breast lump</td>
<td>T2N1M0</td>
<td>Ductal carcinoma in situ</td>
<td>Mastectomy+ axillary LND</td>
<td>In progress</td>
</tr>
</tbody>
</table>

Conclusion

The association between neurofibromatosis type 1 and BC is uncommon. Detection of BC in patients with NF1 can be difficult because skin changes can mask symptoms of the tumor and the patient can treat new changes in the breast as a manifestation of NF1. Therefore, it is recommended to pay constant, increased oncological supervision in women with neurofibromatosis.
BREAST CANCER

ESGO7-1131

COLLOID CARCINOMA OF A MALE BREAST, A VERY RARE ENTITY

M. Rezgani1, O. Jaidane1, I. Sassi1, O. Adouni2, I. Bettaieb2, M. Chemlali1, H. Bouzaïene1, T. Dhièb1, J. Ben Hassouna1, O. Gamoudi2, K. Rahal1

1Salah Azaiez Institute, Oncological Surgery, Tunis, Tunisia
2Institut Salah Azaiez, Department of pathological anatomy, Tunis, Tunisia

Aims

Male breast cancer is a rare disease. It represents less than 1% of all male neoplasms. Colloid carcinoma, also known as Mucinous or gelatinous, is a rare histological form that represents 1 to 6% of all breast cancers.

The aim of this study is to investigate the clinico-pathological features and the treatments of a colloid carcinoma of a male breast.

Method

We retrospectively reviewed the medical records of a male patient treated in our Institute for a colloid carcinoma of the breast.

Results

A 73-year-old, diabetic and hypertensive patient who consults for a mass in the right breast growing for three weeks. Clinical exam found a suspicious retroareolar mass of 30mm. The mammogram showed a well-circumscribed retroareolar opacity. The tumor was classified T2N1M0. The patient underwent a radical mastectomy after the histological confirmation of malignancy. Histopathological diagnosed colloid mucosal carcinoma of 30mm with 14N -. Hormone receptors was positive. The patient had radiotherapy and a hormonotherapy in adjuvant. 39 months after the treatment a local recurrence appeared triggering further surgery and radiation therapy. The patient, after 83 months of follow-up in good general condition, stopped his check-up visits.

Conclusion

Colloid carcinoma affects a specific population and have a better prognosis than other main types of male breast cancer. The typical mammographic image reminds a “cotton ball”. A well-circumscribed or micro lobular opacity should suggest a colloid carcinoma in an elderly person.

SQUAMOUS CELL CARCINOMA ARISING IN A MALE BREAST, ABOUT A VERY EXCEPTIONNEL CASE
1Salah Azaiez Institute, Oncological Surgery, Tunis, Tunisia
2Salah Aziez Institute, Pathological Anatomy, Tunis, Tunisia

Aims

Metaplastic breast carcinoma are tumors with heterogeneous aspects. They are characterized by an intimate admixture of adenocarcinoma with dominant areas of spindle cell, squamous and/or mesenchymal differentiation. These tumors are rare (0.25 to 1% of breast cancers), very aggressive, akin to the prognosis of the triple negative tumors.

The aim of this study is to investigate the clinico-pathological features and the treatments of a very rare case of a squamous cell carcinoma arising in a male breast.

Method

We retrospectively reviewed the medical records of a male patient treated at the "Salah-Azaiz" Institute for a squamous cell carcinoma of the breast.

Results

A 62-year-old diabetic patient consulted for a right breast lump growing for three weeks. The examination found in the upper outer right quadrant a mass of 45mm. The mammogram showed a suspicious opacity of the right breast and gynecomastia on the left side. The tumor was classified T3N1M0. The patient underwent a radical mastectomy. Histopathological examination diagnosed an encysted infiltrating squamous carcinoma of 52mm, SBR III, 11 lymph N-. Hormone Receptors was positive. The patient had in adjuvant 6 cures of chemotherapy type EC and tamoxifen. After 3 years of regular follow-up, the patient did not show any signs of recurrence although being treated for kidney disease at the stage of dialysis.

Conclusion

Metaplastic carcinomas are characterized by their large size linked to rapid growth. Lymph node metastases are the most pejorative prognosis factor in the evolution of these tumors.

METAPLASTIC BREAST CANCER
S. Sakhri1, Z. Ines1, B. Malek1, A. Olfa2, S. Maher1, H. Monia1, B.H. Jamel1, R. Khaled1
1sala azaiez, surgery, Tunis, Tunisia
2sala azaiez, department of pathology, Tunis, Tunisia

Aims

Metaplastic breast cancer (MBC) is a rare and histologically diverse subtype of breast carcinoma. It accounts for less than 1% of all breast cancers but tend to have a worse prognosis. It is characterized by rapid growth and large size that is not usually seen with more common breast cancer tumors.

The aim of this study is to establish the treatments and the prognosis of this disease. Method

We retrospectively reviewed the clinical records of 6 patients with metaplastic breast cancer treated at Salah Azaiez institute, Tunis, Tunisia, in the period from 2007 et 2014

Results

A total of 6 cases were classified as metaplastic cancer of the breast (MBC). The median age of MBC patients was 50 years old. In 2 cases there is a family history of cancer. All patients were women, 3 patients were postmenopausal. The median size of tumor was 50.8 mm, The right breast is most often reached (4 cases). The breast conservation therapy is used only in few cases (2cas). Metastatic carcinoma to lymph node was seen in 3 cases. All cases were estrogen receptor negative and progesterone receptor negative. 4 cases had nuclear grade II and 3 had nuclear grade III. All the patients had received adjuvant chemotherapy and radiotherapy. The median time of follow-up range was 2 years.

Conclusion

Metaplastic carcinoma of the breast is a rare type of breast cancer that is typically more aggressive and can be subcategorized mainly based on the pathologic findings.

PAPILLARY CARCINOMA OF THE BREAST

S. Sakhri¹, J. Olfa¹, B. Malek¹, S. Hasna¹, L. Olfa², H. Monia¹, B.H. Jamel¹, R. Khaled¹

¹salah azaiz, surgery, Tunis, Tunisia
²salah azaiz, department of pathologic, Tunis, Tunisia

Aims

Papillary carcinoma of the breast is a rare malignant tumor, constituting 1-2% of all breast carcinomas in women. The diagnosis is difficult due to different clinical and radiological features. Pathological diagnosis is conclusive.

Method

We retrospectively reviewed the clinical records of 8 patients treated at Salah Azaiez institute, Tunis, Tunisia, in the period from 2004 to 2010.

Results

A total of 8 cases were classified as papillary Carcinoma of the breast (PC). The median age of PC patients was 51 years old. All patients were women, all women were postmenopausal except for one aged 30 years. The median size of tumor was 35.5 mm. The left side is most often reached (5 cases). All tumors were surgically removed (excision or mastectomy). Metastatic carcinoma to lymph node was seen in 1 case. All cases had negative surgical resection margins. All cases were estrogen receptor positive and progesterone receptor positive. Four cases had nuclear grade I, 3 had nuclear grade II and 1 case had nuclear grade III. All the patients received hormone therapy. 2 patients received adjuvant chemotherapy and radiotherapy. The time of follow-up range was 1–117 months with a median of 36.5 months.

Conclusion

Papillary carcinoma of the breast is a rare entity. Being aware of its unique clinical features and the diagnostic difficulties helps in better management of these patients.

RECURRENT RADIATION-INDUCED BREAST ANGIOSARCOMA
H. Salhi1, M. Slimane1, M. Rezgani1, O. Adouni2, I. Bettaieb2, J. Ben Hassouna1, T. Ben Dhiab1, M. Hechiche1, A. Gammoudi2, K. Rahal1
1salah azaiz, oncologic surgery, Tunis, Tunisia
2salah azaiz, pathology, Tunis, Tunisia

Aims

Angiosarcomas are rare malignant tumours of the vascular endothelium. Secondary angiosarcoma can occur after radical mastectomy or breast-conserving treatment. It may develop in a lymphedematous arm or on irradiated chest wall.

The aim of this study is to investigate the clinico-pathological features and the treatments of a recurrent radiation-induced breast angiosarcoma.

Method

We report a case of a patient, initially treated for breast carcinoma, who developed later an angiosarcoma.

Results

A 40-year-old woman underwent a segmental excision with axillary clearance for a 2.7 cm ductal carcinoma in the outer quadrant of the right breast in 2007. The excision margins and the lymph nodes were free of tumour. Postoperatively, the patient received chemotherapy, hormonal therapy and radiation therapy to a dose of 50 Gy in 25 fractions during 5 weeks to the breast followed by a boost of 14 Gy. In February 2015, the patient was examined once more for a violaceous discoloration lesion of her right breast. An incisional breast biopsy was performed and the specimen was interpreted as an angiosarcoma. A mastectomy was performed.

Six months later, she consulted for a recurrence in the internal end of the mastectomy scar extending to the left breast and axillary lymph nodes. The patient underwent a radical left mastectomy.

The evolution was marked by the appearance of liver and bone metastasis. Currently the patient is under chemotherapy with stabilisation of its disease.

Conclusion

Radiation-induced angiosarcoma is a rare but serious complication of radiation therapy for breast carcinoma, and is associated with poor prognosis.

EWING'S SARCOMA: AN UNCOMMON BREAST TUMOR
M.S. Rhim¹, H. Safî², M. Rezgani¹, A. Didouni¹, O. Jaidane², I. Zemni², J. Ben Hassouna², T. Dhiab², M. Hechiche², A. Haddad¹, K. Rahal², R. Faleh¹
¹Maternity Center, Department of Gynaecology and Obstetrics, Monastir, Tunisia
²Salah Azaiz Institute, Surgical Oncology Department, Tunis, Tunisia

Aims

Ewing's sarcoma/primitive neuroectodermal tumors (EWS/PNET) are rare malignant and aggressive tumors, usually seen in the trunk and lower limbs of children and young adults. They are uncommon in the breast.

Method

We report a case of a 43-year-old woman who developed a painless breast mass.

Results

An initial core needle biopsy concluded to a fibrocystic dystrophy contrasting with a rapidly growing mass; thus a large lumpectomy was done. Diagnosis of primary PNET of the breast was established, based on both histopathological examination and immunohistochemical findings. Surgical margins were positive, therefore, left modified radical mastectomy with axillary lymph nodes dissection was performed. The patient was given 6 cycles of adjuvant chemotherapy containing cyclophosphamide, adriamycin and vincristine. Twenty months later, she is in life without recurrence or metastasis. EWS/PNET may impose a diagnostic challenge. Indeed, mammography and ultrasonography features are non specific. The histopathological patterns variable depending on the degree of neuroectodermal differentiation. Immuno-phenotyping is necessary and genetic study is the only confirmatory tool of diagnosis showing a characteristic cytogenetic anomaly; t (11; 22) translocation.

Conclusion

EWS/PNET are rare tumors developed in the breast, their diagnosis need immunohistochemical and genetic investigations. These ancillary techniques are necessary in order to rule out other types of malignant tumor owing poor prognosis and different way of management.
HUMAN UMBILICAL CORD MATRIX-DERIVED STEM CELLS EXPRESSING INTERFERON-B GENE INHIBIT BREAST CANCER CELLS VIA APOPTOSIS

C.J. Shen¹, C. Chien-Chung²

¹Kaohsiung Medical University Hospital, Gynecology/Obstetrics, Kaohsiung, Taiwan R.O.C.
²E-Da Hospital, Department of Plastic and Reconstruction Surgery, Kaohsiung, Taiwan R.O.C.

Aims

Human umbilical cord mesenchymal stem cells (hUCMSCs) have been reported to be used as anti-tumor gene carrier for attenuation of tumor growth and interferon-β (IFNβ) is known to possess robust anti-tumor effects. The present study was aimed to investigate the anti-tumor effect of IFNβ gene-transfected hUCMSCs (IFNβ-hUCMSCs) on breast cancer cells with emphasis on triple negative breast carcinoma.

Method

1. Effect of hUCMSCs and IFNβ-hUCMSCs co-culture on growth of MDA-MB-231 and Hs578T
2. Effect hUCMSCs or IFNβ-hUCMSCs conditioned medium with or without IFNβ neutralizing antibody on growth of MDA-MB-231 and Hs578T
3. Effect of hUCMSCs or IFNβ-hUCMSCs conditioned medium on the induction of apoptosis in MDA-MB-231 and Hs578T
4. Effect of hUCMSCs or IFNβ-hUCMSCs conditioned medium on caspase cascades in MDA-MB-231 and Hs578T
5. Effect of Jak-Stat pathway in IFNβ-hUCMSCs conditioned medium induced apoptosis

Results

Our findings revealed that co-culture of IFNβ-hUCMSCs with the human triple negative breast carcinoma cell lines MDA-MB-231 or Hs578T significantly inhibited growth of both carcinoma cells. In addition, the culture medium conditioned by these cells also significantly suppressed the growth and induced apoptosis of both carcinoma cells. Further investigation showed that the suppressed growth and the apoptosis induced by co-culture of IFNβ-hUCMSCs or conditioned medium were abolished by pretreating anti-IFNβ neutralizing antibody.

These findings indicate that IFNβ-hUCMSCs triggered cell death of breast carcinoma cells through IFN-β production, thereby induced apoptosis and suppressed tumor cell growth.

Conclusion

We demonstrated that IFNβ-hUCMSCs inhibited the growth of breast cancer cells through apoptosis. With potent anti-cancer activity, it represents as an anti-cancer cytotherapeutic modality against breast cancer.

EXPRESSION DISTRIBUTION OF CANCER STEM CELL MARKER, CD44 WITHIN MOLECULAR SUB TYPES OF BREAST CARCINOMA IN INDIAN PATIENTS
K. Singh¹, M. Jain¹, K. Agarwal¹, O.P. Pathania²
¹Lady Hardinge Medical College, Department of Pathology, New Delhi, India
²Lady Hardinge Medical College, Department of Surgery, New Delhi, India

Aims

To determine cancer stem cell marker, CD44 expression in breast carcinoma and to see the association of CD44 expression with molecular subtypes

Method

N = 60 breast carcinoma patients in the Department of Surgery, LHMC were included between December 2013 till March 2015. Tru-cut biopsy was performed on cytologically proven cases. Immunohistochemistry for ER/PR/Her2/EGFR/Ki67/CK5/CD44 expression was performed.

Results

Mean age of presentation was 48.87±11.43 years. 56/60 (93.33%) were infiltrating duct carcinoma, not otherwise specified. Frequency of molecular subtypes: 13.33% Luminal A, 15.0% Luminal B, 25% Luminal Her2neu, 23.33% Her2neu Classic, 5% Basal phenotype, 18.33% non basal, normal breast like phenotype. Non basal normal breast like phenotype, Basal phenotype and Luminal Her2neu showed statistical significant correlation with age group <50 years (p=0.025). CD44 was positive (>10% positive tumor cells) in 32/60 (53.33%) cases. Significant negative statistical correlation between CD44 positive cases and ER, PR status (p=0.002 and p=0.011 respectively). The mean percentage of Ki67 positive cells in CD44 positive cases was higher (43.34%±27.43) than CD44 negative cases (33.75%±26.34) but was not significant. Significant positive CD44 correlation with Her2neu Classic and normal breast like phenotype subgroup and a significant negative CD44 correlation with Luminal A and Luminal B (p=0.016). No statistical significant correlation when CD44 positive molecular subtypes were scored 1+, 2+ and 3+ (p=0.131)

Conclusion

Higher number of CD44 positive cells in triple negative and Luminal Her2neu cases and lower in luminal subtype emphasize the tumor aggressiveness in Indian patients. CD44 can be used as independent marker and as target for development of novel therapies.

³UCL - University College London, Department of Women's Cancer, London, United Kingdom
⁴ONCOTYROL - Center for Personalized Cancer Medicine, Division of Health Technology Assessment and Bioinformatics, Innsbruck, Austria
⁵Harvard Medical School, Institute for Technology Assessment and Department of Radiology- Massachusetts General Hospital, Boston, USA
⁶Harvard T.H. Chan School of Public Health, Center for Health Decision Science- Department of Health Policy and Management, Boston, USA

Aims

To review cost-effectiveness studies evaluating primary and secondary prevention strategies for breast cancer in the European health care setting with specific interest on risk-adapted strategies.

Method

Relevant databases (Medline/Embase/Cochrane Library/CRD/EconLit) were systematically searched for decision-analytic modelling studies evaluating the cost-effectiveness of breast cancer screening and/or prevention strategies in the European health care context. Study characteristics, methodological details and results including the incremental cost-effectiveness ratios (ICER) in cost per quality-adjusted life years gained (QALY) or per life year gained (LYG) were extracted into standardized evidence tables. Economic results were converted to 2015 Euros using the GDP-PPP and CPI.

Results

Twenty five studies evaluating breast cancer screening and two studies evaluating breast cancer prevention strategies were included. The studies varied in terms of target population and evaluated strategies, time horizon, discount rate, and perspective. Among the screening studies, only one considered a risk-adapted screening approach. In all studies the ICERs of currently established breast cancer screening strategies, like biennial or triennial mammography screening age 50-70, fall far below 30,000 Euros/QALY or LYG, which is considered to be cost-effective in most European countries. Prevention studies considered women at high risk for breast and ovarian cancer evaluating prophylactic surgery in BRCA mutation carriers or genetic testing in Ashkenazi Jewish women with prophylactic surgery for mutation carriers. Results suggest that prevention in these populations is cost-effective.

Conclusion

Based on the included studies, breast cancer screening and prevention can be considered cost-effective in the European setting. Future research should include risk-adapted screening and prevention strategies.

REAL-TIME ULTRASOUND ELASTOGRAPHY OF AXILLARY LYMPH NODES IN CLINICALLY NODE NEGATIVE BREAST CANCER

P. Kleditzsch¹, T. Reimer¹, S. Hartmann¹, J. Stubert¹, B. Gerber¹, A. Stachs¹

¹Universitätsmedizin, Breast Department, Rostock, Germany

Aims

Axillary lymph node status remains an important prognostic factor in early breast cancer. Ongoing studies i.e. INSEMA trial deal with the question whether sentinel lymph node biopsy (SLNB) can be avoided without reducing oncological safety. The aim of this study was to evaluate real-time ultrasound elastography for prediction of axillary lymph node metastases in patients with planned SLNB.

Method

In this prospective study 97 patients undergoing breast surgery with SLNB were included. Before surgery, all patients underwent axillary ultrasound with measuring of cortical thickness and elastography of axillary lymph nodes using a high end ultrasound device (Philips iU22). Elastographic strain ratio (SR) was determined and results were compared to histological findings of the removed lymph nodes.

Results

Axillary metastases were found in 33 of 97 patients (34%). The stiffness measurements were significantly different between the group of nodal negative and nodal positive patients (SR mean p= 0.016, SR max p=0.009). The areas under the ROC curves were 0.66 (95% confidence interval [CI]: 0.54-0.79) for SR mean, 0.68 (95% CI 0.56-0.80) for SR max and 0.58 (95%CI 0.45-0.72) for cortical thickness, respectively. Sensitivity/specificity/positive predictive value and negative predictive value were 74.1%/50.9%/41.7% and 80.6% for SR max in comparison with subjective axillary ultrasound evaluation, which reached 33.3%, 98.4%, 91.7% and 74.1%.

Conclusion

In a subgroup of patients with low prevalence of lymph node metastases elastographic strain ratio could improve diagnostic performance of axillary ultrasound by increasing sensitivity and negative predictive value. Further studies with higher number of cases are necessary to confirm these promising results.
RELATIONSHIP QUALITY AFTER BREAST CANCER RECONSTRUCTIVE SURGERY: A PROSPECTIVE FOLLOW UP STUDY

D. Vaidakis¹, N. Poulakaki², G.M. Makris¹
¹Euroclinic Athens, Gynecological Department, Athens, Greece
²Euroclinic Athens, Breast unit, Athens, Greece

Aims
The aim of the present study is to evaluate the effect of reconstructive surgery on relationship quality in women undergoing operation for breast cancer.

Method
We prospectively studied 22 women diagnosed with invasive breast cancer. In half of them, an oncoplastic procedure was performed, while in the rest, only lumpectomy was applied. Twenty-two patients were operated for benign breast lesions, matched for demographic characteristics (control group). In all participants, the comradeship dimension of relationship quality were evaluated at the time of diagnosis and a year postoperatively.

Results
A significant improvement of the “comradeship” and “emotional proximity” dimensions were observed in the study group compared to the control group (4.96±3.35, 5.03±3.85 respectively), but the degree of improvement was greater among older patients in the cancer group (6.35± 3.48, 6.02± 3.84 respectively) (p=0.022, p= 0.147 respectively). Both “relationship quality” and “body image” scores were significantly higher in the reconstruction compared to the no-reconstruction group among younger patients. There was a significant negative correlation between “relationship quality”, “sexual function” and “emotional proximity” (p<0.001).

Conclusion
The psychological effect of cancer diagnosis and treatment seems to explain the observed influence on companionship dimension of relationship quality. Among younger patients, reconstructive surgery improves patient’s satisfaction of body image and self-esteem on the contrary among older patients their relationship is based on comradeship and emotional proximity.

HOW IMPORTANT ARE TUMOR MARGINS OF THE DUCTAL CARCINOMA IN SITU, AN EARLY FORM OF BREAST CANCER? FINE-TUNING OF THE VAN NUYS PROGNOSTIC INDEX

A. Van Cleef1,2, A. Sevilay1, M. Huizing1, W. Tjalma1
1Antwerp University Hospital UZA, Oncology, Edegem, Belgium
2University of Antwerp, Medicine and Health Sciences, Antwerp, Belgium

Aims

We investigated whether the Van Nuys Prognostic Index (VPNI), prospectively applied, is a reliable guideline for the treatment of patients with ductal carcinoma in situ (DCIS) in our hospital. Furthermore, we are going to try to refine the VPNI and thus also our policy. We will do this by using the combination of the obtained VPNI and the more specific score of the tumor margins. Our goal is to keep local recurrence rate less than 20% at 12 years.

Method

From 2004 to 2014, 142 patients diagnosed, treated and followed at the University Hospital of Antwerp are included in our analysis. Exclusion criteria are male gender, treatment with chemo- or endocrine therapy and invasive cancer. Kaplan-Meier plots were used to estimate the probability of remaining free of local recurrences. The statistical significance between the survival curves was determined by the log-rank test.

Results

108 patients were treated according to the VPNI. The local recurrences were 6%, 4% and 4% for group 1, 2 and 3, respectively. The local recurrences in the subgroup of patients who score 9, have margins < 1 mm and were treated with excision and radiotherapy was 20%.

Conclusion

With low numbers of local recurrences we can conclude that the VPNI is a reliable guideline for the treatment of patients with pure DCIS. Mastectomy is required for patients who score 9 and have margins < 1 mm and for all patients who score 10, 11, or 12 to keep the local recurrence rate less than 20% at 12 years.

STATHMIN, A PREDICTIVE BIOMARKER FOR TAXANE RESPONSE IN BREAST CANCER?
S. knappskog¹, K.K. Mauland², E. Hoivik², H.B. Salvesen², J. Trovik², P.E. Lønning¹, H.M. Werner³
¹University of Bergen, Section of Oncology- Department of Clinical Science, Bergen, Norway
²University of Bergen, Center for Cancer Biomarkers CCBIO - Department of Clinical Science K2, Bergen, Norway
³Haukeland University Hospital, Department Of Gynaecological Oncology, Bergen, Norway

Aims

There are no clinically applicable predictive biomarkers for taxane response in (breast) cancer. Stathmin, a critical modulator of microtubule dynamics, has been suggested in preclinical and retrospective studies. We aimed to investigate if stathmin (STMN) or phosphostathmin (pSTMN) expression are linked to response to paclitaxel in a large breast cancer series, and if such treatment response effects are mirrored in differences in survival.

Method

We used data from an open label multicentre study with long follow-up including 223 patients. Patients were stratified to either paclitaxel (n=114) or epirubicin (n=109) neoadjuvant monotherapy prior to surgery/radiation. STMN and pSTMN levels were determined by immunohistochemistry and mRNA expression levels. Response was graded by the UICC system. Immunohistochemistry data for hormone receptors (oestrogen and progesterone) were available. An independent dataset (GSE21997) with mRNA microarray data (STMN005563) was used for validation.

Results

High STMN/pSTMN expression was associated with improved response to paclitaxel (p=0.04; p=0.006), but not epirubicin treatment. Subgroup analysis showed this effect was more pronounced in hormone receptor positive patients (p=0.008 and p=0.005). However, high STMN expression was associated with worse recurrence free and disease specific survival in paclitaxel (p=0.04; p=0.03) but not epirubicin treated patients (p=0.40; p=0.73). The independent dataset confirmed a lower residual cancer burden in patients with high vs. normal stathmin levels after paclitaxel but not doxorubicin treatment (p=0.01; p=1.00).

Conclusion

High STMN/pSTMN levels are associated with improved response to paclitaxel but not epirubicin treatment. This effect is enhanced in hormone receptor positive patients. However, high stathmin levels are associated with worse survival.

EXTENDED-FIELD RADIOTHERAPY WITH CONCURRENT CHEMOTHERAPY (EXTENDED-FIELD CCRT) FOR CERVICAL CANCER WITH PARA-AORTIC OR HIGH COMMON ILIAC LYMPH NODE INVOLVEMENT

M. Nishimura1, M. Irahara1, A. Abe1

1Tokushima University Hospital, Obstetrics and Gynecology, Tokushima, Japan

Aims

Lymph node metastasis in cervical cancer is a potentially important risk factor for recurrence. For cases of suspected para-aortic lymphadenopathy or high common iliac lymph node involvement, extended-field radiotherapy was applied. The present study aimed to retrospectively evaluate the efficacy of extended-field CCRT as primary treatment.

Method

Between January 2010 and December 2014, 26 patients with cervical cancer positive for para-aortic and/or high common iliac lymphadenopathy were treated with extended-field CCRT at our hospital.

Results

The median age was 56 years (range, 30-75), and the median size of the tumors was 55.5 mm (range, 27-106). The distribution of stage was as follows: Ib2, n=2; IIb, n=6; IIIa, n=2; IIIb, n=16, and MA, n=15. The 2- and 5-year OS rates were 86% and 52%, respectively. Eleven patients had a recurrence. Adjuvant therapy was administered to 12 patients (9 in MA), and TC therapy was administered monthly for 3 cycles after extended-field CCRT. Three patients had a recurrence (locoregional failure, n=2; distant recurrence, n=1). The other 14 patients were treated without adjuvant chemotherapy, of whom 8 had a recurrence (locoregional failure, n=4; distant recurrence, n=4). No significant differences were found in PFS or OS between the patients treated with and those treated without adjuvant chemotherapy (p=0.546 and p=0.895, respectively).

Conclusion

Extended-field CCRT appears effective as reported in previous studies. When followed by adjuvant chemotherapy, it decreased the incidence of distant recurrence. However, owing to the small number of cases in this study, the benefits of extended-field CCRT to PFS and OS could not be observed.

ADJUVANT SMALL FIELD PELVIC RADIATION AFTER RADICAL HYSTERECTOMY AND PELVIC LYMPHADENECTOMY IN SELECTED PATIENTS WITH EARLY STAGES CERVICAL CANCER

K. Adabi, F. Yarandi, E. Shir ali, M. Mohseni, N. Saedi, M. Tabatabaeifar, B. Mahmoudian

1Yas Women Hospital- Tehran University of Medical Sciences- Iran, Ob/Gyn, Tehran, Iran
2Yas Women Hospital- Tehran University of Medical Sciences- Iran, Ob/Gyn oncology department, Tehran, Iran
3Imam Hossein Hospital- Shahid Beheshti University of Medical Sciences- Tehran- Iran, Department of Radiotherapy-Oncology, Tehran, Iran
4Tabriz University of medical sciences, Physical medicine and rehabilitation, Tehran, Iran

Aims

In a retrospective cohort study we have evaluated the role of small field (SF) pelvic radiotherapy as adjuvant therapy, in stages 1a2, 1b and 2a FIGO cervical cancer following radical hysterectomy and pelvic lymphadenectomy.

Method

Sixteen women with stage 1b and 2a cervical cancer treated by radical hysterectomy plus pelvic lymphadenectomy, who were considered to be at intermediate risk for recurrence on basis of clinicopathological findings, between 2003-2013 in Yas Hospital Tehran University of Medical Science, were enrolled in our study. These patients were treated by small field pelvic radiation and were followed for average 48.5 month. Their complications and physical exam were recorded. Small field radiotherapy morbidities are compared with standard radiotherapy morbidities in 28 patients with high risk prognostic factors who were treated by radical hysterectomy and adjuvant standard pelvic radiotherapy.

Results

Mean age of these patients is 44.6 ±8.8 and mean follow up duration was 48.5±33 months. In small field group one case was recurred (6.3 %) and two patients had minor morbidities (12.5 %). In standard radiotherapy group, 4 cases were recurred (14.3%) and 6 cases were reported with minor morbidities (21.4%). Although, morbidities in standard pelvic radiotherapy was higher than small field group, this difference was not statistically significant. In our series, 5 cases from 54 patients had recurrence.

Conclusion

Small field pelvic radiotherapy as adjuvant therapy can be useful without enhancing serious morbidity in selected cases of cervical cancer with intermediate clinicopathological risks for recurrence.

SURGICAL VIDEO OF LAPAROSCOPIC RADICAL TRACHELECTOMY (LRT)

M. Adishesh\textsuperscript{1}, B. Decruze\textsuperscript{1}

\textsuperscript{1}Liverpool Women's Hospital, Gynaecology, Liverpool, United Kingdom

Aims

Radical trachelectomy is one of the fertility sparing treatment options for women with early cervical cancer. The first report on laparoscopic radical trachelectomy was presented in 2005. Kim et al 2010, described their procedures were performed by a laparoscopic approach except for vaginal resection and cervical amputation, which were performed by the vaginal approach. Minimal invasive technique has advantages such as reduced length of hospital stay, less blood loss, lower analgesic requirements during the postoperative period, a decrease in the rate of blood transfusions, a decrease in the rate of complications, an early recovery of physiological functions, and better aesthetic outcomes. Our main aim is to describe the technique we use for laparoscopic radical trachelectomies.

Method

Careful and thorough assessment pre operatively or consideration of LRT

Surgical technique:

Laparoscopic approach:

1. Insertion of Uterine manipulator
2. Number of Ports and placements
3. Pelvic lymph node dissection
4. Identifying structures and creating spaces
5. Uterine Artery
6. Vaginal cuff

Vaginal approach:

1. Cervical canal length
2. Amputation of cervix
3. Cervical cerclage
4. Anchoring of vaginal wall to the lower part of the uterine body.

Results

We have performed 3 laparoscopic radical trachelectomies using this technique and women have recovered well and been discharged on the first postoperative day. None of these women needed to undergo any additional treatment.

Conclusion

LRT is a safe and feasible surgical option for women wishing to preserve fertility, but thorough assessment of women and detailed pre operative counselling in addition to trained surgeons are very important.

11Rigshospitalet Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark
12Arizona Oncology US Oncology Network- Gynecologic Oncology at University of Arizona and Creighton University, Gynecologic Oncology, Arizona, USA

Aims

Persistent, recurrent metastatic cervical cancer (PRmCC), largely due to infections with high-risk types of HPV, remains an area of high unmet need for patients progressing after ≥1 line of systemic chemotherapy. ADXS DUAL is an irreversibly attenuated Listeria monocytogenes immunotherapy that secretes a fusion protein, containing both HPV-16 and HPV-18 E7, that induces HPV-specific cytotoxic T-cell generation while reducing immune suppression in the tumor microenvironment. Nivolumab is a programmed death receptor-1 (PD-1) blocking antibody. Preclinical models demonstrated synergistic mechanisms of action and improved tumor elimination when ADXS was combined with a PD-1 inhibitor. In separate clinical studies with PRmCC patients, both ADXS and nivolumab were well tolerated and both have shown anti-tumor activity. This randomized, active-controlled, open-label study will compare the efficacy/safety of ADXS DUAL+ Nivolumab to single-agent chemotherapy in PRmCC patients who failed first-line treatment, with/without bevacizumab.

Method

Eligible patients must have metastatic squamous or non-squamous cell, adenocarcinoma or adenosquamous carcinoma of the cervix. Approximately 400 patients will be enrolled: 300 will be randomly assigned (1:1) to receive ADXS-DUAL + Nivolumab or investigator’s choice of protocol-approved single-agent chemotherapy. An additional 100 patients will also receive (1:1) ADXS-DUAL or Nivolumab monotherapy to characterize the contribution of each. Primary objective is to compare duration of overall survival of the combination versus single-agent chemotherapy; secondary objectives are ORR, PFS (RECIST 1.1), milestone OS rate, and safety. The trial requires ≥ 273 deaths from the combination and single-agent chemotherapy arms to ensure 85% power to detect a statistically significant difference.

DORSAL RHIZOTOMY FOR INTRACTABLE PAIN FROM NEOPLASTIC LUMBOSACRAL PLEXOPATHY IN ADVANCED CERVICAL CANCER

J.H. Ahn¹, B.C. Son², S.I. Kim³, M.J. Song³, S.J. Lee¹, J. Yoon¹

¹St. Vincent’s Hospital- College of Medicine- The Catholic University of Korea, Department of Obstetrics and Gynecology, Suwon-si- Gyeonggi-do, Republic of Korea
²Seoul St. Mary’s Hospital - The Catholic University of Korea, Department of Neurosurgery, Seoul, Republic of Korea
³Daejeon St. Mary’s Hospital - College of Medicine- the Catholic University of Korea, Department of Obstetrics and Gynecology, Daejeon, Republic of Korea

Aims

The present study seeks to find out the effectiveness of selective dorsal rhizotomies for intractable pain from neoplastic lumbosacral plexopathy in terminal cervical cancer patients.

Method

Dorsal rhizotomies of the involved segments were performed on 6 cervical cancer patients in whom neuropathic pain from lumbosacral plexus involvement in terminal cervical cancer had been refractory to other therapies. Clinical efficacy of the procedure was assessed by comparing patient pain ratings and narcotic usage before and after dorsal rhizotomy.

Results

Examination of the results indicated a significant reduction in pain ratings as well as a significant reduction in daily narcotic use. No adverse neurological effects were observed and no recurrence of pain from neoplastic lumbosacral plexopathy was noted.

Conclusion

These findings provide corroborating clinical evidence for the effectiveness of selective dorsal root rhizotomy for the intractable pain from lumbosacral plexopathy in terminal cervical cancer patients.

METASTATIC BREAST CANCER IN UTERINE CERVIX LEADING PROLONGED VAGINAL BLEEDING: A RARE CASE

I. Alanbay1, M. Oztürk2, K.E. Karaşahin3, S. Bodur3, F. Kinct3

1Gulhane Training and Research Hospital, Obstetric and Gynecology, Ankara, Turkey
2Bakirkoy Sadi Konuk Training and Research Hospital, Obstetric and Gynecology, Istanbul, Turkey
3Gulhane Training and Research Hospital, Obstetric and Gynecology, Ankara, Turkey

Aims

Metastasis to cervix from a primary breast cancer is extremely rare. Most cases have been diagnosed in the follow-up of known cases of breast carcinoma. Although metastasis may occur as a disseminated disease or as an isolated involvement of cervix, most cases had disseminated disease at the time of diagnosis of cervical involvement. Patients usually present with abnormal bleeding, pain, and dyspareunia.

Method

We present a case of involvement of the uterine cervix in a patient with previously diagnosed breast cancer.

Results

The patient was a 46-year-old with a history right-sided intraductal carcinoma of the breast who underwent mastectomy. The patient was treated by adjuvant radiation and chemotherapy therapy. The patient had no history of gynecologic problems, including previously normal pap smears. She began to have prolonged vaginal bleeding. Clinical examination raised the suspicion of cervical neoplasia. The cervix was approximately 4 cm wide and abnormal in appearance of barrel-shaped cervix. Computed tomography revealed the 4 cm cervical mass. Cervical biopsy showed infiltrative malignant tumor with cytologic features similar to those observed in the breast biopsy specimen.

Conclusion

We would recommend detailed gynecological examination as an important part of the follow-up investigations in women with primary breast cancer. We should keep in mind that any abnormal bleeding may be caused by cervical involvement of breast cancer. In this case, local control of bleeding has been reported with the use of radiation therapy, hysterectomy, uterine artery embolization, and conization.
CERVICAL CANCER

ESGO7-0952

ENDOMETRIOTIC CERVICAL MASS SIMULATING A MALIGNANT LESION: A CASE REPORT
M. Alcalà Lorente¹, M. Del Pino¹, I. Nicolás¹
¹Hospital Clinic, Obstetrics and Ginecology, Barcelona, Spain

Aims

The patient was a 55-year-old woman referred for an abnormal uterine bleeding in the last month and anemia.

Method

On speculum examination a necrotic cervical mass of about 5cm was identified protruding through the external cervical orifice. Parametrium was free.

Ultrasound examination revealed a poorly defined cystic mass (5 cm in diameter) in the endocervical canal arising from the endometrial cavity with abundant signal observed on color Doppler examination.

Histologic examination of biopsy revealed secretory endometrium with fibrous stroma compatible with endometrial polyp.

Magnetic resonance imaging demonstrated a heterogeneous mass of 6x5x4.5 cm, affecting the ectocervix and extending to the parametrium, bilateral round ligament and the upper third of the vaginal wall.

Serum cancer antigen 125 level was elevated to 130 U/mL.

Results

A total hysterectomy and double anexectomy was performed. Histopathologic examination showed severe cervical endometriosis. Absence of malignancy.

Conclusion

Endometriosis is a common benign gynecologic disorder. The previously reported ratio is 0.11-2.4%.

It usually affects pelvic genital organs. Cervical endometriosis is rarely seen and the main symptoms are vaginal and postcoital bleeding. However, most cases are asymptomatic. On speculum examination, we can see small bluish or fresh red nodules but it also could be a mass and appear like a cyst, polyp, or fibroma. That's why, the diagnosis is difficult and usually is found retrospectively on histopathologic reports.

If we find a mass involving the cervix we have to consider benign disorders and malignancy.

There are few previous reports of cervical endometriosis and there is a retrospective review. Excision is the most commonly used method.
CERVICAL CANCER

ESGO7-0831

LAPAROSCOPIC EXTRAPERITONEAL PARA-AORTIC LYMPH NODE DISSECTION IN LOCALLY ADVANCED CERVICAL CANCER

M.M. Naki, F. Alkhan, E. Karabuk, M. Gungor, M.F. Kose

1Acibadem Atakent University Hospital, Obstetrics and Gynecology, Istanbul, Turkey
2Acibadem Maslak Hospital, Obstetrics and Gynecology, Istanbul, Turkey

Aims

To demonstrate step-by-step laparoscopic extraperitoneal para-aortic lymph node dissection

Method

A 56-year-old lady, smoker, presented with postcoital bleeding. Speculum examination showed a cervical growth measuring around 4 cm. The Right parametrium was obliterated. Biopsy result showed non-keratinizing squamous cell carcinoma. Patient was staged as stage IIB and planned for laparoscopic extraperitoneal para-aortic lymph node dissection. Laparoscopic extraperitoneal paraaortic lymph node dissection performed. The 1st trocar inserted in the umbilicus to explore the abdominopelvic cavity. Then an incision made 3 cm above the anterior superior iliac spine till the fascia reached. Gently finger inserted and the peritoneum dissected along the psoas muscle. When adequate space opened, a trocar inserted and gas insufflated, the 3rd and the 4th trocar inserted in the axillary line. The trocar tip should blunt to avoid any tear in the peritoneum which will compromise the procedure. The gas is released from the abdomen. At the end of the procedure an opening done in the peritoneum to avoid the formation of lymphocele.

Results

Patient was discharged on the 2nd day. The final histopathology results showed no paraaortic lymph node metastasis. Patient was posted for pelvic EBRT, brachytherapy and chemotherapy.

Conclusion

Laparoscopic extraperitoneal paraaortic lymph node dissection is feasible. Also it will allow to start the treatment faster
IMAGE GUIDED BRACHYTHERAPY IN CERVICAL CANCER: PROGRAM INITIATION, LEARNING CURVE AND RESULTS

M. Anttila1, P. Palmgren2, E. Jääskeläinen1
1Kuopio University Hospital, Dept. of Obstetrics & Gynecology, Kuopio, Finland
2Kuopio University Hospital, Cancer Center, Kuopio, Finland

Aims

To report our 10 years’ experience and learning curve of the treatment of cervical cancer patients with chemo/radiotherapy and image guided, high dose rate (HDR) brachytherapy (BT) with combined intracavitary/interstitial (IC/IS) applicators.

Method

Ninety one consecutive patients with cervical cancer were treated between 2007 and 2016. Patients received external beam radiotherapy ± chemotherapy followed by a HDR BT boost. The first 8 patients were treated according CT- and rest with MRI-based plans. Contouring was done according to the GEC-ESTRO recommendations. 85% had stage IIB-IV disease. The mean tumor diameter was 5.5 cm, 40% had mean tumor volume over 40cm³, and 60% had metastatic lymph nodes. 82% patients were treated with IC/IS technique.

Results

Overall, the mean D90 for the HR-CTV were 90 Gy (Fig. 1). There was a learning curve of 16 patients to reach D90 of 85 Gy. Mean needle count per application was five. At a mean follow-up of 34 months, local control rate for all patients was 90%. The overall survival at 3 years was 59%. Patients with D90 over 85 Gy had better prognosis (p=0.028).

Conclusion

Although the majority of the patients presented with advanced disease, excellent local control rate were achieved. Combined IC/IS brachytherapy enables adequate dose for D90 HR-CTV.
KNOWLEDGE OF THE LEBANESE POPULATION TOWARDS HUMAN PAPILLOMAVIRUS AND ITS IMPLICATION IN CERVICAL CANCER

D. Atallah¹  M. Moubarak²  N. El Kassis¹  G. Chahine³  S. Abboud⁴  
¹ Obstetrics and Gynecology, Beirut, Lebanon  
² Saint Joseph University, Obstetrics and Gynecology, Beirut, Lebanon  
³ Saint Joseph University, Oncology, Beirut, Lebanon  
⁴, Beirut, Lebanon

Aims

To evaluate the knowledge of Lebanese women concerning the Human Papillomavirus (HPV), its implication in cervical cancer as well as the screening methods and vaccination. To measure the pap smear and HPV vaccination uptake and to determine the factors influencing them in the same population.

Method

We have recruited randomly Lebanese women over 18 years old, residing in the greater Beirut area and with no medical history. 444 women were asked to fill out a questionnaire composed of 33 questions evaluating their knowledge about HPV and cervical cancer.

Results

14.4% had not heard of cervical cancer and 64.4% had not heard of HPV. Of those who did, 80.4% thought their information was lacking. Only 54.4% and 64.6% were aware of screening tests and vaccination for HPV respectively and over 50% could not correctly identify true facts about HPV, its diagnostic tests and vaccination. Only 37.6% had had a pap smear at least once in their lifetime whereas 9% did not know what a Pap smear was. Screening was significantly associated with cervical cancer awareness and regular visits to a gynecologist (p<0.001). Only 11.7% of participants aged between 18 to 26 years were vaccinated against HPV. Vaccination uptake was significantly associated with religion (p = 0.021), profession (p = 0.03) and regular visits to a gynecologist (p = 0.022).

Conclusion

Lebanese women are not well informed about HPV and cervical cancer. Screening by Pap smear and HPV vaccination uptakes are non-satisfactory. Further interventions are required in order to improve these numbers.
METASTATIC CERVICAL SQUAMOUS CELL CARCINOMA OF THE OVARY
M. Awad¹, F. Drewa¹, R. Jones¹, E. Rzysca¹, R. Howells¹, K. Lim¹, A. Sharma¹
¹University Hospital of Wales, Gynaecology, Cardiff, United Kingdom

Aims

To raise the awareness of late rare metastatic presentations of squamous cell carcinoma of the cervix.

Method

We report one case of a patient with a late recurrence in form of a multi-cystic ovarian mass, who was diagnosed with occult stage I squamous cell carcinoma of the cervix following a simple hysterectomy for CIN3.

Results

A 43 years old patient underwent a cervical cone biopsy for CIN III. Her follow-up smear revealed mild dyskaryosis. Subsequently, she was offered an ovary sparing simple hysterectomy with resection of a vaginal cuff. The histopathological report showed occult stage IAI squamous cell carcinoma with clear resection margins. Following discussion in the loco-regional MDM, it was decided no further adjuvant therapy was indicated.

Nine years following this episode, radiological investigations for vague bowel symptoms and weight loss revealed a right sided multi-cystic ovarian mass as well as and an ileocaecal mass.

A right hemicolecction, bilateral salpingo-oophorectomy and omental biopsy was performed in University hospital Wales.

The post-operative histopathology diagnosed metastatic squamous cell carcinoma of the right ovary and caecum secondary to occult cervical carcinoma. No evidence of teratoma or endometriosis was found. The patient chose to defer her palliative chemotherapy but became unwell with sepsis and subsequently passed away 12 months following the recurrence of her cervical cancer.

Conclusion

Metastatic cervical squamous cell carcinoma to the ovary is infrequent compared to adenocarcinoma of the cervix or from other extraovarian primaries. Unilateral multicystic ovarian tumours should prompt the clinician to exclude recurrence of the primary tumour.

CERVICAL CANCER

ESGO7-0507

SYNCHRONOUS NEUROENDOCRIN TUMOUR OF THE CERVIX AND BREAST DUCTAL CARCINOMA
H. Aydin1, Z. Bayramoglu2, H.E. Pestereli2, G. Erdogan2, T. Simsek1
1Akdeniz University, Gynecologic Oncological Surgery, Antalya, Turkey
2Akdeniz University, Medical Pathology, Antalya, Turkey

Aims

Breast and cervical cancer are the two most common cancers in female. However, synchronous breast and cervical cancer has very rarely been reported. We report such a case of 44 year old woman who has synchronous breast and cervical cancer.

Method

A 44 year-old woman presented with prolonged menorrhagia and a 4x5 cm painless lump in the right breast for the last 8 months. She was multipara and has smoking history. A cervical biopsy was done and showed a large cell high grade neuroendocrine tumours of the cervix. Examination of the right breast showed a 5 cm firm palpable mass in the upper outer quadrant which was not fixed to the skin or chest wall. Axillary examination on the right side revealed a single mobile 1.2 x 0.8 cm lymph node. A breast ultrasound and mammogram were reported as BIRADS V. A Tru-cut biopsy of the right breast mass revealed an Infiltrating Ductal Carcinoma. She underwent radical hysterectomy, bilateral salpingo-oophorectomy, bilateral pelvic lymph node dissection, modified radical mastectomy with axillary dissection. She was thus staged as pT2N2 and planned for four cycles of adjuvant chemotherapy with cyclofosfamide (600 mg/m2) and doxorubicin (60 mg/m2) on day 1; to be repeated every 21 days.

Results

Despite cancer of breast and cervix being among the common malignancies in females, they have diverse etiological factors.

Conclusion

We herein decided to treat our patient with curative intent in view of early stage of disease at both sites.

ISOLATED UPPER ABDOMINAL METASTASIS AFTER SURGICALLY TREATED CERVICAL CANCER

I. Balescu¹, N. Bacalbasa²
¹Ponderas Academic Hospital, Visceral Surgery, Bucharest, Romania
²Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania

Aims

To report the case of a 45-year-old patient who was diagnosed with a solitary splenic metastasis at two year follow up after surgically treated cervical cancer.

Method

The patient was initially submitted to neoadjuvant radiotherapy followed by radical hysterectomy with bilateral adnexectomy and lymph node dissection for stage IIB cervical cancer.

Results

At two year follow up she was diagnosed with an isolated splenic recurrence so a splenectomy was performed (Figures 1,2).
The histopathological studies confirmed the cervical origin.

**Conclusion**

Although not commonly reported, isolated upper abdominal metastases from cervical cancer might develop and seem to be best managed through a radical surgical manner.
SEGMENTAL RESECTION OF THE EXTERNAL ILIAC VEIN FOR PELVIC RECURRENCE AFTER SURGICALLY TREATED CERVICAL CANCER

I. Balescu¹, N. Bacalbasa²

¹Ponderas Academic Hospital, Visceral surgery, Bucharest, Romania
²Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania

Aims

To exemplify the benefits of radical resections for pelvic recurrences after cervical cancer

Method

A 67-year-old patient who had been previously submitted to surgery for stage IIIA pre-irradiated cervical cancer was diagnosed with a pelvic recurrence invading the right ureter and the right external iliac vein.

Results

The recurrent tumor was successfully resected en bloc with the invaded vascular and urinary structures. The continuity of the urinary tract was re-established by ureteral reimplantation while the iliac vein was laterally sutured without any graft interposition (Figures 1-3).
At one year follow up the patient is free of recurrent disease.

**Conclusion**

Although vascular invasion has been considered for long time as a contraindication for pelvic recurrent tumors resection, it seems that it can be safely performed and can improve survival.
THE UTILITY OF THE ILEOCOLIC SEGMENT FOR URINARY TRACT RECONSTRUCTION AFTER SURGERY FOR LOCALLY ADVANCED CERVICAL CANCER

N. Bacalbasa¹, I. Balescu²
¹Carol Davila University of Medicine and Pharmacy, Obstetrics and Gynaecology, Bucharest, Romania
²Ponderas Academic Hospital, Visceral surgery, Bucharest, Romania

Aims

To illustrate the utility of the ileocolic segment for urinary tract reconstruction after surgery for locally advanced cervical cancer with urinary bladder invasion

Method

We present a case series of five patients in whom the ileocolic segment was successfully used for urinary bladder reconstruction

Results

In one case an anterior pelvic exenteration was performed and a neo-bladder was created from the ileocolic segment in which the two ureters were reinserted. In the other three cases a partial cystectomy was needed, so the volume of the remnant urinary bladder was augmented by using the ileocolic loop while the ureters were re-inserted in the digestive segment (Figures 1,2,3).
The postoperative outcome was uneventful in all cases.

Conclusion

The ileocolic segment can be successfully used to reconstruct the urinary bladder after extended pelvic resections for cervical cancer.
CERVICAL CANCER

ESGO7-1159

SIZE OF THE SENTINEL NODE METASTASIS AND THE RISK OF NON-SENTINEL NODE METASTASIS IN CERVICAL CANCER

G. Baiocchi, H. Mantoan, L. Kumaga, L. Badiglian-Filho, C. Faloppa, L. De Brot, A. AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil

Aims

Correlate the size of metastatic sentinel node (SLN) with the risk of non-sentinel node (N-SLN) metastasis in cervical cancer.

Method

The study included 68 patients who met the FIGO staging criteria from IA2 to IB2, treated at AC Camargo Cancer Center from May 2014 to March 2017. The patients underwent SLN mapping using patent blue dye and systematic bilateral pelvic lymphadenectomy.

Results

Median SLN count was 2 (range, 1-8) and median total lymph node (LN) count 24 (range, 6-81). Bilateral pelvic detection was found in 41 (60.3%) cases. We found metastatic LN in 11/56 (19.6%) of patients. Of the 97 hemi-pelvises mapped, SLN was able to predict LN involvement in 96 (98.9%). Two patients had bilateral positive LNS. A total of 12 hemi-pelvises had LN metastasis, and in 11 the SLN was involved, resulting in a sensitivity of 91.7%, NPV of 98.8%. In 3 (6.4%) cases the SLN was positive only after immunohistochemistry – 6 macrometastasis, 2 micrometastasis and 1 ITC. The median positive SLN was 1 (range, 1-3) – 1 patient had 2 positive SLN and another had 3 positive SLN. Of 9 patients with positive SLN, 4 (66.6%) also had positive N-SLN. Of 6 patients with macrometastasis, 2 (33.3%) had positive N-SLN (1 contralateral positive N-SLN) – 1/7 (14.2%) hemipelvises. Of 3 patients with metastasis ≤2mm, 2 (66.6%) had positive N-SLN – 1/4 (25%) hemipelvises.

Conclusion

Macrometastasis (>2mm) of SLN in cervical cancer was not related to a higher risk of N-SLN metastasis compared to SLN metastasis of ≤2mm.

DETECTION OF LYMPH NODE METASTASIS IN CERVICAL CANCER USING THE SENTINEL NODE MAPPING ALGORITHM

G. Baiocchi1, H. Mantoan2, L. Kumaga1, L. Badiglian-Filho2, C. Faloppa2, L. De Brot1, A. 2

1AC Camargo Cancer Center, Gynecologic Oncology, Sao Paulo, Brazil
2, Brazil
3, Pathology, Brazil

Aims

Evaluate the sensitivity and negative predictive value (NPV) of sentinel node (SLN) procedure in cervical cancer, and test the SLN algorithm proposed by Memorial Sloan Kettering Cancer Center (MSKCC).

Method

The study included 68 patients, stages IA2 to IB2, treated at AC Camargo Cancer Center from May 2014 to March 2017. Following the SLN procedure with blue dye, a radical hysterectomy or trachelectomy that included parametrectomy and systematic bilateral pelvic lymphadenectomy was performed.

Results

Median SLN count was 2(range, 1-8) and median total lymph node (LN) count 24(range, 6-81). Fifty-six (82.4%) patients had at least 1 SLN detected. Bilateral pelvic detection was found in 41 (60.3%) cases. We found overall metastatic LN in 14/68 (20.5%) patients and in 11/56 (19.6%) of patients with SLN detected. There were 9 in 11 patients with LN metastasis with a positive SLN (one patient had positive node in hemipelvis where no SLN were found), with an overall sensitivity of 81.8% and NPV of 96.6%. Of the 97 sides mapped, SLN was able to predict LN involvement in 96 (98.9%) hemi-pelvises. A total of 12 hemi-pelvises had LN metastasis, and in 11 the SLN was involved, resulting in a sensitivity of 91.7%, NPV of 98.8%. In 3 (6.4%) cases the SLN was positive only after immunohistochemistry (2 micrometastasis and 1 ITC).

Conclusion

We found that SLN procedure is a safe and accurate technique that increases metastatic nodal detection rates by 6.4% after IHC. We found better performance of the SLN procedure when analyzing per side, however we still had one false negative even applying the MSKCC’s algorithm.
FUNCTIONAL AND ONCOLOGIC OUTCOMES OF RADICAL TRACHELECTOMY IN EARLY-STAGE CERVICAL CANCER: A PROSPECTIVE MULTICENTRIC COHORT OF 61 PATIENTS

7Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8Centre hospitalier universitaire vaudois, Gynecology Department, Lausanne, Switzerland

Aims

To assess the post-operative morbidity of patients who have undergone a radical trachelectomy for early-stage cervical cancer and the oncologic outcomes.

Method

We retrospectively analyzed the data of two prospective trials on sentinel node biopsy for cervical cancer (SENTICOL I & II) between January 2005 and March 2012 from 8 French oncologic centers.

Results

A total of 61 patients have undergone a radical trachelectomy: 41 patients by laparoscopic-assisted vaginal way, 7 patients by total laparoscopic way, 11 patients by total vaginal way and 2 patients by laparotomy. The median age was 33 years (range = 22-68 years). 88.5 % of patients had a stage IB1 disease. There were 63.9% of epidermoid carcinoma and 34.4 % of adenocarcinoma. Eighteen patients (29.5%) had only a sentinel lymph node biopsy and 43 patients (70.5%) had an additional pelvic lymphadenectomy. The median follow-up was 46 months (range = 0-85 months). There were 12 cases of urinary infections (19.6%), 6 cases of dysuria (9.8%), 3 cases of urinary incontinence (4.9%), and one case of ureteral fistula (1.6%). The genito-femoral nerve was injured in 4 cases (6.5%) and the obturator nerve was injured in 5 cases (8.2%). There were 12 cases of limb lymphedema (19.7%) and 5 cases of pelvic lymphocyst (8.2%). During the follow-up, 3 patients (4.9%) had a local recurrence and two patients died: one from a breast cancer and one from a liver metastasis.

Conclusion

The radical trachelectomy is a safe alternative option for young patient with an early-stage cervical cancer to preserve their fertility.

7Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8Service de gynécologie, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Aims

The aim of this study was to assess the post-operative morbidity of patients who have undergone a radical hysterectomy (RH) for early-stage cervical cancer.

Method

We retrospectively analyzed the data of two prospective trials on sentinel node biopsy for cervical cancer (SENTICOL I & II). Patients underwent a radical hysterectomy for early-stage cervical cancer between January 2005 and March 2012 in 23 French oncologic centers.

Results

A total of 412 patients were enrolled and 284 had a radical hysterectomy. Data were complete for 232 patients: 115 by laparoscopic-assisted vaginal way, 80 patients by total laparoscopic way, 9 patients by total vaginal way, 22 patients by laparotomy and 6 patients by robot-assisted way. The median age was 44 years (range = 25-85 years). 89.6% of patients had a stage IB1 disease. 72.4% were epidermoid carcinoma and 24.6% adenocarcinoma. Eighty-one patients (35%) had only a sentinel lymph node biopsy and 151 patients (65%) had an additional pelvic lymphadenectomy. There were 45 cases of urinary infections (19.4%), 17 cases of dysuria (7.3%), 10 cases of urinary incontinence (4.3%), and 6 cases of ureteral or vesical fistula (2.6%). The genito-femoral nerve was injured in 25 cases (10.7%) and the obturator nerve was injured in 22 cases (9.5%). There were 38 cases of limb lymphedema (16.3%) and 14 cases of pelvic lymphocyst (6%).

Conclusion

These complications rates are similar with those found in the current literature. Urinary infections and limb lymphedema are the main complications of RH. The functional outcomes could be improved by applying nerve-sparing techniques.

FUNCTIONAL AND ONCOLOGIC OUTCOMES OF TRACHELECTOMY IN EARLY-STAGE CERVICAL CANCER: VAGINAL VERSUS LAPAROSCOPIC WAYS

V. BALAYA1,2, A.S. BATS1, D. QUERLEU3, E. LEBLANC4, P. MORICE5, H. MARRET6, E. DARAI7, P. MATHEVET8, F. LECURU

1Hôpital Européen Georges Pompidou, Service de chirurgie cancérologique-gynécologique et du sein, Paris, France
2Faculté de Médecine Paris Descartes, URDIA EA 4465, Paris, France
3Institut Claudius Regaud, Département de Chirurgie, Toulouse, France
4Center Oscar Lambret, Département de Cancérologie Gynécologique, Lille, France
5Institut Gustave Roussy, Département de Chirurgie, Villejuif, France
6Centre Hospitalier Universitaire Bretonneau, Service de Chirurgie Pelvienne Gynécologique et Oncologique, Tours, France
7Hôpital Tenon, Service de Gynécologie-Obstétrique et de médecine de la reproduction humaine, Paris, France
8Centre Hospitalier Universitaire Vaudois, Gynecology department, Lausanne, Switzerland

Aims

To compare the vaginal radical trachelectomy (VRT) and the laparoscopic-assisted vaginal radical trachelectomy (LAVRT) surgical approaches and to provide data on functional outcomes.

Method

We prospectively included patients who were elective to a radical trachelectomy for early-stage cervical cancer between March 2009 and March 2012 from 10 French oncologic centers.

Results

A total of 32 patients were included. Eleven patients had a VRT: 5 with a sentinel lymph node detection only and 6 with an additional pelvic lymphadenectomy. Twenty-one patients had a LAVRT: 13 with sentinel lymph node detection only and 8 with additional pelvic lymphadenectomy. The median age was 35 in the LAVRT group and 34 in the VRT group. The median follow-up was 43 months (range = 0-68 months). There were more urinary infection and dysuria in the VRT group than in LAVRT group respectively, 36.4% and 23.8% and, 9% and 4.8%. The genito-femoral nerve and the obturator nerve were more frequently injured in the VRT group (27.3% and 27.3%) than in the LAVRT group (4.8% and 4.8%). There were more limb lymphedema in the VRT group than in LAVRT group, respectively 54.5% and 23.8 % and more lymphocele in the VRT group than in the LAVRT group, respectively 18.2% and 9.5%. There were two recurrences and one death in the LAVRT group and none in the VRT group.

Conclusion

The functional outcomes after a radical trachelectomy seem to be better with a laparoscopic-assisted vaginal approach for the early-stage cervical cancer with an aim of fertility-sparing. Bigger population is needed.

TREATMENT PLANNING COMPARISON OF FIXED FIELD INTENSITY MODULATED RADIOTHERAPY AND VOLUMETRIC ARC THERAPY IN PATIENTS WITH CERVICAL CANCER

K. Banfill1, B. Hunter2, S. Smith2, R. Harrand1, K. Graham1, N. Reed1, A. Sadozye1

1Beatson West of Scotland Cancer Centre, Department of Clinical Oncology, Glasgow, United Kingdom
2Beatson West of Scotland Cancer Centre, Department of Radiotherapy Physics, Glasgow, United Kingdom

Aims

In this study we compared the planning target volume (PTV) coverage and dose to organs at risk (OAR) of intensity modulated radiotherapy (IMRT) plans with volumetric arc radiotherapy (VMAT) plans in 10 patients with localised cervical cancer.

Method

CT datasets of 10 patients previously treated using VMAT for histologically proven, localised squamous cell carcinoma of cervix between May and November 2016 were used to generate 7 field IMRT plans. All patients had received 50Gy in 25 fractions to the pelvis. Plans were optimized to ensure conformal PTV coverage whilst minimising the dose to OARs. Dose volume histograms for IMRT and VMAT plans were compared for each patient and homogeneity index was calculated for PTV as described by RTOG. We examined the mean dose to OARs and V45 for rectum and bladder, excluding PTV.

Results

The median age of patients in this study was 46.6 years. IMRT plans had improved dose homogeneity with median homogeneity index 1.12 compared to 1.15 for VMAT plans. There was no significant difference in the V45 to rectum or mean dose to bowel cavity between the two planning techniques. V45 for bladder minus PTV was significantly higher in IMRT plans (student's t-test, p<0.01).

Conclusion

Both IMRT and VMAT deliver homogenous and conformal radiotherapy plans for localised cervical cancer however, VMAT allows improved bladder sparing.

ESGO7-1217

DOES STAGING PARAORTIC LYMPHADENECTOMY REMOVE OCCULT METASTATIC DISEASE IN LOCALLY ADVANCED CERVICAL CANCER?

N. Barrena¹, C. Arab¹, S. Ramirez¹, M. Meneses²

¹Instituto Oncologico Fundacion Arturo Lopez Perez, Gynecologic Oncology, Santiago, Chile
²Instituto Oncologico Fundacion Arturo Lopez Perez, Pathology, Santiago, Chile

Aims

Staging paraaortic lymphadenectomy (st PALND) has demonstrated occult metastatic disease in locally advanced cervical cancer. Nevertheless, its therapeutic role remains controversial as far as all nodes-positive patients will undergo additional treatment over this area, mainly extended field radiation. We thought to evaluate whether st PALND could potentially remove hidden tumor within nodes initially reported as negative based on routine histopathology work up.

Method

Eighteen consecutive laparoscopic extraperitoneal st PALNDs were assessed. The number of lymph nodes harvested ranging from 7 to 29. Three patients (16.7%) were excluded due to positive results. Among the remaining fifteen node-negative women, pancytokeratine (panCK) stain was performed in nine of them judged to be at the highest risk of harboring occult tumor spreading due to either extensive local disease and/or suspicious/positive pelvic lymph nodes.

Results

Two patients stained panCK (+). Light microscopy reassessment showed a small foci with endometriotic features in one case; however, the second sample appeared as the presence of isolated tumor cells within a lymphatic channel. This latter woman remains without evidence of disease after 17 months of follow up despite the lack of a targeted treatment to the paraaortic region or any additional systemic therapy.

Conclusion

Ancillary pathologic procedures, such as ultrastaging with immunohistochemistry stain, might reveal occult disease involving paraaortic lymph nodes in locally advanced cervical cancer. The potential therapeutic role of st PALN by removing these tumor deposits deserves further investigation.
A COMPARISON OF TOTAL LAPAROSCOPIC RADICAL HYSTERECTOMY (TLRH) VERSUS LAPAROSCOPICALLY ASSISTED VAGINAL RADICAL HYSTERECTOMY (LAVRH) FOR CERVICAL CANCER TREATMENT

A. Bartusevicius, E. Bartuseviciene, R. Kucinskaite

1Lithuanian University of Health Sciences, Obstetrics and Gynaecology, Kaunas, Lithuania

Aims

To compare outcomes and complications of TLRH versus LAVRH for cervical cancer treatment.

Method

A retrospective cohort study, comprising all women who underwent TLRH (n=34) or LAVRH (n=65) for cervical cancer treatment during the period 2008 – 2016 at the Department of Obstetrics and Gynaecology of Lithuanian University of Health Sciences, was carried out. Patients characteristics, intraoperative and postoperative outcomes and complications were evaluated. Statistical analysis was performed using SPSS version 21.0.

Results

Women in the TLRH group had more often history of abdominal operations (32.4%) than women in LAVRH group (15.4%, p=0.04). Other patient’s characteristics (age, body mass index, comorbidities, history of caesarean delivery) did not differ between the groups.

LINA LOOP MONOPOLAR DEVICE FOR CERVICAL AMPUTATION DURING LAPAROSCOPIC RADICAL TRACHELECTOMY

K. Beauchamp1, E. Craig2, V. Bahall2, I. Harley2, D. Brennan1

1Mater Misericordiae University Hospital, Gynaecology, Dublin, Ireland
2Belfast City Hospital, Gynaecology, Belfast, Ireland

Aims

Cervical cancer is the third most common gynaecological malignancy. Irish figures state that 52% of cases are under the age of 45. We present an intraoperative video and case series of 13 patients from two tertiary centres with early stage cervical cancer who underwent laparoscopic radical trachelectomy (LRT) and sentinel pelvic lymph node sampling. LRT involves excision of the cervix, upper 2cm of the vagina, parametrium and paracolpos and is a recognized fertility preserving procedure.

Method

The video demonstrates sentinel node biopsy using ICG, nerve-sparing radical trachelectomy and cervical amputation, performed using the Lina Loop monopolar device at the level of the internal os. The utero-vaginal anastomosis was performed using a V-Loc suture. The Lina Loop allows for an accurate and safe cervical amputation and clear interpretation of pathological margins, which is demonstrated in the video.

Results

13 women (9 nulliparous) were included in the case series with ages ranging between 25 to 39 years. All cases were FIGO stage 1B1. There were eight cases of squamous cell carcinoma, four cases of adenocarcinoma and one large cell neuroendocrine tumour. Two patients received neo-adjuvant chemotherapy. Post-operative margins were clear in all cases, two patients required adjuvant treatment. There was one death in the cohort.

Conclusion

The above cases were done using the Lina Loop monopolar device to amputate the cervix. This 5mm single use device provides a more accurate amputation of the cervix than standard monopolar devices, providing excellent haemostasis and clear, even margins for pathological assessment.

MESONEPHRIC CARCINOSARCOMA OF THE UTERINE CERVIX
I. Ben Safta\textsuperscript{1}, H. Mansouri\textsuperscript{1}, O. Jaidane\textsuperscript{1}, S. Gadria\textsuperscript{1}, J. Ben Hassouna\textsuperscript{1}, K. Rahal\textsuperscript{1}
\textsuperscript{1Institut Salah azeiz of oncology, surgical oncology, TUNIS, Tunisia

Aims

Carcinosarcomas represent less than 5% of uterine neoplasms arising rarely in the uterine cervix. They belong to the histological group of mixed tumors with both epithelial and mesenchymal components. They mainly occur in postmenopausal women and usually associated with poor prognosis.

Method

We report a case of cervical carcinosarcoma. We describe clinical, histological and therapeutic features of a case of cervical carcinosarcoma.

Results

A 57-year-old woman complained of vaginal bleeding and pelvic pain. Clinical examination revealed a 9 cm mass in the cervix extending to the right parametrium. Cervical biopsy concluded to undifferentiated carcinoma. There was no obvious metastasis to pelvic or paraaortic lymph nodes in imaging studies. The patient underwent concurrent chemoradiation therapy at the dose of 45 grays followed by radical hysterectomy with bilateral salpingo-oophorectomy and pelvic lymphadenectomy. Histology confirmed residual carcinosarcoma of the cervix measuring 3 cm extending to the right parametrium. Pelvic lymph nodes, uterus, adnexa, and vagina were not involved. Postoperative high-dose brachytherapy was performed. After 14 months, the patient did not show any signs of relapses.

Conclusion

Cervical carcinosarcomas are rare neoplasm and there is no consensus regarding their prognosis and treatment which remain based on data available for sarcoma uterine corpus.

4Hospital Universitario Dr. Negrín, Medical Oncology, Las Palmas de Gran Canaria, Spain
5Complejo hospitalario universitario insular-materno infantil, Medical Oncology, Las Palmas de Gran Canaria, Spain

Aims

To study risk factors in patients with LACC undergoing pretherapeutic laparoscopic paraaortic lymphadenectomy (LPL), as well as the progression-free and overall survival rates specifically in the subgroup of patients with metastatic paraaortic lymph nodes (PLN).

Method

Prospective study, conducted between 2009-2015, based on the review of data on demography, pathology, surgery, complications and disease-status of patients with LACC undergoing pretherapeutic LPL. All patients were treated with chemoradiotherapy and those with metastatic-PLN received extended lumbo-aortic radiation therapy. Survival analysis was performed with the Kaplan-Meier method. Statistical significance was considered for p-values<0.05.

Results

The study included 139 patients. Their mean age was 49.2 years (SD10). The most frequent histologic type was SCC (77%) and the most frequent FIGO stage was IIB (48.2%). Metastatic PLN were identified in 18.7% of patients (26). The OS rate after 28 months follow-up was 68.2 months (OR2.7; CI95%, 63-73.5). For N- patients, the mean survival time was 76.9 months (OR1.8; CI95%, 73.4-80.4) while for N+ patients; the mean survival time was 24.9 months (OR4.6; CI95% 15.9-33.9; p<0.0001). A logistic regression analysis revealed that the presence of metastatic PLN and tumor size were both independent risk factors for poor OS [(O117.5; CI95% 11.6-990.2; p<0.0001) and (OR 21.5; CI95% 2-230.3; p=0.01)].

Conclusion

Women with LACC with metastatic PLN had a poor prognosis and low survival rate. We postulate that this finding could be accounted for by the presence of hidden systemic disease and high-recurrence rate following therapy. Efforts should be made to improve the available therapeutic schedules for this particular subgroup of patients.

EPIDEMIOLOGY OF CERVICAL CANCER IN A REGION OF SOUTHERN ALGERIA

Z.B. Benlahrech

1University Ammar Telidji, Medicine Faculty, Laghouat, Algeria

Aims

The early stages of cervical cancer can be free of symptoms, Infection with some types of HPV is the greatest risk factor for cervical cancer. Screening is beneficial in women between 25 and 65 years old. Its used in combination with HPV testing

Method

It’s a prospective analysis of data about cervical cancer from 2016 to 2018 in the province (wilaya) of LAGHOUAT (Algeria). During this two-year study period, 400 cervical screening are required. Actually 200 cervical screening were made. The women were between 25 and 64 years old

Results

The results was like this: invasive cases 10 %, high-grade 22%, normal result 54 %

It’s was the first screening for all the 200 women, and 56 percents had only one sexual partner all their life and 12 percent had more than two.

Conclusion

in Algeria an organized screening policy must be set up to reduce the mortality rate from this cancer.
MICRONA PROFILING OF HUMAN PAPILLOMAVIRUS MEDIATED CERVICAL CANCER IN INDIAN WOMEN
M. Bharadwaj
1National Institute of Cancer Prevention & Research, Molecular Genetics, Noida, India

Aims

Though persistent HPV infection is needed for development of cervical cancer but HPV infection alone is not sufficient but together with other genetic factors might be responsible for cervical carcinogenesis. There are two licensed prophylactic vaccines against HPV -16 and -18; but they are prophylactic in nature. So, there is an urgent need to find novel molecular diagnostic markers and therapeutic targets for the treatment of cervical cancer.

Method

We investigated the role of miRNAs in HPV-mediated cervical pre-cancer and cancer cases in Indian population. We analysed the HPV infection and its genotypes both in cases and controls. Also, microRNA profiling was done in a subset of cervical pre-cancer (n = 20), cancer cases (n = 50) and normal samples (n = 30) by real-time quantitative PCR (qRT-PCR).

Results

The miRNA profiling revealed that in cervical pre-cancer, 100 miRNAs were significantly (p < 0.001) differentially expressed with 70 miRNAs upregulated and 30 miRNAs downregulated. In cervical cancer cases, 383 miRNA were found to be differentially expressed (p < 0.001), of which 350 miRNAs were upregulated and 33 miRNAs were downregulated. We also observed that 182 miRNAs were differentially expressed (p < 0.001) in HPV-16/18-positive (SiHa/HeLa) cell lines compared with HPV-negative (C33A) cell line. In addition, we identified the novel microRNAs such as miR-892b, miR-500, miR-888, miR-505 and miR-711 in cervical precancerous lesions and cervical cancer cases in Indian population.

Conclusion

Ultimately, the study demonstrates a crucial role of microRNAs in cervical cancer, which may serve as potential early diagnostic markers for cervical carcinogenesis.

INTRODUCING NERVE SPARING APPROACH DURING LAPAROSCOPIC RADICAL HYSTERECTOMY

G. Bogani¹, F. Ghezzi², A. Ditto¹, F. Martinelli¹, M. Signorelli¹, V. Chiappa¹, D. Lorusso¹, F. Raspagliesi¹

¹National Cancer Institute, Gynecologic Oncology, Milan, Italy
²University of Insubria, Gynecologic Surgery, Varese, Italy

Aims

To evaluate how the introduction of nerve-sparing (NS) approach affects outcomes of locally advanced stage cervical cancer (LACC) patients undergoing minimally invasive radical hysterectomy (LRH).

Method

Data of consecutive patients undergoing minimally invasive surgery for LACC were retrieved between 2010 and 2016. Patients included had minimally invasive class III radical hysterectomy (LRH or NS-LRH). Propensity-score machining and inverse probability weighting algorithms were used to decrease a possible allocation bias when comparing outcomes between groups.

Results

Overall, 66 patients were included. The prevalence of patients undergoing NS approach increased over the study period (from 10% in the year 2010-2011 to 100% in the year 2015-2016; p for trend <.001). Data of consecutive 40 patients undergoing NS-LRH were compared with 26 patients undergoing LRH before the introduction of NS approach. After the application the inverse probability weighting algorithm, we observed that the introduction of NS approach did not increase operative time and blood loss. Postoperative complications rate was similar between groups. Patients undergoing NS-LRH experienced shorter hospital stay than patients undergoing LRH. 30-day pelvic floor dysfunction rates, including voiding, fecal and sexual alterations, were lower in the NS group in comparison to control group (p<.05). Five-year disease-free (p=.76) and overall (p=.81) survivals were similar comparing NS-LRH with LRH.

Conclusion

The implementation of NS approach in the setting of LACC improves patients’ outcomes, minimizing pelvic dysfunction rates. NS approach have not detrimental effects on survival outcomes.

FACTORS PREDICTIVE OF 30-DAY MORBIDITY, READMISSION AND COSTS IN PATIENTS UNDERGOING PELVIC EXENTERATION
G. Bogani¹, A. Ditto¹, F. Martinelli¹, M. Signorelli¹, V. Chiappa¹, S. Perotto¹, C. Lopez¹, U. Leone Roberti Maggiore¹, D. Lorusso¹, F. Raspagliesi¹
¹National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To identify perioperative factors predictive of 30-day morbidity, readmission and cost in patients undergoing pelvic exenteration due to recurrent gynecological malignancies.

Method

Data of consecutive patients undergoing pelvic exenteration (anterior / posterior or total) between 2004 and 2016 were collected prospectively. Complications were graded per the Accordion classification. Only severe (grade 3 or worse) complications were evaluated for the study purpose. Readmissions within 30 days after surgery were recorded. Thirty-day cost analyses were expressed in 2017 euros.

Results

Overall, 58 patients were evaluated. Anterior, posterior and total exenterations were executed in 39 (67%), 9 (16%) and 10 (17%) patients, respectively. Ten (15.5%) severe complications occurred: eight (20.5%), 0 (0%) and one (10%) after anterior, posterior and total exenterations, respectively. Radiotherapy dosage and previous administration of chemotherapy did not increase the risk of developing 30-day complications and readmission. Low postoperative albumin levels (<3g/dl), history of deep vein thrombosis, and ASA score >2 correlated with an increased risk of developing severe postoperative complications (p<.05). The occurrence of postoperative complications did not correlate with adverse survival outcomes. The occurrence of severe complications per se increased costs. After controlling for confounding factors, we observed that low postoperative albumin levels was associated with significant increase in costs; while, the execution of colostomy reduced 30-day costs.

Conclusion

Preoperative patients selection is a key point for the reduction of postoperative complications following pelvic exenteration. The implementation of enhanced perioperative recovery might be useful in reducing morbidity and costs of salvage surgery.

ESGO7-0091

PRETREATMENT NEUTROPHIL:LYMPHOCYTE RATIO IN PREDICTING THERAPEUTIC RESPONSE IN CERVICAL CARCINOMA TREATED WITH CONCURRENT CHEMORADIATION

*D.M. Brazal*

1Jose R. Reyes Memorial Medical Center, Obstetrics and Gynecology- Section of Gynecologic Oncology, Manila, Philippines

Aims

Cancers have been linked with systemic inflammation. Neutrophil-to-lymphocyte ratio (NLR) has been investigated as prognostic markers for different cancers. The aim is to investigate the role of the pretreatment NLR and other factors in predicting response to treatment in cervical cancer patients treated with chemoradiation.

Method

This was a retrospective study with cervical cancer patients treated with chemoradiation at a single institution from January 2012 to December 2014. Primary end point was tumor response to treatment. Logistic regression analysis was used to identify prognostic factors to NLR and treatment response.

Results

A total of 150 subjects were included. The median NLR was 2.43, and patients were divided into high NLR and low NLR. Patients with low NLR had 100% complete response. Among patients with high NLR, 56% had complete response and 44% had incomplete response (p<0.01). Regression analysis showed that stage, tumor size and NLR are significant prognostic factors (p<0.01) with treatment response. The odds ratio for a complete response is decreased by a factor of 0.121 in high NLR, by 0.208 for >4cm tumors, and by 0.050 for stage III disease.

Conclusion

Pretreatment NLR may be used as parameter to predict therapeutic response to chemoradiation in cervical cancer. A low NLR is associated with good treatment response, and patients with advanced stage, larger tumor size and high NLR have lower chances of complete response to treatment.

COMPARISON OF INDOCYANINE GREEN VS RADIOCOLLOID AND/OR BLUE DYE FOR SENTINEL NODE MAPPING IN STAGE IB1 >2 CM–IIB CERVICAL CANCER: A RETROSPECTIVE EUROPEAN EXPERIENCE.

A. Budà1, C. Crivellaro2, G. Di Martino1, B. Bussi3, A. Papadía3, I. Zapardiel4, E. Vizza5, L. Locatelli1, M.L. Gasparri3, B. Diaz de la Nova4

1 AO San Gerardo di Monza, Department of Obstetrics and Gynecology- University Milano-Bicocca, Monza, Italy
2 University of Milano-Bicocca- Tecnomed Foundation, Nuclear Medicine, Monza, Italy
3 Gynecologic Oncology Department, Department of Obstetrics and Gynecology- University of Berne, Bern, Switzerland
4 Gynaecologic Oncology Unit, La Paz University Hospital- IdiPAZ, Madrid, Spain
5 Gynecologic Oncologic Unit “Regina Elena” National Cancer Institute, Department of Oncological Surgery- Rome, Italy

Aims

Compare the detection rate and bilateral mapping of sentinel lymph node (SLN) in women with cervical cancer (CC) with tumor > IB1 (>2cm) by using Indocyanine Green (ICG) versus Tc99m ± blue-dye (BD).

Method

Between 2008 and 2016, 95 women with stage IB1 (>2cm) or IB2, IIA and IIB cervical cancer at final pathology who underwent SLN mapping with Tc99m ± BD (n=47) or ICG (n=48) underwent radical hysterectomy with or without BSO were retrospectively reviewed from 4 European centers. Detection rate and bilateral mapping of ICG were compared with those obtained using the Tc99m radiotracer ± BD. A lymphadenectomy was performed, and false negative rate was assessed.

Results

Overall detection rate of SLN mapping was 91.5 and 100% for Tc99m ± BD and ICG respectively. Bilateral mapping rate for ICG resulted 91.7%, significantly higher with respect to 66% obtained with Tc99m + BD (p=0.025). False negative rate was 11.5% (3 false negative cases in ICG group only). Nine out the 23 SLN-positive patients (39,1%), were exclusively diagnosed as a result of ultrastaging, that allowed to identify micrometastasis or ITC only.

Conclusion

In advanced CC (stage IB1>2cm-IIB) the real-time fluorescence SLN mapping with ICG achieved higher detection rate and higher bilateral migration rate when compared to Tc99m radiotracer ± BD. SLN and ultrastaging could provide additional information on nodal staging also in advanced CC. In this setting, ICG is a promising tool for mapping, as it seems less affected by the higher stage of disease respect to the traditional methods.

MULTIPLE ALLELE SEQUENCE IN MICA INFLUENCE SUSCEPTIBILITY TO CERVICAL CANCER IN A KOREAN POPULATION
S.W. Byun¹, J.S. Park², T.C. Park¹, J.H. Kim¹, T.G. Kim²
¹Uijeongbu St Mary’s hospital - Catholic University Medical College, obstetrics and gynecology, Uijeongbu-si- Gyeonggi-do, Republic of Korea
²Seoul St Mary’s hospital - Catholic University Medical College, obstetrics and gynecology, Seoul, Republic of Korea

Aims
We aimed to identify that variants of MICA (MHC class I chain-related gene A) can influence susceptibility to cervical cancer in a Korean population

Method
A case-control study was conducted on 124 cervical cancer patients and 200 controls in Korean women. The MICA 129 genotypes, MICA 129 alleles, STR allele, and sequencing alleles frequencies of the MICA gene were compared by PCR-SBT (polymerase chain reaction-sequence base typing) method.

Results
We identified protective effects of MICA-A5 (OR = 0.4, P= 2.4 x 10⁻⁵) and MICA*027 (OR = 0.3, P=0.2 X 10⁻²), MICA*008:01 increased the susceptibility to cervical cancer (OR = 1.6, P = 0.043) with the same association shown with MICA-A5.1 but, no association was observed between MICA-129 allele, genotypes and risk of cervical cancer.

In subgroup analysis, MICA * 008: 01 (OR = 2.6 corrected P = 0.045) and MICA * 027 (OR = 0.2, corrected P = 0.005) allele frequency were different in HPV 16 or 18 confirmed cervical cancer patients compared to HPV non-16,18 confirmed cervical cancer patients, the susceptibility was increased and corrected P value was validated.

In MICA * 002.01, there was a difference between the two groups at Stage IIA and below. And in stage IIA and above, Odd ratio was significantly increased in MICA * 002.01.

Conclusion
Our results revealed the susceptible and protective effect of MICA*008:01, MICA*027 in the pathogenesis of HPV 16 or 18 infected cervical cancer in Korean population

POSTOPERATIVE COMPLICATIONS AND SURVIVAL AFTER PELVIC EXENTERATION: OUR EXPERIENCE ON 50 PATIENTS

M.E. Capilna1, B. Moldovan2, B. Szabo1, S.C. Rusu1, J. Becsi1, N. Ioanid3

1University of Medicine and Pharmacy, First Obstetrics and Gynecology Clinic, Targu Mures, Romania
2“Sf. Constantin” Hospital, Department of General Surgery, Brasov, Romania
3Regional Institute of Oncology, Second Department of General Surgery, Iasi, Romania

Aims

The pelvic exenteration became an ultimate, salvage therapy for patients with advanced or recurrent pelvic cancers. The aim of the study was to analyse our results regarding postoperative complications and survival after pelvic exenterations performed in a tertiary referral center.

Method

Between 2011 and January 2017, 50 patients underwent a pelvic exenteration. The indications were advanced or recurrent cervical (35 patients), vaginal (4), advanced or recurrent ovarian (7), advanced endometrial (2), recurrent vulva (1) or advanced bladder cancer (1).

Results

Out of the 50 exenterations, 25 were total, 17 anterior and 8 posterior. In respect to levator ani muscle, a supralevatorian exenteration was performed in 32 cases, an infralevatorian in 9 and an infralevatorian with vulvectomy in 9. A Bricker non-continent ileal or sigmoid urinary conduit was performed in 41 out of 42 anterior and total exenterations, and a continent orthotopic Budapest pouch in one. Four patients (8%) developed grade V Dindo-Clavien complications (perioperative deaths), 3 patients grade IVa (6%), and 12 (24%) grade IIIb. Among the 50 patients, at this moment, 28 are alive; 20 are dead because of the disease, one is dead of non-oncologic cause and one is lost to follow-up.

Conclusion

Pelvic exenteration for recurrent or advanced pelvic malignancies can be associated with long-term survival and even cure without high perioperative mortality in properly selected patients. However, postoperative complications are common and can be lethal.
PREVALENCE OF HUMAN PAPILLOMAVIRUS GENOTYPES IN CERVICAL CANCER SPECIMEN FROM A ROMANIAN POPULATION

M.E. Capila, S.C. Rusu, M. Gheorghe, M.A. Budianu, S. Barbu

1University of Medicine and Pharmacy, First Obstetrics and Gynaecology Clinic, Targu Mures, Romania
2University of Medicine and Pharmacy, Discipline of Medical Laboratory, Targu Mures, Romania

Aims

Persistent HPV infection is a well-established cause of cervical cancer. The prevalence of HPV infection among Romanian women has not been broadly studied.

Method

Eighty histologically confirmed invasive cervical cancer specimens of previously non-irradiated Romanian women were collected and a HPV genotyping was performed. Detection was based on DNA isolation, PCR amplification of target DNA, hybridization of PCR products with oligonucleotide probes and colorimetric identification of products. A statistical analysis was performed.

Results

HPV-DNA prevalence was 87.5%. Among HPV-DNA positive cervical cancers, most of the cases presented as single infections (87.14%); 7 patients harbored 2 HPV types (10%); and in 2 patients, 3 different HPV types were discovered (2.85%). HPV16 was the most detected type, with 72.5% relative contribution as single (58 patients) or multiple infection. It was not found any statistical association between the HPV genotype, patients' age, histology of the tumour or stage of disease (p>0.05).

Discussion. Our results are intriguing, with a high prevalence of HPV16 (72.5%) and 10 other high risk HPV type, with a low prevalence (1.3-2.7%) for each one. Multiple infection was detected in 12.85% of women. HPV18 was detected in only one patient, despite the presence of 4 adenocarcinoma and one neuroendocrine carcinoma histologies.

Conclusion

This high variety of HPV types among Romanian population is quite specific, compared to other recently published data. This study provides important baseline data for improving the acceptance of HPV vaccination in Romania.
ROBOTIC VERSUS LAPAROSCOPIC RADICAL HYSTERECTOMY FOR EARLY CERVICAL CANCER: A CASE MATCHED CONTROL STUDY

V. Gallotta¹, C. Conte¹, A. Federico¹, K. Gaballa², L. Pedone Anchora¹, V. Chiantera³, G. Vizzielli¹, B. Costantini¹, F. Cosentino⁴, S. Gueli Allelli², A. Fagotti¹, G. Scambia¹, M.G. Ferrandina¹
¹Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome, Italy
²Oncology Center Mansoura University, Surgical Oncology, Mansoura, Egypt
³Università di Palermo, Gynecologic Oncology, Palermo, Italy
⁴Fondazione di Ricerca e Cura “Giovanni Paolo II”, Gynecologic Oncology, Campobasso, Italy

Aims

To evaluate the surgical, pathological and oncological outcomes of robotic radical hysterectomy (RRH) versus laparoscopic radical hysterectomy (LRH) in patients with early-stage cervical cancer (ECC).

Method

Between 2010 and 2016, 204 patients underwent RRH (n=70) and LRH (n=134) were retrospectively evaluated and compared.

Results

No statistically significant difference were found between the two approaches with regard to clinical characteristics. Median operative time was longer in RRH (245.5 vs 210 min, p: 0.008) compared to LRH; no difference in terms of EBL, intraoperative complications and rate of conversion to open approach were revealed between the two groups. In all series, 15 patients experienced major postoperative complications, with no difference between the two groups. Pathological characteristics did not differ significantly between the two groups, as well as no significant differences were found in pathological FIGO stage, histology and tumor grade. Pathological results revealed 19 (9.3%) patients with parametrial invasion and 29 (14.2%) patients with lymph nodes metastasis. 96 (47%) patients underwent adjuvant therapy. With a median follow up of 30 months no differences in DFS (p: 0.866) and OS (p: 0.723) were found between the two groups. In all series 22 patients experienced relapse of disease and 5 died of disease.

Conclusion

The present study showed feasibility, safety of minimally invasive approach for ECC with no relevant differences in surgical and clinical outcomes between RRH and LRH.

SPONTANEOUS UTERINE RUPTURE SECONDARY TO PYOMETRA IN A CERVICAL CANCER PATIENT: A CASE REPORT
M.C. Cenizal1, L.F. Aquilizan1
1St. Luke’s Medical Center, Obstetrics and Gynecology, Quezon City, Philippines

Aims
Pyometra is a rare gynecologic disease entity. It is the accumulation of pus within the uterine cavity which is commonly caused by a blockage or compromise in the outflow tract of the uterus. Pyometra in itself is rare, much so is uterine rupture occurring secondary to it.

Method
This is a case of a 63 year old Gravida 5 Para 5 (5-0-0-4), diagnosed case of Cervical Endometrioid Adenocarcinoma Stage IIIB, who was presented with abdominal pain. Computed Tomography Scan of the whole abdomen with intravenous contrast revealed moderate pneumoperitoneum of indeterminate etiology, for which an initial assessment of acute abdomen secondary to pneumoperitoneum probably secondary to ruptured viscus was made.

Results
Patient underwent exploratory laparotomy. Intraoperative finding was ruptured pyometra and peritoneal toilette and insertion of drainage were subsequently done. Culture guided antibiotics were administered and patient underwent radiotherapy and brachytherapy after infection was resolved.

Conclusion
Spontaneous rupture of pyometra with associated malignancy is a serious medical condition which requires prompt surgical and medical management. However, pre-operative diagnosis is difficult despite the presence of advanced imaging techniques, hence high level of suspicion is warranted in identifying this condition. Accurate diagnosis of pyometra prior to rupture may require less invasive management, therefore it is of same importance to identify pyometra even before it causes its catastrophic complications.

CERVICAL CANCER PATIENTS BECOME MALNOUROSHED DURING TREATMENT WITH CONCOMITANT CHEMO- RADIOTHERAPY

M. Sanchez-Lopez1, A.D. Castro-Eguiluz2, R. Jimenez-Lima3, V. Casique-Perez4, U. Velazquez-Morales4, L. Flores1

1Instituto Nacional de Cancerología- Universidad Nacional Autónoma de México- Mexico City- Mexico, Clinical Research, Mexico City, Mexico
2Instituto Nacional de Cancerología- Consejo Nacional de Ciencia y Tecnología- Mexico City- Mexico, Clinical Research, Mexico City, Mexico
3Instituto Nacional de Cancerología- Universidad Nacional Autónoma de México- Mexico City- Mexico, Clinical Research, Mexico City, Mexico
4Instituto Nacional de Cancerología- Universidad Autónoma de Tlaxcala, Clinical Research, Mexico City, Mexico

Aims: To evaluate the magnitude of malnutrition in cervical cancer patients that received cisplatin based chemotherapy concomitant with radiotherapy

Method

55 patients with locally advanced cervical cancer were included in this longitudinal, prospective, observational study, at the National Cancer Institute in Mexico. Nutritional evaluation was performed using objective and subjective tools, including anthropometric, biochemical and dietary data, during and after patients received treatment and standardized dietary recommendations. Percentage change and trajectory analysis were calculated, comparing the initial and final evaluations.

Results

By the end of treatment, 96.3% patients lost weight (p=0.001); of these, 78.2% had severe weight loss (>5.1% weight loss); 62% patients presented anemia and all of them had lymphopenia. All patients consumed less than 95% energy required; carbohydrate intake increased, while protein and fat intakes decreased during treatment.

At the initial nutritional evaluation, 8 patients were undernourished, during treatment 31 patients, and by the third evaluation 45 patients were undernourished, showing a clinical and statistical significance (p<0.001). The percentage change between the initial and third evaluation was 462%. In other words, the number of undernourished patients increased 4 times in a period of 9 weeks. By the end of treatment only 2 patients (3.6%) presented an adequate nutritional status (p=0.001).

Conclusion

Malnutrition in cervical cancer patients undergoing chemo-radiotherapy, is clinically and statistically significant. Since nutritional status has been proven determinant in the quality of life, response to treatment and survival of patients, it is of utmost importance to take individualized nutritional measures to prevent malnutrition.
CHEMORADIOTHERAPY WITH GEMCITABINE IN CERVICAL CANCER PATIENTS WITH RENAL FAILURE: A RETROSPECTIVE ANALYSIS AT THE NATIONAL CANCER INSTITUTE FROM MEXICO

1Instituto Nacional de Cancerología- Universidad Nacional Autónoma de México- Ciudad de México- México, Clinical Research, Mexico City, Mexico
2Instituto Nacional de Cancerología-Ciudad de México- México., Clinical Research- Oncología Médica, Mexico City, Mexico
3Instituto Nacional de Cancerología-Ciudad de México- México., Clinical Research-Oncología Médica, Mexico City, Mexico
4Instituto Nacional de Cancerología-Ciudad de México- México, Clinical Research- Oncología Médica, Mexico City, Mexico
5Instituto Nacional de Cancerología-Consejo Nacional de Ciencia y Tecnología- Ciudad de México- México., Clinical Research, Mexico City, Mexico
6Instituto Nacional de Cancerología-Ciudad de México- México, Clinical Research-Oncología Médica, Mexico City, Mexico

Aims

Introduction: Currently chemotherapeutic scheme is based on platinum with a high renal toxicity, limiting the options to those patients with renal dysfunction. In this respect, Gemcitabine has a saffer toxicity profile and changes in dosage are not required in patients with renal dysfunction, representing a viable option for cervical cancer patients with renal failure.

Objective: To investigate response rate, progression free survival, overall survival and toxicity of chemoradiotherapy combined with gemcitabine in untreated patients with locally advanced cervical cancer undergoing kidney dysfunction and obstructive nephropathy.

Method

This is a retrospective analysis employing data from patients diagnosed with locally advanced carcinoma of the cervix and renal detritment, wich were treated with chemoradiotherapy and gemcitabine at the National Cancer Institute from Mexico from January 2003 to December 2015.

Results

A total of 85 patients were included in the study. We found a 78.8% objective response in patients treated with the chemoradiotherapy plus gemcitabine scheme, with a follow up median of 22.76 months, the progression free survival median was 26.34 months (95% CI, 14.78–37.91) and the overall survival media was 32.69 months (95% CI, 23.0–42.35). Hematologic toxicity was the most common event, white cell decreased and neutropenia were observed in 20.0% and 23.5% of the patients as grade 3 respectively and 1.2% as grade 4 for both cases. Improvements in GRF were seen, with a mean increased of 9.65 mL/min (p=0.000)

Conclusion

This study demonstrates that gemcitabine is well tolerated when used as a radiosensiblizing agent in patients with locally advanced cervical carcinoma affected with renal failure.

CHEMORADIOTHERAPY WITH CISPLATIN VS GEMCITABINE IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER WITH COMORBIDITIES. RETROSPECTIVE ANALYSIS OF PATIENTS TREATED AT THE NATIONAL CANCER INSTITUTE

L. Cetina-Pérez1, L. Lugo-Alferez1, M. Cuba1, R. Jimenez-Lima2, A.D. Castro-Eguilez2

1Instituto Nacional de Cancerología- Mexico City- Mexico, Clinical Research- Medical Oncology, Mexico City, Mexico
2Instituto Nacional de Cancerología- Universidad Autónoma de Mexico- Mexico City- Mexico, Clinical Research, Mexico City, Mexico
3Instituto Nacional de Cancerología- Consejo Nacional de Ciencia y Tecnología- Mexico City- Mexico, Clinical Research, Mexico City, Mexico

Aims

Cervical cancer is third most frequent cancer in worldwide. In Mexico it represents 49% of new cancer cases in women. Standard treatment consists of chemoradiotherapy with cisplatin, which could be cause impair renal function, neuropathy and ototoxicity. Currently, two emerging problems are being presented: the increase in the geriatric population and the chronic noncommunicable diseases. These variables impose an increased risk of adverse effects in patients with cervical cancer and comorbidities, which may limit them to receive standard treatment

Objective: To Evaluate the activity and Toxicity of cisplatin vs gemcitabine chemoradiotherapy in locally advanced cervical cancer

Method

A retrospective review was conducted of 212 patients with cervical cancer diagnosis (stage FIGO IB2-IVA) and fragility data (Diabetes Mellitus type 2, systemic arterial hypertension or geriatric patients) treated with cisplatin vs gemcitabine chemoradiotherapy

Results

Significantly more acute hematologic and gastrointestinal toxicity was present in cisplatin group. Changes in creatinine clearance, pretreatment, posttreatment, and one year after treatment were analyzed; creatinine clearance declined at one year in cisplatin group (p= 0.0001). No difference was found in terms of response rates, overall survival (OS) and disease-free survival (SLE) between the two groups. The 5-year OS was 77.2% for gemcitabine group and 86.4% for cisplatin group (p= 0.15). The 5-year SLE for the gemcitabine group was 76.8% vs 84% for the cisplatin group (p= 0.827).

Conclusion

Response and survival rates of gemcitabine group were similar to those of cisplatin, but in cisplatin group, renal function was significantly deteriorated at one year after the end of treatment, compared with gemcitabine.

THE ROLE OF HUMAN PAPILLOMAVIRUS-52 E6 IN CARCINOGENESIS

P. Chan¹, L. Lai¹, S. Boon¹, P. Law¹, M. Thomas², L. Banks²

¹The Chinese University of Hong Kong, Microbiology, Hong Kong, China
²ICGEB, Tumour Viology Group, Trieste, Italy

Aims

To investigate the geographical/ethno predilection in disease burden and the biology of HPV-52 that exhibits an unexpected high prevalence in East Asia.

Method

An epidemiological study was conducted to examine HPV-52 variations and their associated risk with cervical cancer in East Asia. The role of HPV-52 E6 and its variants in carcinogenesis was determined using molecular and functional assays.

Results

An HPV-52 variant, designated as V1, which was more frequently detected in East Asia, was identified to be significantly associated with higher risk for cervical cancer. Similar to HPV-16 E6, HPV-52 E6 was found to bind E6AP and degrade p53, but could only recognize Psd95/Dlg/ZO-1 (PDZ) proteins weakly. V1 did not show any significant difference in E6AP association and p53 degradation as compared with the wild type and other variants. Functional assays with HPV-52 E6 V1-transformed baby rat kidney (BRK) primary cells were conducted to determine its effect on anchorage-independent growth, cell migration and invasion.

Conclusion

HPV-52 E6 V1 is the most prevalent variant associated with cervical cancer in East Asia. It might exert its higher oncogenicity through association with proteins other than E6AP and p53. Our findings will help to devise new strategies for improving HPV surveillance and therapeutic design, especially in East Asia.

3Chang Gung Memorial Hospital at Linkou, Biostatistics Unit- Clinical Trial Center, Taoyuan, Taiwan R.O.C.
4Chang Gung Memorial Hospital at Linkou, Medical Imaging and Intervention, Taoyuan, Taiwan R.O.C.
5Chang Gung Memorial Hospital at Linkou, Radiation Oncology, Taoyuan, Taiwan R.O.C.
6Chang Gung Memorial Hospital at Linkou, Pathology, Taoyuan, Taiwan R.O.C.

Aims
The study was to investigate the outcomes and prognostic factors of cervical cancer that relapsed more than 5 years after primary treatment (late recurrences).

Method
Total 45 cervical cancer patients with late recurrences treated at Chang Gung Memorial Hospital between January 1993 and March 2017 were retrospectively reviewed. The survival outcomes and the related prognostic factors, including treatment, clinicopathological, demographic, and HPV, were analyzed.

Results
The time to recurrence (TTR) was not significantly different between the primary surgical group and the non-surgical group. HPV 18 (HR 2.8, 1.1-7.7, p=0.038) or (HR 3.0, 1.2-7.7, p=0.020) positivity at recurrence were significant prognostic factor (HR 0.4, 0.1-0.9, p = 0.029) for shorter TTR. The median survival after recurrence (SAR) of the surgical group was 8.18 years and non-surgical group was 1.32 years (p = 0.123). Those with asymptomatic late relapse had significantly better SAR than those relapse with symptoms (5.25 vs 0.93 years, p = 0.003). By multivariate analysis, the SAR of total cohort was significantly decreased for those failed at pelvic+ distant (HR 5.50, 1.5-19.7; p = 0.009), while HPV 16 positivity at recurrence was confirmed as a good prognostic factor (HR 0.4, 0.1-0.9, p = 0.029).

Conclusion
Pelvic with distant failure had poor SAR in patients with late recurrent cervical cancer, but HPV 16 positivity at recurrence implied good prognosis. Since asymptomatic late recurrence had better SAR, the further follow-up strategy beyond 5 years of remission should be deliberated to detect asymptomatic late relapses.
SAFETY AND EFFICACY OF A QUADRIVALENT HPV (QHPV) VACCINE IN CHINESE WOMEN: RESULTS OF BASE STUDY WITH 30-MONTH FOLLOW-UP

W. Chen¹, Y. Zhao², X. Xie³, J. Liu⁴, X. Liao⁵, Q. Shou⁶, M. Zheng⁷, A.J. Saah⁷, L. Wei⁸, Y. Qiao⁹

Aims

To assess safety and efficacy of a quadrivalent HPV (types 6, 11, 16, 18) L1 virus-like particle vaccine (qHPV vaccine, Gardasil®) in women of mainland China.

Method

A randomized, double-blind, placebo-controlled, multicenter trial was conducted among 3006 women subjects aged 20-45 years who were randomized (1:1) to receive 3 doses of vaccine/placebo at Day 1, Month 2 and 6, and followed up for 30 months (base study). The co-primary efficacy endpoints of base study were combined incidence of HPV 6/11/16/18-related 6-month persistent infection (PI) and genital disease endpoints in two age groups (20-45 and 20-26 years). Efficacy against 6-month and 12-month PI was also analyzed. Safety measurements included adverse events (AEs) within 15 days after each vaccination, deaths, vaccination-related serious AEs (SAEs), and pregnancy outcomes. (ClinicalTrials.gov registry: NCT00834106)

Results

The co-primary efficacies were 76.8% (95% CI: 44.8, 91.7) in women aged 20-45 years (N=3006) and 82.3% (95% CI: 38.3, 96.7) in women aged 20-26 years (N=1840). The base study met the co-primary efficacy objectives. The efficacies against HPV6/11/16/18-related 6-month persistent infection (PI) and genital disease endpoints in two age groups (20-45 and 20-26 years). Efficacy against 6-month and 12-month PI was also analyzed. Safety measurements included adverse events (AEs) within 15 days after each vaccination, deaths, vaccination-related serious AEs (SAEs), and pregnancy outcomes. (ClinicalTrials.gov registry: NCT00834106)

Conclusion

The qHPV vaccine is generally well-tolerated and highly efficacious against HPV6/11/16/18-related PI and genital disease among Chinese women aged 20-45 and 20-26 years.
WHO'S TALKING ABOUT GYNAECOLOGICAL ONCOLOGY ON TWITTER

M. Cheung¹, R. McVey¹, D. Brennan¹, W. Boyd¹, T. Walsh¹, R. Arnett², E. Clarke³
¹Mater Misericordiae University Hospital, Gynaecology, Dublin, Ireland
²Royal College of Surgeons, Quality Enhancement Office, Dublin, Ireland
³Royal College of Surgeons, Foundation Year Medicine and Physiotherapy, Dublin, Ireland

Aims

Patients and physicians live in an information era dominated by the Internet and social media. Patients have unparalleled access to medical information from all sources. Much of present-day patient education occurs online through social media platforms like Twitter.

The aim of this study was to gain a better understanding of what online conversations about gynaecological cancers are taking place and what sources most commonly provide information to the general public.

Method

Over an 80 day period, individual tweets containing hashtags relating to women’s cancer were collected via the Twitter API. Data collection was limited to 14 terms relating to women’s cancers, sourced from the CDC web site.

Results

Of the 200 most linked websites on Twitter, 14% were social media (e.g. www.youtube.com), 13% were general news (e.g. www.telegraph.co.uk), 12% were medical/science news (e.g. www.medicalnewstoday.com), 12% were charity/advocacy websites (e.g. www.jostrust.org.uk), 11% were commercial websites (e.g. www.amazon.co.uk) and 8% were academic journals (e.g. oncology.jamanetwork.com).

Conclusion

The dissemination of good quality information by Healthcare professionals to patients has always presented challenges. Social media presents further challenges, as any users may broadcast or promote content without regulation. Also, social media organizations need to generate revenue and depend on advertising and other commercial entities. Our results demonstrate that only 20% of Twitter conversations that specifically tag gynaecological cancers contain links to web sites associated with credible medical or scientific professional sources. Analysis and deeper understanding of social media content allows healthcare professionals to enter this global social conversation and to leverage it for the benefit of patients.

COMPARING OUTCOMES OF COMBINATION CHEMOTHERAPY BETWEEN PACLITAXEL/IFOSFAMIDE/CISPLATIN AND PACLITAXEL/CISPLATIN FOR THE PATIENTS WITH RECURRENT OR PERSISTENT CERVICAL CANCER: RETROSPECTIVE ANALYSIS

H.J. Choi1, J.H. Kim1, J.Y. Park2, J. Lee1
1Samsung medical center, OBGYN, Seoul, Republic of Korea
2Samsung Medical center, OBGYN, Seoul, Republic of Korea

Aims

Palliative chemotherapy for recurrent cervical cancer is combination of paclitaxel and cisplatin (TP). Our institution had used paclitaxel, ifosfamide and cisplatin combination chemotherapy (TIP) for recurrent cervical cancer before the national health insurance approved combination therapy of TP. We compared response and toxicity between TP and TIP.

Method

We retrospectively reviewed the medical records of recurrent or persistent cervical cancer patients treated between 2003 and 2015 at Samsung medical center. Response rate, progression free survival (PFS) and overall survival(OS) of TIP was compared with Paclitaxel and cisplatin combination therapy. Toxicity was measured by dose reduction of therapeutic agents, regimen modification and treatment schedule delay.

Results

The overall response rate of TIP was significantly higher (69 patients, 52.7%) than that of TP (28 patients, 36.4%, P = 0.031). Median OS and median PFS were similar for TP and TIP. (OS: 22.43 months vs.18.5 months p=0.44, PFS:6.37 month vs. 8.3 months, p = 0.48).

Conclusion

The TIP showed higher response rate in recurrent cervical cancer patients without increase of severe complications. Considering high response rate, TIP could be an option for neoadjuvant chemotherapy.
Aims

Pelvic exenteration (PE) offers a chance of 40–60% for long-term survival to selected patients with recurrent pelvic malignancies and no other curative alternative. Traditionally, the involvement of large vessels, nerves, and pelvic bones are considered contraindications. The aim of the paper is to present the outcome of the procedures performed with curative intent that go beyond the traditional limits of PE.

Method

Extended pelvic resections (EPR) were defined as procedures that included the resection of large pelvic nerves, external and common iliac vessels, and pelvic bones.

Results

EPR were performed in 20 patients with the recurrence of gynecological malignant tumours between 2011–2017. The spectrum of procedures comprised nerve resections in 18, bone resection in 5, and large vessel resection in 6 patients. No patient died of complications, but postoperative complications occurred in 12 patients, 9 of which required re-operation. Bone resection was not associated with any specific morbidity. Two cases of vascular resection required femoro-femoral artery bypass. Resection of large nerves caused functional loss and loss of sensation corresponding to individual nerve injury. Within the median follow-up of 18 months, 6 patients died of disease progression, 1 died of another cause, 2 are alive with disease, and 11 are without evidence of disease.

Conclusion

EPR is associated with specific short- and long-term morbidity; it is, however, feasible. The involvement of large vessels, nerves and bones do not represent an absolute contraindication for surgery in selected cases with pelvic recurrence.

A NEED FOR ADJUVANT RADIOTHERAPY IN HIGH-RISK STAGE IB LYMPH-NODE-NEGATIVE PATIENTS WITH CERVICAL CANCER AFTER PROPER SURGICAL TREATMENT? THE SEDLIS CRITERIA REVISITED AFTER 30 YEARS.

D. Cibula¹, L. Dostalek¹, M. Zikan¹, M. Fischerova¹, R. Kocian¹, A. Germanova¹, F. Fruhaufl, L. Dusek², J. Slama¹

¹First Faculty of Medicine- Charles University in Prague and General University Hospital in Prague, Department of Obstetrics and Gynaecology, Prague, Czech Republic

²Faculty of Medicine- Masaryk University, Institute for Biostatistics and Analysis, Brno, Czech Republic

Aims

The role of adjuvant radiotherapy (RT) in LN negative patients with high-risk stage IB cervical cancer is not uniformly accepted. It is advocated based on GOG RCT, which was initiated in 1989. The aim of the current study was to assess the oncological outcome of a similar cohort of patients treated recently by surgery without adjuvant radiotherapy.

Method

Data from patients who were treated by radical surgery in a single institution and who fulfilled the inclusion criteria for original GOG RCT were reviewed. None of the patients received adjuvant treatment.

Results

136 patients were included in the final analysis. Distribution of histological types and tumor size groups did not differ significantly from the GOG trial. The 2-year recurrence rate (RR) reached 7% in our study, while in the GOG trial the figures were 12% and 21% in groups with and without RT. The corresponding figure for 5-year RR was 13% in our study, but 15% and 28% in the GOG trial. The isolated pelvic RR was 4% in our trial, and 14% and 21% in the GOG trial. Only the adenosquamous histological type and the presence of micrometastases in LN were significant prognostic factors in univariate analysis in our study.

Conclusion

Excellent oncological outcome, especially pelvic control, was achieved by tailored radical surgery in high-risk IB cervical cancer patients without adjuvant RT. The substantially better outcome than in the GOG trial can be attributable to more accurate pre-operative or pathologic LN staging, improvement in surgical standards, or both.

TREATMENT OF LOCALLY ADVANCED CERVICAL CANCER WITH POSITIVE FDG-PET AORTIC NODES WITH HELICAL INTENSITY MODULATED RADIATION THERAPY

A. Carlier¹, A. Escande¹, E. Bogart², H. Gauthier³, F. Le Tinier¹, F. Narducci¹, E. Leblanc¹, A. Lesoin¹, E. Lartigau¹, X. Mirabel¹, A. Cordoba¹

¹Centre Oscar Lambret, Department of Radiotherapy, Lille, France
²Centre Oscar Lambret, Biostatistics Unit, Lille, France
³Centre Oscar Lambret, Nuclear Medicine Unit, Lille, France
⁴Centre Oscar Lambret, Department of Gynecological Oncology Surgery, Lille, France
⁵Centre Oscar Lambret, Department of Gynecologic Oncology, Lille, France

Aims

To evaluate toxicity and disease outcome among patients treated with extended-field helical tomotherapy (EFHT) in locally advanced cervical cancer (LACC) with para-aortic nodes (PAN) uptake on ¹⁸FDG-PET. Few data are available as regard to extended-field chemoradiation in the treatment of PAN gross disease without previous lymphadenectomy.

Method

We retrospectively evaluated 34 patients with LACC (FIGO stage IB1 to IVA) and PAN involvement on ¹⁸FDG-PET, treated with EFHT, concurrent chemotherapy and intra-cavitary brachytherapy. Patients received a median dose of 50.4 Gy to the pelvic volume and PAN, and 59.92Gy in simultaneous integrated boost (SIB) to the primary cervical tumor and macroscopic lymph nodes. Patients were assessed for toxicity using NCI-CTCAE v4.0 scale.

Results

At a median follow-up of 34 months, 18 patients (53%) relapsed. The sites of persistent/recurrent disease were as follows: metastatic (41%), local (26%), pelvic lymph nodes (15%) and PAN (15%). No patient had isolated PAN recurrence. Five patients developed PAN recurrence and always experienced synchronous metastatic evolution. The 3-year OS, PFS and loco-regional relapse free survival (LRFS) rates were 67%, 37% and 54% respectively. Neutrophilia, defined as a neutrophils count >7500μl, was the only significant univariate prognostic factors for poorer LRFS (HR= 3.74, p=0.038). Grade 3 gastrointestinal late toxicity occurred in only 1 (3%) patient.

Conclusion

EFHT with SIB to involved nodes was well tolerated. Nevertheless, the prognosis of these patients remained poor with a high rate of metastatic relapse. More studies are expected to statuate on the potential benefit from adjuvant chemotherapy.

ROLE OF ST3GAL5 POLYMORPHISM (RS72842068) IN CERVICAL CANCER DEVELOPMENT

D. Danolić¹, M. Heffer², J. Wagner², I. Skrlec³, I. Alvir¹, I. Mamic¹, L. Susnjar¹, M. Banovic³, M. Puljiz³

¹University Hospital for Tumors- University Hospital Centre Sestre Milosrdnice, Department of Gynecologic Oncology, Zagreb, Croatia
²University of Osijek, Faculty of Medicine, Osijek, Croatia
³University of Zagreb, School of Medicine, Zagreb, Croatia

Aims

To determine whether polymorphisms in the ST3GAL5 gene represents risk factor for cervical cancer.

Method

In total, 164 women participated in our study. Peripheral blood samples were obtained from 81 cervical cancer patients and 83 healthy controls at University Hospital for Tumors, Zagreb, Croatia. The diagnosis of cervical cancer was confirmed by histological examinations of tissues from biopsies or resected specimens. The controls were represented by age-matched females with a normal Pap smear and no previous history of cervical dysplasia or malignant disease. Informed written consent was obtained from all participants. A 3 mL sample of venous blood was collected from each subject into a test tube containing EDTA as anticoagulant. Genomic DNA was extracted by QIAamp DNA Blood Mini Kit (Qiagen Company) according to the manufacturer’s protocol. The ST3GAL5 (rs72842068) single nucleotide polymorphism was genotyped with TaqMan allele-specific PCR amplification technology on an Applied Biosystems 7500/7500 Real-Time PCR System.

Results

There was no significant difference between the two groups in the frequency distributions of age (P = 0.786) suggesting that matching of subjects based on this variable was adequate. We detected only one genotype for the ST3GAL5 (rs72842068) polymorphism. All genotyped subjects carried the homozygous wild-type genotype AA, while heterozygous genotype AG and homozygous genotype GG were not detected.

Conclusion

The present study did not show association of the ST3GAL5 polymorphism (rs72842068) with cervical cancer, but it opened future research direction. In our opinion, the relationship between ganglioside biosynthesis and cervical cancer is far from being elucidated.

LAPAROSCOPIC LYMPHADENECTOMY IN ADVANCED CERVICAL CANCER: PROGNOSTIC AND THERAPEUTIC VALUE

M. del Pino1, J. Pahisa1, À. Rovirosa2, S. Martínez-Román1, B. Gil-Ibañez4, P. Fusté1, A.G. Glickman1, L. Gavà3, J. Ordi4, A. Torné1, A. Rodríguez1

1Hospital Clinic, ICGON Gynecology Oncology Unit, BARCELONA, Spain
2Hospital Clinic, Radiation Oncology Department, BARCELONA, Spain
3Hospital Clinic, Clinic Institute of Hematological and Oncological Diseases, BARCELONA, Spain
4Hospital Clinic, Department of Pathology-, BARCELONA, Spain

Aims

Objective: To analyze the prognostic and therapeutic value of laparoscopic paraaortic lymphadenectomy and selective excision of suspicious pelvic nodes in patients with locally advanced cervical cancer.

Method

Study Design: Retrospective study including 146 women treated in a single institution from 2000 to 2013. FIGO stage was Ib2 in 15 women, IIb in 77 and IIIb-IVa in 51. None had suspicious paraaortic nodes by pre-surgical imaging evaluation. All patients underwent extraperitoneal paraaortic laparoscopic lymphadenectomy with selective excision of enlarged pelvic nodes and received pelvic radiotherapy with concomitant chemotherapy. Extended lumboaortic radiation therapy was added to patients with metastatic paraaortic nodes. The mean follow-up was 43.1 ± 33.7 months.

Results

Results: Metastatic lymph nodes were identified in 29/146 (19.9%) patients in the paraaortic area and in 36/65 (55.4%) patients who underwent selective excision of pelvic nodes. Patients with nodal metastases had increased risk of mortality than those with negative nodes, independently of the location (pelvic and/or paraaortic) of the metastases (hazard ratio: 4.07; 95%CI: 1.36-12.16 for patients with pelvic; p=0.012, and 3.73; 95%CI 1.38-10.09 for patients with paraaortic metastases; p= 0.010). The subset of women with paraaortic metastases were at higher risk of distant metastasis compared with women showing positive pelvic nodes and negative pelvis and paraaortic lymph nodes (27.5% vs. 17.6% vs. 5.2%; p=0.016).

Conclusion

Conclusion: Paraaortic and pelvic lymphadenectomy provides valuable information about mortality risk in patients with locally advanced cervical cancer. Current treatment seems not enough to decrease distant metastasis.

EFFECT OF TRACHELECTOMY ON QUALITY OF LIFE, AND ONCOLOGICAL OUTCOMES IN PATIENTS WITH EARLY STAGE CERVICAL CANCER

N.U. Dogan¹, G. di Favero², T. Pfiffer³, X. Le², C. Köhler²
¹Akdeniz University School of Medicine, Ob&Gyn, Antalya, Turkey
²Asklepios Klinikum Altona, Gynecologic Oncology, Hamburg, Germany
³Asklepios Klinikum Harburg, Gynecology, Hamburg, Germany

Aims

to follow up patients undergoing laparoscopic assisted vaginal trachelectomy by objective questionnaires in order to evaluate changes in bladder, bowel and sexual functions and compare these with patients undergoing vaginal assisted laparoscopic radical hysterectomy (RH).

Method

51 patients were included prospectively. Control group consisted of patients undergoing RH. German pelvic symptom questionnaire was used preoperatively and re-evaluated 6 months after surgery.

Results

Mean age of patients was 38.6 years. 26 patients underwent trachelectomy. 25 patients underwent RH. In preoperative testing median scores of all four items were comparable between patients with trachelectomy and RH. In six month control all four items and pelvic scores were comparable in two groups. When difference between changes in scores preoperatively and six months postoperatively were evaluated, all scores were also comparable but there is a tendency for higher scores in bladder function of patients undergoing RH. Regarding urinary morbidity 4 out of 26 patients (15%) undergoing trachelectomy experienced urinary problems while 40% of patients undergoing RH had urinary problems in 6 month control. Urinary morbidity in early postoperative period was more prevalent in patients with RH. However, urinary morbidity was not pronounced as higher scores in questionnaires in 6 months control. Regarding the oncological outcomes, two patients experienced early relaps.

Conclusion

Radical trachelectomy is a reasonable option for fertility preservation in young patients. Urinary morbidity is acceptable. Urinary, sexual, pelvic prolapse and bowel symptoms are not augmented after 6 months which all are important aspect long term effects of radical oncologic surgeries.

ESGO7-1134

RELIABILITY OF SLN BIOPSY IN PATIENTS WITH BULKY CERVICAL CANCER

L. Dostalek¹, M. Zikan¹, D. Fischerova¹, R. Kocian¹, A. Germanova¹, F. Frühau², L. Dusek2, J. Slama¹, D. Cibula¹

¹First Faculty of Medicine- Charles University in Prague and General University Hospital in Prague,
Gynecologic Oncology Center- Department of Obstetrics and Gynecology, Praha, Czech Republic
²Masaryk University- Brno, Institute for Biostatistics and Analyses- Faculty of Medicine, Brno, Czech Republic

Aims

Lower detection rate of SLN was reported in cervical cancer tumors ≥ 2 cm and SLN biopsy is considered unreliable in tumors ≥ 4 cm. The importance of intraoperative detection of SLN however grows with the size of the tumor as the risk of LN involvement increases. The aim of the study was to assess the detection rate, sensitivity and false negative rate of SLN in LN staging in tumors ≥ 2 cm.

Method

Data from patients with stage IA1 - IIB cervical cancer who were referred for surgical treatment including SLN biopsy followed by systematic pelvic lymphadenectomy were retrospectively analyzed. Combined technique with blue dye and radiocolloid was modified to inject the tracer into the residual stroma.

Results

350 patients were included into the study with stages IA (6%), IB1 (67%), IB2 (13%) and II (14%). Median number of retrieved LN was 37. Macrometastases, micrometastases and isolated tumor cells were found in 9%, 9% and 4% of cases. Macrometastases were detected in tumors < 2 cm, 2-3.9 cm, and ≥ 4 cm in 2%, 4% and 11%.

Conclusion

This is the first study showing that SLN biopsy can be reliable in LN staging in large tumors. The bilateral detection rate, FNR and sensitivity did not differ in tumors < 2 cm, 2-3.9 cm, and ≥ 4 cm.
WHY TRANSVAGINAL ULTRASOUND IS A „MUST-DO” IN STAGING OF CERVICAL CANCER

G.E. Dragnea¹
¹CMI Dragnea Geanina, gynecology, pitesti, Romania

Aims

Transvaginal ultrasound (TVS) is an accurate method to assess the pelvis. Indications for its use are expanding and it can „see” increasingly more details of pelvic organs.

This cheap and accessible investigation becomes extremely useful in experienced hands, contributing to a precise staging of cervical cancer since the first consultation.

Method

The treatment plan can be quickly established and the cases are triaged into operative and nonoperative categories. Transvaginal ultrasound can assess tumor size, stromal and parametrial invasion, the extension to the ureters, bladder and rectum.

Results

It can differentiate the parametrial invasion of a concomitant rigidity caused by endometriosis; it can identify the accurate size and extension of an endocervical tumour with minimal exocervical expresion or detect the imminence of the ureteral invasion to prevent the loss of renal function. Local extension of cervical cancer can be determined with an accuracy at least similar to MRI. In addition to MRI, ultrasonography allows a dynamic evaluation of tumour’s mobility over the surrounding tissues.

Conclusion

Therefore, TVS is a feasible and valuable imaging method for the assessment of cervical cancer and should be used routinely for the staging of this disease.
CHANGES IN EPIDEMIOLOGY OF OPERATED CERVICAL CANCER AT PRETORIA ACADEMIC HOSPITAL COMPLEX: 2000 VS 2010

G. Dreyer¹, D. Fosu-Amoah¹, J. Biko¹, A. Mouton¹, L.C. Snyman¹, B.G. Lindeque¹, C. Visser¹

¹University of Pretoria, Department of Obstetrics & Gynaecology, Pretoria, South Africa

Aims

Our objective was to compare and evaluate epidemiology data on cervical cancer patients collected during two periods, ten years apart, at the Pretoria Academic Hospital Complex.

Method

Data were collected on cervical cancer patients with FIGO stage Ib1 – Ila during two retrospective descriptive studies, each study extending over a 5-year interval and performed ten years apart. Data obtained included demography, HIV status, FIGO stage, tumour histology type & grade and referral for adjuvant therapy.

Results

The first study (A) included 188 patients treated 1 Jan 1999 to 31 Dec 2003, while the second study (B) included 242 patients treated 1 Jan 2008 to 31 Dec 2012. Age distribution was comparable in both studies. HIV positivity rates were 2.5-fold higher in the second study: 9.4% vs 24.9%. FIGO stage Ib1 (43.5% vs 48.3%) and stage Ila (22.6% vs 17.8%) differed in the respective studies (A vs B), but stage Ib2 was similar in both (33.9%). Histological type differed slightly (A vs B): squamous- (76.6% vs 68.8%); adeno- (13.3% vs 20.2%) and adenosquamous carcinoma (10.1% vs 5.8%). Referral for adjuvant therapy were higher in study B: 40.4% vs 51.7%.

Conclusion

Longitudinal data from operated cervical cancer patients indicate a favourable trend toward downstaging. This could be due to increased screening, mainly targeting HIV positive women.

TRANSLEVATOR PELVIC EXENTERATION WITH VULVECTOMY: VIDEO PRESENTATION

P. Dursun¹, A. Ayhan²

¹Kızılimak Mh. 1450. Sk. Ankara Ticaret Merkezi B Blok kat 3 d:17, Gynecologic Oncology, Ankara, Turkey
²Baskent University School of Medicine, Gynecologic Oncology, Ankara, Turkey

Aims

Total pelvic exenteration is a radical operation, involving en bloc resection of visceral pelvic organs, including uterus, ovaries, vagina, bladder, and rectosigmoid together with their parametrial structures and lymph nodes. The aim of this video is to demonstrate the surgical steps of the translevator pelvic exenteration with vulvectomy.

Method

Video demonstration of translevator anterior and total pelvic exenterative procedures with vulvectomy.

Results

complete surgical clearance of disease (R0 resection) was reached in all patients who underwent this procedures.

Conclusion

Exenterative procedures for gynecological cancers are rarely performed and present clinical challenges both for patients and clinicians.
A multidisciplinary surgical approach is essential to reach good patient outcome.

PREGNANCY COMPLICATED BY CERVICAL SQUAMOUS INTRAEPITHELIAL LESIONS IN WOMEN FROM MACEDONIA

E. Dzikova¹, G. Dimitrov²

¹University Clinic for Gynecology and Obstetrics- Medical faculty- University Ss. “Cyril and Methodius”Skopje- Macedonia, High risk pregnancy, Skopje, FYR Macedonia
²University Clinic for Gynecology and Obstetrics- Medical faculty- University Ss. “Cyril and Methodius”Skopje- Macedonia, Gynecologic oncology, Skopje, FYR Macedonia

Aims

The aim of our study was to evaluate the persistence, progression and regression of cervical intraepithelial neoplasia (CIN) during pregnancy compared to non-pregnant-women.

Method

We have analyzed 50 patients, 25 pregnant and 25 no- pregnant, in the University clinic for gynecology and obstetrics. The rates of persistence, progression and regression of CIN were estimated according to histological findings in the initial visit and after delivery. The results were compared with the non-pregnant group of women followed up for nine months.

Results

A total of 50 pregnant women with cervical intraepithelial neoplasia were included into the study. LSIL and HSIL was histologically proved in 17 and 33 of all pregnant women, respectively. The histological findings after delivery showed a considerably higher affinity to spontaneous regression (28 vs. 16 patients $p=0.010$) On the other hand, the persistence rate was significantly lower than in non-pregnant women (20 vs. 29 patients, $p=0.048$). The progression rate was very low in pregnant women.

Conclusion

The regression rate of cervical intraepithelial neoplasia is significantly high after delivery. For that reason, the decision for the definite type of treatment should be made according to the findings after delivery. On the other hand, the time and the method of treatment should be made according to the severity of the lesion.

THE ASSESSMENT OF RECURRENT OR RESIDUAL CERVICAL INTRAEPITHELIAL NEOPLASIA LESIONS AFTER CO2 LASER VAPORIZATION AND COLD KNIFE CONISATION

G. Dimitrov¹, E. Dzikova²
¹University Clinic for Gynecology and Obstetrics- Medical faculty- University Ss. "Cyril and Methodius"Skopje- Macedonia, Gynecologic oncology, Skopje, FYR Macedonia
²University Clinic for Gynecology and Obstetrics- Medical faculty- University Ss. "Cyril and Methodius"Skopje- Macedonia, High risk pregnancy, Skopje, FYR Macedonia

Aims

Cervical cancer ranks as the 4th leading cause of female cancer in the World. Annual incidence for CIN 1 and CIN 2,3 was 1.6 and 1.2 per 1,000 women, respectively. Current estimates indicate that every year 527,624 women are diagnosed with cervical cancer and 265,672 die from the disease. Incidence was highest among women aged 21 to 30 years (3.3 and 3.6 per 1,000) and women aged 31 to 40 years (2.9 and 2.7 per 1,000). The aim of our study is to assess recurrent or residual cervical intraepithelial neoplasia lesions after CO2 laser vaporization versus cold knife conisation.

Method

We evaluated 100 patients in the University Clinic for Gynecology and Obstetrics with histologically proved high grade squamous intraepithelial lesions (HSIL). 54% were qualified for cold knife conisation according to World Health Organisation guidelines, and 46% were treated with CO2 laser vaporization. The patients were followed up every 4 months for two years, and afterwards twice a year for the next 3 years.

Results

In our study we have found that the effect of the treatment depends on the type and number of HPV, localization of the cervical intraepithelial lesion, and the free margins of the removed tissue. In the most cases recurrent or residual disease was found within the first year after treatment.

Conclusion

Our study showed that the positive endo-cervical or ecto-cervical margin, positive ECC specimens, and severity of cervical disease were all predictors of residual/recurrent disease.

PROMISING SURVIVAL RESULTS FOR DOSE-INTENSE NEOADJUVANT WEEKLY CHEMOTHERAPY, CONCURRENT CHEMOIRRADIATION, HDR BRACHYTHERAPY AND PELVIC SIDE WALL BOOSTS IN PATIENTS WITH CERVICAL CANCER

L. Eastlake¹, R. Moyeed², S. Dubey¹, G. Hughes³, A. Talaat³, D. Yiannakis¹,⁴
¹Plymouth Hospitals NHS Trust, Oncology, Plymouth, United Kingdom
²University of Plymouth, School of Computing - Electronics and Mathematics, Plymouth, United Kingdom
³Plymouth Hospitals NHS Trust, Gynaecology, Plymouth, United Kingdom
⁴Lancashire Teaching Hospital NHS Trust, Oncology, Preston, United Kingdom

Aims

To audit our survival results for cervical cancer patients treated with radical radiotherapy.

Method

Retrospective review of 32 patients from Derriford Hospital (Plymouth, UK) treated March 2012-April 2015. Median follow-up 29.6 months (data locked November 2016).

Patients received pelvic external beam radiotherapy[EBRT] with concurrent chemotherapy, HDR brachytherapy and pelvic side wall boosts[PSWB]. Stage IIB+ disease offered neoadjuvant dose-intense weekly chemotherapy.

Results

Median age: 54 years (range25-83). Histology: 18 squamous, 8 adenocarcinoma and 6 adenosquamous. TNM staging: IB=1, IIB=17, IIIb=10 and IVB=4 patients. PET staging in 31 patients; median SUV of 12 (range0-59). Median EBRT dose to pelvis 50.4Gy/28 fractions[#]; 2 patients received 45Gy/25#. 12/32 received PSWB; median dose of 3.6Gy/2# (range3.34-5Gy/2-3#). Fourteen received neoadjuvant chemotherapy; median of 6 cycles (range2-6). 29/32 received concurrent chemotherapy, median 5 cycles (range3-6). Median duration of EBRT/brachytherapy was 45 days (range38-86, IQR44-50); median duration of EBRT/brachytherapy/PSWB was 49 days (range38-86, IQR45-55). 6 patients relapsed; 3 within the radiotherapy field. Median time (months) from diagnosis to relapse was 12.5 (range0-17). Four patients died. 2 year actuarial overall survival [OS] was 92% (95%Ci 76-100) and 3 year OS 88% (95%CI 76-100). Actuarial relapse-free survival at 2 years 81% (95%CI 68-96) and at 3 years 76%. 10/32 patients experienced grade 3+ toxicities. Nil exploratory analyses were significant.

Conclusion

Our survival data are promising, giving credence to current hypotheses being explored in clinical trials of definitive chemoradiotherapy in cervical cancer (e.g. minimum 5 cycles of concurrent chemotherapy, total treatment time <50 days, adequate brachytherapy dosage (ICRU 89), and use of neoadjuvant/adjuvant chemotherapy).

ANALYSIS AND TREATMENT RESULTS OF CANCER CERVIX; TEN YEARS EXPERIENCES IN ALEXANDRIA CLINICAL ONCOLOGY DEPARTMENT

S. Elkhateeb\textsuperscript{1}, A. Bela\textsuperscript{2}, Y. Rostom\textsuperscript{2}, W. Arafat\textsuperscript{2}

\textsuperscript{1}SUN, Oncology, Alexandria, Egypt
\textsuperscript{2}Alexandria Main University, Clinical Oncology, Alexandria, Egypt

Aims

1. Reviewing the demographic and clinicopathological features of these patients.
2. Reviewing all the treatments lines received by these patients (chemotherapy protocols and radiotherapy).
3. Assessment of treatment results.

Method

We conducted a retrospective analysis of patients with cervical cancer who presented at a Alexandria main hospital department of oncology between 2003 and 2012. A total of 162 patients with the median age of 54 years (20-80) were studied. The demographic and clinical variables included age, marital status, menstrual history, comorbidities, pathology, degree of differentiation, clinical stage and treatment administered.

Results

In our study, most of patients presented with vaginal bleeding. 17\% associated with anaemia either at diagnosis or during treatment. Majority of the patients (60 patients 37.7\%) had regional spread disease. Since majority presented at later stages, chemotherapy-radiotherapy was the most common treatment modality used in our population. On histopathology, 116 patients (71.6\%) had squamous cell carcinoma while 5 patients (3\%) had adenocarcinoma and 3 patients (1.9\%) had liposarcoma. In 80 patients (49\%), the tumour differentiation was not known in 80 (49.8\%) while it was moderate, poorly & undifferentiated in 44 (27\%), 35 (21\%), and 3 (1.9\%) patients, respectively. The 5 years overall survival was 53.7\%. The significant factors affecting survival were age, stage at diagnosis and treatment modality (P=0.003, P=<0.001 and P=<0.001 respectively)

ESGO7-0797

INTRAOPERATIVE AND POSTOPERATIVE MORBIDITY IN SENTINEL LYMPH NODE BIOPSY VS PELVIC LYMPHADENECTOMY IN EARLY-STAGE CERVICAL CANCER

S. Escura1, A. Rodríguez-Trujillo1, B. Gil-Ibáñez1, P. Fusté1, M. Del Pino1, J. Pahisa1, M. Munmany1, I. Nicolás1, A. Glickman1, A. Torné1
1Hospital Clinic, ICGON, Barcelona, Spain

Aims

To compare the morbidity associated to lymph node staging in patients with early-stage cervical cancer undergoing sentinel lymph node biopsy (SLNB) vs. bilateral pelvic lymphadenectomy (LDN).

Method

Retrospective cohort study in patients with FIGO IA1-IB1/IIA1 cervical cancer. From February 2001 until May 2011 lymph node staging was performed by SLNB and LDN and between June 2011 and October 2016 by only SLNB, being LDN performed when SLNB was unilaterally or non-detected. When SLNB was intraoperatively positive, para-aortic lymphadenectomy was performed in order to plan the radiation field. Otherwise, radical surgical treatment was performed. Intraoperative and early postoperative complications following Clavien-Dindo classification were assessed.

Results

We recruited 134 patients. Fifty-four patients were included in the SLNB group and 80 in the LDN group. The median age of the whole cohort was 43 years (range 22-76). Ninety patients (67.2%) presented tumors ≤ 2cm. Most of the patients had FIGO stage IB1 (121/134, 90.3%) and squamous cell carcinoma (91/134, 67.9%). No differences regarding type of surgery (trachelectomy vs. hysterectomy) and rate of para-aortic lymphadenectomy was observed between both groups.

In the SLNB group we observed 1 (1.8%) intraoperative complication (urinary tract lesion). In the LDN group, we observed 4 (5%) intraoperative complications (2 urinary tract lesion, 1 vascular lesion and 1 intestinal lesion). We observed a lower rate of Clavien-Dindo ≥ II complications in SLNB group compared with LDN group (5.5% vs. 11.2%). All these differences were not statistically significant.

Conclusion

SLNB seems to be associated with less intraoperative and early postoperative morbidity compared with LDN.

MULTI CENTRIC PAGET’S DISEASE AND REVIEW OF LITERATURE

M. Farazestanian¹, Z. yousefi¹
¹ghaem hospital, Obstet & Gynecol, Mashhad, Iran

Aims

The aim of this report is to introduce a case of multi centric Paget's disease and review of literature.

Method

A 62-year-old woman with complaints of vulvar pruritus, painful vulvar lesion for 4 years was referred to oncology department of Ghaem hospital, Mashhad University of Medical Sciences in 2016. Pathological results of erythematous and exfoliated lesion of the major and minor labia extend to anus was reported as PDV with full-thickness involvement. In investigations, she had persistent hematuria. Pelvis and abdomen investigation revealed irregularity in the posterior wall of the bladder and biopsy detected urothelial carcinoma in the bladder. Radical cystectomy was performed subsequently. In addition, complete response of vulvar lesion to imiquimod cream was seen after 6 weeks of therapy. The patient is free of disease and now she is under serial follow-up.

Results

Generally standard treatment modality in patients who experienced multicenteric Paget's disease is surgical resection, also topical 5% imiquimod cream may be considered as an alternative option in setting metastatic vulvar Paget.

Conclusion

Generally standard treatment modality in patients who experienced multicenteric Paget's disease is surgical resection, also topical 5% imiquimod cream may be considered as an alternative option in setting metastatic vulvar Paget.

THE EFFICACY OF NEOADJUVANT CHEMOTHERAPY FOLLOWED BY FERTILITY AND NERVE SPARING ROBOT-ASSISTED LAPAROSCOPIC RADICAL TRACHELECTOMY IN PATIENTS WITH FIGO STAGE IA2-IB1 UTERINE CERVICAL CANCER.

S. Farghaly¹
¹The Joan and Sanford Weill Medical college and NYPH/ WCUMC- Cornell University, GYN. & OB, New York, USA

Aims

To evaluate the efficacy of neoadjuvant chemotherapy followed by single port access robot-assisted radical trachelectomy in patients with FIGO stage Ia2-Ib1 uterine cervical cancer.

Method

Patients who are of child bearing potential, with FIGO stage Ia2-Ib1 are selected for platinum based Neoadjuvant Chemotherapy. The tumor size should be 2 cm in diameter or less. The patients are assessed with Transvaginal ultrasound, hysteroscopy, MRI, and pre-and postsurgical Color Doppler ultrasound of the uterine arteries. Neoadjuvant chemotherapy is given, according to the following schedule: Cis-platinum 50 mg/ m²/day 2-3; Paclitaxel 175 mg/ m²/day 1; 5-fluororacil (5FU) 800 mg/ m²/day 1-2-3. Four cycles, every 21 days, are given and the surgery is performed one month after the last cycle. Single port access robot-assisted laparoscopic radical trachelectomy is performed. This surgical procedure consists of 3 steps. First, after the insertion of the trocar, the intra-abdominal cavity is explored with a laparoscope. da Vinci surgical system docking followed. Second, a robotic uterine artery preservation and hypogastric nerve plexus-sparing radical trachelectomy with pelvic lymphadenectomy are carried out. Finally, after undocking the da Vinci surgical system, puncture site repair and drainage insertion are performed.

Results

This chemotherapeutic regimen followed by single port access radical trachelectomy achieved satisfactory oncologic and surgical outcomes for those patients.

Conclusion

The combined neoadjuvant chemotherapy regimen and the minimally invasive robot assisted radical trachelectomy for early stage cervical carcinoma is safe, and has satisfactory oncologic and obstetric outcomes. It does provide those patients with the opportunity to become pregnant.
Aims

The first aim of our study was to report retrospectively our fertility sparing treatment assessing the overall and disease free survival rate in women affected by FIGO IB1 (> 2 cm) – IIA1 cervical cancer. The second aim of our study was to investigate the rate of pregnancy after our conservative treatment.

Method

Between March 2006 and September 2017, 17 patients affected by invasive CC with a size greater than 2 cm were addressed to our institutions. All the patients were undergone NACT followed by laparoscopic SLN mapping, laparoscopic PND and vaginal radical trachelectomy.

Results

The median age was 27.4 years
Tumor stages were: IB1, tumor size > 2 cm in 8 patients, IB2 in 5 patients, and IIA1 in 4 patients.
Nine patients were diagnosed with squamous cell carcinoma, eight patients with adenocarcinoma, two of which with clear cells.
At least one pelvic SLN was identified per patients and at the frozen section assessment all the SLNs resulted negatives.
Median removed pelvic LNs were 16 (7-25).
All the patients addressed were undergone FST. 4 out of 17 patients attempted to conceive.
Only three out of 4 patients become pregnancy. Nowadays three patients are trying to conceive and other three patients have decided to continue oral progestin contraceptive.
Two patients out of 17 presented early pelvic relapse and radical treatment was proposed.
After median follow up of 38 months the other patients are free of disease (5-112 months).

Conclusion

NACT followed by conservative surgery is an innovative approach that allows a FST in many young women affected by CC.
CONTINENT CUTANEOUS ILEOCECAL RESERVOIR USING THE SUBMUCOSALLY EMBEDDED APPENDIX AFTER ANTERIOR EXENTERATION FOR GYNAECOLOGICAL MALIGNANCIES: TECHNIQUE AND COMPLICATIONS

M. Friedrich¹, M. Friedrich²
¹HELIOS Hospital, Department of Gynecology, Krefeld, Germany
²HELIOS Klinikum, Department of Urology, Krefeld, Germany

Aims

Patients with advanced gynecological malignancies or recurrences of gynecological malignancies (vaginal carcinoma, endometrial carcinoma and cervical carcinoma), who had to be treated by anterior exenteration and did not have an appendectomy, were reconstructed by continent cutaneous ileoccel reservoir using the submucosally embedded appendix. Data of 14 patients from the years 2008 and 2014 were analysed for intraoperative and early postoperative complication rate.

Method

The appendix-pouch technique starts with the transsection of the terminal ileum about 12 cm away from the ileoceleal valve and of the colon ascendens about 15 cm away from the hepatic flexure. In order to reduce the tension of the wall of the pouch a teniamyotomy of the colon is performed. The efferent segment of the pouch is built by the appendix and is passed out at the umbilicus.

Results

The mean operation time for the complete anterior exenteration was 280 (range 230 – 320) minutes, for the reconstruction by the appendix pouch 75 (range 60 – 90) minutes. The main complications were: problems with wound healing and retention of secretion in the small pelvis. Insufficiencies of the sutures were not observed.

Conclusion

Our experience shows, that the appendix-pouch-technique is a good alternative for continent reconstruction of the bladder after anterior exenteration. This technique is combined with a quite low complication rate.

A PHASE III STUDY OF ORAL ONDANSETRON VERSUS TRANSDERMAL GRANISETRON FOR WOMEN WITH GYNECOLOGIC CANCERS RECEIVING PELVIC CHEMORADIATION

M. Frumovitz1, A. Jhingran2, M. Munsell3, P. Eifel2, A. Klopp2, R. Coleman1, L. Ramondetta1

1University of Texas MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA
2University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA
3University of Texas MD Anderson Cancer Center, Biostatistics, Houston, USA

Aims

Pelvic radiation with cisplatin is highly emetogenic and late onset (days 4-7) nausea and vomiting occurs in > 25% of these women. The objective of this study was to measure response rates to anti-emetic therapies of granisetron administered via a transdermal patch (TG) compared to orally administered ondansetron (OO) in women with cervical, endometrial or vaginal cancer undergoing chemoradiation therapy.

Method

Eligible patients were assigned either granisetron formulated in a transdermal patch replaced every 7 days or 8 mg of ondansetron orally thrice daily starting with cisplatin administration and continued for 72 hours after chemotherapy infusion using outcome adaptive randomization. The primary endpoint was complete response to anti-emetic therapy on days 4-7 of chemoradiation therapy. Data on compliance/ease of administration, amount of nausea and vomiting, and effect of nausea and vomiting on quality of life were collected.

Results

Seventy-five women were randomized. The majority of patients were receiving chemoradiation for cervical cancer (83%) followed by endometrial (14%) and vaginal cancers (3%). TG achieved a success rate of 49.8% (90% CI 37.5-62.1%) and OO achieved a success rate of 39.7% (90% CI 26.6%-53.5%). The posterior probability that TG achieved a higher success rate in controlling late onset nausea and vomiting compared to OO was 82%. There was no difference between the 2 groups in the compliance or in the effect of nausea and vomiting on quality of life.

Conclusion

Transdermal granisetron is better than oral ondansetron in controlling late onset nausea and vomiting from pelvic radiation with weekly cisplatinum in women with gynecologic malignancies.

ESGO7-0782

SEMI-NERVE SPARING RADICAL HYSTERECTOMY WITH SHORT-TERM ELECTRICAL STIMULUS HAVE POSITIVE EFFECTS ON POST-OPERATION BLADDER FUNCTION

Y. Fu1, Y. Chen1, Y. Zhang1, K. Hua1
1Obstetrics and Gynecology Hospital of Fudan University, Gynecology, Shanghai, China

Aims

Radical hysterectomy (RH) is the standard primary treatment for early stage invasive cervical cancer. Patients may have poor quality of life. Nerve-sparing radical hysterectomy (NSRH) is aimed to improve the post-operation pelvic dysfunction, which its safety is under controversy. Therefore, we propose a surgical method which partially spare the pelvic splenic nerve and bladder branch, along with post operation short-term electrical stimulus, to evaluate the effects on post-operation bladder, bowel and sex dysfunction.

Method

Retrospective case-control study and prospective cohort study with consecutive patients who underwent RH ad semi-nerve-sparing RH (semi-NSRH) were included in the study. Patients were assigned to a semi-NSRH + stimulus group (group 1) vs. a RH + stimulus group (group 2) vs. semi-NSRH group (group 3) vs. RH group (group 4). In group 1 and 2 bladder-sacral plexus electric stimulus began 5 days after surgery, qd × 5 days. Self-reported questionnaire and urodynamic test were performed.

Results

It was found that there were significant differences in irrigative and obstructive scores of PFDI scoring system, between pre and post operation group (P = 0.004, P = 0.0016). Radical hysterectomy had significant deteriorating effect on sexual life, based on scores of PISQ-12. Urodynamic is consistent with the inventory. The results had relevance with the factor of parametrium width taken during the surgery. The bladder syndrome and rectal syndrome had a significant improvement in the group of nerve-sparing radical hysterectomy and stimulus group (P = 0.028, P = 0.017).

Conclusion

Semi-radical hysterectomy along with post-op bladder-sacral plexus electric stimulus can give a better outcome of bladder and rectal function. Otherwise, the effect of post-op bladder-sacral plexus electric stimulus towards the sexual function is not clear.

VALUE OF HUMAN PAPILLOMA VIRUS GENOTYPING IN TISSUE FROM CERVICAL CANCER, LYMPH NODES AND RECURRENT TISSUE IN POSTSURGICAL MANAGEMENT

A.H. Lauridsen¹, E. Mejgaard², L.K. Petersen³, J. Blaakaer⁴, T. Steiniche², K. Fuglsang¹

¹Aarhus University Hospital, Dept. of Obstetrics and Gynecology, Aarhus, Denmark
²Aarhus University Hospital, Dept. of Pathology, Aarhus, Denmark
³Randers Regional Hospital, Dept. of Obstetrics and Gynecology, Randers, Denmark
⁴Odense University Hospital, Dept. of Obstetrics and Gynecology, Odense, Denmark

Aims

Human Papilloma Virus (HPV) is obligate for the development of cervical cancer. HPV has previously been detected in tissue from cervical tumor, lymph nodes and recurrent disease. The aim of this study was to evaluate the value of HPV genotyping in postsurgical management.

Method

We conducted a hospital-based case-control study. All patients had previously undergone surgery for early-stage cervical cancer during 2003 to 2014 at the Department of Obstetrics and Gynecology, Aarhus University Hospital, Denmark. Formalin-fixed, paraffin-embedded tissue from the primary tumor, pelvic lymph node stations, and recurrent disease were genotyped using INNO-LIPA HPV Genotyping Extra (Fujirebio, Europe, Ghent, Belgium).

Results

Thirty-three patients with HPV positive primary cervical tumor were included, 18 recurrent and 15 non-recurrent cases. Not surprisingly, women diagnosed with lymph node metastases were more likely to be diagnosed with recurrence compared to women without metastases (86% vs. 46%, p=0.10). Metastatic lymph nodes were more likely HPV positive than non-metastatic lymph nodes (71% vs. 27%, p=0.07). Women with HPV positive lymph nodes, with and without metastases, were more likely to be diagnosed with recurrence than women with HPV negative lymph nodes (83% vs. 38%, p= 0.03). From ten women with recurrence tissue biopsies were available and sufficient for HPV genotyping and HPV was detected in eight (80%). For all women the HPV genotype in the three tissues was consistent.

Conclusion

Preliminary, the presence of HPV in the lymph nodes seems to be associated with an increased risk of recurrence and HPV genotyping may very likely be valuable in postsurgical management.
CERVICAL CANCER STAGING IN THE NORDIC COUNTRIES - SURVEY FROM THE NORDIC SOCIETY OF GYNECOLOGICAL ONCOLOGY (NSGO)

K. Fuglsang1, K. Woie2, M. Anttila3, P. Päivi4, G. Lindahl5, A. Thoroddson6, H. Roed7, I.S. Haldersen8, E. Avall-Lundqvist5, J. Blaakaer9

1Aarhus University Hospital, Dept. of Obstetrics and Gynecology, 8200, Denmark
2Haukeland University Hospital, Dept. of Gynecologic Oncology, Bergen, Norway
3Kuopio University Hospital, Dept. of Gynecology, Kuopio, Finland
4Helsinki University Hospital, Dept. of Gynecology and Obstetrics, Helsinki, Finland
5Linköping University Hospital, Dept. of Oncology, Linköping, Sweden
6Landspitali University Hospital, Dept. of Obstetrics and Gynecology, Reykjavik, Iceland
7Copenhagen University Hospital, Dept. of Oncology, Copenhagen, Denmark
8Haukeland University Hospital, Dept. of Radiology, Bergen, Norway
9Odense University Hospital, Dept. of Obstetrics and Gynecology, Odense, Denmark

Aims

In the Nordic countries much resources are spent on pretreatment imaging like ultrasound, MRI, PET-CT or CT, and sentinel node for cervical cancer patients. The NSGO surgical group performed this survey to collect information about the use of these modalities, handling of the information gained, and how the information is integrated into the treatment algorithm.

Method

We conducted a questionnaire-based survey from 1 January to 31 March 2017. The NSGO surgical group elaborated a questionnaire in the fall 2016. In the five Nordic countries, all 22 Gynecological Oncology Centers were invited to participate. (Denmark 5, Finland 5, Iceland 1, Norway 4, and Sweden 7).

Results

The questionnaires were returned by 19 (86%) centers. The median number of cases treated in each center was 32 (15-120). All, except one center that only used PET-CT, used a combination of imaging for treatment planning. Eighteen (94%) centers used MRI and 15 (79%) centers used PET-CT. The clinicians knew the imaging results before FIGO clinical staging in 14 (74%) centers. The result of the imaging had an influence on the clinical staging in more than half of the centers, 11 (58%). Sentinel node was a routine procedure in three (16%) centers and was used in protocol in five (28%) centers.

Conclusion

The majority of the Nordic Gynecological Oncology Centers report a FIGO clinical stage influenced by pretreatment imaging. Therefore, the NSGO surgical group plans to elaborate a proposal for future amendments of the staging guideline and streamlining the reporting of the stage to increase transparency of results.

XPA EXPRESSION IS A POTENTIAL PREDICTIVE MARKER OF NEOADJUVANT CHEMOTHERAPY EFFECTIVENESS FOR LOCALLY ADVANCED UTERINE CERVICAL CANCER

T. Wada1, T. Fukuda1, Y. Inoue1, M. Shimomura1, H. Matsubara1, M. Kawanishi1, R. Tasaka1, T. Yasui1, T. Sumi1

1Osaka City University Graduate School of Medicine, Obstetrics and Gynecology, Osaka, Japan

Aims

We examined the correlation between XPA (xeroderma pigmentosum complementation group-A) expression and the efficacy of Neoadjuvant chemotherapy (NAC) for locally advanced uterine cervical cancer.

Method

We reviewed 56 cases of locally advanced uterine cervical cancer stage IIIA-IIIB from 1995 to 2010. Cases were divided into two groups: one group in which NAC was effective, surgery was possible and radiotherapy was performed (group A; n=31), and another group in which NAC was ineffective and radiation therapy was performed (group B; n=25). XPA expression was examined immunohistochemically in paraffin-embedded sections using the avidin-biotin peroxidase complex method. This study was approved by the institutional review board in our facility.

Results

The expression of XPA was significantly higher in the group B than in the group A (p=0.001). The overall survival of group A was significantly longer than of group B (P<0.01). Cases were divided into two groups: one group in which XPA expression was low level (weighted score≤3, n=17), and another group in which XPA expression was high level (weighted scores≥4, n=39). Low XPA expression group might be responsive to NAC than high expression group (p=0.001).

Conclusion

It is suggested that the expression of XPA may predict the efficacy of NAC as a treatment for locally advanced uterine cervical cancer.

AMPHICRINE CANCER OF THE CERVIX
M. Gabrys¹, D.M. Klotz², K. Friedrich³, U. Canzler², P. Winberger⁴
¹Carl Gustav Carus University Hospital, Obstetrics and Gynaecology, Dresden, Germany
²Carl Gustav Carus University Hospital, Obstetrics and Gynaecology, Dresden, Germany
³Carl Gustav Carus University Hospital, Pathology, Dresden, Germany
⁴Carl Gustav Carus University, Obstetrics and Gynaecology, Dresden, Germany

Aims

Only 1-2% of all cervical cancers are neuroendocrine cancers, which are known to be one of the most aggressive forms of cervical cancer and are associated with poor prognosis. Tumours can also have a (neuro-)endocrine and exocrine differentiation, called amphicrine cancer, which is a relatively uncommon cancer type.

Method

A 30-year old patient was admitted to hospital due to a histologically-confirmed adenocarcinoma of the cervix uteri, with a sonographically suspicious ovary. We planned primary surgery per laparatomy. The intraoperative frozen section of the right ovary and fallopian tube was first reported as a granulosa cell tumour. A total mesometrial resection (TMMR) with pelvic and inframesenteric para-aortal lymph node dissection, bilateral salpingo-oophorectomy, and infragastric omentectomy were performed.

Results

The final histological analysis of the samples confirmed an amphicrine cervical carcinoma with ovarian metastases (FIGO IIA1, pT2a1, pN0 (0/62), L0, V0, pM0, G3, R0). The diagnosis of an amphicrine cancer of the cervix was made due to the parallel expression of neuroendocrine (Synaptophysin, Chromogranin) and exocrine (CEA) markers.

Due to the neuroendocrine differentiation, the patient received 6 cycles of cisplatin/etoposide. The adjuvant chemotherapy was performed within the standard duration. There has been no evidence of tumour recurrence at the end of chemotherapy.

Conclusion

While amphicrine cancers have commonly been reported in the gastrointestinal tract, this is the second reported case of an amphicrine cancer of the cervix uteri to date. The differential diagnoses include cervical metastases of amphicrine gastrointestinal cancers and adenocarcinoma of the cervix, containing isolated cells that demonstrate a neuro-endocrine differentiation.
A CASE OF PRIMARY DIFFUSE LARGE B-CELLS LYMPHOMA OF THE UTERINE CERVIX

H. Mansouri, S. Gadria, M.A. Ayadi, A. Chabchoub, S. Slim, M. Slimane, L. Charfi, I. Ben Safta, M. Hechiche, J. Ben Hassouna, K. Rahal

1Salah Azaiz Institute, Surgical oncology departement, Tunis, Tunisia
2Salah Azaiz Institute, Pathology departement, Tunis, Tunisia

Aims

Extranodal Non-Hodgkin’s Lymphoma (NHL) of the female genital tract account for only 0.5% to 1% of cases. Among all cervical malignancies, the overall incidence of primary cervical lymphoma is less than 1%. The most common histological subtype is diffuse large B-cell lymphoma. We describe clinical, histological and therapeutic feature of a case of NHL of the cervix.

Method

We describe clinical, histological and therapeutic feature of a case of NHL of the cervix.

Results

A 59-year-old female presented with flank pain and irritative urinary voiding. Clinical examination revealed a 5 cm mass in the cervix and extending to the middle third of vagina, involving both parametria. Cystoscopy revealed an external mass effect distorting the bladder without mucosal invasion. Imaging studies showed a pelvic mass centering on the cervix and extending into the bladder and the right ureter with hydronephrosis and retroperitoneal nodes measuring 46 mm in diameter, there were no evidence of secondary cerebral, hepatic or mediastinal localizations. Cervical biopsy demonstrated a cervical proliferation of lymphoid cells positive for CLA and CD20, and negative with cytokeratin and Myeloperoxidase suggesting a diffuse large B-cell lymphoma of the cervix. Bone marrow was uninvolved. This patient was treated with four cycles of ACVBP (adriamycine, cyclophosphamide, Bleomycin, vincristine and prednisolone) chemotherapy followed by consolidation with radiotherapy. The patient showed complete clinical, histological and radiological response.

Conclusion

NHL of uterine cervix is rare entity. Standard treatment is not established. Combination of radiotherapy and chemotherapy is the treatment of choice with encouraging results.

ESGO7-1359

TOTAL LAPAROSCOPIC RADICAL SURGERY FOR CERVICAL CANCER

K. Galaal¹
¹Royal Cornwall Hospital NHS Trust, Gynaecological Oncology, Truro, United Kingdom

Aims

Objective: To compare surgical complications of laparoscopic approach to laparotomy in single institution

Method

We describe the technique for laparoscopic radical hysterectomy LRH and total laparoscopic radical trachelectomy for women diagnosed with FIGO stage 1b1 cervical cancer. The surgical approach in our institution involved the use of harmonic scalpel and bipolar diathermy, monopolar diathermy was not used. Detailed pre-op MRI are presented as well as intra-op pictures and short videos to illustrate our technics. We also report on the perioperative morbidity and mortality. The medical records of the first 20 patients who had undergone LRH/total laparoscopic radical trachelectomy for invasive cervical cancer between October 2012 and April 2017, were reviewed retrospectively.

Results

There was significant reduction in blood loss in the laparoscopic cases compared to laparotomy. 6% of cases have had urinary retention, none last than 30 days, the urinary retention cases were managed expectantly. None of the patients had had urinary fistulas. There was no post-operative mortality. One patient had a pelvic haematoma.

Conclusion

This is an observational study, laparoscopic approach is feasible and associated with significant reduction in perioperative morbidity and should be standard approach in women diagnosed with cervical cancer.

ESGO7-0039

COST UTILITY ANALYSES DEMONSTRATING SUPPORT FOR INDICATION SPECIFIC PRICING FOR THE TARGETED THERAPY BEVACIZUMAB

J. Geisler¹, R. Navarro², K. Manahan¹

¹CTCA, Newnan, USA
²University of Florida, Pharmacy, Gainesville, USA

Aims

Medications in the U.S. are approved because of safety and efficacy not price. The object of this study was to see what potential prices would look like if indication specific pricing existed for bevacizumab in cervical and colon cancer using various willingness to pay (WTP) thresholds ($50,000 – 150,000/QALY).

Method

Information from two phase III studies was examined with pharmacoeconomic techniques, specifically Markov analysis and deterministic sensitivity analysis.

Results

The per cycle cost of bevacizumab for both indications is currently $10830 for a standard 100 kg patient ($72.03/10mg, Medicare Average Sales Price (ASP)+6%). If a WTP of $50,000/QALY was used, the cost of bevacizumab should be lowered to $29.15/10mg for cervical cancer and $11.80/10mg for colon cancer. If instead a WTP of $100,000/QALY was the target, the cost would be decreased to $63.38/10mg for cervical cancer and $30.22/10mg for colon cancer. Alternatively, if a WTP $150,000/QALY was chosen, the price would be increased to $97.63/10mg for cervical cancer and still decreased to $48.78/10mg for colon cancer. This would be a 36% increase in cost per dose for a cervical cancer indication and a 32% decrease in cost per dose for an indication of colon cancer.

Conclusion

Indication specific pricing would change prices for bevacizumab when used for cervical cancer and colon cancer depending on the WTP target.
PROGNOSTIC VALUE OF THE CONUT - SCORE IN PATIENTS WITH CERVICAL CANCER

L. Gensthaler¹, R. Schwameis¹, C. Grimm¹, S. Polterauer¹, A. Reinthaller¹, S. Aust¹
¹Medical University of Vienna, Gynecology and oncologic Gynecology, vienna, Austria

Aims

The pretreatment Controlling Nutritional Status (CONUT) Score was established as a screening tool for early detection of poor nutritional status. However, it is an independent prognostic marker in oncologic patients, the prognostic value in patients with cervical cancer is still unknown.

Method

The pretreatment CONUT — Score of 429 patients with cervical cancer was calculated. Patients were classified as either as „low risk or „high – risk” depending on their score. The Patients’ prognosis was calculated by uni- and multivariated analysis.

Results

371 patients (86.3%) had a low risk, 59 (13.7%) patients a high risk CONUT Score. In univariate analysis, patients in the high risk group were associated with a shorter overall survival (p=0.024). Thus, those results couldn’t be verified in the multivariate analysis (HR 1.3 [0.8-2.3], p=0.33). There was a significant association between the CONUT – Score and tumor stage (OR 3.4 [1.8-6.2], p<0.001) and tumor Grading (OR 6.6 [0.9-49.1], p=0.04) There was no significant result regarding the patients’ age or the histological subtype.

Conclusion

The overall survival of patients with cervical cancer and a CONUT – Score > 2 was significantly shorter. A CONUT Score >2 was associated with severe malnutrition. The benefit of nutritional intervention in patients with pretherapeutic malnutrition should be investigated in further studies.

ESGO7-1006

THE PROGNOSTIC VALUE OF PRETHERAPEUTIC HYPONATREMIA IN PATIENTS WITH CERVICAL CANCER.
L. Gensthaler1, C. Grimm1, R. Schwameis1, A. Reinthaller1, S. Polterauer1, S. Aust1
1Medical University of Vienna, Gynecology and oncologic Gynecology, vienna, Austria

Aims

Preoperative hyponatremia is associated with postoperative mortality and morbidity in women with ovarian cancer. However, the prognostic impact in patients with cervical cancer is still unknown.

Method

429 patients with cervical cancer, who were treated at the Medical University of Vienna, were included in this retrospective study. The preoperative sodium was classified as normal (135 mmol/L – 142 mmol/L) or hyponatremic (<135 mmol/L). The patients’ prognosis was calculated by uni- and multivariate analysis.

Results

16 (3.7 %) patients had a pretherapeutic hyponatremia. In univariate analysis, patients with preoperative hyponatremia and cervical cancer were associated with a shorter overall survival (p=0.004). Thus, those results couldn’t be verified in the multivariate analysis (HR 1.8 [0.8 - 3.9], p=0.15). Interestingly, there was a significant association between pre-treatment hyponatremia and tumor grading (HR 3.4 [1.8 - 6.2], p<0.001). Nevertheless, there was no significant result regarding the patients age, the stage or histological subtype of the tumor.

Conclusion

In univariate analysis, the overall survival of patients with cervical cancer and a preoperative hyponatremia was significantly shorter. A preoperative hyponatremia was associated with higher grade of the tumor. Additional work is needed to determine if correction of hyponatremia in the preoperative period alters the patients’ outcome.

SMALL CELL NEUROENDOCRINE TUMORS OF THE CERVIX (SCNEC). DO TUMOR CHARACTERISTICS AND ORDER OF MULTIMODALITY THERAPY INFLUENCE OUTCOMES IN EARLY STAGE DISEASE?

1Oslo University Hospital - The Norwegian Radium Hospital, Department of Gynecologic Oncology, Oslo, Norway
2Oslo University Hospital - The Norwegian Radium Hospital, Department of Oncology, Oslo, Norway
3Oslo and Akershus University College of Applied Sciences, Department of Public Health, Oslo, Norway
4Oslo University Hospital - The Norwegian Radium Hospital, Department of Pathology, Oslo, Norway

Aims

To report our experience in the management of women with SCNEC. To explore favorable tumor and treatment characteristics related to survival.

Method

All cases with SCNEC treated at our institution from 01/1978-12/2015 were identified. Demographic, pathologic, treatment and survival data were collected. Appropriate statistical methods were applied.

Results

64 women met inclusion criteria. 22 (34%) presented as early stage (ES) (I-IIA). 41% (9/22) had lymph node metastasis (LNM). 20/22 (91%) ES cases underwent initial radical surgery accompanied by platinum-based neoadjuvant chemotherapy (NACT) in 10/20 (50%), adjuvant chemotherapy (AdCT) in 6 (30%) and adjuvant radiotherapy in 4 (20%). NACT versus surgery as initial therapy did not influence overall survival (OS) (p=0.72). There was no association between ≤3 NACT<3 cycles and recurrence free survival (RFS) (p=0.61) or OS (p=0.55). Tumor size ≤ 4cm< did not influence RFS (p=0.31) or OS (p=0.08). Early versus advanced stage (AS) was not associated with RFS (p=0.073), it was however associated with OS (p=0.002). Presence of LNM negatively influenced RFS (p=0.015) and OS (p=0.008). With a median follow up of 23.3 months (range 0.4-315.7) 1 patient is currently without evidence of disease. Median time to recurrence was 28.1 months in ES and 13.5 months in AS. The 5-year OS was 49.4% for ES and 18.1% for AS.

Conclusion

SCNEC is an aggressive disease. LNM and AS were negatively associated with survival. NACT versus AdCT did not influence survival. Targeted therapies being investigated for small cell lung cancer should also be tested for patients with SCNEC.

ESGO7-0549

SURGICAL MORBIDITY OF WOMEN WITH CERVICAL CANCER: THE ROLE OF LAPAROSCOPY

P. Giamougiannis¹, K. Galaal¹
¹Royal Cornwall Hospital, Gynaecology Oncology, Truro, United Kingdom

Aims

The aim of this study was to identify surgical outcomes of cervical cancer patients undergoing radical hysterectomy or trachelectomy at the Royal Cornwall Hospital, a gynaecology oncology centre in the UK.

Method

Retrospective study of women undergoing radical surgery for treatment of cervical cancer from 2007 to date.

Results

In total 41 women were identified with stage 1B1 - 2A. 37 patients underwent radical hysterectomy and 4 radical trachelectomy. At diagnosis mean age was 46 years and mean BMI 26.9 Kg/m². 15 patients underwent laparotomy and 26 laparoscopy. Conversion rate from laparoscopy to laparotomy was 7.7%. Median tumour distance to parametrial and vaginal resection margins was 5mm and 11mm respectively. Median number of lymph nodes removed was 14, positive in 3 cases. Median intraoperative EBL in laparotomies was 600 mls whereas in laparoscopies 200 mls (p<0.00001). Median in-hospital length of stay was 5 days.

Intraoperative complications included 1 bladder injury and 1 superficial obturator nerve injury. Other postoperative complications included: sepsis (4), ileus (2), thromboembolism (1), urinary incontinence (1), obturator neuropathy (1), lymphoedema (8) and lymphocyst formation (2). Only 3 patients (7.3%) experienced major complications compared to published rates up to 30%. 2 had laparotomy and 1 had laparoscopy. The complications were ureteric stricture, ureterovaginal fistula and infected haematoma requiring re-operation. 7 patients received adjuvant radiotherapy or chemoradiation. 2 developed cervical cancer recurrence and eventually died.

Conclusion

Laparoscopic radical surgery for cervical cancer was associated with lower major morbidity compared to published rates and low recurrence rate.
CERVICAL CANCER

ESGO7-0774

RECURRENT FREE SURVIVAL AFTER SENTINEL LYMPH NODE BIOPSY IN PATIENTS WITH EARLY-STAGE CERVICAL CANCER

1Hospital CLINIC, Gynecology Oncology Unit, Barcelona, Spain

Aims

To compare recurrence free survival (RFS) in women with early-stage cervical cancer who were primarily treated by radical surgery and pelvic bilateral lymphadenectomy (LDN) versus sentinel lymph node biopsy only (SLNB).

Method

From 02/2001 until 05/2011, patients with FIGO stage IA1-IB1/IIA1 cervical carcinoma underwent SLN biopsy followed by complete pelvic LDN as part of their primary treatment in University Hospital Clinic (Barcelona, Spain). Between 06/2011 and 10/2016, patients underwent radical surgery after SLNB. Patients underwent complete preoperative staging workup and were treated by radical hysterectomy or radical tachelectomy. Patients in whom SLN were detected unilaterally or not detected underwent a complete lymphadenectomy of the failed mapped side. SLN were evaluated by pathologic ultrataging. Intraoperative and postoperative as well as follow up data were prospectively recorded. SPSS 20.0 was used for statistical analysis.

Results

80 patients underwent radical surgery plus LDN and 54 patients underwent surgery with SLNB. No differences regarding age at diagnosis, size of the tumor (≤ 2cm vs > 2cm), FIGO stage, histology type and type of surgery were seen between both groups. Median follow up time was 60.6 months (0.13-190.3). Detection rate of the sentinel node group was 96% and it was bilaterally detected in 47 patients (87%). 121 patients were node negative patients, 73 LDN- and 45 SLNB-. No statistically significant differences were seen in term of RFS between both groups with negative nodes.

Conclusion

Patients with SLNB negative at the time of primary surgery seem to have the same RFS than patients with LDN negative nodes.

LAPAROSCOPIC PELVIC EXENTERATION FOR RECURRENT OR COMPLICATED PELVIC TUMORS: ANALYSIS OF
TECHNIQUE AND POSTOPERATIVE OUTCOMES
S. Baydo\textsuperscript{1}, A. Vinnytska\textsuperscript{2}, D. Golub\textsuperscript{2}, S. Pryndyuk\textsuperscript{3}, A. Goman\textsuperscript{1}
\textsuperscript{1}LISOD – Israeli Oncological Hospital, surgery, Kyiv, Ukraine
\textsuperscript{2}LISOD – Israeli Oncological Hospital, gynecology, Kyiv, Ukraine
\textsuperscript{3}LISOD – Israeli Oncological Hospital, urology, Kyiv, Ukraine

Aims
Pelvic exenteration is an ultraradical surgical procedure with both palliative and curative intent in management of pelvic tumors. It remains one of the most difficult with high postoperative morbidity (31-90%). We want to represent our experience in performing laparoscopic pelvic exenteration (LPE).

Method
In 2012-2017 we performed 16 LPE (9 total, 4 anterior and 3 posterior). Indications were central pelvic recurrence of cervical (9), colorectal (6) and bladder cancer (1) after combined chemo-radiotherapy and surgery, complicated with different fistulas. Five ports technique was used in all cases. Dissection was performed with harmonic scissors and bipolar. Colorectal reconstruction: terminal colostomy (7) or anastomosis (5). For urinary diversion an ileal-loop conduit (the Bricker technique) was used. Uretero-ileostomy and stenting were performed intracorporally (2) and extracorporally (11).

Results
Average age 44.2(31-66) years. Average operative time 392(295-520) minutes. Estimated blood loss 295(95-500) ml. Mean length of hospital stay 8,9(5-14) days. The number of lymph nodes harvested 16 (5-34). Postoperative complications grade IIIB-IV (Clavien-Dindo, 2004) occurred in 6 patients (37,5%): anastomotic leak (4) with 2 relaparoscopy; small intestine perforation (1) with relaparoscopy and suturing; arterial thrombosis with multiple organ failure and death (1). Grade I-IIIA complications: gastroparesis (3), seroma (2), lymphocyst (2), positional fibular neuritis (1). After 1 year 10 out of 15 patients (66,7%) were alive, after 2 years: 4 out of 12 (33,3%).

Conclusion
Laparoscopic pelvic exenteration is technically feasible and can be offered to carefully selected patients with locally advanced pelvic tumors. Potential postoperative advantages of laparoscopic approach are faster recovery and relatively low morbidity.

Copyright © 2017 by IGCS and ESGO. Unauthorized reproduction of this article is prohibited.
Aims

To evaluate the prognosis value of pretreatment leucocyte, platelet and hemoglobin disorders in locally advanced cervical cancer (LACC).

Method

We conducted a prospective study of 240 patients treated from 2007 to 2015 at Gustave Roussy for LACC with negative PET imaging of the PA area and undergoing laparoscopic PA lymphadenectomy. Patients with a poor prognosis histologic subtype or peritoneal carcinomatosis were excluded. All patients were treated by chemo-radiation and brachytherapy. All patients had preoperative blood cell count and clinical follow-up.

Results

Patients had clinical International Federation of Gynecology and Obstetrics stages IB2 (n=79), IIA (n=10), IIB (n=124), III (n=18), or IVA (n=9). One hundred ninety-one patients had squamous carcinoma, 43 had adenocarcinoma/adenosquamous lesions and 6 clear cells carcinoma. Twenty-two patients (9%) had nodal involvement (false-negative PET imaging). median follow-up was : 53 months [48-59]. We identified three cut-off whose impact disease free survival at 36 months: 114 g/L for hemoglobin (81% [75-89] vs 62% [52-74], p < 0.001); 11,7x10^9/L for leucocyte (48% [32-73] vs 79% [73-85], p < 0.0001); 308x10^9/L for platelet (65% [54-77] vs 79% [73-87], p = 0.005) for patients above and under the cut-off respectively.

Conclusion

Leucocyte, platelet and hemoglobin are significant prognostics factors for relapse in locally advanced cervical cancer. Those biomarkers could help identifying patients with higher risk of relapse and requiring new strategies as neo-adjuvant and adjuvant chemotherapy.
MUCOSAL MELANOMA OF THE FEMALE GENITAL TRACT

S. Haddad1, I. Zemni2, N. Boujelbene2, M. Bouhani1, M. Slimene1, K. Mrad1, M. Hechiche1, H. Bouzaiene1, K. Ben Rahal1
1Salah Azaiez Institute, Surgery, Tunis, Tunisia
2Salah Azaiez Institute, Anatomy Pathology, Tunis, Tunisia

Aims

Malignant melanomas of the female genital tract, including the cervix, vulva and vagina, are rare. These lesions arise from melanocytes, which can be found within the mucosa lining the female genital tract. Surgical resection is the mainstay of therapy, with little use for other modalities. We conducted a retrospective analysis of female genital tract melanoma, focusing on the high local recurrence rate of this tumor.

Method

Thirteen patients with primary mucosal melanoma of the female genital tract diagnosed and treated at Salah Azaiez Institution during a 15-year period were studied retrospectively. Specific information was obtained from the patients’ clinic charts. We excluded cases unsuitable for surgical curative treatment.

Results

Seven vulvar, four vaginal, and two cervical lesions were identified. The median age at diagnosis was 59 years. At initial presentation, two thirds of the patients had localized disease only. Tumor ulceration and thickness of the primary lesion had a measurable impact on prognosis. All patients underwent resection with curative intent. Many of the treatment failures were the result of local recurrences, hinting at the need to improve local control. Four patients underwent postoperative adjuvant treatment. Despite therapy, the overall 5-year survival rate was less than 50%.

Conclusion

Although malignant melanoma of the female genital tract is uncommon, all suspicious pigmented lesions found on a routine examination should be biopsied. The use of immunohistochemical assays could markedly improve diagnosis. Prospective multicenter trials for patients with vulvovaginal and cervical melanoma could be helpful in establishing uniform, standardized surgical protocols.

RHABDOMYOSARCOME UTERINE CERVIX IN THE YOUNG WOMAN BY THE WAY OF A CASE WITH REVIEW OF THE LITERATURE

F. Hadjarab¹, A. TAIBI¹, K. BOUZID¹
¹Center Pierre Marie Curie Algiers, Medical Oncology, Algiers, Algeria

Aims

Is a rare tumor. It electively occurs at the young woman. One currently recommends a preserving treatment sometimes limited to a conisation, associated with chemotherapy and whose results are encouraging.

Method

19 years old, followed since 2014 for rhabdomyosarcoma of the uterine cervix, marked by protrusion through the vagina of an operated mass has 4 recoveries of the type exteriorized part whose histological study was in favor of a rhabdomyosarcoma embryonic botriode type keeps II.

The therapeutic decision of the multi-field committee was to make a chemotherapy 1ère has standard 8 IVAO (Ifosfamide, Mesna, Vincristine, Doxorubicine).

Results

The answer is considered to be partial with atumoral weight saving, disappearance of the hemorrhage it profited from an ovarian transposition by coelioscopy then an exérèse of the mass (pédiqulée of the uterine collar of 5 cm and been confined by the vagina) by gynaecological way, whose anapath was in favor of cervical embryonic Rhabdomyosarcome with healthy zones of resection the treatment was continued by a curiethérapie.

The patient is in complete remission with a pelvicscanner thoraco abdomino and MRI pelvic of evaluation without characteristic, it had a return of the menstruations, retreat of survival since the diagnosis is 3 years.

Conclusion

The RMS of the uterine collar is a rare tumour which occurs primarily in the young girl. The extension is especially locorégionale. The treatment consists of a surgical gesture with minima associated with an perish operational chemotherapy.

CLINICAL AND PATHOLOGICAL FACTORS ASSOCIATED WITH RESIDUAL DISEASE IN HYSTERECTOMY AFTER CONIZATION FOR MICROINVASIVE CERVICAL CANCER (STAGE IA1 AND IA2) TREATMENT.
C.A. Hartman¹, L. Andrade LA², J.C. Teixeira¹, O. Rangel Neto¹, H.D.C. Machado³, J. Braganca Bastos¹
¹Campinas State University, Gynecology and Obstetrics, Campinas, Brazil
²Campinas State University, Pathology Department, Campinas, Brazil
³Campinas State University, Statistics Department of ObGyn, Campinas, Brazil

Aims

Evaluate clinical and pathological factors associated with residual disease in hysterectomy after conization for microinvasive cervical cancer (stage IA1 and IA2) treatment.

Method

603 patients diagnosed and treated for squamous cervix microinvasive carcinoma, FIGO stage IA1 and IA2 (MIC), from 1975 to 2013 were included.

Results

CKC was performed in 333 patients (55.2%) and 270 (44.8%) LEEP. The analysis of surgical resection margins showed 489 (81.1%) free ectocervical margins and 331 (54.8%) endocervical margins. Cervical conization was definitive treatment in 170 (28.2%) patients, but in 433 (71.8%) women, a further hysterectomy was performed. Of these, 387 women with stage IA1 were treated with extra fascial hysterectomy and 46 women with stage IA2 disease or with LVSI were treated with radical hysterectomy with pelvic lymphadenectomy. Residual disease (CIN3 or MIC) was found in 179 (41.3%) hysterectomies specimens. Only one case of positive lymph nodes was detected, 32 women (5.3%) recurred during the follow up and two patients died due to the disease.

Multivariate analysis showed that conization margins involvement (OR=6.80, p<0.001) were significantly associated with residual disease. Absence of residual disease in hysterectomy specimens was associated with conization depth >19mm in woman >40yr (p=0.001) and >19.2 for all women (p<0.001) There was no significant difference in the presence of residual disease in hysterectomies, in women treated with both types of conization (p=0.204).

Conclusion

In Women, which fertility desire is a concern, the conservative treatment is a possible option. However, conization margins involvement and conization depth <19mm should be strongly avoided in exclusive conization treatment.

12Memorial Sloan Kettering Cancer Center, Gynecologic Medical Oncology Service, New York- NY, USA
13Arizona Oncology US Oncology Network- Gynecologic Oncology at University of Arizona and Creighton University, Gynecologic Oncology, Phoenix- AZ, USA

Aims

Prognostic biomarkers that identify high-risk patients may guide treatment decisions for patients with persistent, recurrent or metastatic cervical cancer (PRmCC). To identify such biomarkers, we evaluated the association between baseline inflammation-related serum protein levels and overall survival (OS) in 45 of the 50 AXAL-treated PRmCC patients participating in the phase 2 GOG/NRG-0265 trial (NCT01266460).

Method

The levels of inflammation-related analytes in PRmCC patients’ sera, collected prior to AXAL treatment, were measured using multiplex immunoassays. Linear regression and Kaplan-Meier analysis with log-rank test were used to evaluate the association of baseline levels of individual serum proteins with OS.

Results

Baseline levels of 4 serum proteins were significantly associated with OS (P < .01) and were significantly lower in patients surviving ≥12 months than in those surviving <12 months (P < .01). Unsupervised hierarchical clustering with complete linkage identified 2 patient clusters, distinguishable by low (cluster 1) or high (cluster 2) baseline levels of the 4 serum proteins. Survival analyses revealed that while the total patient population (n=50) exhibited a 12-month OS rate of 38%, cluster 1 (n=25) exhibited a rate of 56% and cluster 2 (n=20) exhibited a rate of 15%, suggesting that the baseline levels of these 4 serum proteins have prognostic value for OS (HR=0.23; 95% CI: 0.10-0.48; P<.001).

Conclusion

We have identified baseline levels of 4 distinct serum proteins as candidate prognostic biomarkers of clinical outcome in PRmCC patients. Cluster 1 criteria may identify PRmCC patients most likely to benefit from AXAL treatment.

CERVICAL BIOPSY AFTER CHEMORADIATION FOR LOCALLY ADVANCED CERVICAL CANCER TO IDENTIFY RESIDUAL DISEASE

Y. Hoeijmakers1, P. Zusterzeel1

1Radboud University Nijmegen Medical Center, Department of Obstetrics and Gynecology, Nijmegen, The Netherlands

Aims

To evaluate the value of cervical biopsies 12 to 16 weeks post chemoradiation (CRT) in patients with locally advanced cervical cancer (LACC), in order to identify patients, eligible for salvage surgery.

Method

All patients with LACC, who received chemoradiation as primary treatment at the Radboud University Medical Center in Nijmegen between 1998 and 2015, were included in this retrospective study. In patients without suspicious lymph nodes on imaging and suitable for salvage surgery, a cervical biopsy was taken post CRT under general anesthesia, to evaluate if complete clinical remission was obtained. The follow-up of all patients as well as biopsy results, patient characteristics, and subsequent treatment were investigated.

Results

In total 154 patients with LACC received CRT. The median follow up time was 30.5 months. Sixteen (10.4%) patients were lost to follow up. Of the remaining 138 women, 78 patients underwent a cervical biopsy post CRT. Eight out of 78 patients (10.3%) had residual disease, whereas 70 had no vital tumor cells in the biopsy. Six of the patients with residual disease after CRT underwent salvage surgery. Long-term complete remission was achieved in 4 of them (66.7%).

Conclusion

Post CRT cervical biopsy in locally advanced cervical cancer patients was beneficial in 4 out of the 78 patients (0.5%). As 1 in 20 patients will achieve long-term survival by salvage hysterectomy, this biopsy remains advisable. This policy may cure a small subset of patients.

COUNTY/CITY OF RESIDENCY IS A PROGNOSTIC FACTOR OF OVERALL SURVIVAL IN CERVICAL CANCER

E.Y. Huang¹, H. Lin²

¹Kaohsiung Chang Gung Memorial Hospital, Radiation Oncology, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Chang Gung Memorial Hospital, Gynecologic Oncology, Kaohsiung, Taiwan R.O.C.

Aims

Although some prognostic factors are studied for cervical cancer, environment factors are seldom investigated. The aim of present study is to investigate the impact of county/city of residency on survival of cervical cancer.

Method

We used Chang Gung Cancer Registry database to investigate the largest medical cancer in North Taiwan (Linkou Chang Gung Memorial Hospital: LCGMH) and South Taiwan (Kaohsiung Chang Gung Memorial Hospital: KCGMH). From January 2004 to December 2012, 8746 patients with cervical cancer were retrospectively reviewed in this study. The major country of patients in LCGMH was Taoyuan (Area 1A). The Area 1B and Area 1C of County and City is in the north and south of Taoyuan, respectively. The major country of patients in KCGMH was Kaohsiung City (Area 2A). The Area 2B and Area 2C of County is in the north and southeastern of Kaohsiung City, respectively. Cox regression model was used for multivariate analysis of overall survival.

Results

In addition to stage, age, and pathology, county/city of residency (p<0.001) is an independent factor of overall survival in cervical cancer. Compared with the Area 1A, there was no statistical significance in Area 2A (p=0.278) and Area 1C (p=0.381). Better survival was noted in Area 1B (p=0.046). Worse survival was noted in Area 2B (p=0.004) and Area 2C (p<0.001).

Conclusion

Because of no survival difference of major area between LCGMH (1A) and KCGMH (2A), county/city of residency should be considered for care of cervical cancer. The survival difference caused by residency is worth investigating in further studies.
PRELIMINARY RESULTS OF EXTENDED FIELD IMRT CHEMO-RADIOTHERAPY OR PELVIC IMRT CHEMO-RADIOTHERAPY FOLLOWED BY OPERATION IN PATIENTS WITH MULTIPLE PELVIC LYMPH NODE METASTASIS (PHASE II CLINICAL TRIAL)

W. Luo¹, G. Ke², Y. Li¹, X. Wu², X. Huang²
¹Minhang Branch of Fudan University Shanghai Cancer Center, Department of Radiation Oncology, Shanghai, China
²Fudan University Shanghai Cancer Center, Department of Gynecologic Oncology, Shanghai, China

Aims

We use prospective randomize method to analysis the response rate and side effect rate of EF-IMRT and pelvic-IMRT combined with cisplatinum chemotherapy in patients with multiple pelvic lymph node metastasis.

Method

From 2012 to 2015, 96 cases enrolled into this study. Median Age was 46 years old. ECOG score was 0-2.FIGO stage was IB1-II A2. Histology included squamous 87cases, adenocarcinoma 3cases, squamous-adenocarcinoma 2 cases, low grade 4 cases. No adjuvant chemotherapy was done.All patients underwent radical operation, 20 cases of them were preserved both ovaries,2 cases were preserved one ovary.Para-aortic LN resection was done in 21 cases, while biopsy was done in one case. The median number of lymph nodewas 26(11~39).Patients were randomized into two groups: group A (EF-IMRT) or group B (pelvic-IMRT). The tumor dose was 45Gy/1.8-2Gy/25Fx, combined with cisplatinum 40mg/m2 weekly for 5 cycles. We used CTCAE3.0 to analysis the side effect.

Results

All the patients fulfilled the whole therapy.49 cases of them were enrolled into group A and 47 cases into group B. Blood and GI system were mainly side effects. Grade 4 of blood effect occurred only in one case group (A). Grade 1-2 of GI effect occurred in 10 cases (group B) and 20 cases (group A). With regards to acute or late toxicities, no statistically significant difference was observed between the two treatment groups.

Conclusion

Postoperative EF radiotherapy plus concurrent chemotherapy was effective and acceptable for treating patients with FIGO Stage IB1-II A2 cervical cancer displaying multiple pelvic lymph node metastases. This clinical trial is ongoing and long-term follow up is needed.
A LATE OMENTAL METASTASIS IN A PATIENT WITH CERVICAL CANCER

E. Galati1, C. Iavazzo1, N. Kalinoglou1, G. Vorgias1
1Metaxa Cancer Hospital, Gynaecological Oncology, Piraeus, Greece

Aims

To report a case of a late omental metastasis in a patient with cervical cancer.

Method

A 55-year-old woman presented with a history of a radical hysterectomy, bilateral salpingo-oophorectomy and bilateral pelvic lymph node dissection due to cervical adenocarcinoma of endometrioid type grade 3 St IB1 ten years ago and a left radical mastectomy due to ductal invasive breast cancer grade 2 three years ago. The patient was asymptomatic for 10 years. She was admitted in our gynaecologic oncology department with an upper abdominal cystic lesion which was found in follow-up imaging. The CT scan showed a cystic lesion next to the spleen measuring 3.3cm and a second cystic lesion in the transverse mesocolon of diameter 4.2cm. The PET/CT scan confirmed the diagnosis showing increased metabolic activity in the areas of the greater curve of the stomach, the left upper abdominal quadrant and the transverse mesocolon. Colonoscopy revealed involvement of sigmoid and transverse colon and gastroscopy showed no signs of malignancy.

Results

The patient underwent surgical excision of the splenic and gastric lesions as well as omentectomy. The pathology and immunohistochemistry report described a recurrence (grade 2-3 adenocarcinoma of cervical origin). The MDT decision was for the patient to start chemotherapy.

Conclusion

A late omental metastasis on a patient with history of cervical cancer is very rare, and this is the second case described in the current literature. We remind the role of long term follow-up in patients with cervical cancer and raise awareness of such a rare entity.

ASSISTED MOLECULAR STAGING GUIDED BY ONE-STEP NUCLEIC ACID AMPLIFICATION (OSNA) IN ADVANCED CERVICAL CANCER: A PROSPECTIVE STUDY

I. jafre, G. selmes, O. kerdraon, P. jezequel, J.M. classe, J.S. FRENEL

1Institut cancerologie de l'ouest, surgery, nantes, France
2Institut cancerologie de l'ouest, surgery, nantes, France
3Institut cancerologie de l'ouest, pathology, nantes, France
4Institut cancerologie de l'ouest, biology, nantes, France
5Institut cancerologie de l'ouest, oncology, nantes, France

Aims

Radiochemotherapy is the standard treatment for locally advanced cervical cancer. Para-aortic (PA) lymph nodes metastases remain a poor prognostic factor. Recently, a multicentric prospective study has reported the same survival rate for patients with PA nodal metastases ≤ 5 mm treated by an extended radiation field and patients pN0. Detecting occult metastases in PA lymph nodes may have an impact on survival.

We aimed to compare prospectively the accuracy of OSNA with both standard Hematoxylin and Eosin (H&E) analysis and intensive histopathology for the detection of lymph node metastases of cervical cancer

Method

A total of 127 lymph nodes from 10 patients with stage FIGO ≥ IIb cervical cancer were assessed. Among them, 68 were also assessed by OSNA. Half of each lymph node was analyzed initially by H&E followed by an intensive histologic workup: 5 levels of H&E and immunohistochemistry analyses. The other half was analyzed using OSNA. The OSNA method is based on the detection of CK19 mRNA as a marker for cervical cancer. The positivity of the CK19 was investigated on the prior cervical biopsy. A cut off value of 250mRNA copies/µL was used

Results

The concordance rate was 79%. 14 cases were discordant: 12 OSNA-positive/ histology negative (11 micrometastasis) and 2 OSNA-negative/histology positive (2 macrometastasis). OSNA was more sensitive for detecting micrometastasis compared with H&E and resulted in an upstaging of 5 of 10 patients

Conclusion

OSNA appeared to be a promising molecular tool for the detection of lymph nodes metastasis and may lead to an interesting upstaging

RADICAL VERSUS MODIFIED RADICAL HYSSTERECTOMY IN THE TREATMENT OF EARLY CERVICAL CANCER

S. Jeon¹, H. Jeon¹
¹Soonchunhyang university Cheonan hospital, OB & Gyn, Cheonan, Republic of Korea

Aims

To compare survival outcomes and urologic morbidity of modified radical (type 2) hysterectomy with radical (type 3) hysterectomy in the treatment for early-stage cervical cancer patients

Method

Since February 2007, we retrospectively analysed oncologic outcomes and urologic complication in 72 patients with FIGO stage IA2, IB and IIA cervical cancer who treated with modified radical hysterectomy(MRH) (n=42) or radical hysterectomy(RH) (n=30) at our center

Results

Patients’ age and FIGO stages across the two types of surgeries were similar. Mean operation time and urologic morbidity were significantly less in MRH group. The mean number of lymph node obtained was similar across the two types of surgeries but lymph node metastasis and additional therapy after surgery was more frequent in the RH group. There was no significant differences in recurrence free and overall survival between two groups.

Conclusion

Modified radical hysterectomy appears to be similar efficacy, survival and associated with lower rates of urologic complications for patients with stage IA2 to IIA cervical cancer compared with radical hysterectomy.

3D-PRINTING NON-COPLANAR TEMPLATE ASSISTANT CT - GUIDED 125I SEEDS IMPLANTATION ON PELVIC RECURRENT CERVICAL CANCER

P. Jiang¹, F. Guo¹, Y. Jiang¹, Z. Ji¹, J. Wang¹, H. Sun¹, J. Fan¹
¹Peking University Third Hospital, radiation oncology, Bei Jing, China

Aims

To investigate the accuracy of 3D-printing non-coplanar template (3D-PNCT) assisted ¹²⁵I seed implants with CT guidance in the pelvic recurrent cervical between the pre-plan and post-plan dosimetric parameters.

Method

9 patients with pelvic recurrent cervical cancer in our center received ¹²⁵I seeds implantation under the CT guidance with 3D-PNCT assistant. A pre-plan based brachytherapy treatment planning system (B-TPS) with 3D-PNCT assistant for seed needle depth, direction and angle was designed. The dosimetry parameters including homogeneity index (HI), dose of 90% target volume (D90), volume of 100% prescribed dose(V100), volume of 150% prescribed dose(V150) and organ at risk between the pre-plan and post-plan were compared. Pair t-testing were used for statistics analysis with SPSS19.0 software.
Results

Total seeds number of 675 (median 44, 25-114) according to pre-plan and 669 (median 47, 25-113) seeds implanted actually. Total 138 needles (median 9, 6-21) according to preplan and 132 (median 9, 6-21) needles were implanted actually. The mean entrance point angle of all 675 needles designed in pre-plan were 30º~133º, and real angle from post-plan were 31º~129º, and the median deviation was 1.99º±2.94º(0~13º). There was no significant difference (F=0.1511, P=0.698) of angle deviation between per- and post-plan. The mean D90 of pre- and post- plan are 128.62±12.90Gy, 131.61±13.34Gy respectively, there were no significantly difference (F=0.012, P=0.913). The differences of V100, V150 and HI between pre- and post-plan were not shown significant.

Conclusion

The concidence of pre-plan and post-plan for 3D-PNCT assisted $^{125}$I seeds implantation in the pelvic recurrent cervical cancer could accurately perform under CT guidance.

HELICAL TOMOTHERAPY SYSTEM FOR ADVANCED CERVICAL CARCINOMA
S. Jiang¹, Q. Li², X. Sheng¹
¹Shandong Cancer Hospital and Institute, Department of Gynecologic Oncology, Jinan, China

Aims

We evaluated the feasibility, effectiveness, safety and adverse events of Helical Tomotherapy system versus conventional intensity-modulated radiation therapy (IMRT) for cervical carcinoma.

Method

We examined the records from December 5, 2014 to date. 41 patients were identified undergone chemoradiation therapy. For HT treatment planning, tumor, pelvic, with or without paraaortic lymph nodes were defined as planning target volume (PTV) with a prescribed dose of 2.0/50 Gy (25 fractions). The lower target constraints were 95% of the prescribed dose in 95% of the target volume, and the upper dose constraint was 107%. The irradiated small-bowel volumes were kept as low as possible. The patients delivered by IMRT were identified as the comparative group. Patients were monitored for chronic toxicity using the Common Terminology Criteria for Adverse Events version 3.0 criteria.

Results

Both HT and IMRT techniques allowed excellent target volume coverage. Conformity index and conformity number results for PTV were significantly better with HT than IMRT. The median age of all patients was 50.4 years. The median overall radiation treatment time was 54 days. No patient developed a chronic Grade 3 GI complication. No other Grade 3 or 4 complications were observed. All patients are following up to date.
Conclusion

Both HT and IMRT techniques provide optimal treatment of gynecological oncology patients with acceptable levels of chronic toxicity. HT was significantly favored with regard to target conformity, homogeneity.

MUTATIONAL ANALYSIS OF KRAS AND ITS CLINICAL IMPLICATIONS IN CERVICAL CANCER PATIENTS

W. Jiang1, L. Xiang1, X. Pei1, T. He1, H. Yang1
1Fudan University Shanghai Cancer Center, Gynecologic Oncology, Shanghai, China

Aims

The predictive and prognostic role of KRAS mutations in cervical cancer remains inconclusive. The aim of this study was to explore the clinicopathological and prognostic relevance of KRAS mutations in invasive cervical cancers (ICC).

Method

Reverse transcription polymerase chain reaction (PCR) and Sanger sequencing were employed to detect KRAS mutations in 876 ICC patients. Quantitative real-time PCR was used to detect human papillomavirus (HPV) 16 and HPV 18.

Results

Non-synonymous mutations of KRAS were identified in 30 (3.4%) patients. These mutations were more common in non-squamous carcinoma than in squamous cell carcinoma (8.2% vs 2.2%, respectively, p<0.001) and were associated with HPV18 infection (p=0.003). The prevalence of mutations was highest (18.2%) in the uncommon histological subtypes followed by adenocarcinoma (7.3%) and adenosquamous carcinoma (5.8%). During the median follow-up of 55 months, compared to patients with wild-type KRAS, a greater percentage of patients with mutant KRAS relapsed (20.0% vs 42.9%, respectively, p=0.007; Fisher’s exact test). The 3-year relapse-free survival (RFS) was poorer in patients with mutant KRAS than in patients without KRAS mutations (57.1% vs 81.9%, respectively, p=0.001). Furthermore, the multivariate analysis showed that the presence of a KRAS mutation was an independent predictor for disease recurrence (HR=2.064, 95% CI: 1.125–3.787, p=0.019).

Conclusion

KRAS mutations were predominant in non-squamous cell carcinomas of the cervix and were associated with HPV 18 infection. A combination of KRAS mutation detection and HPV genotyping would be useful in identifying patients with poor prognosis for further interventions.

OUTCOMES OF ELECTROSURGICAL EXCISION PROCEDURE FOR CERVICAL INTRAEPITHELIAL NEOPLASIA IN BRAZIL

A.J. Souza Junior¹, M.L.F. da Silva¹, M.G.B. Dantas¹, M.S.O. Wanderley¹, V.L.M. Luna¹, B.G. Ferraz¹, G.A.M. Conrado¹

¹Universidade de Pernambuco, Medicine, Serra Talhada, Brazil

Aims

To analyze the short and long-term complications of women underwent electrosurgical excision procedure (LEEP) in a public hospital of an endemic area of cervical intraepithelial neoplasia in Brazil.

Method

A retrospective study was performed from January 2011 to August 2016, with a total of 223 medical records obtained from women underwent LEEP conization and had had follow-up on a public hospital of the Brazil were analyzed. In short-term outcomes were evaluated the histological status of endocervical margins and blood loss, and in long-term outcomes were included persistence/recurrence of the lesions and cervical stenosis. Were excluded patients with follow up < 12 months.

Results

A total of 223 women were analyzed, with a mean age of 37.08 ± 12.48 years (IC95%: 34.95-39.21 years). In these patients, 2.96% had positive margin in the histopathologic result. No patient had blood loss. The mean long-term follow-up time was 30.84 ±14.54 months (IC95%:28.35 ± 33.32 months) and included 134 women. 6.72% presented ASC-US as the worst result during follow-up and one patient had LIE-AG. No sample had residual lesion. Two patients presented cervical stenosis, five underwent hysterectomy, including the one with LIE-AG, and 2 faced up to another LEEP. In Squamocolumnar Junction (SCJ) analysis 89 patients (66.42%) hadn't visible SCJ.

Conclusion

Low index of positive margin in short-term outcomes associated with low complications and no recurrence of lesion in long-term outcomes suggests the efficacy of LEEP in patients treated for cervical intraepithelial neoplasia in endemic area of Brazil.
EPIDEMIOLOGIC PROFILE OF WOMEN UNDERWENT ELECTROSURGICAL EXCISION PROCEDURE IN BRAZIL
M.L.F. da Silva1, A.J. de Souza Junior1, M.G.B. Dantas1, M.S.O. Wanderley1, V.L.M. Luna1, B.G. Ferraz1, G.A.M. Conrado1
1Universidade de Pernambuco, Medicine, Serra Talhada, Brazil

Aims
To evaluate epidemiologic profile of women underwent LEEP conization in a public hospital of northeast of Brazil.

Method
A total of 240 medical records obtained from women underwent LEEP conization, between January 2011 to August 2016, on a public hospital in northeast of Brazil. Dates was obtained from medical record, and was composed by age, menarche, first age of sexual intercourse, smoking habits, parity and lifetime number of sexual partners.

Results
Mean age of selected patients was 36.90 ± 12.59 years, with mean menarche age of 13.11 ± 1.75 (CI95%: 12.89-13.33) and mean age of the first sexual intercourse of 17.65 ± 3.86 years (CI95%: 17.18-18.12). Smokers represent 10.42% of patients, with mean 8.76 ± 6.11 cigarettes/day. The mean sexual partners was 3.14 ± 3.83 (CI95%: 2.65-3.63), with 39.59% relating only one partner and 10% referred 6 or more. Permanence time with current partner was 10.61 ± 11.06 years (95% CI: 9.20-12.02) and 10% living with partner for at least 28 years. The mean of delivery was 2.83 ± 2.56, with 87.50% had at least one pregnancy and 28.33% reported at least one case of miscarriage.

Conclusion
The profile of patients underwent LEEP conization consisted of young adult women with high mean age of first sexual intercourse. Number of smokers and partners was low in our sample.
CERVICAL CANCER
ESGO7-0323

OUTCOME OF WOMEN WITH HIGH-GRADE CERVICAL INTRAEPITHELIAL NEOPLASIA (CIN 2/3) AFTER RECEIVING LOOP ELECTROSURGICAL EXCISION PROCEDURE (LEEP)

U. JU1, W. KANG1, S. KIM1

1Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Aims

The aims are to present the long-term outcome after loop electrosurgical excision procedure (LEEP) for high-grade cervical intraepithelial neoplasia (CIN2/3) and to identify the rate and risk of treatment failure.

Method

We reviewed retrospectively 1105 cases, confirmed to CIN2/3 after LEEP at our center from 2000 to 2009. Patients were followed with cervical cytology and HPV test. If the results were abnormal, patients received cervical biopsy. The CIN2 or worse was considered as treatment failure.

Results

During a mean follow-up of 94.6 months (range, 60-144), 100 cases (9.0%) had treatment failure; 6.1% in the first 2 years, 1.8% between 2 and 5 years, and 1.1% beyond 5 years. Excision margin involvement and positive result of immediate endocervical cytology after LEEP were significant risk factors for treatment failure (HR=4.280; 95% CI, 2.579-7.105; p<0.001 and 6.696; 2.832-15.833; p<0.001, respectively). Especially, positive endocervical margin had higher risk compared to positive ectocervical margin (5.743; 3.665-9.742; p<0.01 vs. 3.725; 2.627-6.835; p<0.01). Persistent or recurrent infection with HPV-16 (2.417; 1.527-4.484; p<0.01), HPV-18 (3.518; 1.941-6.715; p<0.01) or HPV-58 (1.460; 1.143-2.815; p=0.03) was associated with treatment failure in positive margin group. Persistent or recurrent infection with HPV-16 (3.742; 2.590-6.743; p<0.01), HPV-18 (4.155; 2.610-8.594; p<0.01), or HPV-31 (1.385; 1.092-2.475; p=0.03) was associated in negative margin group.

Conclusion

LEEP is effective, however, treatment failure can appear for a long time. Excision margin involvement and positive endocervical cytology after LEEP are strong predictors for treatment failure. Persistence or recurrence of HPV-16/18 increase the probability of treatment failure regardless of excision margin involvement.
IMIQUIMOD AS A VALUABLE OPTION FOR YOUNG WOMEN WITH HIGH GRADE SQUAMOUS EPITHELIAL LESION (HSIL): A RETROSPECTIVE STUDY

D.W. Jung¹, J.H. Kim¹, K. Dae-Yeon¹, S. Dae-Shik¹, K. Jong-Hyeok¹, N. Joo-Hyun¹, K. Young Tak¹, K. Yong Man¹
¹ASAN Medical center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

In young women, it is not easy to decide on excisional therapy for cervical intraepithelial neoplasia (CIN). We aimed to evaluate how effective topical imiquimod is in the treatment of high-grade CIN in young women.

Method

Patients with high-grade CIN were allocated to this study. They required a once-a-week hospital visit for 8 weeks for the application of imiquimod to the cervix by a specialist. If the lesion got worse, we decided to convert to excisional therapy.

Results

A total of 55 patients with a median age of 30 years (range, 22–42 years). Twenty-nine patients (52.7%) had cervical intraepithelial neoplasm 3 (CIN3), and 24 (43.6%) had CIN2 on initial biopsy. Two patients had high-grade squamous intraepithelial lesion (HSIL) on their PAP without punch biopsy. Fifty-two patients (94.5%) finished the 8-week imiquimod therapy and two patients were treated with additional imiquimod therapy. One patient stopped treatment because of pregnancy. On the last examination, 32 patients (59.2%) had negative intraepithelial lesions, 7 (12.7%) had atypical squamous cells of undetermined significance, and 4 (7%) had LSIL. Three patients (5.6%) had ASC-H. Two of them underwent loop electrosurgical excision procedure (LEEP). The results were CIN3. Eight patients (14.8%) had persistent HSIL: 5 patients underwent LEEP, resulting in CIN 3 except two patients with superficially invasive squamous cell carcinoma.

Conclusion

This study showed that topical imiquimod therapy was effective for the treatment of high-grade CIN, with a regression rate of 79.6%, and HPV eradication rate of 33.3%. To confirm its efficacy, a phase II study with larger cohort would be needed.

ESGO7-0064

RISK FACTORS OF DIAGNOSTIC DISCREPANCY BETWEEN COLPOSCOPICALLY DIRECTED BIOPSIES AND LOOP ELECTROSURGICAL PROCEDURE CONIZATION OF THE UTERINE CERVIX

Y. Jungår, S.J. Leeår, Y.S. Leeår, E.K. Parkår
årCollege of Medicine- The Catholic University of Korea, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

This study aimed to determine the factor of pathologic discrepancy between colposcopically directed punch biopsies and LEEP conization.

Method

A total of 1,200 patients with conization were identified in our center between 2004 and 2016, 667 patients of whom underwent all of cervical cytology, HPV test, punch biopsy, and conization were included in retrospective study. We analyzed patient’s age, menopausal status, number of delivery, abortion times, visualization of the entire transformation zone, number of punch biopsies and duration of between punch and conization.

Results

Logistic regression analysis of the final diagnosis showed that reproductive age and HPV type were associated with cancer diagnosis, while ASC-H, HSIL and HPV type 16 affected the diagnosis of CIN2. The overall concordance rate of histopathology between the punch biopsy and LEEP conization was 43.3%. The rates of detecting a more severe lesion by LEEP conization than gained by biopsy (biopsy underestimation) were 23.1%. The rates of a less severe lesion detected by LEEP conization than gained by biopsy (biopsy overestimation) were 33.6%. Logistic regression analysis of discrepancy has demonstrated that less than 1 time of vaginal delivery, HSIL, number of punch biopsies and HPV type were factors of biopsy underestimation. Punch biopsies number is a unique factor of biopsy overestimation.

Conclusion

Patients with ASC-H, HSIL and HPV type 16 may undergo conization immediately without punch biopsy by the colposcopic findings. Number of 3 or 5 punch biopsies affected both biopsy underestimation and overestimation. We suggest that colposcopically directed 3-5 punch biopsies may be used to determine conization.
THE TOLERANCE OF MULTIMODALITY TREATMENT FOR UTERINE CERVIX CANCER EMPLOYING ANTICERVICAL GROPRINOSIN THERAPY

I. Kasenka¹, T. Serova²
¹NN Alexandrov National Cancer Center, Gynaecological cancer group, Minsk, Belarus
²NN Alexandrov National Cancer Center, Diagnostic department with radiologic diagnosis group, Minsk, Belarus

Aims

Assessing the tolerance of multimodality treatment for stage III uterine cervix cancer employing antiviral therapy.

Method

The materials are the results of experimental and clinical studies including the testing of the new techniques in 12 patients diagnosed with stage III squamous cell cervical cancer, T2-3N0M0, aged 29 to 64 years. The immunoassay included determining the absolute number of lymphocytes, subpopulation lymphocyte content, activation molecules, as well as analyzing the concentration of M, G, A, E immunoglobulins (lg).

Results

The procedure of multimodality treatment has been devised, including external-bean radiotherapy on the small pelvis area at a total target dose of 44-50 Gy and cisplatin radiosensibilization once a week, a total dose of 160-200 mg/m² with concurrent administration of Inosin pranobex (Groprinosin®) 1000 mg 3 times daily for 30 days. Then the patient received contact radiotherapy at a total dose of 20-30 Gy. Radiation morbidity was observed in one case. Hematologic toxicity and local morbidity were not noted. The study of immunological status found an increase in the percentage of T-killers, cytotoxic lymphocytes and a greater gain in the percentage of activated T-lymphocytes (p<0.05), MHC II expression of HLA-DR+ class vs standard chemoradiotherapy.

Conclusion

The inclusion of antiviral drug in the multimodality treatment regimen facilitates improving the tolerance of chemoradiotherapy for stage III cervical cancer and normalizes the immune status indices of the body.

MEDICOBIOLOGICAL PROPERTIES OF PHOTOLON IN A EXPERIMENTAL MODEL

I. Kasenka¹, E. Alexandrova¹, T. Litvinova², D. Tserkovsky³, A. Vasileuski⁴

¹NN Alexandrov National Cancer Center, Gynaecological cancer group, Minsk, Belarus
²Belarusian State Medical University, Department of Oncology, Minsk, Belarus
³NN Alexandrov National Cancer Center, Laboratory of Photodynamic Therapy and Hipperthermia with Chemotherapy Group, Minsk, Belarus
⁴NN Alexandrov National Cancer Center, Isotopic laboratory with unsealed sources complex, Minsk, Belarus

Aims

Evaluating the dynamics of Photolon sensitizer accumulation in HeLa tumor cells and it’s photodynamic activity by the criteria of cytostatic and cytotoxic effects.

Method

The in vitro studies were performed on a monolayer culture of HeLa tumor cells. The cellular culture was grown in the nutritious Medium 199 with addition of 10% blood serum of cow fetuses and canamicin 50 mg/ml. On the third day after the cell culture sowing in the nutritious medium, chlorin e6 conjugated with polyvinyl pyrrolidone (Photolon ®) solution was added. The photoradiation of the HeLa cells tumor was performed with a laser of 667 nm wavelength at a dose of 5 J/cm².

Results

Photolon accumulation in tumor cells was found to be lasting for 2 hours. No further significant change in its cell level was noted. For this reason, a 3-hour incubation time was selected for studying dark cytotoxicity and photodynamic activity of Photolon. Cell incubation with Photolon for 3 hours with 25 or 50 mg/ml end concentration of the photosensitizer resulted in dose-dependent inhibition of HeLa culture growth, and with a concentration higher than 100 mg/ml it led to intensive cell death. IC⁵₀ of Photolon cytostatic effect index was 43.60 ±3.67 mg/ml, and LC⁵₀ cytotoxic effect index was 152.63±3.67 mg/ml.

Conclusion

Photolon accumulation in tumor cells occurs in the course of 2 hours, with no further significant change in its level. Photoradiation of HeLa tumor cells at dose of 5 J/cm² after the incubation with the photosensitizer for 3 hours produces strong cytotoxic and cytostatic effects.

PRIMARY CHEMOTHERAPY FOLLOWED BY RADIATION THERAPY IN CERVICAL CANCER
H. Kato¹, Y. Todo¹
¹Hokkaido Cancer Center, Gynecologic Oncology, Sapporo, Japan

Aims

A therapeutic significance of primary chemotherapy followed by radiation therapy was negated before the advent of taxane derivatives and concurrent chemoradiotherapy. The aim of this study was to revisit a significance of primary chemotherapy followed by radiation therapy in the present era.

Method

This study included 101 consecutive patients with cervical cancer treated with primary chemotherapy followed by surgery (n=70) or definitive radiation therapy (n=31). Impact of radiation therapy on survival was assessed by Cox regression multivariate analysis.

Results

A total of 91 (90%) patients had stage II-IV disease. Forty-nine (49%) patients had radiologically pelvic lymph node (PLN) enlargement. The 5-year overall survival (OS) rate of the entire cohort was 62.1% with the median follow-up period of 50 months. Response rate to primary chemotherapy was 68.3%. Tumor diameter ≥ 6 cm, PLN enlargement, and stable disease or progressive disease to primary chemotherapy were confirmed as independent unfavorable prognostic factors. Selection of radiation therapy as locoregional treatment had an unadjusted hazard risk (HR) of 2.4 [95% confidence interval (CI) = 1.2–4.5, P=0.0089], but an adjusted HR of 1.2 (95% CI = 0.6–2.5, P=0.63) after adjusting for tumor diameter, PLN enlargement, and response to primary chemotherapy. In a subgroup of complete response or partial response to primary chemotherapy, the 5-year OS rates were almost the same (surgery, 75.8% vs. radiation, 71.4%; log-rank test, P=0.82).

Conclusion

As for selection of locoregional treatments following primary chemotherapy, radiation might not be inferior to surgery on survival under chemo-sensitive condition.
E Y. Ki¹, S. Min Jong¹, K. Jin Hwi¹, L. Sung Jong¹
¹The Catholic University of Korea, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims
The aim of this study was to evaluate the immunocytochemical expression of human papillomavirus (HPV) L1 capsid protein in patients with atypical squamous cells of unknown significance (ASCUS), and low grade squamous intraepithelial lesions (LSIL) at high risk of HPV infection.

Method
Between January 2013 and December 2015, we performed immunocytochemistry of HPV L1 protein in cervical cytology samples obtained from 334 patients using the Cytoactiv® HPV L1 screening set. The expression of HPV L1 capsid protein was assessed by using cytology and was compared with the results of histopathological examination.

Results
Patients with ASCUS (n=70) or LSIL (n=215) showed negativity for L1 capsid protein when they were diagnosed as ≥ cervical intraepithelial neoplasia(CIN) 2 (ASCUS group : 82.6%, P=0.0046; LSIL group : 72.2%, P=0.02). The risks of developing ≥ CIN2 were 6.9 folds higher in patients with HPV16 and 18 infection and negativity for HPV L1 capsid protein in the ASCUS group (OR 6.9, 95% CI 2.2-22.2, P=0.001) and 6.7 folds higher in the LSIL group(OR 6.7, 95% CI 2.5-18.3, P=0.0002). Model comparison analysis revealed that cytology plus HPV capsid protein immunocytochemistry or cytology plus HPV test improved the diagnosis rate compared with cytology alone (AIC:191.7 vs 207.5 vs 216.4; SC: 206.3 vs 218.4 vs 223.7).

Conclusion
The results of this study siggest that immunochemistry negativity for L1 protein negativity can be used for detection of high grade cervical lesions(≥ CIN2) in ASCUS and LSIL patients.
BIM OF APOPTOTIC MARKER PREDICTS FAVORABLE SURVIVAL OUTCOME IN CERVICAL CANCER

B. Kim1, H. Cho2, J.Y. Chung3, J.H. Kim2, S. Hewitt3

1International St.Mary’s hospital- Catholic kwandong university, Obstetrics and Gynecology, Incheon, Republic of Korea
2Gangnam Severance Hospital, Obstetrics and Gynecology, Seoul, Republic of Korea
3National Institutes of Health, Experimental Pathology laboratory, MD, USA

Aims

Bcl-2 interacting mediator (BIM) is a pro-apoptotic protein belonging to the BCL 2 protein family. BIM elicits cell death by binding to prosurvival BCL-2 proteins. Even though association of BIM expression and cell death has been investigated, clinical survival significance for BIM is not investigated in cervical cancer. Prognostic significance of BIM was investigated by immunohistochemical analysis in cervical cancer.

Method

The study subjects included cervical intraepithelial neoplasia (CIN, n = 275) and invasive cervical cancer (n = 164). Immunohistochemistry (IHC) was performed to identify BIM protein expression. IHC scoring was performed using automated digital image analysis and the association of BIM with prognostic factors was investigated.

Results

BIM expression was higher in cervical cancer than normal cervix (p=0.001). Well and moderate differentiation showed higher expression of BIM than poor differentiation (p=0.001). Squamous cell type revealed high expression of BIM compared to non-squamous cell type (0.008). BIM expression was highly observed in radiation sensitive cervical cancer compared to radiation resistant cancer (P=0.049). High expression of BIM showed better 5-year disease-free survival and overall survival rate (p=0.049 and 0.030, respectively) than low expression group. In multivariate analysis, BIM was shown as an independent risk factor with hazard ratio of 0.22 (p=0.006) for disease-free survival and hazard ratio of 0.46 (p=0.046) for overall survival in cervical cancer.

Conclusion

BIM is associated with favorable prognostic marker to predict disease-free and overall survival in cervical cancer. High expression of BIM, apoptotic marker of tumor, might be significant survival factor in cervical cancer.

SENTINEL LYMPH NODES MAPPING WITH INDOCYANINE GREEN IN CERVICAL CANCER STAGE IAI – IIB : A SINGLE CENTER EXPERIENCE

J.H. Kim¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹Asan Medical Center, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To determine the validity of sentinel lymph nodes (SLN) mapping using Indocyanine green (ICG) in cervical cancer.

Method

We have performed a retrospective study of cervical cancer patients with SLN mapping from 2015 to 2017 at the Asan Medical Center. Hundred-three patients were included. After using ICG to detect SLN during surgery, we removed SLN following standard radical surgery and bilateral pelvic lymphadenectomy.

Results

The most common surgery was a laparoscopic radical hysterectomy (44.7%). Stage IB1 was most common (61.2%). The median tumor size was 2.4cm. At least One SLN was detected in all cases. Eighty-eight patients (85.4%) had bilateral pelvic SLN. Side specific detection rate was 92.7%. Twenty-seven patients had nodal metastasis after lymphadenectomy on final H&E. On a side-specific basis, the sensitivity of SLN was 71.43%, specificity was 100% and Native predictive value (NPV) was 93.98%. In the case of tumor size less than 2 cm and negative lymph node metastasis at imaging test, sensitivity was 100%, specificity was 100%, and NPV was 100% as side-specific. The size over 4cm, lymphovascular space invasion, parametrium (PM) invasion and previous LEEP history were the risk factors affecting false negative detection of SLN.

Conclusion

It may be possible to perform SLN Biopsy alone in an early stage in which the size is less than 2 cm and the lymph node metastasis is not suspected in the imaging test. However, if tumor size is large and vagina extension is suspected, and if any suspicion of PM invasion, we should be cautious in doing the SLN biopsy alone.

THE COMPARISON OF SURGICAL OUTCOMES AND LEARNING CURVES OF RADICAL HYSTERECTOMY BY LAPAROSCOPY AND ROBOTICS FOR CERVICAL CANCER: AN EXPERIENCE OF A SINGLE SURGEON

Y.J. Heo1, S. Kim2, K.J. Min3, S. Lee2, J.H. Hong4, J.K. Lee4, N.W. Lee5, J.Y. Song2

1Korea University, College of medicine, Seoul, Republic of Korea
2Korea University Anam Hospital, Department of obstetrics and gynecology, Seoul, Republic of Korea
3Korea University Ansan Hospital, Department of obstetrics and gynecology, Ansan, Republic of Korea
4Korea University Guro Hospital, Department of obstetrics and gynecology, Seoul, Republic of Korea

Aims

The aim of this study was to compare and determine the feasibility, surgical outcomes, learning curves of robotic radical hysterectomy with lymph node dissection (RRHND) to conventional laparoscopic radical hysterectomy with lymph node dissection (LRHND) in patients with cervical cancer by a single surgeon.

Method

Between April 2009 and March 2013, 22 patients underwent LRHND and 19 patients underwent RRHND. Variables such as patients’ age, body mass index, International Federation of Gynecology and Obstetrics (FIGO) stage, histology, number of dissected lymph nodes, operative time, estimated blood loss, days of hospitalization, amount of transfusion and complications were analyzed.

Results

Most of characteristics were similar between two groups, except FIGO stage (p=0.034). LRHND group had more IB1(12 vs 8) and IB2(5 vs 0) patients, and RRHND had stage IIB(6 vs 0) patients predominantly. In surgical outcome analysis, RRHND(61.3±28.9 min) showed longer preparing time than LRHND(43.0±14.3 min). More positive lymph nodes were dissected through LRHND(0.6±1.3) than RRHND(0.1±0.2). In the LRHND group, 9 patients experienced a postoperative complication. On the other hand, in the RRHND group, 4 patients experienced a postoperative complication. The regression analysis failed to yield a learning curve for LRHND group, so comparison of learning curves between LRHND and RRHND could not be made.

Conclusion

During about 20 cases, the surgical outcomes and complication rates of RRHND were comparable to those of LRHND. A long-term follow-up study with larger cases is required to define the nature of the learning curve.

THERAPY MODALITIES, PROGNOSTIC FACTORS AND OUTCOME OF THE PRIMARY CERVICAL CARCINOSARCOMA: META-ANALYSIS OF EXTREMELY RARE TUMOR OF CERVIX

G. Kimyon Comert1, O. Turkmen2, A. Karalok2, D. Basaran2, D. Bulbul2, T. Turan2

1Etlik Zubeyde Hanim Women’s Health Teaching and Researching Hospital, Gynecologic Oncology Clinic, Ankara, Turkey
2Etlik Zubeyde Hanim Women’s Health Teaching and Researching Hospital, Pathology, Ankara, Turkey

Aims

To evaluate prognostic factors, treatment options and survival outcomes of the primary carcinosarcoma of the uterine cervix.

Method

The literature electronic search was conducted from 1951 to February 2017 to identify articles about primary cervical carcinosarcoma. After comprehensive evaluation of case series and case reports including additional two cases from our institution, the study included 81 cases (figure 1).

Results

The most clinical FIGO stage was IB with 53%. Median follow-up time was 15 months (range: 1.75-156). 2-year disease free (DFS) and overall (OS) survival of the entire cohort were 49% and 60%, respectively. Both 2-year DFS and OS were significantly higher in patients with stage-I compared to those with stage-II≤ disease (73% vs. 22%, p=0.000 and 82% vs. 33%, p=0.000 (figure 2), respectively). 2-year OS was 17% for patients received primary radiotherapy, whereas it was 68% for those underwent only surgery (p=0.003). Surgery followed by adjuvant radiotherapy with or without chemotherapy was significantly related with improved DFS and OS than primary radiotherapy (table 1). 2-year DFS was 63% in patients who underwent primary surgery, whereas it was 100% in patients treated with primary surgery followed by adjuvant radiotherapy with chemotherapy (p=0.030). Only stage was independent prognostic factor for risk of both recurrence and death (Hazard Ratio (HR): 9.8; p=0.004 and HR: 14; p=0.018) (table 2).

Conclusion

The stage in due course of presentation has a great importance and is only independent factor for prognosis. Surgery followed by adjuvant radiotherapy with or without chemotherapy seems to be related with better OS and DFS.

DO PATIENTS AND PHYSICIANS ACCEPT LESS RADICAL PROCEDURES OFFERING LOWER MORBIDITY IF THEY ARE ASSOCIATED WITH HIGHER ONCOLOGICAL RISK?

K. Gungorduk¹, R. Kocián², D. Basaran³, T. Turan³, A. Ozdemir¹, D. Cibula²

¹Muğla Sıtkı Koçman University Education and Research Hospital, Department of Gynecologic Oncology, Muğla, Turkey
²First Faculty of Medicine Charles University, Gynecologic Oncology Center Department of Obstetrics and Gynecology, Prague, Czech Republic
³Etlik Zübeyde Hanım Education and Research Hospital, Department of Gynecologic Oncology, Ankara, Turkey

Aims

This prospective survey study aimed to evaluate the opinions of women who underwent radical surgery for cervical cancer (CC) and physicians who treat CC about the acceptability of increased oncological risk after less radical procedures in the surgical treatment of CC.

Method

Patients (n=182) and physicians (n=101) were asked whether they would accept any additional oncological risks, which can be attributable to the omission of parametrectomy (radical hysterectomy/trachelectomy vs. simple hysterectomy/trachelectomy) and omission of PLND (systematic resection vs. sentinel lymph node (SLN)) sampling, if these less radical procedures offered diminished postoperative morbidity.

Results

Although more than half of the patients (52.2%) reported morbidity related to the previous treatment, the majority of them would not accept less radical surgical treatment if it was associated with any increased risk of recurrence (50–55 % No risk and 17–24% risk < 0.1%). Physicians tend to accept a significantly higher risk than patients in the Czech Republic but not in Turkey (Table 1). Risk acceptance was not significantly modified by the type of the procedure. Patients with higher education levels, advanced stage disease, adverse events related to previous cancer treatment, and patients that received adjuvant therapy were significantly more likely to accept an increased oncological risk. Physicians’ risk acceptance increased only with age (Table 2).

3Stavanger University Hospital, Department of Pathology, Stavanger, Norway
4University of Stavanger, Department of Mathematics and Natural Science, Stavanger, Norway
5Maastricht University, Department of Molecular Cell Biology, Maastricht, The Netherlands

Aims

Approximately 20-40% of high-grade cervical intraepithelial neoplasia (CIN) lesions show spontaneous regression. Nonetheless, most high-grade lesions are treated by surgical excision, because the prognosis of an individual lesion is unpredictable. This leads to overtreatment and associated complications. Gain of the 3q26 gene locus, which contains the human telomerase RNA gene, is frequently found in CIN and cervical carcinoma and has prognostic properties in low-grade CIN. The aim of this study is to assess 3q26 gain as a prognostic biomarker in high-grade CIN lesions.

Method

Patients were extracted from a study database, consisting of patients with histologically confirmed high-grade CIN who were conservatively managed for a median period of 16 weeks, after which they underwent loop excision. Punch biopsies taken at baseline were analyzed by fluorescence in situ hybridization to determine the 3q26 gene copy number.

Results

Nineteen women were included in the study (table 1). Mean age and biopsy-cone interval did not differ between patients with and without disease regression. Gain of 3q26 was found in 16 out of 19 patients (table 2). All patients with disease persistence showed gain of 3q26, whereas all patients without 3q26 gain showed disease regression. The positive and negative predictive values of 3q26 gain for disease persistence are 63% and 100%, respectively.

NON HODKING LYMPHOMA OF UTERINE CERVIX – A CASE REPORT.
M. Komatsu¹, T. Almeida¹, M. Brandão², V. Santos², A. Sousa², C. Gomez², V. Galleto², L. Mauri²
¹Hospital Santa Marcelina, Gynaecology, Sao Paulo, Brazil
²Hospital Santa Marcelina, Gynaecology, São Paulo, Brazil

Aims

Primary non Hodgkin lymphoma at young woman is report in this paper

Method

Case report of patient admitted at emergency room of Santa Marcelina Hospital on september 2016, diagnosed and treated at department of gynaecology oncology.

Results

Female genital tract lymphoma representing less then 1% of all extra nodal diseases. There is no consensus about treatment when the primary site is on the uterine cervix. Paps smears does not have specificity, so the definition of diagnosis preferably by incisional biopsy.

VMMS, 48 years old, submitted to a sub total hysterectomy by uterine mioma at 8 months ago, admitted at emergency room of Santa Marcelina Hospital with lombar pain and clinical condition suggestive of acute renal insufficiency; the tumor size at examination was 5 cm with positive bilateral infiltration of parametrium until pelvic wall and proximal infiltration of vaginal wall; CT scan revealed bilateral hydronephrosis, bulky and heterogenous cervical tumor. Incisional biopsy was performed, histopathology and immunochemistry revealed large cell b diffuse non Hodking’s lymphoma high grade(positive CD20, Ki-67, PAX-5) stage IIE, radiotherapy was performed 45Gy/25Fr at pelvis followed by chemotherapy.

Conclusion

The staging follow the extra nodal lymphoma protocols and depeps of the histological type, at present case the radiotherapy was the first option of treatment because the infiltration of parametrium was extensive, the rare incidence of this disease at cervix tend to difficult stabilish protocols of treatment.

ACCEPTABILITY AND THOUGHTS ABOUT MULTIPURPOSE HUMAN PAPILLOMAVIRUS VACCINES AND 2-DOSE HPV VACCINATION IN KOREAN MOTHERS OF ADOLESCENT GIRLS

J.H. Koo1, C.J. Kim1, T.C. Park2, K.H. Lee1, M.J. Jeong1, J.S. Park1

1The Catholic University of Korea, Obstetrics and Gynecology, Seoul, Republic of Korea
2The Catholic University of Korea, Obstetrics and Gynecology, Kyunggi Do, Republic of Korea

Aims

Cervical HPV infection is a common sexually transmitted infection. Most women are infected shortly after beginning their first relationship. In Korea, given the high priority of preventing HPV-associated cervical disease including cancers, HPV vaccines were integrated into national vaccination programs in 2016. Multipurpose vaccines (MPVs) could be formulated to prevent multiple sexually transmitted infections simultaneously. We aimed to assess the acceptability of hypothetical MPVs for STI/HIV prevention and 2-dose HPV vaccination, we conducted a mixed-methods study among adolescent vaccine providers and mothers of adolescent girls.

Method

We conducted in-depth interview with 30 physicians for the acceptability of MPVs for STI/HIV/HPV and 2-dose HPV vaccination. We conducted focus group discussion (FGD) with the 31 mothers of adolescent daughter. Focus group discussion (FGD) with 31 mothers of adolescent girls was done in 4 groups according to their daughter’s HPV vaccination status and social status.

Results

The research showed 71% of the mothers preferred single-purpose HPV vaccines over MPVs. Concerns about safety and efficacy was common barriers to accepting MPVs. MPV support was higher among mothers of vaccinated girls than unvaccinated girls (37.5% vs. 26.1%). Mothers with occupations were more vulnerable to information on vaccines. For the two-dose HPV vaccination, most mothers said “yes” because of convenience. Providers have positive attitude toward 2-dose vaccination and MPVs both.

Conclusion

In Korea, maternal acceptability of MPVs was relatively low. To increase the acceptability of MPV and two dose HPV vaccination, physicians provide parents with additional MPV vaccine safety and efficacy information.

THE CLINICAL UTILITY OF SENTINEL LYMPH NODE MAPPING IN THE CONSERVATIVE MANAGEMENT OF EARLY STAGE CERVICAL CANCER

I. KOUROTROUMA1, N. THOMAKOS1, M. SOTIROPOULOU2, D.E. VLACHOS1, M. LIONTOS3, D. HAIDOPoulos1, G. VLACHOS1, A. RODOLAKIS1

1University of Athens, 1st Obstetrics & Gynaecology Department- Division of Gyn/Oncology- Alexandra Hospital-, Athens, Greece
2University of Athens, Department of Hystopathology- Alexandra Hospital, Athens, Greece
3University of Athens, Department of Clinical Therapeutics- Alexandra Hospital, Athens, Greece

Aims

Lymph node (LN) metastasis is a critical attribute to prognose recurrence in cervical cancer (CaCx). Our aim consists of a single algorithm detecting the sentinel lymph nodes (SLNs) and combining SLNs status with individual metastatic factors as an enhancement in the conservative management of early stage CaCx.

Method:

Prospective study including patients with CaCx, stage IA1- IB2 (tumour size, TZ 0.5-3cm). Intracervical superficial injection of patent blue, after induction of anaesthesia, detection and removal of dyed LNs, sent for frozen section biopsy, bilateral pelvic lymphadenectomy/radical hysterectomy and correlation with final histopathology.

Results

Fifty five patients were included in our study. At least one SLN (range 0-6) was identified in 87.3% (48/55), whereas bilateral detection was succeeded in 78.2% (43/55). SLNs were located at the external (62.6%) or internal iliac region (11.2%), obturator fossa (16.1%), and ventral to the hypogastric vessels (10.1%), whereas 8.3% found in an unexpected area (parametrium) in certain cases. False negative SLN and micrometastasis was identified in only two cases (TS ≥2.2 cm). Frozen section biopsy was positive in 4 cases (4.3%) and the procedure was aborted. Sentinel lymph node sensitivity in detection of metastasis was 100 % for TS < 2.2 cm, LVSI negative and DOI ≤5 mm. Median follow-up was 18.2 months (range 1-32) and all patients remain without evidence of disease.

Conclusion

Our technique is established as adequate in clinical significance of SLN mapping in early stage cervical cancer and support a more conservative surgery with greater safety in cases with small tumours.
CERVICAL CANCER

LYMPHOCELE FORMATION AND PREVALENCE AFTER RADICAL HYSTERECTOMY WITH PELVIC LYMPH NODE DISSECTION FOR CERVICAL CARCINOMA

S. Kovachev¹, A. Ganovska¹

¹Military Medical Academy, Gynecology, Sofia, Bulgaria

Aims

The objective of our study was to establish the frequency of pelvic lymphocele after radical hysterectomy with pelvic lymph node dissection for cervical carcinoma.

Method

Our study included 195 women (aged 32-75 years) with radical hysterectomy (Type C2) with systematic pelvic lymphatic dissection for histologically proven cervical carcinoma. Patients were followed up for the development of pelvic lymphocele at 20 and 40 postoperative days – clinically (for complaints) and with imaging tests: ultrasound and/or computerized axial tomography. Patients with established lymphocele over 4 centimeters in diameter or less, but with overt clinical complaints undergo a new surgical treatment for its removal.

Results

Of the 195 women included for postoperative examinations at 20 and 40 day after surgical treatment appeared only 180 (100%) women. Only their results are included in our research data. At 23 (12.8%) of all 180 (100%) women evolved, we find out lymphocele. Clinical complaints connecting with lymphocele have 11 (47.8%) women. Thirteen (56.5%) of the women included have lymphocele over 4 cm. In 18 (78.3%) of all women with lymphocele repeated surgery (endoscopic or classic abdominal) for removal of lymphocele was needed, for the possibility of follow-up therapy in conjunction with the underlying disease.

Conclusion

Lymphocelle is a common postoperative complication of radical pelvic surgery with systemic lymphatic dissection on the occasion of the female genital cancer diseases. For his prevention during surgical treatment should be thought or at the first postoperative examinations of women with or without certain clinical complaints.
OVARIAN FUNCTION AFTER RADICAL HYSTERECTOMY FOR CERVICAL CANCER WITH OVARIAN TRANSPOSITION

S. Kovachev¹, A. Ganovska¹
¹Military Medical Academy, Gynecology, Sofia, Bulgaria

Aims

The objective of our study is to investigate ovarian function after radical hysterectomy with ovarian preservation for cervical cancer.

Method

In our study we included 21 women aged 31-44 years with cervical carcinoma. All women undergo surgical treatment: radical hysterectomy (type C1) with pelvic (sometimes para aortic) lymph dissection and with ovarian preservation and transposition. At all of the women surgical treatment was follow by radiotherapy. Ninety days after we asked patients to come for gynecological exam with ultrasound (current and 10 days later) and hormonal status. Blood test for: estradiol, progesterone, luteinizing hormone, follicle stimulating hormone was taken. All of the patients answered questionnaire about sexual life and symptoms of menopause.

Results

From 21 (100%) women included, 9 (42.9%) have all signs (clinical, ultrasound, hormonal) of menopause. Three (14.2%) of patients have clinical symptoms (questionnaire) but not hormonal for menopause. The rest 9 (42.9%) of the patients have normal clinical, ultrasound and hormonal data. Blood hormonal test is the best indicator for ovarian steroids production lost and for occurred menopause. Sexual life problems have 11 (52.4%) of our patients.

Conclusion

Menopause and sexual life problems are very often among women after radical hysterectomy for cervical carcinoma even with ovarian preservation. This is most likely the result of post-operative radiotherapy.

ESGO7-1377

REGIONAL HYPERTERMIA AND CHEMORADIATION IN ADVANCED CERVICAL CANCER PATIENTS WITH DIFFERENT TYPES OF PARAMETRIAL INVASION

J. Kreynina¹, L. Shevchenko¹, M. Kaskulova¹
¹Russian scientific center of roentgenradiology, Brachytherapy, Moscow, Russia

Aims

Objectives. Cervical cancer patients with deep parametrial invasion still have a very poor prognosis because of incomplete local response to chemoradiation (CHRT). Hyperthermia is known as the most effective sensitizer for radiation and chemotherapy, so its advantages were used to improve local control and treatment results in locally advanced cervical cancer patients (LACC) with different types of parametrial invasion.

Method

Methods. 35 pts, T2b−T4a LACC, parametrial invasion >1/2, were included, one side involved in 21 (60%), both − in 14 (40%) pts. Three main types of parametrial invasion were defined (US, MRI) – direct disease spread from cervix; metastatic lymph nodes and cancer lymphangitis – with different response to CHRT. Conformal EBRT (3D–CRT, IMRT) in 2Gy, 46–48Gy for pelvic or extended paraaortic fields, Cisplatin 40mg/m² or Carboplatinum AUC2 weekly and regional hyperthermia (Oncothermia) EHY-2000, 60-90’ 3 t/, 90-120Wt6 before irradiation, 10–13 per course.

Results

Results. 396 fractions of Oncothermia were performed in all included pts with no serious adverse events. Effects (RECIST 2.0): CR − in 8 (22,9%) pts, PR >70% – in 15 (42,8%), stable − 9 (25,7%) больных, progression ( paraaortic LN and liver)− 3(8,6%), no local progression. Observation mediana 22,6 mnth. DFS 88,5%.

Conclusion

Conclusion. Chemothermoradiation is effective ans safe way of treatment for advanced cervical cancer patients with deep parametrial invasion.

1Clinical center Nis- Clinic for oncology, University of Nis- Faculty of Medicine, Nis, Serbia
2Clinical center Nis- Clinic for gynecology and obstetrics, University of Nis- Faculty of Medicine, Nis, Serbia
3University of Nis, Faculty of Medicine, Nis, Serbia
4Clinical center Nis- Center for anesthesiology and reanimatology, University of Nis- Faculty of Medicine, Nis, Serbia
5Clinical center Nis, Clinic for oncology, Nis, Serbia
6Clinical center Nis, Clinic for gynecology and obstetrics, Nis, Serbia

Aims

The objective of this study was to determine diagnostic and therapeutic management in patients with ASC PAP findings.

Method

The samples from the Gynecology and Obstetrics Clinic, Clinical Center Nis that were analyzed in this study included 2820 PAP tests.

Results

In our samples, there were 3.93% ASC-US and 0.67% ASC-H findings. In 52 patients with ASCUS, colposcopic finding was normal, but in 53.15% patients cervical biopsy was performed since the colposcopic finding was abnormal, in 61% patients with performed biopsy the results were normal, meaning that in relation to the total number of ASC-US that were monitored, the benign findings was in 79.27%, 16.2% patients had CIN I – LSIL, 3.6% patients CIN II and only 0.9% patients had CIN III – HSIL. In patients with ASC-H finding of the PA test, benign pathohistological results were found in 42.1% cases, 31.5% patients had CIN I, 10.52% patients had CIN II, while 15.78% patients had CIN III – HSIL. So, there was a total of 26.3% HSIL findings. The results obtained showed statistically significantly higher percentage of HSIL in the group of patients with ASC-H findings in comparison to the group with ASC-US findings.

Conclusion

Patients with ASC require individual approach in monitoring and further treatment. A high percentage of benign histopathological results in patients with ASC-US necessities the employment of the expectation approach. Patients with ASC-H smear have a high percentage of SIL on biopsy, so these patients with pathological colposcopic findings require a more active approach.

EXPLORING IMMUNE REGULATORY NETWORKS CONTRIBUTING PRECANCER AND EARLY-STAGE CERVICAL CANCER PROGRESSION

O. Kurmyshkina¹, P. Kovchur¹, L. Schegoleva², T. Volkova¹
¹Petrozavodsk State University, Institute of High-Tech Biomedicine, Petrozavodsk, Russia
²Petrozavodsk State University, Institute of Mathematics and Information Technologies, Petrozavodsk, Russia

Aims

Regulatory relationships between diverse types of cells involved in tumor-induced immune reactions are being successfully studied at molecular level using various experimental approaches. In an organism, these simultaneously acting mechanisms form a complex immune regulation network that may differ from experimental systems and thus requires special investigation for each type and stage of cancer. In this sense, cervical cancer-associated alterations in cellular immunity are one of the least understood.

Method

60 women with cervical intraepithelial neoplasia grade 3 or microinvasive cervical carcinoma and 30 healthy women were involved. Multicolor flow cytometry was used to phenotype peripheral blood lymphocytes from controls and patients before any treatment. Mathematical tools were applied to the results to explore putative relationships between functionally different types of circulating lymphocytes.

Results

We analyzed the percentages of several rare but having potent regulatory properties cell populations, specifically CD4 and CD8 regulatory T cells (CD25pos/highCD127dim/negFoxP3pos), regulatory natural killers (CD3negCD16dim/negCD56bright), and CD3bright (including CD56pos) populations, and observed statistically significant expansion of immunosuppressive cell types in cancer patients. Additional evidence of regulatory disbalance came from decreased CD8/CD4CD25FoxP3 T-cell and CD56dim/CD56bright NK-cell ratios. As a direct effect of this disbalance, upregulation of apoptotic markers in circulating T- and NK-cell subsets was evaluated. Another feature of altered activation status of T cell subpopulations was found to be Stimulator of Interferon Genes expression.

Conclusion

Statistical analysis suggested systemic alterations of regulatory networks affecting different immune cell subsets may contribute the earliest stages of cervical cancer progression. The work was supported by the Russian Scientific Foundation (project No.17-15-01024).
ADJUVANT TREATMENT STRATEGY AFTER RADICAL SURGERY OF LOCALLY ADVANCED CERVICAL CANCER WITH NEoadjuvANT CHEMOTHERAPY

Y.S. Kwon¹, H.J. Roh¹, S.H. Lee¹, J.Y. Kwack¹
¹Ulsan University Hospital, Obstetrics and Gynecology, Ulsan, Republic of Korea

Aims

The aim of this study is to evaluate a proper adjuvant therapeutic strategy in patients who have locally advanced cervical cancer (LACC) after neoadjuvant chemotherapy (NACT).

Method

Between June 2005 and October 2015, forty-nine patients who had locally advanced cervical cancer (LACC) IB2-IIB were eligible for radical surgery after neoadjuvant chemotherapy (NACT).

Results

The 35 patients who received adjuvant treatment, which included chemotherapy (7, 20%), radiotherapy alone (3, 8.6%), or concurrent chemoradiotherapy (25, 71.4%). The eleven of the fourteen patients were divided into the two groups. Group A, did not have any risk factors for adjuvant therapy and who does not meet the Sedlis criteria. The other three patients, group B, received adjuvant therapy who had have parametrial invasion microscopically or LN metastasis microscopically. Among group A, the nine patients did not receive an adjuvant therapy and the other two patients received adjuvant treatment though they had no risk factors on base of the final pathologic report, because of dependence on the initial high stage before NACT. The group B, all three patients received adjuvant therapy. Consequently, total five patients were in the adjuvant group after NAC followed by radical surgery. The comparison analysis showed no significant difference between the adjuvant treatment group and the no-adjuvant treatment group in the recurrence and survival data (p value=0.23).

Conclusion

In the patients who had radical surgery with NACT, our study suggests that a proper and clear practical guideline of adjuvant therapeutic strategy should be necessary in patients with remarkable changes after radical operation following neoadjuvant chemotherapy.
LAPAROSCOPIC RADICAL HISTERECTOMY: A SINGLE INSTITUTION EXPERIENCE

R. Lampé¹, R. Póka¹
¹University of Debrecen Faculty of Medicine, Department of Obstetrics and Gynaecology, Debrecen, Hungary

Aims

Laparoscopic radical hysterectomy is a widely accepted operative treatment of early stage cervical cancer. Our aim was to analyze retrospectively our initial results and the feasibility of this technique.

Method

Between July 2016 and April 2017 we performed laparoscopic type-C radical hysterectomy and pelvic lymphadenectomy in ten patients with early stage (IA2-IIB) cervical cancer.

Results

The mean operation time was 165 min (range, 135-198). During surgery, the average decrease in hemoglobin and hematocrit levels was 20.3 g/L and 0.07, respectively. The average width of parametrial resection was 3.7 cm and the mean lymph node count was 16.3. There was no conversion to laparotomy. One intraoperative urinary bladder injury occurred and treated laparoscopically at the same time. No postoperative complications higher than grade 2 occurred according to the Clavien-Dindo classification. The mean hospital stay was 4.7 days.

Conclusion

According to our initial results, introduction of laparoscopic radical hysterectomy is a feasible approach to change practice in surgical treatment of early stage cervical cancer. It is associated with low blood loss and short hospitalization. In addition, it is a safe and effective technique for staging and treating cervical cancer. In comparison to open surgery, pathological evaluation suggests non-inferior prognosis, but further analysis is required to assess long term outcome measures.

DECISIONAL VALUE OF PRETHERAPEUTIC LAPAROSCOPIC EXTRAPERITONEAL ILIO-PARAAORTIC (EL-PALND) VERSUS PET-CT IN LOCALLY ADVANCED CERVICAL CARCINOMAS (LACC)

E. Leblanc, F. Narducci, D. Hudry, L. bresson, Y. Borghesi, S. Taieb, A.S. Lemaire, A. Lesoin, H. Gauthier

1centre oscar lambret, gynecologic oncology, lille, France

Aims

Management of LACC (FGO stage IB2-IVA) is usually based on definitive chemoradiation therapy (CRT), tailored upon the results of pretherapeutic imaging (MRI, CTscan and/or PET-CTscan). As accuracy of imaging is low especially in case of low-volume metastases. EL-PALND has been suggested to better define the indication and upper limit of CRT fields. To clarify the indications of this procedure, we prospectively compared the results of systematic pretherapeutic ilio-infrarenal EL-PARPLND to PET-CT in LACC patients with no contra-indication for surgery, nor evidence of distant metastasis.

Method

From 2005 to 2015, all consecutive LACC patients, with normal morphological imaging (MRI and/or CTscan), were submitted to hybrid PET-CTscan, systematically followed by an ilio-infrarenal EL-PARPLND. All PET-CT results were reviewed, then compared to those of pathological node dissections. This study was approved by our local IRB.

Results

207 informed LACC patients entered the protocol. 162 had a totally extra-uterine negative PET CT, 30 had external iliac only additional hot spots, 12 had common iliac/paraaortic and 2 distant hot spots. With a mean of 21 PA nodes, pathological involvement was found in 10/162 (6.1%), 12/40 (40%), 9/13 (70%) and 2/2 (100%) patients respectively. All except 7 had less than 5mm metastases. Overall morbidity of EL-PALND (all ≤ Clavien 3a) interested 54 (30%) patients with 50% lymphocysts, but none delayed CRT more than 2 weeks.

Conclusion

Given the significant rate of occult nodal involvement at PET-CTscan, EL-PALND seems an interesting option to tailor CRT fields, especially in case of negative PET-CT beyond the level of external iliac vessels.
CERVICAL CANCER

RISK SCORING SYSTEM FOR THE PREOPERATIVE ESTIMATION OF PELVIC LYMPH NODE METASTASIS IN PATIENTS WITH FIGO STAGE IA-IIA CERVICAL CANCER

H.J. Lee1, D.Y. Kim2

1Kangwon National University School of Medicine, Department of Obstetrics and Gynecology, Chuncheon-si, Republic of Korea
2University of Ulsan College of Medicine- Asan Medical Center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To develop a risk scoring system (RSS) for preoperative estimating pelvic lymph node (PLN) metastasis in patients with the International Federation of Gynecology and Obstetrics (FIGO) stage IA-IIA cervical cancer.

Method

A total of 255 patients with FIGO stage IA-IIA cervical cancer undergoing hysterectomy and PLN dissection from January 2013 to January 2016 were included retrospectively reviewed. Model-development cohort (n=162) and validation cohort (n=93) were composed according to the date of operation; pre- and post-2015, respectively. Univariate and multivariate analyses of preoperative clinicopathological factors were performed to identify predictors for PLN metastasis, and a RSS was developed and validated.

Results

Multivariate analysis with backward elimination method identified PLN metastasis assessed by 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT, odds ratio [OR] 8.423; 95% confidence interval [CI] 3.295-21.513; P<0.001) as an independent predictor. And tumor size (OR 1.327; 95% CI 0.992-1.774; P=0.057) and cervical invasion depth (OR 6.360; 95% CI 0.809-49.989; P=0.079) appeared to be marginally significant. The concordance indices of the RSS including these three predictors were 0.850 (95% CI 0.788-0.912) in the model-development cohort and 0.749 (95% CI 0.648-0.851) in the validation cohort, respectively. RSS-predicted probabilities of PLN metastasis revealed good agreement with observed probabilities in calibration plots of both datasets.

Conclusion

We developed the RSS for preoperative estimation of PLN metastasis in patients with FIGO stage IA-IIA cervical cancer. After external validation, it could provide valuable information for predicting the risk of PLN metastasis to gynecologic oncologists before surgery.
CERVICAL CANCER

USE OF A COGNITIVE COMPUTING SYSTEM FOR TREATMENT OF CERVICAL CANCER

K.B. Lee¹, J.M. Lee²
¹Gachon University Gil hospital, OBGY, Incheon, Republic of Korea
²Kyoung-Hee University Hospital, OBGY, Seoul, Republic of Korea

Aims

IBM Watson for Oncology (WFO) is a Memorial Sloan Kettering Cancer Center-trained cognitive computing system that uses natural language processing (NLP) to provide oncologists with ranked, evidence-based treatment options for cancer. WFO treatment options are presented in three categories: "Recommended", "For Consideration" and "Not Recommended". This study examined the concordance of cervical cancer adjuvant treatment options between WFO and our institute treatment from Gachon University Gil Medical Center (GMC), Incheon, South Korea.

Method

Gynecologic oncologists at GMC retrospectively enrolled patients with FIGO stage I to II cervical cancer who underwent surgical treatment between 2014 and 2016. Cases were processed in blinded fashion using WFO, and the output was compared to our institute recommendations. WFO treatment options were considered concordant when the GMC recommendation was included in the "Recommended" or "For Consideration" categories provided by WFO.

Results

Overall, treatment recommendations were concordant in 82 (71.9%) of the 114 evaluated cervical cancer cases. Of 50 patients treated in the adjuvant setting, 30 (60%) of treatment recommendations were concordant. 17 patient received adjuvant chemotherapy and it was unknown treatment option in WFO system. Patients with metastatic and recurrent (central/locoregional) disease were not supported by WFO system yet.

Conclusion

Treatment options suggested by WFO were concordant with the GMC treatment in the majority of cervical cancer patients treated in the adjuvant setting. Further analysis about recurrent and metastatic setting is needed. Geography-specific customization in WFO is needed and it may be helpful for physicians and patients to benefit from WFO worldwide.

PREDICTIVE VALUE OF P16/KI-6DUAL-STAINED CYTOLOGY FOR THE PROGRESSION OF CERVICAL DYSPLASIA

Y.K. Lee1

1Cheil General Hospital, Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

The objective of this study was to investigate the predictive value of p16/Ki-67 dual-stained cytology for the progression of disease.

Method

Cytology p16/Ki-67 dual-staining test was performed on 250 liquid-based residual samples from a cohort of women with ASC-US/LSIL and co-testing human papillomavirus (HPV) positive. Study end points were atypical squamous cells-cannot exclude high-grade lesion (ASC-H) or high-grade squamous intraepithelial lesion (HSIL) detection in 1 and 2 year’s follow-up.

Results

Positivity of p16/Ki-67 dual stained cytology was well correlated to progression of disease compared with positivity of HPV 16/18. During 1 year follow-up, 23 of 250 women experienced progression of disease into ASC-H or HSIL. For positivity of p16/Ki-67 dual stained cytology, Sensitivity (60.9%) for the detection of ASC-H or HSIL and specificity (81.5%) for normal or low grade cytology was higher than those of HPV 16/18 tests (13.0% and 89.0%, respectively) (p<0.001). During 2 years follow-up, 11 of 190 women experienced progression of disease into ASC-H or HSIL. For positivity of p16/Ki-67 dual stained cytology, Sensitivity (45.5%) for the detection of ASC-H or HSIL or specificity (82.1%) for normal or low grade cytology was also higher than those of HPV 16/18 tests (18.2% and 89.9%, respectively) (p=0.025).

Conclusion

p16/Ki-67 dual stained cytology could provide both high sensitivity and specificity for the prediction of ASC-H or HSIL in Pap cytology in the future. Positive p16/Ki-67 dual-stained cytology in low grade cytology was highly associated with the progression of disease in 1 or 2 years follow-up.

ESGO7-0882

FERTILITY-SPARING SURGERY FOR YOUNG PATIENTS WITH RARE TUMORS INVOLVING THE UTERINE CERVIX

J. Li, X. Wu

Fudan University Cancer Hospital, Department of Gynecologic Oncology, Shanghai, China

Aims

The surgical radicality and oncological safety of abdominal radical trachelectomy for patients with cervical cancer has been widely acknowledged. However, whether ART could be offered to young patients who have rare tumors involving the uterine cervix is largely unknown. Here we presented our data, discussing proper selective criteria for fertility-sparing surgery in those patients.

Method

We conducted a retrospective review all patients underwent fertility-sparing surgery for rare tumors involving the uterine cervix at our institution from 08/2006 to 01/2017.

Results

Thirteen patients with rare tumors were included in this study. All patients presented with favorable outcomes except for one distant metastasis. One lady with botryoid sarcoma had tumor metastasized to her left kidney and vertebra 5 years after her primary treatment. However, there was no evidence of local recurrence. Patient characteristics were listed in Table 1 and details of all 13 patients were described in Table 2.

Conclusion

Although the very patient who died in our study had tumor metastasis to her kidney and died, we found in properly selected cases of rare cervical malignancies, conservative surgeries without compromising in survival were feasible. Abdominal radical trachelectomy appeared to secure local disease control well and may be considered an alternative to hysterectomy in some young patients with rare tumors involving the uterine cervix. For patients who require adjuvant chemotherapy after fertility-sparing surgery, more attention should be paid to maintain ovarian function.
PATHOLOGICAL ULTRASTAGING OF SENTINEL AND NON-SENTINEL LYMPH NODES CAUSES STAGE MIGRATION IN EARLY STAGE CERVICAL CANCER

M. Śniadecki1, S. Wojtylak2, E. Wycinka3, S. Sawicki1, M. Liro1, J. Kobierski1, N. Śniadecka4, D. Wydra1
1Medical University of Gdansk, Gynecology- Gynecologic Oncology and Gynecologic Endocrinology, Gdansk, Poland
2Medical University of Gdansk, Patomorphology, Gdansk, Poland
3University of Gdansk- Faculty of Management, Statistics, Sopot, Poland
4Gdansk University of Technology- Faculty of Chemistry, Chemical Technology, Gdansk, Poland

Aims

The aims of study were to assess the impact of pathological ultrastaging (PU) processing on postoperative staging (TNM system) and to assess influence of PU on prognosis of patients with early stage cervical cancer according to International Federation of Gynecology and Obstetrics (FIGO) classification (IA2-IB1).

Method

In the study group (n1=27 patients) at least one sentinel lymph node (SLN)/patient was detected with blue dye. All extracted LNs in this group were subjected to PU (4 µm slices/150 µm intervals) with hematoxylin-eosin staining and immunohistochemistry (AE1-AE3 antibodies). Control group (n2=27 patients) had no SLN concept used nor PU. All patients underwent radical hysterectomy and systemic lymphadenectomy. Effect of PU in „n1” group was expressed as (pu)TNM and compared to FIGO classification. Disease-free (DFS) and overall survival (OS) were calculated for PU LN-event (isolated tumor cells, ITC, micrometastases, MICs, or macrometastases, MACs), PU LN-non-event and „n2” groups in median time of 4.2 years.

Results

Five-hundred-sixteen LNs were extracted (66 SLNs, 36% bilaterally). MIC or ITC were detected in 34 of 482 LNs (7.1%). False negative rate was 11.2%. PU revealed 5 cases of inconsistency between FIGO and (pu)TNM. Both N and M features were changed in two separate cases (from pN0 to puN1 - detection of MIC in pelvic nSLN, and pMx to puM1 - MIC in para-aortic nSLN). No differences in DFS and OS were found for any of the groups.

Conclusion

Underestimation of stage (staging bias) by FIGO classification in early stage cervical cancer, disclosed in PU, has no predictive nor prognostic significance.

CERVICAL CARCINOMA IN THE LAST 6 YEARS IN CHUH
E. López González¹, C. Forero Díaz¹, J.A. Rojas Luna¹, F. Larre Meneses¹
¹Complejo Hospitalario Universitario de Huelva Juan Ramón Jimenez, Ginecology, Huelva, Spain

Aims

Determine the incidence of cervical cancer from January 2010 to January 2016 in our hospital, differentiating cases of pathology anatomy of invasive, microinvasive, and in situ carcinoma.

Method

Retrospective study of pathological anatomy in women diagnosed carcinoma of the cervix in the last 6 years.

Results

We diagnosed a total of 126 cases of cervical carcinoma at different stages of development, and different histological types. The annual incidence is comparable to that of other hospitals of the same level of care.

Of the 126 cases of cervix cancer, is observed in the majority of cases (115 cases = 91%) corresponds to the subtype histology of epidermoid carcinoma; 3 corresponds to endometrioid carcinoma (= 3.78%), 2 cases corresponds to serous. The rest of de cases belong to an other minor histological subtypes.

Conclusion

It has been shown that epidermoid subtype is the most common and is related to the invasion of epithelium of VPH.

The process of cervical cancer is periodically evaluated by a multidisciplinary working group comprising the heads of the same in the various Units. Given the natural history of cervical cancer is necessary to wait for developments in the coming years.

ESGO7-0087

POSTOPERATIVE CLINICOPATHOLOGICAL FACTORS AFFECTING CERVICAL ADENOCARCINOMA: STAGE I-IIB
H. Lou, J. Zhou
1Zhejiang Cancer Hospital, Gynecology oncology, Hangzhou, China

Aims

Currently, cervical adenocarcinoma receives the same, but not suitable, standard treatments as squamous cell carcinoma. The present study was conducted to discriminate the prognostic role of postoperative clinicopathological factors in patients with stage I–II B cervical adenocarcinoma.

Method

All consecutive patients consisted of 312 patients with stage I to IIB cervical adenocarcinoma who underwent radical hysterectomy, including pelvic lymphadenectomy, at our institutions between Oct. 2006 and Sept. 2014. Overall survival and relapse-free survival was analyzed by the Kaplan–Meier method. Sites of recurrence were classified as local and distant locations.

Results

The 5-year OS and RFS rates were 88.2% and 83.8%, respectively. And the 5-year OS rates for patients with FIGO stage IA, IB, IIA, and IIB were 100.0%, 90.7%, 82.8%, and 55.6%, respectively, in adenocarcinoma. Cox model identified No. of positive pelvic nodes and Age at surgery as independent prognostic factors for survival, and No. of positive pelvic nodes and post-operation tumor diameter (4cm) as independent prognostic factors for relapse. 35 women suffered a cancer recurrence. The top three recurrence sites were pelvis, vaginal stump and lung.

Conclusion

A more aggressive therapeutic strategy, which was different from current adopted for cervical cancer, is urgently required for cervical adenocarcinoma. As a new prognostic factor, post-operation tumor diameter should be paid special attention in adenocarcinoma treatment.
THE EFFICACY AND TOXICITY OF THREE DIFFERENT CONCURRENT CHEMORADIOThERAPY IN LOCALLY ADVANCED CERVICAL CANCER: A PRELIMINARY REPORT.

H. Lou

1 Zhejiang Cancer Hospital, Gynecology oncology, Hangzhou, China

Aims

To observe the clinical effects and toxicity of three concurrent chemotherapy regimens in the radiotherapy of advanced cervical cancer.

Method

Between April 2014 and December 2015, 105 patients with FIGO stage IIB-IIIB cervical cancer were treated with concurrent chemoradiotherapy in Zhejiang Cancer Hospital, and all cases were randomly divided into three groups. Group A (35 cases), received cisplatin weekly for 4-5 cycles. Group B (35 cases), received fluorouracil and cisplatin combined chemotherapy every three weeks for 2 cycles. Group C (35 cases), received paclitaxel and cisplatin combined chemotherapy every 3 weeks for 2 cycles. Then record acute adverse reaction and observe the short-term efficacy of all patients.

Results

The complete remission rate of the three groups were 88.6%, 82.9%, 82.9%, the partial remission rate were 11.4%, 17.1%, 11.4% at one month after radiotherapy. The complete remission rate was 97.1%, 97.1%, 94.3% at three months after radiotherapy, there were no significant difference (P > 0.05). The main acute adverse reactions were bone marrow suppression and gastrointestinal reactions. Grade 3-4 leucopenia and neutropenia incidence were more common in paclitaxel and cisplatin group. Grade 3-4 nausea-omitting, diarrhea and intestinal obstruction were more common in fluorouracil and cisplatin group (P < 0.05).

Conclusion

The short-term efficacy of the three concurrent chemotherapy for the treatment of advanced cervical cancer were similar. The paclitaxel and cisplatin group arises more severe bone marrow suppression. The fluorouracil and cisplatin group arises more severe gastrointestinal reactions.

COMPARISON BETWEEN ROBOT-ASSISTED AND LAPAROSCOPIC PARA-AORTIC LYMPHADENECTOMY IN 217 PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER

L. Loverix1, R. Salihi2, E. Van Nieuwenhuyzen2, N. Concir2, S. Han2, I. Vergote2

1University Hospital Leuven, Gynaecology and Obstetrics, Leuven, Belgium
2University Hospital Leuven, Gynaecological oncology, Leuven, Belgium

Aims

To compare robot-assisted (RPAO) with laparoscopic (LPAO) para-aortic lymphadenectomy in patients with locally advanced cervical cancer (LACC).

Method

In this monocentric retrospective study, we included 217 patients with LACC (FIGO-stage IB2-IVA or IB1 with suspicious pelvic LN), who underwent a para-aortic lymphadenectomy up to the inferior mesenteric artery (LPAO,N=162; RPAO,N=55) between 1994-2016 (RPAO starting from December 2012).

Results

Median age for LPAO and RPAO respectively (53 years vs 49 years), BMI (24,7 vs 24,4) were similar. FIGO-stage for RPAO was IB1, IB2, IIA, IIB and IV15%, 6%, 17%, 53%, 9% and 0, and for LPAO5%, 12%, 23%, 44%, 14% and 2%, respectively. In RPAO and LPAO 85% and 83% were squamous carcinomas, respectively. RPAO had a higher ASA-score (ASA2: 62% vs 56% and ASA3: 20% vs 2%, p<0.001) and more prior major abdominal surgery (18% vs 6%, p:0.016), less estimated blood loss (median, 25,0 mL vs 62,5 mL, p<0.001), more removed PAO LNs (11 vs 6, p<0.001) and shorter postoperative stay (1,8 vs 2,5 nights, p:0.002), and a tendency for more patients with metastatic PAO LNs (13% vs 5%, p:0,065), compared with LPAO respectively. There was no difference in complications. Overall survival (OS), progression free survival (PFS) and time-to-progression were similar.

Conclusion

RPAO resulted in less blood loss, shorter postoperative hospitalization, higher amount of sampled PAO LNs and tendency for a higher number of positive PAO LNs compared to LPAO.

IMPACT OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) AND HYPOXIA – INDUCIBLE FACTOR-1ALPHA (HIF-1) EXPRESSION ON RESPONSE TO RADIO-CHEMOTHERAPY IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CARCINOMA.

J. Madani1, A. Herrero1, B. Eizaguirre2, V. Alonso1, T. Puertolas1, J. Lao1, A. Artal1, A. Anton1
1Hospital Universitario Miguel Servet, Medical Oncology, Zaragoza, Spain
2Hospital Universitario Miguel Servet, Anatomía Patológica, Zaragoza, Spain

Aims

Combination of radiotherapy plus platinum-based chemotherapy (RT-CT) is considered the standard treatment in locally advanced cervical carcinoma (LACC).

Aims: To identify clinical and molecular variables with predictive value of response to RT-CT in LACC.

Method

Expression of VEGF and HIF-1 was assessed by an immunohistochemistry (IHC) assay in 115 patients (p). Correlation of both parameters with response was measured using the chi-squared test. To evaluate the impact of the rest of variables on the probability of complete response (CR) to RT-CT uni- and multivariate analysis were performed. The following variables were included: Age, Performance Status, Histology, Hemoglobin levels (basal, nadir, post-treatment), CA 125 (basal, post-treatment), p16, CD31 and p53.

Results

By stage, 34p IB2-IIA, 59p IIB and 22p III-IVA. All were treated with RT-CT between January/2003-December/2012. IHC revealed absence of expression of VEGF in 12p, slightly positive (+) in 34p, moderate (++) in 30p and strongly positive (+++) in 39p. The expression of HIF-1 was negative in 63p and positive (weak or moderate) in 52p.

Absence or weak expression of VEGF were significantly correlated with a CR to RT-CT and strong expression with non CR (p<0.001). The absence of expression of HIF-1 was significantly correlated with a CR and weak/moderate expression to non CR (p=0.01). VEGF and HIF-1 maintained their statistical significance in the multivariate analysis along with basal hemoglobin and CA 125 post-treatment.

Conclusion

IHC-assessed low expression of VEGF and absence of expression of HIF-1 were independent predictors of CR in patients with LACC treated with RT-CT. IHC determination of VEGF and HIF-1 could be useful in clinical practice.
THE USE OF INTENSITY MODULATED RADIOTHERAPY AS A MEANS OF REDUCING DOSE TO BONE MARROW FOR PATIENTS WITH CANCER CERVIX TREATED AT NCI, CAIRO, EGYPT

M. Mahmoud1,2, M. Shosha3, M. Hassan4

1Radiation Oncology Department, National Cancer Institute, Cairo University, Egypt
2Radiation Oncology Department, Shefaa Alorman Oncology Hospital, Egypt
3Radiation Physics Department, Shefaa Alorman Oncology Hospital, Egypt
4Radiation Physics Department, National Cancer Institute, Cairo University, Egypt

Purpose: In this study, our aim is to make the BM as organ at risk in the treatment planning process to reduce the irradiated bone marrow volume in cases treated for cancer cervix.

Patients and methods: At the NCI, Cairo, Egypt, C-T simulation was done for thirteen patients with cervix cancer with contrast and full bladder. The clinical target volume was contoured on axial CT slices consisting of the upper one-half of the vagina, parametria, uterus, cervix, presacral region, and regional lymph node regions (common, internal, and external iliac lymph nodes). 1cm margin was added around the clinical target volume to form the planning target volume. The organ at risk (OAR) included the bladder and rectum. Also, the external contour of the pelvic bones was delineated to define the Bone marrow (BM).

Four plans were done for every patient with AP/PA, 3DCRT, IMRT, BMS-IMRT.

Results: BMS-IMRT reduced the BM volume receiving dose 20, 30, 40 and 45 Gy compared with 3DCRT and IMRT plans. A significant reduction in V20 BMS-IMRT compared with 3DCRT (P< 0.03). The PBM volume receiving 5, 10 and 20Gy with AP/PA was lower than BMS-IMRT (p < 0.01, p <0.001 and p <0.04 respectively). BMS-IMRT provided a significant reduction in the rectum and bladder volumes received 40 and 45 Gy compared with AP/PA and 3DCRT planning techniques.

Conclusion: BMS-IMRT reduced the BM volume compared to other techniques as 3DCRT and AP/PA without compromise in target volume coverage. More-over it reduces also the volume of the rectum and bladder irradiated.

STEWART-TREVES SYNDROME (ANGIOSARCOMA ON LYPHOEDEMA): A RARE COMPLICATION OF LYPHOEDEMA

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Stewart-Treves syndrome (SST) or former lymphangiosarcoma is a rare complication of chronic lymphoedema mainly related to the breast cancer (90% of cases). It is extremely uncommon in the lower extremities. The aim of this study is to report a case of angiosarcoma in the lower extremity after cervical cancer.

Method

We report a case of angiosarcoma diagnosed and treated at Salah Azaiez institute in 2017.

Results

Here, we present the case of a 66-year-old female patient with bulky squamous-cell cervical carcinomas (stade II A of Figo). She underwent chemotherapy, radiotherapy and brachytherapy, followed by radical hysterectomy with bilateral pelvic lymphadenectomy in 2005. She had chronic lymphedema of the lower extremities. Twelve years after she developed multiple confluent, hemorrhagic and necrotic elevated purple-black papules in the right lower extremity. The biopsy was performed. The pathology results of the punch biopsies were consistent with angiosarcoma. The CT body scan didn’t show any metastatic lesion. The patient underwent acetabulum desarticulation.

Conclusion

This is a rare complication that usually occurs in the arms of women with breast cancer who underwent mastectomy with lymph node dissection. We report a rare case of angiosarcoma of lower extremity. The treatment is based on a wide excision associated with radiation therapy. However the risk of local recurrence and especially of metastases (lungs and bones) is important. The prognosis remains poor with a 5-year survival rate of 10%.

EFFECTIVENESS OF NATIONAL HUMAN PAPILLOMAVIRUS VACCINATION PROGRAM FOR JAPANESE YOUNG WOMEN

M. Yamaguchi1, R. Kudo1, S. Adachi1, M. Sekine1, A. Yagi2, Y. Tanaka2, Y. Ueda2, E. Miyagi3, T. Enomoto1

1Niigata University, Obstetrics and Gynecology, Niigata, Japan
2Osaka University, Obstetrics and Gynecology, Osaka, Japan
3Yokohama city University, Obstetrics and Gynecology, Yokohama, Japan

Aims

In Japan, human papillomavirus (HPV) vaccinations became public aid from 2010 and subsequently became routine for girls aged 12–16 years from April, 2013. However, after extensive news of adverse vaccine events and suspension of the governmental recommendation in June 2013, inoculation rate of HPV vaccine dramatically decreased. The present study was aimed to investigate the effectiveness of national human papillomavirus vaccination program for Japanese young women.

Method

We recruited 20-22 years old females who attended the public cervical cancer screening program from April 2014 to March 2017 in Niigata, Japan. HPV testing was performed using HCII® (Qiagen) and TM HPV kit® (MEBGEN) and questionnaire about HPV vaccination was conducted. A Chi-square test was used in this statistical analysis.

Results

HPV testing was performed to a total of 2196 registrants and 1972 women replied to questionnaire. A total of 1297 (65.8%) participants self-reported they were vaccinated, and 675 (34.2%) were unvaccinated. High risk HPV infection rate was 11.6% in vaccinated group and 15.9% in unvaccinated group, respectively. The prevalence of vaccine types 16 and 18 was significantly lower in vaccinated group (0.2%) than in unvaccinated group (1.8%; p = .0004). Similarly, the prevalence of HPV 31,33 and 45 which are cross-protected by HPV bivalent and quadrivalent vaccination was significantly lower in vaccinated group (0.3%) than in unvaccinated group (1.5%; p = .008).

Conclusion

Our study demonstrates evidence of high effectiveness of national HPV vaccination program in Japanese young women. National vaccination encouragement should resume as soon as possible.
THE VALUE OF THE PET/TC AND MRI IN THE LYMPH NODE STUDY IN THE LOCALLY ADVANCED CERVICAL CANCER.

C. Martí, M. Del Pino, P. Paredes, A. Rodriguez, L. Fernández

Hospital Clinic de Barcelona- IDIBAPS, ICGON, BARCELONA, Spain

Aims

Lymph node (LN) status is one of the main prognostic factors in cervical cancer (CC). Surgical evaluation of LNs in patients with locally advanced cervical cancer (LACC) is the gold standard to analyze LN status. Pretreatment evaluation of the LN through imaging techniques might be a good alternative to surgery. However, the adequacy of avoiding lymphadenectomy in patients with LACC by using imaging is controversial. The aim of this study is to compare the accuracy of magnetic resonance imaging (MRI) and positron emission computed tomography (PET/TC) to evaluate LN status in patients with LACC.

Method

Between 2011 and 2015, 14 patients diagnosed with LACC at Hospital Clinic of Barcelona underwent PET/TC, MRI and paraortic lymphadenectomy, 12 women underwent also pelvic lymphadenectomy. Sensitivity and specificity of PET/TC and MRI were analyzed.

Results

PET/TC showed a sensitivity and specificity of 55.6% and 60%, respectively. Sensitivity and specificity of MRI was 33.3% and 80%, respectively (table 1). In the pelvic area, the MRI showed higher sensitivity and specificity than PET/TC (71.4% and 80% vs. 42.9% and 60% respectively). In the paraaortic area, the sensitivity and specificity of MRI was 50% and 87.5%, respectively vs. 66.7% and 75%, respectively of the PET/TC.

<table>

<tr>
<td>Positive</td>
<td>1</td>
<td>6</td>
</tr>
</tbody>
</table>

Table 1.

Conclusion

The accuracy of PET/TC and MRI to evaluate LN’s status in patients with LACC do not allow us to avoid the surgical evaluation of the lymph node. Larger studies are warranted.

OUTCOMES FOLLOWING BY RADICAL HYSTERECTOMY TYPE IN THE TREATMENT OF CERVICAL CANCER

E. Martinez Lamela1, J. Molero Vilchez2, S. Sancho Garcia3, M. Rejas Gutierrez4, S. Peco Adrover4, E. Bancalari Rojnic5

1Nuestra Señora del Rosario Hospital/Infanta Leonor University Hospital, oncological gynecology, Madrid, Spain
2Ntra. Sra. del Rosario Hospital - Toco-Gyn Gynecologic Center, Oncological Gynecology, Madrid, Spain
3Ramón y Cajal University Hospital, Radiation Oncology, Madrid, Spain
4Ntra. Sra. del Rosario Hospital, Obstetrics and Gynecology, Madrid, Spain
5Jiménez Ayala Institute, Pathology, Madrid, Spain

Aims

To study the long-term outcomes of the radical hysterectomy (RH) in patients with cervical cancer (CC)

Method

Retrospective study included 40 patients underwent RH: 5 cases B1 type, 7 C1 type, 27 C2 type (nerve sparing) and 1 case D1 type (pelvic exenteration); combined with 31 pelvic lymphadenectomy (PL) and 6 PL and paraaortic lymphadenectomy. The histological type was the squamous carcinoma (47.5%) and adenocarcinoma (42.5%). The frequent stages of presentation were stage IB1 (60%). Three-year overall survival (OS) and a disease-free survival (DFS) was performed using the Kaplan-Meier

Results

Statistical analysis between laparoscopic group (27 cases, 67.5%) and laparotomy group (12 cases) was: Mean hospital stay 4.5 vs 5.9 days (p 0.02), blood loss 910.6 vs 1216.1 cc (p 0.16) and mean resected pelvic nodes 27 vs 16.6 nodes (p 0.005) respectively. Overall complication rate was 17.5%; 2 bladder and one ureteral injury during C2 RH. Postoperative complications: 3 vesical dysfunction were observed in C1 RH and ureteral fibrosis in C2 RH group. Median follow-up in the study group was 48.4 months. The frequency of local or loco-regional recurrences of CC were diagnosed in 7 patients (17.5%) and DFS was 12.7 months: 5 patients in the group RHC2, 3 distant metastases and 2 local or loco-regional recurrences. The OS in different groups by RH type was B1 100%, C1 100%, C2 92%; D1 0%. Statistical analysis of OS in groups C1 RH and C2 RH showed no significant differences (log rank p 0.44)

Conclusion

Laparoscopic RH C1 type is safe

CERVICAL CANCER STAGE IB1 – OPPORTUNITY FOR SAFE AND LESS RADICAL SURGERY

K. Mastilovic1, J. Rajovic2, M. Popovic3

1Institute of Oncology Vojvodina, Gynecology Oncology Surgery, Sremska Kamenica, Serbia
2Institute of Oncology Vojvodina, Gynecology Oncology Surgery, Sremska Kamenica, Serbia
3Institute of Oncology Vojvodina, Gynecology Oncology Surgery, Sremska Kamenica, Serbia

Aims

We evaluated patients that are candidates for less radical surgery with tumor smaller than 2 cm, but who were pathohistologically diagnosed with metastases in pelvic lymph nodes. We evaluated prognostic factors: lymphovascular invasion, histological grade of tumor and stromal invasion. The goal of this scientific work is determining most important prognostic factor which leads to occurrence of metastases in pelvic lymph nodes.

Method

This work included 147 patients who had pathohistological confirmation of plancellular carcinoma of cervix uteri stage I b1. All of patients had radical hysterectomy with pelvic lymphadenectomy. None of patients had preoperative conisation.

Results

29 patients (19.7%) were histologically diagnosed with metastases in pelvic lymph nodes. The average number of the removed lymph nodes was 15. 9 patients (9/29) had positive lymphovascular invasion. 6 (6/29) patients had histologic tumor grade 3. 7 patients had stromal invasion less than 1/3 and 12 patients had stromal invasion over 1/3. Data analysis shown that greatest number of patients that had metastases in the pelvic lymph nodes had stromal invasion over 1/3 with negative lymphovascular invasion.

Conclusion

To make a decision on less radicality, or conservative treatment, in addition to imaging procedure, to preoperatively evaluate prognostic factors that lead to the occurrence of metastases in the pelvic lymph nodes. Given that data from biopsy sample of the cervix alone cannot give data precise enough, the most important information is given by conisation, ex tempore during the surgery, and surgical / pathological scoring system within preoperative evaluations.
THE EFFECT OF CLINICAL GUIDELINES IMPLEMENTATION ON FIVE-YEARS SURVIVAL OF CERVICAL CANCER PATIENTS IN BELARUS
V. Matylevich¹, O. Sukonko¹
¹NN Alexandrov National Cancer Center, Gynecologic Oncology Department, Minsk, Belarus

Aims

In 1999 NCI recommended changes in treatment protocol for stages IIB-IVA cervical cancer from radiotherapy to concurrent chemoradiotherapy. In Belarus, these guidelines were implemented in 2007. We conducted statewide population-based study to analyze the impact of clinical guidelines on 5-years survival rates of patients with cervical cancer.

Method

14220 patients diagnosed with cervical cancer in 2000–2015 were identified from Belarusian Cancer Registry. Overall 5-years survival was compared in patients diagnosed in 2001-2007 and 2008-2015 (before and after guidelines implementation).

Results

5-years overall survival rate (2000-2015) was 0.583 (95% CI [0.575, 0.592]), with statistically significant difference in urban and rural patients (0.614 (95% CI [0.603, 0.624]) vs 0.511 (95% CI [0.504, 0.535]), p < 0.0001. Survival rates before and after implementation of guidelines did not prove to be significantly different (0.577 (95% CI [0.565, 0.589]) vs 0.595 (95% CI [0.582, 0.608]), p = 0.194. When analyzed by cancer stage survival rate after guidelines implementation did not change for stage I, was 5% lower for stage II (0.576 (95% CI [0.556, 0.597]) vs 0.521 (95% CI [0.499, 0.545]), p = 0.007, and was 10% higher for stage III (0.280 (95% CI [0.256, 0.306]) vs 0.395 (95% CI [0.365, 0.428]), p < 0.001.

Conclusion

There was no difference in 5-years survival rates in patients treated for cervical cancer before and after implementation of NCI clinical guidelines in Belarus in 2007. These results must be reevaluated in 2020 when all patients included in this study can be assessed for 5-years survival.
CERVICAL CANCER

ESGO7-0395

DISTINCTIVE FEATURES OF UNRESECTABLE UTERINE CERVIX CANCER IN BELARUS

T. Litvinova¹, O. Matylevich², I. Kosenko¹, O. Moiseyeva¹, A. Gur¹, I. Pronovich¹
¹Belarusian State Medical University, Oncology Department, Minsk, Belarus
²N.N.Alexandrov National Cancer Center, Gynecologic Oncology Department, Minsk, Belarus

Aims

Distinctive features of unresectable uterine cervix cancer (UCC) in patients from Minsk City over the period of 2012-2016 were evaluated on the data of the National Cancer Registry.

Method

Annual incidence rates, stage distribution, tumor histotypes, age distribution were assessed in 324 UCC patients; antitumor therapies, the number of relapses and metastases were also studied.

Results

Stage IIB cancer incidence varied from 3.8 to 1.9/0000, stage III – from 3.2 to 2.3/0000, stage IVA – from 0.4 to 0.7/0000, accounting for 7.4-4.2/0000 in 2012-2016. Squamous-cell carcinoma was diagnosed in 79.6% of the cases, adenocarcinoma in 12.6%, rare histotypes in 7.8%.

UCC was detected in 94 (29.0%) young women. Squamous-cell carcinoma was in 86.7% of them, adenocarcinoma in 10.0%. Stage IIB was diagnosed in 43 (45.7%) patients of this group, stage III in 49 (52.2%), stage IVA in 2 (2.1%).

The patients were treated with combined split-course (38.3%) and continuous course (26.2%) radiotherapy and external-beam radiation (35.5%).

Recurrence was less common than metastatic disease: 7.7% vs 36.4%. The number of the latter was associated with UCC stage: the metastatic rate for stage IIB was 23.3%, for stage III 43.1%, for stage IVA 62.5%. Relapses were more common with stage IIB UCC (9.0%).

Conclusion

Young women account for 29.0% of all UCC patients with stages III and IVA occurring in 54.3% of the cases. Recurrence after UCC treatment is diagnosed less common than metastatic disease. The latter develops in 23.3% of stage IIB patients, in 43.1% with stage III, and in 62.3% with stage IV.

DIFFERENT OPTIONS OF FERTILITY-SPARING TREATMENT FOR EARLY STAGE CERVICAL CANCER: CASE SERIES
V. Matylevich¹, S. Mavričev¹, E. Zavrič²
¹NN Alexandrov National Cancer Centre, Gynecologic Oncology Department, MINSK, Belarus
²NN Alexandrov National Cancer Centre, Medical Oncology Department, Minsk, Belarus

Aims

Evaluating the shot-term results of fertility-preserving options for early cervical cancer patients in childbearing age.

Method

A total of 46 patients with early cervical cancer were included. The patients were stratified into three groups with regards to the organ-sparing therapy option. Eight women with stage IA1LVSI+~IA2 (group 1) underwent ultraconservative surgery: amputation of uterine cervix with lymphadenectomy. Group 2 (31 patients with stage IA2-IB1, tumor size up to 2.0 cm) were subjected to radical abdominal trachelectomy. Seven women of group 3 (four with stage IB1 and tumor size more than 2 cm and three with stage IIA1) received multimodality therapy with neoadjuvant chemotherapy followed by radical abdominal trachelectomy.

Results

The follow-up time was 7 to 62 months. To prevent inflammatory and commissural changes in the small pelvis in the postoperative period, enzymatic drugs containing streptokinase-streptodornase were used. Pregnancy occurred in three women of the 1st group, two of them gave birth of time with no complication, one had a miscarriage at 15 weeks.

Conclusion

Our data suggest that less radical surgery than radical trachelectomy in patients with early low-risk cervical cancer improve the chances of reproductive function implementation; in case of early high-risk cervical cancer, multimodality treatment offers opportunities for radical surgical intervention of the organ-sparing option. However, the application of the mentioned methods of organ-sparing therapy is possible only after a thorough patient selection assessing all the risks in the selling of a highly-specialized cancer institution arranging multidisciplinary panel including an expert morphologist, a trained MRI specialist and qualified gynecologic oncologist.

INCIDENCE OF LYMPH NODE METASTASES IN WOMEN WITH LOW-RISK EARLY CERVICAL CANCER WITHOUT LYMPH-VASCULAR INVASION

L. Minig¹, A. Fagotti², G. Scambia², G. Salvo³, M.G. Patrono⁴, C. Zorrero¹, D. Haidopoulus⁵, S. Maria⁶, I. Zapardiel⁷, C. Arispe⁷, D. Santiago⁸, I. Juárez Pallarés⁸, G. Chisholm³, P.T. Ramirez³

¹Instituto Valenciano de Oncología, Gynecology department, Valencia, Spain
²Catholic University of the Sacred Heart, Department of Women’s and Children’s Health, Rome, Italy
³The University of Texas MD Anderson Cancer Center MDACC, Department of Gynecologic Oncology and Reproductive Medicine, Huston, USA
⁴Hospital Italiano de Buenos Aires, Gynecology Department, Buenos Aires, Argentina
⁵Alexandra University Hospital, Gynecology Department, Athens, Greece
⁶Alexandra University Hospital, Pathology Department, Athens, Greece
⁷La Paz University Hospital, Gynecological Department, Madrid, Spain
⁸La Fe Hospital, Gynecology Department, Valencia, Spain

Aims

To determine the incidence of lymph node (LN) metastasis in women with low-risk cervical cancer stage IA2, and IB1 (<2 cm) without lymph-vascular space invasion (LVSI) stratified by histology, depth of stromal invasion and tumor grade.

Method

A multicenter retrospective study was performed in patients who underwent radical or simple hysterectomy, conization, or trachelectomy plus pelvic lymphadenectomy for cervical cancer between January 2000 and June 2016.

Results

A total of 271 patients were included in the study. Mean (SD) age and BMI was 47.3 (12.9) years and 25.4 (5.1) kg/m²; respectively. Twenty-two patients had stage IA2 (8.1%), 247 (91.1%) had stage IB1, and 2 (0.7%) had stage IIA. The median tumor size was 14 (range, 5-20) mm. Tumor grades were 1 (n=63; 23.2%), 2 (n=120; 44.3%), 3 (n=63; 23.2%), and missed (25; 9.2). Mean (SD) depth stromal invasion was 8.1 (4.4) mm. Histology subtypes included squamous (n=171, 63.1%), adenocarcinoma (n=92, 33.9%), and adenosquamous (n=8, 3.0%). Overall incidence of LN metastasis was 2.9%. The incidence of LN involvement in G1, G2 and G3 was 0% (0/63), 5% (2/120) and 3.1% (2/63); respectively. Multivariate analysis did not identify any independent factor predicting LN metastasis.

Conclusion

No patient with G1 (well differentiated) cervical cancer less than 2 cm and without lymph vascular space invasion had lymph node metastasis. In such low-risk patients, there may not be a need for lymph node evaluation. Consideration for sentinel lymph node alone should be a standard in the setting of patients with grade 2 and 3 disease.

PRE-THERAPEUTIC NUTRITIONAL STATUS FOLLOW-UP FOR PREDICTING SEVERE ADVERSE EVENTS IN PATIENTS WITH CERVICAL CANCER TREATED BY CHEMO-RADIONTHERAPY

E. Miralpeix1, S. Gayete2, S.S. Josep Maria2, C. Ramon2, M. Gemma2

1Hospital Del Mar, Obstetrics and gynaecology department, Barcelona, Spain
2Barcelona, Spain

Aims

Cervical carcinoma remains a significant health problem for women worldwide. Locally advanced cervical cancer (LACC) (stage IB2 to IVA) is a common presentation. Chemo-radiation with a platinum-based agent is the recommended treatment for LACC. Palliation with platinum agent remains the standard of care for inoperable patients who have metastatic or recurrent disease. Malnutrition is common in patients with cervical cancer and it may be related to severe adverse toxicity as a result of radiotherapy. The aim was to investigate nutritional screening factors for severe adverse events.

Method

A retrospective analysis over patients newly diagnosed of cervical cancer from 2015 to 2016 in Hospital del Mar Barcelona was recruited. Patients with locally advanced cervical cancer who underwent chemo-radiation were included to predict severe adverse events. The pre-treatment nutritional parameters evaluated were hemoglobin (Hb), serum albumin (Alb), total protein (Prot), total lymphocyte counts (TLC) and Prognostic Nutritional Index (PNI).

Results

Of 38 patients diagnosed of cervical cancer, 25 were treated by chemo-radiation for LACC and 24 patients were included in the pre-therapeutic nutritional analysis. Approximately 20% of the patients were manourished before treatment. A total of 6 patients (24%) presented severe adverse events according to EORTC definition. The pre-treatment nutritional parameters were not found to be significant predicotrs of chemo-radiation severe adverse events.

Conclusion

Although nutritional status could be considered a useful predictor for cervical cancer survival; our results suggest that nutritional status not predict severe adverse events in patients underwent chemo-radiation. However more studies are needed to confirm that preliminar results.

THE ADDITIONAL ROLE OF DIFFUSION WEIGHTED MAGNETIC RESONANCE IMAGING FOR THE ASSESSMENT OF PARAMETRIAL INVASION OF CERVICAL CARCINOMA, A PROSPECTIVE STUDY

J. Mongula¹, F. Bakers², C. Mih³, T. van Gorp¹, R. Kruitwagen¹, B. Slangen¹
¹Maastricht University Medical Centre, Gynecologic Oncology, Maastricht, The Netherlands
²Maastricht University Medical Centre, Radiology, Maastricht, The Netherlands

Aims

The treatment of cervical cancer is dependent on FIGO stage, with conventional staging, 15-25% of parametrial invasion is missed. MRI is increasingly used to optimize staging for cervical cancer. This study aimed to evaluate the diagnostic performance of diffusion weighted MRI in addition to conventional T2 weighted sequences and fusion images for the assessment of parametral invasion.

Method

Prospective cohort study; conventional T2W MRI, the addition of high B-value diffusion weighted MRI sequences and fusion images (T2W with diffusion weighted MRI) for assessing parametrial invasion. Two blinded radiologists independently scored the likelihood of parametrial invasion with a 6-point confidence scale. The reference standard consisted of surgical-pathologic results after radical hysterectomy with pelvine lymphadenectomy. Diagnostic performance was evaluated by ROC curve analyses. P-values <0.05 were considered statistical significant. Ethical board approval was obtained.

Results

The cohort consisted of 65 patients, 8 patients showed parametrial invasion after surgery. Both observers (1-2) showed a statistical increase in diagnostic performance for the assessment of parametrial invasion, especially decreasing false positive findings. The corresponding areas under the ROC curve were .80-.67 for T2W MRI compared to .94-.94 for fusion imaging (p<0.05). Positive predictive value increased significantly 29-23% versus 50-50%. No significant difference was found between T2W imaging and T2W imaging with high B-value sequences without fusion images.

Conclusion

This is the first prospective study showing conventional T2 weighted MRI combined with diffusion weighted MRI to result in an increase in diagnostic performance for the assessment of parametrial invasion in suspected early-stage cervical carcinoma.

DIFFUSION WEIGHTED MAGNETIC RESONANCE IMAGING OF CERVICAL CARCINOMA: APPARENT DIFFUSION COEFFICIENT MEASUREMENT TECHNIQUES RELATED TO PARAMETRIAL INVOLVEMENT AND LYMPH NODE METASTASES

J. Mongula¹, C. Mihl², F. Bakers², T. van Gorp¹, R. Kruitwagen¹, B. Slangen¹
¹Maastricht University Medical Centre, Gynecologic Oncology, Maastricht, The Netherlands
²Maastricht University Medical Centre, Radiology, Maastricht, The Netherlands

Aims

Staging of cervical cancer is dependent on FIGO stage, advanced imaging as diffusion weighted MRI is increasingly used to optimize staging for cervical cancer. Apparent Diffusion Coefficient (ADC) is a potential interesting quantitative parameter for assessing tumor aggressiveness. This study aimed to compare different ADC measurement techniques for cervical cancer and to assess mean ADC as a predictor for parametrial involvement and lymph node metastases.

Method

This was an ethical board approved prospective cohort study. Two blinded readers independently scored ADC\textsubscript{mean} within the range of interest (ROI). The ROI was defined as total tumor ADC, single slice freehand ROI or a single round like ROI at the largest tumor diameter. The reference standard consisted of surgical-pathologic results after radical hysterectomy with pelvic lymphadenectomy. Diagnostic performance was evaluated by ROC curve and regression analysis. P-values <0.05 were considered statistical significant.

Results

The cohort consisted of 65 patients, 3 patients were excluded due to unavailability of ADC map. Interrater agreement (preliminary analyses) was excellent for assessing ADC\textsubscript{mean}. The predictive value did not significantly differ between the three used measurement techniques. The area under the curve for ADC\textsubscript{mean} for assessing parametrial invasion and lymph node metastases was good-excellent (AUC 0.76-0.84) In our preliminary uni- and multivariate analyses ADC\textsubscript{mean} was superb and independent compared to other predictive criteria (HR: 10.6 (1.2-92)).

Conclusion

The potential of ADC\textsubscript{mean} as an independent parameter for predicting parametrial invasion and lymph node metastases is suggested by our results. The definitive analyses will be available at the ESGO 2017 Meeting.

LOW VALUE OF PET/CT IN PREDICTING TUMOR RESPONSE IN LOCALLY ADVANCED CERVICAL CANCER UNDERGOING NEOADJUVANT CHEMOTHERAPY

A. Ditto¹, C. Borghi², G. Bogani³, A. Alessi², F. Martinelli³, M. Signorelli², L. Montanelli², V. Chiappa¹, U. Leone Roberti Maggiore¹, D. Lorusso¹, F. Raspagliesi¹, C. Scaffa¹, D. Recalcati¹

¹IRCCS National Cancer Institute- Milan, Gynecologic Oncology, Milan, Italy
²University of Ferrara- Sant’Anna University Hospital- Ferrara, Department of Obstetrics and Gynecology, Ferrara, Italy
³IRCCS National Cancer Institute- Milan, Nuclear Medicine and PET Unit, Milan, Italy
⁴University of Milano-Bicocca- San Gerardo Hospital- Monza, Department of Obstetrics and Gynecology, Monza, Italy

Aims

To assess the ability of PET/CT in predicting tumor response to neoadjuvant chemotherapy (NACT) in patients affected by locally advanced cervical cancer (LACC)

Method

This is a prospective study involving LACC patients undergoing NACT plus radical surgery between 2013 and 2016. Data of SUV max detected by PET/CT, at pre- and post-NACT examinations were compared with pathological findings. Concordance was used to assess the ability of PET/CT to predict tumor response.

Results

Overall, 37 patients were included. There were very low concordances between pre- and post-NACT SUV max on cervical tumor with response to chemotherapy (concordance <0.2). Similarly, concordance between pre- and post-NACT SUV max on pelvic lymph nodes was low (concordance < 0.2). Considering the ability of PET/CT in assessing lymphatic disease, we observed that post-NACT PET/CT was characterized by a relative low positive predictive value (0.66) but a high negative predictive value (0.92). One (1/67 negative pelvic sides; 1.5%) false positive result was observed. Five false negative (5/7 positive pelvic sides; 71.4%) results were observed. True positive and true negative accounted for (2/7 positive pelvic side; 28.5%) and (66/67 negative pelvic sides; 98.5%)

Conclusion

SUV Max is not adequate in predicting tumor response of LACC patients undergoing NACT. A negative PET/CT is likely to correlate with negative nodes; however, the positive predictive value of PET/CT is not adequate. Further tools are needed to better predict response to treatment in LACC
HPV16 VARIANTS AND IGF1R OVEREXPRESSION INDUCES RESISTANCE TO RADIOTHERAPY IN UTERINE CERVICAL CANCER

P. Moreno-Acosta¹, M. Molano², O. Gamboa³, A. Huertas⁴, A. Vallard⁵, A. Romero-Rojas⁴, D. Mayorga⁶, M. Cotes⁷, C. Rancoule⁵, N. Magné⁵

¹National Cancer Institute, Research Group in Radiobiology Clinical- Molecular and Cellular- Research Group in Cancer Biology, Bogota, Colombia
²Microbiology and Infection Diseases- The Royal Women’s Hospital, Microbiology and Infection Diseases, Melbourne, Australia
³National Cancer Institute, Analysis Unit- Research Group in Radiobiology Clinical- Molecular and Cellular, Bogota, Colombia
⁴National Cancer Institute, Pathology, Bogota, Colombia
⁵Institut de Cancérologie de la Loire-Lucien Neuwirth, Department of Radiation Oncology, Saint-Priest en Jarez, France
⁶National Cancer Institute, Research Group in Radiobiology Clinical- Molecular and Cellular, Bogota, Colombia
⁷National Cancer Institute, Group of Radiotherapy and Medical Physical- Research Group in Radiobiology Clinical- Molecular and Cellular, Bogota, Colombia

Aims

Several causes of the variable radiotherapy (RT) efficacy have been studied without convincing results. HPV16 infection has been hypothesized to be a predictor of poor response to RT; Moreno-Acosta et al., 2012, found that the over-expression of IGF1R is a predictive marker for patients (HPV16 (+)) undergoing radiotherapy. The aim was to prospectively report the detection of HPV16 variants, gene expression IGF1R and assess the relationship with treatment response.

Method

Detection of HPV16 variants of 19 patients by PCR-SSCP and direct sequencing and analysis of IGF1R gene expression by real-time PCR. Of these patients, 15 underwent exclusive radiotherapy and four underwent radiochemotherapy.

Results

Three months after treatment completion, out of the 15 patients receiving exclusive RT, 8 experienced complete responses: 3 with the European T350 variant (E-T350 and IGF1R low expression, 2 with the European G350 variant (E-G350) and IGF1R negative expression), 2 with an undetermined European variant (E-Nd) and IGF1R negative expression), and 1 with an Asian-American variant (AAa) and IGF1R negative expression. The other 7 experienced no complete response: Three patients were diagnosed a partial response (2 E-T350, 1 E- G350, and IGF1R overexpression), 3 had a stable tumor (2 E-G350, 1 E-Nd and IGF1R overexpression) and 1 experienced tumor progression (AAa and IGF1R overexpression).

Conclusion

The presence of E-G350 and non-european (eg. AA) variants and overexpression of IGF1R in the no complete response group could be related with radioresistance. Larger prospective trials are needed to validate the presence of HPV-16 variants and IGF1R expression as a biomarkers of radioresistance.

WEST OF SCOTLAND OUTCOMES AND TOXICITY FOR CERVICAL CANCER, COMPARING CONFORMAL RADIOTHERAPY WITH VOLUMETRIC-MODULATED ARC THERAPY (VMAT)

A. Morton1, A. Kerr1, M. Alfayez2, K. Graham1, R. Harrand1, N.S. Reed1, A.H. Sadozye1
1Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom

Aims

Between 2011 and 2013 the standard radiotherapy given for definitive treatment of cervical cancer in the Beatson West of Scotland Cancer Centre changed from conformal fields at a dose of 45Gy in 25 fractions to VMAT 50Gy in 25 fractions. Our aim was to establish whether there is a difference in cancer related outcomes and severe toxicity between the two regimes.

Method

Information was collected on the treatment of patients January 2010- March 2011 for the group receiving 45Gy in 25 fractions and from June 2013-Dec 2014 for the 50Gy in 25 fraction group.

Demographic, treatment, toxicity and outcome data was obtained from Aria, PACS and Clinical Portal.

Results

73 patients were in the group receiving 45Gy and 95 patients were in the group receiving 50Gy.

At two years for patients receiving 45Gy survival data was available for 71 patients, 72% were alive at this stage. Out of 71 patients 15% suffered a grade 3/4 late toxicity of radiotherapy (Gastrointestinal, Urinary or Bone).

Of patients receiving 50Gy, survival data was available for 90 patients, 71% were alive at 2 years. 87 patients had follow up information and of these 18% suffered from grade 3/4 late toxicity of radiotherapy. Included in this 8% of patients actually suffered two toxicities.

Conclusion

Two year survival and proportion of patients suffering severe toxicity was similar between the two treatments. There appears to be an increase in patients suffering two grade 3/4 toxicities with 50Gy which will be analysed further.

ESGO7-0310

THE EFFECT OF PARA AORTIC LYMPH NODE DISSECTION IN STAGING AND COMPLETE CYTOREDUCTIVE SURGERY OF OVARIAN CANCER

M. Mottaghi
d, Z. yousefi
d
1ghaem hospital, Obstet & Gynecol, Mashhad, Iran

Aims

The aim of this study was to evaluate the effect of Para aortic lymph node dissection in ovarian cancer patients.

Method

This descriptive cross-sectional study was performed on 100 ovarian cancer patients who were admitted in the department of gynecology oncology of Ghaem Hospital, Mashhad University of Medical Sciences from November 2013 to November 2014. All patients underwent surgical staging surgery and optimal debulking surgery as much as possible. In addition, concurrent systematic pelvic and para-aortic lymphadenectomy up to the level of inferior mesenteric artery was performed.

Results

A total of 100 patients were studied. The mean age of patients was 47 years (SD=13). In 73 patients optimal cytoreductive surgery was performed with para aortic lymphadenectomy. Fifty-three cases (72.6%) underwent primary cytoreductive surgery and 20 cases (27.3%) had interval debulking surgery. Positive paraaortic lymph node was found in 6 cases (11.3) of first group and 2 cases (10%) of second group. Twenty-seven patients were apparently in stage I and 46 patients were in stages II, III and IV of disease. We found positive paraaortic lymph node in (11%) of patients. positive paraaortic lymph node without positive pelvic lymph node was observed in two patients.

Conclusion

Lymph node dissection will produce a significant benefit in accurate and complete surgical staging; it reduces disease residual and increases progression-free survival.

ROLE OF INTERNAL ILIAC LYMPH NODE DISSECTION IN RADICAL HYSTERECTOMY FOR CERVICAL CANCER: A RETROSPECTIVE STUDY

N. Hiroaki¹, Y. Furukawa¹, Y. Tachibana¹, M. Ueno¹, M. Muraoka¹, K. Takagi¹
¹Tokyo Women's Medical University - Medical Center East, Obstetrics and Gynecology, Tokyo, Japan

Aims

To investigate the role of internal iliac lymph node (IIN) dissection, which is occasionally neglected in radical hysterectomy, in uterine cervical cancer patients.

Method

We examined the clinical and pathological records of cervical cancer patients (FIGO stage IB1-IIB) with lymph node metastases, who underwent radical hysterectomy between October 2007 and December 2014 in our institute. The number and site of lymph node metastases as well as history and site of recurrence were investigated.

Results

Of the total 53 patients with radical hysterectomy, 20 showed lymph node metastases. Twelve patients with only one positive node showed no IIN metastases, whereas five out of eight patients with two or more positive nodes showed IIN metastases. Eighteen patients, including five with positive IIN, received platinum-based chemotherapy, and two were treated with radiotherapy as adjuvant therapy. Five patients, including three with positive IIN, experienced disease recurrence. Among these three patients, two with mucinous adenocarcinoma relapsed with dissemination into the peritoneum and pelvic cavity, and one with small cell carcinoma relapsed with pulmonary metastasis.

Conclusion

In conclusion, considering the high prevalence of IIN metastases in patients with multiple lymph node metastases, IIN dissection should be performed in radical hysterectomy. IIN metastasis may be one of the important factors for recurrence in cervical cancer. Further prospective studies are warranted.
PHASE II STUDY OF CARBOPLATIN PLUS DOSE DENSE PACLITAXEL BEFORE AND AFTER RADICAL HYSTERECTOMY FOR LOCALLY ADVANCED CERVICAL CANCER (SANKAI GYNECOLOGIC STUDY GROUP 016 STUDY).

S. Nagao¹, A. Kogiku¹, M. Nonaka², S. Yuko³, T. Oishi⁴, S. Yamaguchi⁵, K. Takehara³, M. Shimada⁴, J. Kigawa⁵
¹Hyogo Cancer Center, Gynecologic Oncology, Akashi-city, Japan

³Shikoku Cancer Center, Gynecologic Oncology, Matsuyama-city, Japan
⁴Tohoku University, Obstetrics and Gynecology, Sendai-city, Japan
⁵Matsue City Hospital, Hospital Director, Matsue-city, Japan

Aims

The primary objective of this study was to assess efficacy and safety of carboplatin plus dose dense paclitaxel (ddTC) before and after radical hysterectomy (RH) for locally advanced cervical cancer.

Method

Patients with FIGO stage IB2, IIA2, or IIB cervical cancer received 3 cycles of carboplatin at an area under the curve of 6 on day 1 and paclitaxel at 80mg/m² on day 1, 8, and 15 every 21 days followed by RH. Patients with high-risk factors including lymph vascular invasion, parametrial invasion, lymph node metastasis, or positive margin received additional 3 cycles of ddTC.

Results

Between September 2014 and July 2016, 50 women including 13 with FIGO stage Ib2, 5 with stage IIA2, and 32 with stage IIB were enrolled in this study. There were 37 squamous cell carcinoma, 10 adenocarcinoma, 2 adenosquamous carcinoma, and 1 large cell neuroendocrine carcinoma. Forty-three women (86%) completed planned 3 cycles of chemotherapy before RH. The overall response rate was 92% (18 CR, 28 PR, 3 SD, 1 PD). Forty-nine patients (98%) completed planned RH. Eleven patients (10 with SCC, 1 with large cell neuroendocrine carcinoma) achieved pathological CR. Grade 3/4 hematological toxicities included neutropenia (58%), thrombocytopenia (2%) and anemia (24%). One patient experienced neutropenic fever. Grade 3/4 non-hematological toxicities were observed in 4 patients (1, grade 3 nausea; 1, grade 3 carboplatin allergy; 1, grade 3 paclitaxel allergy; 1 grade 3 elevated liver enzyme).

Conclusion

DdTC before and after RH has good efficacy and acceptable toxicity in women with locally advanced cervical cancer.
Aims

The average life span of Japanese women is 86.99 years. It is necessary to provide appropriate medical care for the late-stage elderly. The aim of this study is identification of comorbidities and complications of the late-stage elderly patients with cervical cancer at our hospital.

Method

Medical records of patients treated from 2004 - 2015 at our hospital were reviewed. Nineteen patients aged 75 years or older undergoing primary treatments for cervical cancer were analyzed. We examined the comorbidities, treatment methods and complications.

Results

Age was 75–85 years (median, 79 years) and performance status (PS) was poor (median: PS1). No patients underwent surgery therapy because of comorbidities. Radiotherapy/concurrent chemoradiotherapy (RT/CCRT) was performed on 18 patients (94%) and chemotherapy alone was performed on 1 patient (2.7%). All patients except 1 patient with FIGO stage IVB were chosen RT/CCRT. The number of patients whose treatment changed into less invasive therapies was 14 (73%). Among the patients who received RT/CCRT, 2 patients had complication of renal dysfunction (11.1%). Radiation-induced fractures were found in 2 patients (11.1%) and cognitive dysfunction was found in 2 patients (11.1%). PS declined in 3 patients after treatment (15.8%).

Conclusion

This research indicates that the late-stage elderly patients tend to have more comorbidities and complications that may affect their ADL. Thus, minimal invasive treatment should be considered especially in the late elder patients.
HPV-NEGATIVE CARCINOMA OF THE UTERINE CERVIX: CLINICAL IMPLICATIONS

I. Nicolás1, L. Rodríguez-Carunchio2, A. Saco2, E. Barnadas2, N. Abu-Ligha1, P. Fusté1, J. Pahisa1, B. Gil-Ibáñez1, L. Marimon2, A. Glickmam1, A. Rodríguez1, J. Ordí2, A. Torné1, M. Del Pino1

1Hospital Clinic de Barcelona- IDIBAPS, Department of Gynecology, Oncology Unit, BARCELONA, Spain
2Hospital Clinic de Barcelona- IDIBAPS, Department of Pathology, BARCELONA, Spain

Aims

Almost all studies focus on cervical cancer (CC) found that a small proportion is negative for human papillomavirus (HPV). It has been suggested that HPV-negative CC may represent a biologically distinct subset of tumours carrying a poorer prognosis. However, the significance of HPV-negativity in CC remains unclear. We aimed to provide insight into the differential clinical-pathological characteristics of the unusual HPV-negative CCs.

Method

A cohort of 215 women with CC diagnosed in the Hospital Clinic (Barcelona) from 1999 to 2014 underwent HPV/DNA detection and genotyping using a highly sensitive polymerase chain reaction (PCR): SPF10PCR/DEIA/LiPA25 system and p16INK4a immunostaining. Clinical, histological and immunological characteristics of the cases included were recorded.

Results

21 out of 215 tumors (9.8%) were negative for HPV detection. Nine of them (9/21; 42.9%) showed a negative p16INK4a immunostaining result. These double negative tumors were considered as confirmed HPV-negative CC and all of them were diagnosed at advanced FIGO stage. Within the confirmed HPV-negative CC, 5 were squamouscarcinoma, 2 were adenocarcinoma and 2 were neuroendocrine. Patients with confirmed HPV-negativity had significantly worse disease free survival than women with HPV-positive tumours [47.46 months (95%CI: 8.7-86.22 months) vs. 130 months (95%CI: 116.66-143.33 months); p=0.01] and overall survival (OS) [72.1 months (95%CI 25.44-118.80 months) vs. 151.4 months (95%CI 139.70-163.05 months); p=0.056].

Conclusion

DNA-HPV negative result is an uncommon finding in women with CC, and in almost half of these cases p16INK4a immunostaining shows a positive result. Confirmed HPV-negative CC seems to be associated with advance FIGO stages and worse prognosis.

ESGO7-0292

HPV POSITIVE CARCINOMA OF THE UTERINE CERVIX. CLINICAL IMPLICATIONS AS A FUNCTION OF GENOTYPE
L. Nogué1, I. Nicolás1, A. Saco2, L. Rodríguez-Carunchio2, E. Barnadas2, N. Abu-Ligha1, P. Fusté1, J. Pahisa1, B. Gil-Ibáñez1, A. Glickmam1, A. Rodríguez1, L. Marimon2, J. Ordí2, A. Torné1, M. Del Pino1
1Hospital Clínic de Barcelona-IDIBAPS, Department of Gynecology. Oncology Unit, BARCELONA, Spain
2Hospital Clínic de Barcelona-IDIBAPS, Departament of Pathology, BARCELONA, Spain

Aims

It is hypothesized that human papillomavirus (HPV) genotype may have a role in prognosis of patients with uterine cervical cancer (CC). Results of previous studies on this topic are not conclusive. The aim of this study is to analyze whether there are clinical or prognostic differences in women diagnosed of CC depending on the HPV genotype.

Method

Women diagnosed of CC in the Hospital Clinic (Barcelona) from 1999 to 2014 underwent HPV/DNA detection and genotyping using a highly sensitive polymerase chain reaction (PCR): SPF10/DEIA/LiPA 25 system. Within the 215 women eligible, 194 had an HPV-positive CC and were finally included in the study. Clinicopathological features, disease-free survival (DFS) and overall survival (OS) were analyzed using SPSS version 23.

Results

Mean age at diagnosis was 50.52 years. Squamous cell carcinoma was the most frequent histological diagnosis (156/194;80.4%). Advanced FIGO stage was found in 110 (56.7%) cases. HPV-16 was the most frequent genotype (142/194;73.2%) followed by HPV-18 (25/194;12.9%). Multiple infection was observed in 30 women. From them, 12 showed co-infection with HPV-16/18. No differences were observed in terms of DFS and OS according to HPV genotype.

HPV: Human papillomavirus. HR: High risk. OS: Overall Survival. DFS: Disease free survival. CI: Confidence Interval.

Conclusion

HPV 16 was the most frequent genotype in our series. HPV genotype does not seem to have any impact on prognosis in women with CC.
INVESTIGATION THE FACTORS OF RADIO-RESISTANCE FOR CERVICAL CANCER

M. Nishimura1, A. Mineda1, T. Kawakita1, A. Abe1, M. Irahara1

1Tokushima University, Obstetrics and Gynecology, Tokushima, Japan

Aims

The purpose of this study is to investigating the factors of failure of local control of radiotherapy for cervical cancer

Method

122 cases who received radiotherapy and examined the effect of treatment during 2011-16. Concurrent chemoradiotherapy (CCRT) was done for patients under 80 years old. Weekly cisplatin (40mg/m2) was given before August 2014, and weekly paclitaxel (50mg/m2) and cisplatin (30mg/m2) was given for the patients with non-SCC after September 2014.

Results

Clinical stages are as follows, 1B 14, 2A 5, 2B 47, 3A 2, 3B 28, 4A 5, 4B 21. Histological subtypes are as follows, SCC 97, adeno and adenosquamous carcinoma (non-SCC) 19, others 6. Local recurrence rate are as follows 1B 1/14(7%), 2A 0/5(0%), 2B SCC 3/38 (8%), 2B non-SCC 4/6(50%), 3B SCC 3/21 (14%), 3B non-SCC 6/9 (67%). Local recurrence was significantly frequent in non-SCC than SCC of same stage (p<0.01). For the relation with tumor diameter, local recurrence was 5/78(6%) in SCC (<7cm), 6/18 (33%) in SCC (≥7cm), 0/1 in non-SCC (<4cm), 11/19 (58%) in non-SCC (≥4cm). For the relation with treatment period, local recurrence was occurred 11/32 in patients who took 50days or more for treatment, but 14/92 in patients with completed within 49 days (p<0.05). For the patients received weekly TP, tumor residue was seen in mucinous types of adenocarcinoma.

Conclusion

Improvement of treatment was necessary for large tumor patients (SCC with over 7cm and non-SCC with over 4cm). Management of adverse event is needed to complete the treatment within 49 days.

CERVICAL CANCER A CASE OF CAUTION: LYMPHOCELE FORMATION, COMPLICATED APPENDIX TRANSPOSITION BETWEEN EXTERNAL ILIAC VESSELS, AFTER LAPAROSCOPIC RADICAL HYSTERECTOMY

A. Ogurtsov¹, N. Vedeneeva¹, E. Arkanova¹, J. Kornyichuk¹
¹Yaroslavl Region Hospital, Gynecological, Yaroslavl, Russia

Aims

Pelvic lymphadenectomy in the treatment of cervical cancer has an effect of postoperative formation of lymphocele. We report a case of radical hysterectomy, complicated with right symptomatic lymphocele, involving appendix with its interposition between external iliac vessels.

Method

A 36 year-old woman with carcinoma of cervix (IB1 G2) underwent laparoscopic radical hysterectomy (type B). Postoperative period was complicated by a symptomatic right iliac lymphocele, confirmed by a US scan up to 8 cm in diameter. Laparoscopic exploration of the lesion was done on day 17 after primary surgery. It revealed massive pelvic adhesions, involving intestines and bladder. Adhesiolysis led to the opening of right pelvic lymphocele cavity and identification of appendix partially located between the right common iliac vessels. Appendix was released and returned into the abdominal cavity.

Results

Our finding increases awareness, that the extensive tissue dissection of parametrial spaces and along iliac vessels develops a longstanding aperture between skeletonizing trunks.

Conclusion

In theory, its availability may regard as a risk factor of intestinal strangulation or seriously complicated appendectomy perspective. In fact, it is hard to avoid. So, it is necessary to check for specific symptoms relating to it in postoperative period. We need in additional data and long-term follow-up to establish the correct management of this condition, especially in young patients without history of appendectomy.

CERVICAL CANCER: AN URGENT NEED TO SCALE UP SCREENING IN THE DEVELOPING WORLD

E. Ohazurike1, I. Anorlu1, K. Okunade1, A. Okunowo1, A. Sajo1
1Lagos University Teaching Hospital, Obstetric and Gynaecology, Lagos, Nigeria

Aims

The aim of the study was to look at the types of gynaecological malignancies, incidence of cervical cancer, and the histologic types of cervical cancer at the Lagos University Teaching Hospital, Lagos Nigeria.

Method

The records of the women who presented with gynaecological malignancies between January 2005 and December 2012 were retrieved. A structured form was used to extract information on socio-demographic characteristics, types of gynaecological malignancy and histologic types of cervical cancer.

Results

A total of 994 gynaecological cancer cases were seen at the Lagos University Teaching Hospital during the period. Cervical cancer was the most common 741 (74.6%) followed by ovarian cancer 127 (12.8%) and endometrial cancer 80 (8.1%). The mean age of the patients was 54.9 ± 13.1 years (range 25-80 years). 453(61%) were in the age group 30 and 59 years. Most common histologic type is squamous cell carcinoma 703 (94.8%) followed by adenocarcinoma 33 (4.5%) and adenosquamous 5(0.7%).

Conclusion

In the developed countries, the incidence of the adenocarcinoma of the cervix histotype has been increasing while the squamous cell type has been decreasing. This has been attributed to effective cervical cancer screening programmes.

The study has shown that cervical cancer affects women in their active productive years in Nigeria. The proportion of squamous cell was still very high- this is a reflection of lack of screening. This result underscores the need for urgent scale up of screening in the developing countries.

PET/CT AND SENTINEL LYMPH NODE BIOPSY COMBINED FOR THE SURGICAL STAGING OF CERVICAL CANCER
A. Papadia¹, M.L. Gasparri³, S. Genoud¹, B. Klaeser², M.D. Mueller¹
¹University Hospital of Bern and University of Bern- Bern- Switzerland, Department of Obstetrics and Gynecology, Bern, Switzerland
²Bern University Hospital and University of Bern- Bern- Switzerland, Department of Nuclear Medicine, Bern, Switzerland

Aims

Aim of the study was to evaluate the use of PET/CT and/or sentinel lymph node (SLN) mapping alone or in combination in cervical cancer patients.

Method

Data on stage IA1-IIA cervical cancer patients undergoing PET/CT and SLN mapping were retrospectively collected. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of PET/CT and SLN mapping, alone or in combination, in identifying cervical cancer patients with lymph node metastases were calculated.

Results

Sixty patients met the inclusion criteria. PET/CT showed a sensitivity of 68%, a specificity of 84%, a PPV of 61% and a NPV of 88% in detecting lymph nodal metastases. SLN mapping showed a sensitivity of 93%, a specificity of 100%, a PPV of 100% and a NPV of 97%. The combination of PET/CT and SLN mapping showed a sensitivity of 100%, a specificity of 86%, a PPV of 72% and a NPV of 100%. For patients with tumors of > 2cm in diameter, the PET/CT showed a sensitivity of 68%, a specificity of 72%, a PPV of 61% and a NPV of 86%. SLN mapping showed a sensitivity of 93%, a specificity of 100%, a PPV of 100% and a NPV of 95%. The combination of PET/CT and SLN mapping showed a sensitivity of 100%, a specificity of 76%, a PPV of 72% and a NPV of 100%.

Conclusion

PET/CT represents a “safety net” that helps the surgeon in identifying metastatic lymph nodes, especially in patients with larger tumors.

CLINICAL SIGNIFICANCE OF ATYPICAL GLANDULAR CELLS IN CERVICAL PAP SMEARS: AN ANALYSIS OF 329 CASES AT A SINGLE INSTITUTION

T.K. Jang¹, S.W. Lee¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹, J.Y. Park¹

¹Asan Medical center, University of Ulsan College of Medicine, Seoul, Korea, Department of Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

To determine the rate of clinically significant histopathologic lesions by analyzing patients identified as atypical glandular cells (AGC) in Papanicolaou (pap) test

Method

Data were collected from histopathologic results of women identified as AGC in the pap test from 1999 to 2008. There were 503 cases reported as AGC, 329 women with AGC who underwent histopathologic evaluation including colposcopy directed biopsy, loop electrical excision procedure, endocervical curettage and endometrial biopsy were analyzed to correlate with AGC on pap test.

Results

Among 329 women with AGC who underwent histologic follow up, clinically significant histologic results including pre-cancerous lesions and cancer lesions were diagnosed in 58 women with AGC (17.6%). Of the 58 patients, 23 (7%) were diagnosed with pre-cancerous lesions including cervical intraepithelial neoplasia (CIN) 2-3 and endometrial hyperplasia (EH), and 35 (10.6%) were diagnosed with cancer including cervical / endometrial carcinoma. Cervical carcinoma in situ (CIS)/invasive carcinoma and endometrial carcinoma were identified in 5.5%, 2.7%, and 2.1% of cases, respectively.

Conclusion

AGC results on pap test indicated clinically significant lesions in approximately 15% of our cases. These results support that women with AGC should require the need for histologic confirmation of the uterine cervix and endometrium including colposcopy directed biopsy, endocervical curettage and endometrial sampling.

COMPARISON OF MRI, PET-CT, AND FROZEN BIOPSY IN THE EVALUATION OF LYMPH NODE STATUS BEFORE FERTILITY-SPARING RADICAL TRACHELECTOMY IN EARLY STAGE CERVICAL CANCER

G.W. Lee¹, S.W. Lee¹, J.Y. Park¹, D.Y. Kim¹, D.S. Suh¹, J.H. Kim¹, Y.M. Kim¹, Y.T. Kim¹, J.H. Nam¹
¹as an medical center, obstetrics and gynecology, Seoul, Republic of Korea

Aims

To compare the accuracy of magnetic resonance imaging (MRI), positron emission tomography/computed tomography (PET/CT) and frozen biopsy before fertility-sparing radical trachelectomy in early stage cervical cancer.

Method

This was a retrospective study including 73 young women with early stage cervical cancer who tried fertility-sparing laparoscopic or robotic radical trachelectomy. All patients underwent preoperative MRI and PET-CT. Comprehensive lymph node dissection was performed during surgery, and all retrieved lymph nodes were sent to frozen biopsy before proceeding radical trachelectomy. The diagnostic accuracy of MRI, PET-CT, and frozen biopsy was compared using McNemar test and logistic regression using generalized estimating equation. The final pathologic report on lymph nodes was the gold standard for diagnosis.

Results

A total number of retrieved lymph nodes was 1448, and mean some retrieved lymph nodes was 20 (range 2-61). Sixteen lymph node areas were positive in 11 patients (15.1%). There was no significant difference in sensitivity (27.27% versus 54.55%, P=0.18), specificity (80.36% versus 76.79%, P=0.41), accuracy (71.64% versus 73.13%, p=0.76) of MRI versus PET-CT. There was significant difference in sensitivity (100% vs. 27.27%, P=0.005), specificity (100% vs. 80.36%, P=0.001), accuracy (100% vs. 71.64%, P<0.001) of frozen biopsy versus MRI. There was significant difference in sensitivity (100% vs. 54.55%, P=0.025), specificity (100% vs. 76.79%, P<0.001), accuracy (100% vs. 73.13%, P<0.001) of frozen biopsy versus PET-CT.

Conclusion

Frozen biopsy of all retrieved lymph nodes during surgery is still the best way to evaluate lymph node status before fertility-sparing radical trachelectomy.

THE STUDY OF ATYPICAL SQUAMOUS CELLS OF UNDETERMINED SIGNIFICANCE IN DETECTING PREINVASIVE CERVICAL LESIONS IN POSTMENOPAUSAL KOREAN WOMEN

S. Park¹, H.Y. Cho¹

¹Hallym University, Obstetrics and gynecology, Seoul, Republic of Korea

Aims

To evaluate the clinical significance of atypical squamous cells of undetermined significance (ASCUS) in PAP test in postmenopausal women and compare with reproductive age women.

Method

A total of 367 patients were included to the study between October 2014 and September 2015. Data for 164 post-menopausal (group 1) and 203 pre-menopausal (group 2) women with ASCUS cytology were evaluated retrospectively. Immediate colposcopy and endocervical curettage was performed for both groups and conization for all women with a result suggestive of CIN2-3. Histopathological results and demographic features of patients were compared between the two groups.

Results

Mean age of the patients was 54.6±6.5 years in group 1 and 38±6.6 years in group 2. Totals of 38 (23.2%) post-menopausal and 64 (31.5%) pre-menopausal women were assessed for HPV-DNA. High risk HPV was detected in 7 (4.3%) and 21 (10.3%), respectively (p=0.029). Final histopathological results recorded were normal cervix, low grade cervical intra-epithelial neoplasia (CIN 1), and high grade cervical intra-epithelial neoplasia (CIN2-3). In group 1 results were 84.8%, 12.2% and 1.8%, respectively, and in group 2 were 71.9%, 23.2% and 4.9%. There were no cases of micro invasive or invasive cervical carcinoma in either group. Two cases were detected as endometrial carcinoma in the menopausal group (1.2%).

Conclusion

In current study we found that preinvasive lesions were statistically significantly higher in pre-menopausal women than post-menopausal women with ASCUS. Therefore, we think that in case of ASCUS in a post-menopausal woman there is no need for radical management.

INDIVIDUALIZATION OF CHEMOTHERAPY BY 3-D HISTOCULTURE CHEMOSENSITIVITY ASSAY IN ADVANCED SQUAMOUS CELL CERVICAL CANCER PATIENTS

K. Hong Bae1, P. Young-Han2

1Hallym University Sacred Heart Hospital Kangnam, OBGY, Seoul, Republic of Korea
2Hallym University Sacred Heart Hospital, OBGY, Anyang, Republic of Korea

Aims

The purpose of this study is to investigate the effective chemotherapeutic agents with 3-dimensional histoculture chemosensitivity assay for cervical cancer patients.

Method

A retrospective study of 30 patients with squamous cell carcinoma of the uterine cervix between July 2003 and June 2007 was performed. Tumor specimens were taken by biopsy. The following drugs were tested with primary 3-dimensional histoculture culture of cervical cancer tissues; Vinblastin, VP16, 5-FU, Bleomycin, Cisplatin, Carboplatin, Mitomycin C, Gemcitabin, Docetaxel, Paclitaxel, CTX, Topotecan, Methotrexate, Doxorubicin, Ifosfamide and Mitomycin C.

Results

None of the patients had received any previous chemotherapy or radiation therapy before tissue sampling. 7 out of 15 patients (46.7%) showed sensitivity for Vinblastin, 4 out of 24 for VP16 (16.7%), 6 out of 26 for 5FU (23.1%), 12 out of 23 for Bleomycin (52.2%), 6 out of 15 for Cisplatin (40%), 11 out of 19 for Carboplatin (84.2%), 8 out of 27 for Gemcitabin (29.6%), 6 out of 17 for Docetaxel (35.3%), 6 out of 21 for Paclitaxel (28.6%), 6 out of 21 for CTX (28.6%), 13 out of 15 for Topotecan (86.7%), 4 out of 21 for Methotrexate (19.0%), 14 out of 26 for Doxorubicin (53.8%), 1 out of 8 for Ifosfamide (12.5%) and 2 out of 5 for Mitomycin C (40%). Carboplatin (49.5±17.8%) and topotecan (44.9±17.1%) showed significant higher mean inhibition rate (P=0.000 and 0.005, respectively).

Conclusion

Carboplatin and topotecan showed significant higher mean inhibition rates in in-vitro assay. VP16, methotrexate, and ifosfamide seem to be ineffective for cervical cancer.

THE EFFECTS OF GROUP COUNSELING ON KNOWLEDGE AND PERFORMANCE ABOUT CERVICAL CANCER SCREENING AMONG RURAL WOMEN IN IRAN

P. Parsa

Chronic Disease home care Research Center - Hamadan University of Medical Sciences, Mother and Child Health, Hamadan, Iran

Aims

Cervical cancer has high incidence and mortality rate but the screening program can detect it in early stages. Due to the high prevalence of this cancer counseling sessions to raise awareness and improve screening programs for cervical cancer is essential. This study aimed to determine the effect of group counseling on knowledge and practice regarding cervical cancer screening in rural women.

Method

In this quasi experimental study 80 married women under coverage of rural health centers in Iran. Women were selected randomly and allocated in two experimental and control groups (each group n = 40). Data collection tool was a questionnaire including demographic information, knowledge and women’s performance. First, both groups completed a questionnaire then, Intervention group participated in counseling held by three weekly sessions, using of GATHER steps. It involves consulting about cervical cancer, its symptoms and prevention of cervical cancer. Follow-up study assessed the effects of group counseling on the Pap-Smear performance of rural women for cervical cancer screening after two months.

Results

Before the intervention, the two groups showed no significant difference in terms of awareness (P=.292). After intervention, the difference of knowledge score between the two groups was significant (P < 0.001). Two months after intervention 17 women (42.5%) in the intervention group and 4 (10%) women in the control group (10%) underwent Pap smear test (P < 0.001).

Conclusion

Implementation of counseling programs can increase awareness and performance about cervical cancer in rural women.
CYCLES OF CISPLATIN AND ETOPOSIDE AFFECT TREATMENT OUTCOMES IN PATIENTS WITH EARLY-STAGE SMALL CELL NEUROENDOCRINE CARCINOMAS OF THE CERVIX

X. Pei

Fudan University Shanghai Cancer Center, Department of Gynecological Oncology, Shanghai, China

Aims

To explore the outcomes and prognostic factors in patients with FIGO stages I-II small cell neuroendocrine carcinoma of the cervix (SCNEC), and to determine the effects of adjuvant treatment on survival after radical surgery.

Method

A single-institution retrospective analysis was carried out in 92 patients receiving radical surgery for SCNEC. All clinico-pathological variables and treatment strategies were reviewed. Kaplan-Meier and Cox regression methods were used for survival analyses.

Results

After a median follow-up of 38 months (23.6-52.4), 43 (46.7%) patients experienced disease recurrence, of which, distant metastases was documented in 35 patients. The 5-year recurrence-free survival (RFS) was 45.2% and the median RFS was 39 months. In multivariate analysis, lymph node metastasis and parametrial extension were confirmed to be independent prognostic factors for disease recurrence. Adjuvant treatment containing etoposide plus platinum (EP) and its analogs for at least 5 cycles (n=39) was associated with improved 5-year RFS compared to other treatments (n=46) (Kaplan-Meier: 67.6% vs 20.9%, p<0.001; Cox regression HR: 3.68, 95% CI, 1.81-7.50, p<0.001) . Additional radiotherapy or concurrent chemoradiation failed to validate further improved RFS in patients with EP 5+. It was consistent in subset of patients with high-risk factors (positive lymph node or positive parametrium).

Conclusion

Half of the stages I-II SCNEC patients experienced disease failure within 3 years and distant metastases is an outstanding issue. EP combination therapy for at least 5 cycles is beneficial for long-term recurrence-free survival after radical surgery. Additional radiation therapy seems unnecessary even in patients with high risk factors.

OUTCOMES OF ROBOTIC RADICAL HYSTERECTOMY FOR CERVICAL CANCER IN COMPARISON TO OPEN AND LAPAROSCOPIC CASES; A POPULATION BASED STUDY IN THE UNITED STATES

S. Piedimonte1, N. Czujoh-Shulman2, W. Gotlieb3, H.A. Abenhaim1

1. Jewish General Hospital, Obstetrics and Gynecology, Montreal, Canada
2. Jewish General Hospital, Epidemiology and Biostatistics, Montreal, Canada
3. Jewish General Hospital, Gynecologic Oncology, Montreal, Canada

Aims

For early stage cervical cancer treated with radical hysterectomy, the robotic platform may improve visualization, ergonomics and finite dissections within the parametria. We report nationwide outcomes of robotic radical hysterectomy as compared to laparoscopic and open procedures.

Method

Using the National Inpatient Sample between 2008-2013, we performed a retrospective cohort study of all women with cervical cancer undergoing radical hysterectomy. We compared baseline characteristics, length of stay, intraoperative, postoperative and mortality outcomes between robotic, laparoscopic and open procedures. We used t-test for continuous variables, chi-square for categorical and confidence intervals using SAS.

Results

Among 33,213 women with cervical cancer, 2999 underwent radical hysterectomy; 18.2% robotic, 6.8% laparoscopic and 74.9% open. Over time, there was a significant decline in open procedures with an increase in robotic surgeries and stable trend in laparoscopic cases. There were no differences in baseline characteristics (age, BMI, race, smoking status and comorbidities) between robotic and open cases. There was no difference in intra-operative complications. There were less cumulative post-operative complications (6.95% vs 16.4%, p<0.01), in particular less wound infections (0.37% vs 1.91%, p=0.019) and ileus (2.74 vs 9.21, p<0.01). The length of stay was significantly reduced in the robotic group (mean 1.95 days vs 4.33 open, p<0.01). There were no deaths in either group. The cost was $53,928.47 for robotic, compared to $45,620.89 for open (AI 7,983.52, p<0.01).

Conclusion

Robotic radical hysterectomy is increasingly being adopted by experienced gynecologic oncologists and leads to diminished length of stay and less post-operative morbidity at the expense of increased cost.
THE VALUE OF PRETREATMENT SERUM PSEUDOCHOLINESTERASE LEVEL AS NOVEL PROGNOSTIC BIOMARKER IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER

N. Poetsch¹, A. Sturdza², S. Aust¹, S. Polteraüer¹, C. Grimm¹, R. Schwameis¹, H. Koelbl¹, A. Reinthaller¹, V. Seebacher¹
¹Medical University of Vienna, Department of Gynaecology and Gynaecologic Oncology - Comprehensive Cancer Center – Gynaecologic Cancer Unit, Vienna, Austria
²Medical University of Vienna, Department of Radiotherapy - Comprehensive Cancer Center – Gynaecologic Cancer Unit, Vienna, Austria

Aims

Deficiency in pseudocholinesterase (PChE), a condition commonly noticed in liver damage, inflammation, and malnutrition, has previously been associated with impaired prognosis in different malignancies, such as oral and upper tract urothelial cancer. The aim of the present study was to investigate the value of pretreatment serum PChE levels as prognostic biomarker in patients with locally advanced cervical cancer (LACC).

Method

Data of a consecutive series of patients with LACC treated with primary (chemo-)radiotherapy between 1998 and 2015 were retrospectively analyzed. Pre-treatment serum PChE levels were correlated with clinico-pathological parameters and response to treatment. Uni- and multivariate survival analyses were performed to assess the association between decreased serum PChE levels and progression-free (PFS), cancer-specific (CSS), and overall survival (OS).

Results

A total of 365 patients could be included into the present analysis. The median (IQR) pretreatment serum PChE level was 6180 (4990 – 7710) IU/l. Median pretreatment serum PChE levels were significantly decreased in patients with lower body mass index, advanced FIGO tumor stage, and disease progression under (chemo-) radiotherapy ($p<0.001$, $p=0.004$, $p=0.004$, respectively). In uni- and multivariate analyses decreased pretreatment serum PChE levels were independently associated with shorter PFS (HR 1.7 [1.2 -2.5]; $p= 0.006$), CSS (HR 2.0 [1.3 – 3.2], $p = 0.002$), and OS (HR 1.8 [1.3 -2.7]; $p= 0.001$).

Conclusion

Decreased pretreatment serum PChE level is associated with advanced tumor stage and impaired response to treatment, and serves as independent prognostic biomarker for shorter PFS, CSS and OS in patients with LACC.

QUALITATIVE ASSESSMENT VS. STANDARDIZED UPTAKE VALUE MEASUREMENT OF FDG-UPTAKE IN ADVANCED CERVICAL CANCER PATIENTS FOR PREDICTION OF RECURRENT DISEASE AND OVERALL SURVIVAL

O. Raban1, A. Hochberg1, G. Sabah1, H. Bernstine2, R. Eitan1

1Rabin Medical Center- Sackler Faculty of Medicine- Tel Aviv University, Gynecologic Oncology Division, Petah Tikva, Israel
2Rabin Medical Center- Sackler Faculty of Medicine- Tel Aviv University, Department of Nuclear Medicine, Petah Tikva, Israel

Aims

To determine whether qualitative evaluation of FDG uptake measured by standardized uptake value (SUV) was as good as quantitative assessment of tumor metabolic activity for prediction of treatment response, disease recurrence and overall survival.

Method

A retrospective cohort study including cervical cancer patients treated with chemoradiation between 05/2007-01/2016, who underwent a pretreatment PET/CT scan. PET/CT scans were re-evaluated by a nuclear medicine specialist for tumor size, lymph-node involvement, distant metastasis and metabolic activity features including SUVmax and a qualitative FDG-uptake score. An adjusted ratio compared to liver FDG-uptake was calculated for SUVmax.

Results

Fifty patients with cervical cancer staged 1B2 to IV with a pretreatment PET/CT scan, were detected. Qualitative FDG-uptake score was high in 40 scans and low in 10, and showed positive correlation with SUVmax of the cervical tumor. Qualitative assessment was not significantly associated with primary treatment response or PFS. Conversely, a higher SUVmax was associated with a lower response rate to primary treatment (p=.046) and a lower 2-year survival (p=.031). In addition, higher SUVmax was significantly associated with lower OS (p=.0285). In ROC analysis, a cutoff SUVmax of 16.3 had a sensitivity of 84% and specificity of 60% for prediction of 2-year post-treatment survival with a NPV of 83.3%.

Conclusion

In this preliminary study, whilst quantitative measurement of SUVmax was significantly associated with response to treatment and survival, using a qualitative score for tumor metabolic activity failed to demonstrate similar results. These findings suggest that quantitative measurement of SUVmax is superior to qualitative assessment in advanced cervical disease.
CERVICAL CANCER

ESGO7-0236

QUALITATIVE ASSESSMENT VS. SUV MEASUREMENT OF FDG-UPTAKE IN SURGICALLY TREATED CERVICAL CANCER PATIENTS FOR PREDICTION OF PROGNOSTIC FACTORS

O. Raban¹, L. Salman¹, G. Sabah¹, H. Bernstine², R. Eitan¹
¹Rabin Medical Center- Sackler Faculty of Medicine- Tel Aviv University, Gynecologic Oncology Division, Petah Tikva, Israel
²Rabin Medical Center- Sackler Faculty of Medicine- Tel Aviv University, Department of Nuclear Medicine, Petah Tikva, Israel

Aims

To determine whether the clinical implication of using a qualitative evaluation of FDG uptake is as good as quantitative assessment of tumor metabolic activity for the prediction of prognostic features.

Method

A retrospective study including cervical cancer patients, who were treated, between 03/2007 and 01/2015, with primary surgery and underwent a pretreatment PET/CT scan at the Rabin Medical Center. Patients' files were reviewed for clinic-pathologic data. All PET/CT scan were re-evaluated by a nuclear medicine specialist for tumor size, lymph-nodes involvement and metabolic activity features including maximal standardized uptake value (SUV), SUVmean and a qualitative FDG-uptake score.

Results

Twenty six patients with cervical cancer staged 1B1 to 2A, who had a pre-surgery PET/CT scan, were detected. Qualitative FDG-uptake score was classified as high in 16 of scans and Low in 10, and showed positive correlation with SUVmax of the cervical tumor. High Qualitative FDG-Uptake was not associated with prognostic features including histology, LVSI, deep tumor penetration, parametrial involvement, surgical margins involvement and positive Lymph-Nodes. However, no significant correlation was found between SUVmax to prognostic features either.

Conclusion

In this preliminary study, the clinical implication of using qualitative score for tumor metabolic activity did not differ from using quantitative score and both were not associated with prognostic features.

TOPOGRAPHIC DIFFERENCES OF THE AUTONOMIC NERVES IN THE POSTERIOR LEAF OF VESIOCUTERINE LIGAMENT

P. Radović1, A. Ćetković1, S. Nikolić1, V. Galogaža1

1Institute for Oncology and Radiology of Serbia, Clinic for Surgical Oncology, Belgrade, Serbia

Aims

The posterior leaf of the vesicouterine ligament (PLVUL) contains autonomic nerve fibers which innervate the bladder. Fujii was described surgical anatomy of PLVUL and emphasized importance of preserving the bladder branch of the inferior hypogastric plexus (IHP) for saving bladder function after radical hysterectomy (RH). In our population, we noticed that the bladder branch of IHP could be divided in two or three branches which also pass through PLVUL. There is one main branch located dorsomedially from the inferior vesical vein (IVV) and one or two small additional branches positioned lateral of the IVV.

Method

In this study, we evaluate the operative findings at 98 cervical cancer patients surgically treated in Institute of Oncology and Radiology of Serbia, from January 2013 till December 2015 using Fujii-Okabayashi technique of nerve-sparing RH. The surgery was performing without magnifying glass and implies complete bilateral dissection and selective resection of PLVUL. In all patents the main bladder branch of IHP was successfully preserved bilaterally.

Results

In the lateral part of PLVUL, before separation of the IVV we noticed at least one small additional nerve branch at 61 patents (62.2%), what was also confirmed on the other side at 52 patents (53.1%). In 15 patents (15.3%) we recognized two additional nerve branches what could be seen bilaterally in 6 of them (6.1%).

Conclusion

Anatomical variation according the number of nerve branches in PLVUL may exist in significant number of patients. Resection of small nerve branches and sparing the main one is the safe method of preserving bladder function.

IS SIMPLE TRACHELECTOMY WITH PELVIC LYMPHADENECTOMY A VIABLE TREATMENT OPTION IN PREGNANT PATIENTS WITH STAGE IB1 (>=2CM) CERVICAL CANCER: BRIDGING THE GAP TO FETAL VIABILITY

G. Salvo1, M. Frumovitz2, A. Jhingran2, M. Bevers1, P. Ramirez1
1The University of Texas- MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston- TX, USA
2The University of Texas- MD Anderson Cancer Center, Department of Radiation Oncology, Houston- TX, USA

Aims

Cervical cancer (CC) is the most common gynecologic cancer occurring in pregnancy. Standard recommendation for patients with early-stage disease is radical hysterectomy or radiotherapy, ultimately resulting in loss of pregnancy. The aim of this study is to describe our experience with simple trachelectomy and pelvic lymphadenectomy in patients with stage IB1 (>=2cm) CC who wished to maintain their pregnancy

Method

We included patients with stage IB1 (>=2cm) CC who underwent simple trachelectomy and minimally invasive pelvic lymphadenectomy during pregnancy from January, 2004 to June 2016. Data analysis included demographics, perioperative, obstetrics and oncologic outcomes

Results

Five patients were included. Median age was 30 years (range; 26-38). Median gestational age at diagnosis was 12 weeks (range; 7-18) and at treatment 16.5 weeks (range; 12-19). Histologic subtypes included: adenocarcinoma (3 patients) and squamous cell carcinoma (2 patients). Median tumor size was 27 mm (range; 20-40) and DOI 10 mm (range; 1.5-12). Patients underwent minimally invasive pelvic lymphadenectomy and vaginal simple trachelectomy. Median operative time was 234 minutes (range; 155-360), EBL 100 ml (range; 50-550) and LOS 2 days (range; 1-3). There were no intra or postoperative complications. Median number of lymph nodes removed was 14 (range; 5-15). One patient had positive nodes. Median GA at delivery was 38 weeks (range; 28-40.6). After delivery only one patient had no definitive treatment. After a median follow up of 75 months (range; 8-146), all patients are alive without disease

Conclusion

Simple trachelectomy with pelvic lymphadenectomy may be a safe option for treatment in pregnant patients with early-stage CC
ADJUVANT RADIOTHERAPY TREATMENT IN EARLY CERVICAL CANCER TREATED WITH RADICAL HYS TRECTOMY AND PELVIC LYMPHADENECTOMY

O.F.N. Rangel¹, L.C. Zeferino², D. DO VALE¹, H.D.C. Machado³, J.H.T. Freganani⁴, J.Y. Yoneda¹, J.F. Bragança²

² Department of Obstetrics and Gynecology, Campinas, Brazil
³ University of Campinas - School of Medical Sciences, Obstetrics and Gynecology Department, Campinas, Brazil
⁴ Barretos Cancer Hospital, Gynecologic Oncology Division, Barretos, Brazil

Aims

Evaluate disease-free survival (DFS) and recurrence rates in women with early cervical cancer who undergone radical hysterectomy and pelvic lymphadenectomy, treated or not with adjuvant radiotherapy.

Method

Between 1988 and 2014, 516 women with clinical stage IB cervical cancer underwent oncological treatment in two large Brazilian cancer centers.

Results

The mean age was 43 years and the most common histological type was squamous cell carcinoma (71.7%). There were 73 relapses (14.6%) and 49 deaths (9.4%). Lymph node metastases were associated with a higher rate of recurrence even in the group of patients who received radiotherapy (P <0.001), parametrial and surgical margins involvement were not, (P = 0.141 and P = 0.173). Tumor diameter> 20mm, depth of invasion> 10mm and lymph vascular space invasion (LVSI) had lower rates of relapse in radiotherapy group (P = 0.481, P =0.422, P = 0.221). Among women who didn’t recived radiotherapy, LVSI alone, tumor size> 20mm alone, association between LVSI and depth of invasion> 10mm and association of three factors were associated with higher rates of relapse (P = 0.021, P = 0.043, P = 0.002, P = 0.001).

Conclusion

Positive lymph node is related to high recurrence rate and lower DFS even in women undergoing adequate radiotherapy treatment. Chemoradiotherapy as adjuvant therapy should be strongly considered in this group of patients. Intermediate risk factors, especially depth of invasion and LVSI were associated with 1.7-time higher risk of relapse and lower DFS. Patients with intermediate risk factors treated with adjuvant radiotherapy have similar recurrence rate as non-risk patients.

CLINIC PATHOLOGIC FACTORS ASSOCIATED WITH LOW-RISK EARLY-STAGE CERVICAL CANCER

O.F.R. Rangel1, L.C. Zeferino1, D. do Vale1, J.H.T. Fregnani2, J.Y. Yoneda1, J.F.B. Bastos1

1. Campinas, Brazil
2. Barretos Cancer Hospital, Gynecology Oncology Division, Barretos, Brazil

Aims

Evaluate oncological outcomes in a cohort of women with clinical stage IB cervical cancer with favorable pathological factors who undergone radical hysterectomy and pelvic lymphadenectomy, submitted or not to radiotherapy.

Method

Between 1980 and 2014, 516 women with clinical stage IB cervical cancer underwent radical hysterectomy and adjuvant radiotherapy in two large Brazilian cancer centers. Demographic data, pathological findings of surgical specimens and follow-up information were analyzed.

Results

Were identified 52 women with tumor diameter < 20 mm, absence of LVSI and depth of invasion < 10 mm. Ten patients were <35 years (19.2%) and 42 > 35 years (80.8%). The most common histological type was squamous cell carcinoma 38 (73%), 13 (25%) adenocarcinoma and one patient had adenosquamous carcinoma (2%). The mean of dissected lymph nodes was 20. Parametral involvement and lymph node metastases was not present in any patient and 3 patients had surgical margins involvement. Twelve patients received adjuvant radiotherapy treatment and two relapsed. No patient died at an average follow-up of 80 months.

Conclusion

The standard treatment for women with early-stage cervical cancer (IA2-IB1) remains radical hysterectomy with pelvic lymphadenectomy. In select patients interested in future fertility, the option of radical trachelectomy with pelvic lymphadenectomy is also considered a viable option. The possibility of less radical such as conization with pelvic lymphadenectomy may be appropriate not only for patients desiring to preserve fertility but also for patients with low-risk early-stage cervical cancer.

EVALUATION OF CONIZATION HIGH ASSOCIATED WITH FREE MARGINS FOR MICROINVASIVE CERVICAL CARCINOMA TREATMENT

A.H. Caio1, J.C. Teixeira1, L.D.A. Andrade2, O.F. Rangel1, M.S.C. Gurgel1, J.F.B. Bragança1

1. Campinas, Brazil
2. Department of Pathological Anatomy, Campinas, Brazil

Aims

The definitive diagnosis of micro invasion must be obtained by histopathological analysis of cervical conization specimens, either cold knife conization (CKC) or loop electrosurgical excision procedure (LEEP). The aim of this study is to evaluate the clinical and pathological factors related to free margins in women with cervical microinvasive carcinoma submitted a conization.

Method

603 patients diagnosed and treated for squamous cervix microinvasive carcinoma, FIGO stage IA1 and IA2 (MIC), from 1975 to 2013 were included. CKC was performed in 333 patients (55.2%) and 270 (44.8%) LEEP.

Results

The analysis of surgical resection margins showed 489 (81.1%) free ectocervical margins and 331 (54.8%) endocervical margins. Univariate analysis showed that conization height, age ≥40yr (OR=2.55, p<0.001), LEEP (OR=1.75, p<0.001) and micro invasion depth > 3mm (OR=3.74, p=0.006) were associated with conization margins involvement. Multivariate analysis showed: conization height, age ≥40yr (OR=3.47, p<0.001), LEEP (OR=1.99, p<0.001) and micro invasion depth > 3mm (OR=3.99, p=0.007), were independent risk factors for conization margins involvement. Higher proportion of positive conization margins was observed in women who underwent LEEP, when compared to CKC (p<0.001). Specimens from CKC were larger than in LEEP (p<0.001) for all patients.

Conclusion

Free conization margins was statistically associated with conization depth bigger than 18.9 mm in women < 40yr and 20.6mm in women ≥ 40 yr, (p<0.001). ROC curve for the prediction of free conization margins by conization height, was 0.664 (p<0.001). Conization height with best performance was 19.5mm.

³European Institute of Oncology, Division of Gynaecology, Milan, Italy
⁴Sapienza University of Rome, Department of Gynaecology, Rome, Italy
⁵University of Cagliari, Department of Gynecology, Cagliari, Italy

Aims

Cervical sarcomas are rare neoplasms, accounting for less than 1% of all cervical malignancies and characterized by an aggressive course despite complete excision. We report a case of a Malignant Peripheral Nerve Sheath Tumor (MPNST) arising as an endocervical polyp.

Method

a G4P2 45-yr-old Caucasian woman with a previous negative pap smear 2 years before diagnosis underwent a clinical examination for AUB that revealed a cervical tumor measuring 40 x 45 mm and a secondary detached polypoid mass free in the vagina, clinically staged FIGO IB1. We performed a hysterectomy with type B radicality and systematic pelvic bilateral lymphadenectomy and BSO, with free surgical margins.

Results

Microscopic examination of the surgical specimen revealed a mildly atypical spindled-cells proliferation, growing underneath the cervical mucosa. Neoplastic cells had scant, eosinophilic cytoplasm, elongated nuclei with inconspicuous nucleoli. Neoplastic cells displayed a “fibrosarcoma-like” parallel or “herringbone” pattern of high cellular fascicles. Mitotic activity was high, with up to 40 mitoses per 10 HPF. Immunohistochemically, the tumor had a focal immunoreactivity for S100. Interestingly, neoplastic cells showed a focal, strong positivity for CD34. Immunoreactivity for CD10, ER, SOX10, desmin, ALK, EMA, Bcl2, CD99 was negative. FISH analysis for t(X;18) turned out negative. The patient underwent follow up and she is currently NED after 14 months.

Conclusion

MPNSTs are highly aggressive sarcomas rarely involving uterine cervix, with an unfavourable clinical course. Main differential diagnosis to consider are spindle cell melanoma, leiomyosarcoma, endometrial stromal sarcoma, synovial sarcoma and other spindle cell neoplasms.

IS NODAL RECURRENCE INCREASED AFTER SENTINEL LYMPH NODE BIOPSY IN PATIENTS WITH EARLY-STAGE CERVICAL CANCER?

A. Rodríguez-Trujillo1, B. Gil-Ibañez1, S. Escura1, P. Fusté1, M. del Pino1, J. Pahisa1, M. Munmany1, I. Nicolás1, A. Glickman1, A. Torné1

1Hospital Cínic de Barcelona, Gynecology, Barcelona, Spain

Aims

To describe recurrences in women with early-stage cervical cancer with negative nodes who were primarily treated by radical surgery and pelvic bilateral lymphadenectomy (LDN) or only sentinel lymph node biopsy (SLNB).

Method

A total of 134 patients with FIGO stage IA1-IB1/IIA1 cervical cancer were treated in our hospital. Of them, 121 had negatives nodes (73 LDN and 45 SLNB). From February 2001 until May 2011 patients underwent SLNB followed by complete pelvic LDN as part of their primary treatment. Between 06/2011 and 10/2016, patients underwent only SLNB. The SLNB was achieved by laparoscopic approach after intracervical injection with radiocolloid and blue dye. Patients in whom sentinel lymph nodes were detected unilaterally or non-detected underwent a complete lymphadenectomy of the failed mapped side. SLN were evaluated by pathologic ultrastaging. Follow-up data were prospectively recorded. SPSS 20.0 was used for statistical analysis.

Results

No differences regarding age at diagnosis, size of the tumor (≤ 2cm vs. > 2cm), FIGO stage, histology type and type of surgery were seen between both groups. In both groups the pattern of recurrence and metastases was similar. Ten patients recurred, 3 patients in the SLNB group and 7 in the LDN group. After SLNB there were 1 nodal recurrence, 1 loco-regional recurrence and 1 distant metastasis. After LDN, 3 nodal recurrences, 3 loco-regional recurrences and 1 metastasis were diagnosed. These differences were not statistically significant.

Conclusion

The rate of nodal recurrence was not increased after SLNB in early-stage cervical cancer.

CERVICAL CANCER RELAPSE RATES IN PATIENTS WITH PARA-AORTIC NEGITIVE PET SCANS: A FIVE-YEAR ANALYSIS IN AN IRISH GYNAEONCLOGY CENTRE

A. Rowan¹, T. Walsh¹, R. McVey¹, W. Boyd¹, D. Brennan¹
¹UCD School of Medicine- Mater Misericordiae University Hospital, Dept of Gynaecological Oncology, Dublin, Ireland

Aims

To review the rates of cervical cancer relapse in our patients with no gross metastatic spread to the para-aortic nodes (PA nodes) at initial diagnosis as defined on positron emission tomography (PET).

Method

Data contained in our gynaeoncology cancer registry was combined with hospital records. All cervical cancers over a period August 2011-July 2016 were selected for analysis. Data was collected on patients staged ≥1B2 to 4A. Patients were excluded if no PET scan was performed and diagnosis of metastasis was based on PET report.

Results

Of 105 patients, 97 had a reported PET scan. Seventy-eight percent of cases were squamous pathology. At diagnosis, 71% (n=69/97) of patients were PA node-negative. Relapse rates were higher in PA node negative patients than PA node positive 20% (n=14/69) vrs 14% (n=4/28). Of PA node-negative patients, 41% (n=28/69) had pelvic nodes positive on PET scan at diagnosis, of these 39% (n=11/28) received para-aortic radiation, 25% of patients (n=7/28) relapsed, the majority 71% (n=5/7) failing systemically. Of those negative for pelvic and PA-node disease 17% (n=7/41) relapsed, 86% (n=6/7) systemically, none received extended field radiation.

Conclusion

Although PET imaging is the standard for assessment of gross metastatic disease, overall 20% of PA node-negative patients experienced a subsequent relapse. Outcome was worse in relapsed patients who had no pelvic or PA disease at diagnosis. This review shows the importance of micro-metastasis in cervical cancer not yet identifiable by PET imaging.

PRIMARY CERVICAL MELANOMA WITH VULVAR AND BRAIN METASTASIS: A CASE REPORT

A.K. RUBIN1, J. MARIANO1
1UNIVERSITY OF SANTO TOMAS HOSPITAL, DEPARTMENT OF OBSTETRICS AND GYNECOLOGY, MANILA, Philippines

Aims

Present a rare case of Primary cervical melanoma, discuss diagnostic approaches, management and to raise impact on awareness.

Method

This is a case report. A 61 y/o, female, nulligravid, presented with post-menopausal bleeding. Initially, a fractional curettage, with biopsy showed a malignant mixed mullerian tumor (MMMT) with heterologous component. Interval history showed persistence of symptoms and on examination, the cervix was converted to a 6 x 6 cm necrotic and friable, bluish black mass that extended to the middle third of the vagina with a 2 x 3 cm solid mass, which was 0.5 cm from the hymenal ring, right lateral vaginal area. Assessment was MMMT, Cervical carcinoma Stage IIIB.

Results

Cervical punch biopsy and vaginal mass biopsy showed Round cell malignancy with clear cell features and Squamous hyperplasia with chronic inflammation and hyperkeratosis, respectively. Proceeded with immunohistochemical stainings. Primary Cervical Melanoma Stage IIIB was made due positive Vimentin, S100 and Melan-A. Hence, Dacarbazine chemotherapy was advised. Cranial CT scan with contrast showed a complex low density cystic mass with irregular soft tissue attenuation. She underwent whole brain radiotherapy with a total of 3000 cGy which she tolerated well.
Conclusion

Primary cervical melanoma is a poorly understood disease and diagnosis often presents a challenge where results of histopathology may be confused with other etiologies; hence an expert pathologist is needed. Immunohistochemical stainings: S100, vimentin, Melanin A, MART1 and HMB45, are the key to the diagnosis to this rare entity. Therefore, prompt recognition is important to immediately establish a diagnosis and appropriate management planned.

IS THE ONCOLOGIC OUTCOMES OF CERVICAL CANCER PATIENTS WHO UNDERWENT SIMPLE HYSTERECTOMY WORSE THAN THOSE OF PATIENTS WHO DIAGNOSED AND SURGERY PROPERLY?

I. Ruengkhachorn1, N. Phithakwatchara2, K. Nawapun2, S. Hanamomroongruang3, B. Viriyapak1
1Faculty of Medicine Siriraj Hospital- Mahidol University, Division of Gynecologic Oncology- Department of Obstetrics & Gynecology, Bangkok, Thailand
2Faculty of Medicine Siriraj Hospital- Mahidol University, Division of Maternal-Fetal Medicine- Department of Obstetrics & Gynecology, Bangkok, Thailand
3Faculty of Medicine Siriraj Hospital- Mahidol University, Department of Pathology, Bangkok, Thailand

Aims

To evaluate clinical characteristics, causes, and survival outcomes of cervical cancer patients who underwent simple hysterectomy.

Method

Medical records of patients who underwent surgical treatment for presumed leiomyomas, from January 2006 to December 2014, were retrospectively reviewed. Clinical characteristics, subsequent treatment, and outcomes were analyzed by descriptive statistics. This study includes follow-up data through December 31, 2016.

Results

A total of 565 medical records of cervical cancer patients who underwent primary surgery. Of which 52 patients (9.2%) were inadvertent hysterectomy. Comparable with FIGO stage IA2, IB1, IB2 and IVB in 3, 44, 3, and 2 patients, respectively. Histopathology was classified as squamous cell carcinoma in 29 patients, adenocarcinoma in 21 patients, endometrioid carcinoma in 1 patient, and neuroendocrine types in 1 patient. Median age was 48.0 years (IQR 42.0-56.0 years). Causes of inadvertent hysterectomy were represent in Table 1. 9/52 patients were refused further treatment. Forty-three patients were prescribed the following treatment: radiation in 39 patients, surgery in 1 patient, and chemotherapy in 1 patient, and 2 patients were appropriate for long term surveillance. The median time before definite treatment was 1.6 months (IQR 0.5-9.2 months). 42/43 patients had complete response and one patient was disease progression. Two patients had recurrent disease and none patients died of their disease. The median overall survival (OS) was 58.5 months (IQR 7.2-114.4 months).

Conclusion

9.2% of cervical cancer patients were inadvertent hysterectomy. Treatment outcome was favorable with almost 4.6% of recurrence rate, and median OS was nearly 5 years.

EVALUATION OF THE EFFECT OF HUMAN PAPILLOMA VIRUS (HPV) POSITIVITY ON PATIENT ANXIETY
G. Sahin¹, T.T. Ilhan², S. Akar¹, A. Gül¹, Ç. Celik¹, O. SECİLMİS KERİMÖGLU¹
¹SELCUK UNIVERSITY, gynecologic oncology, KONYA, Turkey
²MERSİN RESEARCH AND TRAİNİNG HOSPİTAL, Gynecologic oncology, Mersin, Turkey

Aims

It is known the relationship between Human papilloma virus (HPV ) and cervical cancer. HPV screening is used for screening of cervical cancer and preinvasive lesions. The aim of this study was to evaluate the effect of HPV positivity on patient anxiety

Method

This study was carried out at the Selcuk University Medical Faculty, Gynecology and Obstetrics Department. 300 patients were included in this study. Patients divided into the two groups, 150 patients were HPV positive group and 150 patients were HPV negative group as a control group. The patients were filled with an immediate and continuous anxiety scale questionnaire (STAİ FORM-1 and STAİ FORM-2). The results were assessed statistically.

Results

The mean age of HPV positive group was 42.2 years and the HPV negative group was 45.3 years. 68 patients were HPV 16-18, 82 patients HPV others in the HPV positive group. The HPV positive group had higher anxiety level than the HPV negative group. There was statistically significant difference in the comparison of the immediate anxiety scale questionnaire (51.27± 5.4 and 45.31± 4.2, p< 0.05).

Conclusion

The immediate and continuous anxiety scale levels of patients with HPV screening positive were detected high compared to HPV negative patients. Patients should be informed before and after screening to reduce anxiety.

COMPARISON OF THE EFFECT OF HUMAN PAPILLOMA VIRUS (HPV) SCREENING ON PATIENT ANXIETY WITH CONVENTIONAL METHODS

T.T. Ilhan¹, G. Sahin², S. Akar², A. Gu³, C. Celik², M.G. UCAR²

¹Mersin Research and Training Hospital, gynecologic oncology, MERSIN, Turkey
²Selcuk University Medical Faculty, Gynecologic Oncology, KONYA, Turkey

Aims

After identification of the relationship between Human papilloma virus (HPV) and cervical cancer, screening and treatment methods for sexually transmitted disease have been identified. HPV screening is used for screening of cervical cancer and preinvasive lesions. The purpose of this study was to compare the effectiveness of this screening method on patient anxiety with the conventional methods.

Method

This study was carried out at the Selcuk University Medical Faculty and Mersin Research and Training Hospital. The HPV group consisted of 255 patients who were referred to the outpatient clinic for HPV screening test and the Smear group included 250 patients who were referred to the outpatient clinic as a result of Smear scan. A total of 505 patients were included in this study. Before treatment, the patients were filled with an immediate and continuous anxiety scale questionnaire. The results were evaluated statistically.

Results

The mean age of HPV group was 45.3 years and the smear group was 47 years. 75 patients were HPV 16-18, 180 patients others in the HPV group. 115 patients were ASCUS, 35 patients ASC-H, 75 patients were LGSIL, 25 patients were HGSIL in the smear group. The HPV group had significantly higher anxiety level (57.9±6.1 and 36.1±4.2, p< 0.001). There was no statistically significant difference in anxiety level among the HPV subgroups.

Conclusion

The anxiety levels of the patients with HPV results were higher than smear group. There was no difference in the subgroup comparisons made by the type of HPV-detected patients.

IMPORTANCE OF UTERINE CERVICAL CERCLAGE TO MAINTAIN A SUCCESSFUL PREGNANCY FOR PATIENTS WHO UNDERGO VAGINAL RADICAL TRACHELECTOMY.

T. Saito1, M. Kim1, S. Ishioka1, M. Matsuura1, M. Iwasaki1, S. Satohisa1, M. Teramoto1, N. Terada1, M. Tamate1

1Sapporo Medical University, Obstetrics and Gynecology, Sapporo, Japan

Aims

We have performed 36 vaginal radical trachelectomies (RTs) for patients with early invasive uterine cervical cancer and experienced 10 deliveries. Pregnancy after RT has far higher risks of prematurity and complications such as preterm premature rupture of the membrane (pPROM) and chorioamnionitis. We report the significance of transabdominal cerclage in the follow-up of pregnancy after vaginal RT.

Method

Our operative procedure is based on that of Dargent et al. We amputated the cervix approximately 10 mm below the isthmus. For the removal of the parametrium, we cut at the level of type II hysterectomy. A nylon suture is also placed around the residual cervix. Pregnancy courses after vaginal RT were studied in 9 patients (10 pregnancies) with respect to cervical length and several infectious signs.

Results

Obstetric prognosis after RT was improved with our follow-up modality. Four patients who were followed up with this modality were able to continue their pregnancies until late in the third trimester. However, it was not effective for four patients who showed cervical incompetence due to slack cerclage. They suffered from pPROM without any infectious signs and uterine contraction. Though we performed transabdominal uterine cervical cerclage for one patient in her 19th week of pregnancy, it was unsuccessful.

Conclusion

Cervical cerclage placed at the time of RT played an important role in preventing dilatation of the uterine cervix and the subsequent occurrence of pPROM. Transabdominal cervical cerclage should be performed earlier in pregnancy or before pregnancy in patients who have experienced problems with cervical cerclage.

TRANS PERITONEAL PARA-AORTIC LYMPHADENECTOMY IN LOCALLY ADVANCED CERVICAL CANCER

Y. Salhi1, C. Mimoun1, E. Marchand1, M. Mezzadri1, J. Sroussi1, M. Perrin1, H. Lorphelin1, J.L. Benifla1

1Hôpital Lariboisière, Gynecologie, Paris, France

Aims

The aim of this study was to evaluate feasibility and morbidity of transperitoneal para-aortic lymphadenectomy in locally advanced cervical cancer (LACC).

Method

A retrospective review, between March 2011 to September 2016, included all patients who underwent transperitoneal para-aortic lymphadenectomy for LACC in a University hospital (n=21). Transperitoneal pelvic lymphadenectomy were performed along for 19 patients. According to FIGO classification, there were 15 stage IIB, 3 stage IIA, 2 stage IB2 and 1 stage III B.

All patients benefited of PET Scan before surgery which were negative.

Results

The mean number of lymph nodes was 14.23 (6.22). The mean number of latero-aortic lymph nodes was 8.09 (6.09). The mean duration of surgery was 237.37 minutes (75.34). No transfusions were reported. No per-operatory or post-operatory complications were reported either (particularly lymphoceles).

Conclusion

Trans peritoneal para-aortic lymphadenectomy is safe and an efficient procedure for ganglionic staging.
SENTINEL NODE MAPPING WITH FLUORESCENCE INDOCYANINE GREEN IS PROMISING IN 94 PATIENTS WITH CERVICAL OR ENDOMETRIAL CARCINOMA

R. Salihi¹, E. Van Nieuwenhuysen¹, K. Leunen¹, N. Concin¹, I. Vergote¹
¹UZ Leuven, Leuven, Belgium

Aims

Retrospective study on sentinel lymph node (SLN) mapping with fluorescence indocyanine green (ICG) in early stage cervical (CC) and endometrial cancer (EC), using robot-assisted minimal invasive endoscopy.

Method

We included all patients who underwent SLN mapping by ICG and fluorescence imaging from 12/2014, to 03/2017. Ninety-four patients were analysed, 50 with EC (47pts FIGO-stage I and 3pts FIGO-stage II) and 44 with CC. Eighteen patients with EC and all patients but two with CC underwent a complete pelvic lymphadenectomy. In all cases, we injected 1mL of diluted ICG(2mg) into the 4 quadrants of the cervical stroma. In CC the injection was submucosal, in EC it was given 1cm deep in the cervical stroma. All SLNs were ultra-staged on final pathology.

Results

Twenty CC patients(45%) underwent neoadjuvant chemotherapy (NACT) (19 IB2-IIB and 1 Ib1). Excluding NACT CC patients (2 IA2(5%) and 22 lb1(50%)), 92% had bilateral mapping and 8% unilateral. NACT CC resulted in a worse SLN detection (bilateral:60%, unilateral:20%). Eight EC patients had a too deep (intraperitoneal) IGC-injection (N=6) or had fibrosis due to previous surgery(N=3). Excluding them, bilateral mapping was observed in 33(81%), unilateral in 4(10%) and no sentinel in 3 cases(7%). 12 positive sentinels were found (CC:9, EC:3). Only one patient, with a clinical stage II carcinosarcoma of the endometrium, had a false negative SN node. No recurrences in the pelvic lymph nodes were observed.

Conclusion

Fluorescence imaging with ICG using the robotic approach shows promising results in cervical and endometrial cancer. NACT seems to decrease the reliability of the technique.
Aims

This study investigated potential preoperative predictors of pelvic lymph node (PLN) and para-aortic lymph node (PaLN) involvement in cervical cancer (CC).

Method

The study retrospectively analyzed 238 patients diagnosed with early (stage IA1–IIA) CC who underwent retroperitoneal LN dissection between January 1992 and February 2015. Several risk factors that are believed to influence PLN and PaLN involvement in CC were analyzed: age > 50 years, lymphovascular space invasion (LVSI), tumor size ≥ 2 cm, hemoglobin < 12 g/dL, and non-squamous cell histologic type.

Results

LVSI (OR=11.3, 95% CI=5.2–24.3) and tumor size (OR=3.2, 95% CI=1.4–7.2) were independent predictors of PLN involvement. None of the factors predicted PaLN involvement in a regression analysis. However, all nine patients who had PaLN involvement also had PLN involvement.

Conclusion

LVSI and tumor size independently increase the risk of PLN involvement.

⁴Tepecik Education and Research Hospital, Gynecologic Oncology, İzmir, Turkey
⁵Muğla Sıtkı Koçman University- Education and Research Hospital, Gynecologic Oncology, Muğla, Turkey

Aims

We sought to identify risk factors and management options for uterine cervical cancer (UCC) patients with a vertebral metastasis (VM) treated over the course of 23 years.

Method

Among 844 UCC patients, 18 were diagnosed with a VM. Thirty-six control patients with UCC but without recurrence were matched to these 18 in terms of stage and histological tumor type using a dependent random sampling method. A logistic regression analysis was employed to identify factors prognostic of VM; the results are presented as odds ratios with 95% confidence intervals (CIs).

Results

The mean survival time after VM treatment commenced was 12.1 ± 2.7 months (95% CI=5.3–12.6 months) in patients who received chemotherapy (CT) and 15.0 ± 2.3 (95% CI=9.7–14.2) months in those treated via chemoradiotherapy (CRT) (P=0.566). In patients who underwent CT, the 1- and 2-year survival rates after recurrence were 19.2% and 0%, respectively. However, these figures were 50% and 8.3% in those treated via CRT. Both lymphovascular space invasion (LVSI) and mean corpuscular volume were risk factors for VM. Cox’s regression analysis showed that these prognostic factors had no effect on survival duration after recurrence.

Conclusion

We found that patients with LVSI were at high risk for isolated VM and that the survival times after CT and CRT were similar.

ESGO7-0367

DIAGNOSTIC VALUE OF PAP SMEAR AND COLPOSCOPY IN NON-BENIGN CERVICAL LESIONS

M. Sayyah-Melli¹, V. Rahmani²

¹Women’s Reproductive Health Research Center- Tabriz University of Medical Sciences, Ob & Gyn, Tabriz, Iran

Aims

Although cervical cancer is a very common and lethal condition, owing to longstanding premalignant lesions, preventing morbidity and mortality by screening measures is feasible. Pap smear, colposcopy and biopsy are main modalities in this regard, but there is still no consensus on the diagnostic utility of the first two methods. The aim of this study was to examine the diagnostic utility of Pap smear and colposcopy to cytology in evaluating non-benign cervical lesions.

Method

A cross sectional study was carried out between 2015 and 2016 in an out-patient setting at the Alzahra Teaching Hospital of the Tabriz University of Medical Sciences. In 315 participants with abnormal Pap test colposcopy and biopsy from the abnormal areas were carried out. Cervical biopsy was considered as a gold standard and the diagnostic value of Pap smear and colposcopy was individually compared by calculating sensitivity, specificity and likelihood ratio.

Results

The mean age of patients was 38.49±10.31 years. Non-benign cervical lesions were present in 31 cases (9.8%). Accordingly, the sensitivity, specificity, positive predictive value, negative predictive value and accuracy of Pap smear in revealing non-benign cervical lesions was 77.4%, 69.7%, 21.8%, 95.6% and 70.7%, and for colposcopy, was 90.3%, 90.9%, 51.9%, 98.9% and 90.8%, respectively.

Conclusion

According to our results, the colposcopy is a sensitive and specific method in differentiating benign from non-benign cervical lesions. The accuracy of Pap smear is intermediate, and the utility is limited and this method should not be considered as a principal factor in therapeutic decision making.

INDO CYANINE GREEN (ICG)-INDUCED ANAPHYLACTIC-SHOCK FOLLOWING INTRACERVICAL INJECTION FOR SENTINEL LYMPH NODE (SLN) MAPPING: A CASE REPORT

A. Sebastianelli1, N. Body1, J. Grégoire1, M.C. Renaud1, M. Plante1

1CHU de Québec- l'Hôtel-Dieu de Québec, Gynecologic Oncology, Quebec city, Canada

Aims

ICG is a novel dye used for sentinel node mapping in gynaecologic malignancies. The aim of this study is to report a case of a anaphylactic-shock following an ICG intracervical injection for cervical cancer in a patient without any prior known iodine allergy.

Method

We performed case description followed by a systematic litterature review.

Results

A 52-year-old woman with a stage IA2 squamous cell carcinoma of the cervix was scheduled for a simple hysterectomy with bilateral salpingo-oophorectomy and SLN. She had been exposed to intravenous iodine contrast for radiologic studies few weeks prior to surgery without any adverse reaction. Under general anesthesia, five minutes following the 3 mL intracervicial ICG injection, the patient presented a sudden and severe hypotension associated with a diffuse urticarial rash and desaturation. The shock was reversed with vasopressors, intravenous corticosteroids administration and antihistamine. Surgery was cancelled and the patient was sent to ICU for monitoring. The patient underwent extensive allergy testing for the usual allergens involved in the peri-operative setting. The only positive result on the Prick test was found for ICG. Recommandation was made not to use ICG again even if not considered iodine allergic. No anaphylactic reaction following intracervial ICG injection was found in the litterature.

Conclusion

ICG is considered a safe and efficient dye for SLN mapping. ICG-allergic reactions following IV administration have been reported. To our knowledge, this is the first case of ICG-induced anaphylactic-shock following intracervical injection in the absence of any prior known iodine allergy.

COMMON AORTIC AND OBTURATOR LYMPH NODE METASTASES MAY PREDICT PARAORTIC NODE INVOLVEMENT IN CERVICAL CARCINOMA

I. Selcuk1, E. Sari1, Z.F. Cuylan1, N. Cetinkaya1, T. Gungor1, M.M. Meydanli1
1Zekai Tahir Burak Women’s Health Education and Research Hospital, Gynaecologic Oncology, Ankara, Turkey

Aims

To evaluate the risk factors associated with paraaortic lymph node metastasis in cervical carcinoma patients.

Method

A total of 205 consecutive cervical carcinoma patients with a histopathologic diagnosis of squamous cell or adenocarcinoma were analysed retrospectively at Zekai Tahir Burak Women’s Health Education and Research Hospital. Type 3 hysterectomy and bilateral pelvic paraaortic lymphadenectomy was the standard surgical procedure. Pathologic characteristics that were revealed with final pathology reports were analysed within univariate and multivariate analysis.

Results

Median age of the patients was 52.5 and most of the patients were having a squamous cell carcinoma (n=161, 78.5%). Median tumor diameter, pelvic and paraaortic lymph node counts were 3.5cm, 39 and 14 respectively. Paraortic lymph node metastasis was detected in 15 (7.3%) patients. In univariate analysis paraaortic lymph node metastasis was significantly related with parametrial involvement, lymphovascular space invasion and pericervical, obturator, external iliac, presacral and common aortic lymph node involvement (p<0.05). However multivariate logistic regression analysis showed that common iliac (p=0.003 OR:1.61, 95% CI:2.59-10) and obturator (p=0.021 OR:1.51, 95% CI:1.49-14) lymph node metastases were the only significant parameters of paraaortic lymph node involvement.

Conclusion

Common iliac and obturator lymph nodes may be used for the prediction of paraaortic lymph node metastasis during surgery for cervical carcinoma.
CLINICAL SIGNIFICANCE OF HMGB1 EXPRESSION AND ITS ASSOCIATED MOLECULES IN CERVICAL CANCER

A. Sharma¹, R. Khan¹, M. Sharma²

¹All India Institute of Medical Sciences, Biochemistry, New Delhi, India
²Maulana Azad Medical College, Radiation Oncology, New Delhi, India

Aims

Cervical cancer (CaCx) is the fourth most common malignancy in women worldwide. Aberrant expression of high mobility group box 1 (HMGB1) is associated with tumor development, progression and poor prognosis. We have investigated the association between HMGB1 and its associated molecules (RAGE, p53 & p62) in CaCx. We have also evaluated the clinical significance of serum HMGB1 in CaCx diagnosis.

Method

Total of 50 subjects, where 20 patients of CaCx, 20 healthy women (controls) and 10 controls having gynecological disorder other than malignancy were recruited. Circulatory levels of HMGB1 were measured by ELISA. mRNA and protein levels of HMGB1 and its associated molecules were quantitated using Q-PCR and western blotting, respectively. HeLa cells were used as positive control for HMGB1. Data was statistically analyzed.

Results

Circulatory levels of HMGB1 were significantly higher in patients as compared to healthy controls. mRNA and protein expression of HMGB1 were significantly higher in patients than that in normal controls. The levels of RAGE, p53 and p62 were also significantly elevated than their expression in controls at mRNA as well as at protein levels.

Conclusion

HMGB1 and its associated molecules were found to be overexpressed in CaCx. Serum HMGB1 level could be a useful and specific marker for evaluating the disease and diagnosis. HMGB1/RAGE pathway might play a significant role in the pathogenesis of CaCx. Validation in larger patient cohort might exploit HMGB1 as a novel therapeutic target and diagnostic marker for CaCx in future.

ESGO7-1300

QUALITY OF LIFE AFTER ULTRA RADICAL CHEMO-SENSITIZED RADIATION TREATMENT OF LATE STAGE CANCER OF UTERINE CERVIX

M. Sharma¹, A. Sharma²

¹Maulana Azad Medical College, Radiation Oncology, New Delhi, India
²All India Institute of Medical Sciences, Biochemistry, New Delhi, India

Aims

Study of Long term survival outcomes of ultraradical treatment with NACT Chemo sensitized Tele-Brachytherapy, Adjuvant chemotherapy for beyond FIGO stage cancer cervix is presented.

Method

The higher cure rates and survival have been achieved however at the cost of long term side effects, because of its relation to the replacement of treatment zone by cheap fibrous tissue of the hollow that is created by massive tumour bulk that has been exterminated. Since all the cases studied after treatment was late stage bulky disease there could not be randomisation for less aggressively treated patients.

Results

The main issues faced by these patients were

1- Post-therapy obesity
2- Persistent GIT problems
3- Reduced urinary bladder capacity.
4- Weakness
5- Pelvic, arteriovenous, perineural fibrosis
6- Bone demineralisation
7- Hydrouretronephrosis , recto-sigmoid narrowing.
8- Vaginal Narrowing / shortening
9- Dyspareunia non-performing sexual life
10- Persistent low or borderline haemoglobin
11- Persistent pedal oedema
12- Occasional episodes of hematurea or bleeding per rectum.

Conclusion

In Indian scenario, the women were not indisposed and were continuously attending their house chores and responsibilities. A cautious follow up that was necessitated in these cases or the vice-versa that patients had been on frequent follow up to keep vigil and remedy on their symptoms and complaints. It was also observed that these patients had shown remarkable improvement in self rehabilitation and quality of life when they were kept on adjuvant Tibetan Medicine as advised from Institutions of HH Dalai Lama.

LAPAROSCOPIC VAGINAL ASSISTED RADICAL TRACHELECTOMY WITH PELVIC LYMPHADENECTOMY IN YOUNG WOMEN WITH INVASIVE UTERINE CERVIX CANCER

A. Shevchuk¹, E. Novikova¹, S. Anpilogov¹
¹P. Herzen Moscow Oncology Research Institute, Oncogynecology, Moscow, Russia

Aims

Nowadays radical trachelectomy (RT) as a fertility-sparing option for patients with invasive cervical cancer is applied in clinical practice in many medical centers worldwide. Vaginal and abdominal approaches are the most common. Vaginal surgery is not widely spread in oncogynecology in Russia and application of vaginal RT in clinical practice requires long training with limited radicality. Abdominal RT demonstrates acceptable oncologic results but poor fertility outcomes. As an alternative for these approaches laparoscopic vaginal assisted radical trachelectomy (LVART) has been implemented in our Institute.

Method

From 2014 29 LVARTs for IA2-IB1 cervical cancer have been performed. Pelvic lymphadenectomy, developing spaces, unroofing the ureters and parametrial resection were done laparoscopically. Colpotomy, resection of uterine cervix and uterovaginal anastomosis were performed through the vaginal route.

Results

Mean operative time was 214 min, with minimal blood loss and fast recovery. We didn’t observe any significant complications in this group of patients. In 4 (13.8%) patients fertility sparing procedure was abandoned due to positive lymph nodes or resection margins and radical hysterectomy was performed. At median follow up of 13 month 1 recurrence in residual cervix was observed. All other women have no evidence of disease, demonstrates normal menstrual pattern, 2 women had pregnancies and 1 live birth.

Conclusion

Laparoscopic technique provides adequate parametrial resection, vaginal assistance makes it easier to identify the correct level of cervix resection and to perform uterovaginal anastomosis. We expect that after longer period of follow-up combination of minimally invasive and vaginal surgery with their advantages will show acceptable oncologic and fertility outcomes.

IMPACT OF ADJUVANT HYSTERECTOMY ON PROGNOSIS IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER TREATED WITH DEFINITIVE CONCURRENT CHEMORADIOThERAPY: A META-ANALYSIS

S.H. Shim1, S.H. Chae1, J.W. Seo1, S.N. Kim1

1School of Medicine - University of Konkuk, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

We investigated the effect of adjuvant hysterectomy (AH) on prognosis in locally advanced cervical cancer (LACC) patients treated with concurrent chemoradiotherapy, through meta-analysis.

Method

EMBASE and MEDLINE databases and the Cochrane Library were searched for published studies comparing LACC patients who received AH after chemoradiotherapy with those who did not, through April 2016. Endpoints were mortality and recurrence rates. For pooled estimates of the effect of AH on mortality/recurrence, random- or fixed-effects meta-analytical models were used.

Results

Two randomized trials and six observational studies (AH following chemoradiotherapy, 630 patients; chemoradiotherapy, 585 patients) met our search criteria. Fixed-effects model-based meta-analysis indicated no significant difference in mortality between the groups [odds ratio (OR) = 1.01, 95% confidence interval (CI): 0.58-1.78, P = 0.97] with low cross-study heterogeneity (P = 0.73 and I² = 0). This pattern was observed in subgroup analysis for study design, radiation type, response after chemoradiotherapy, and hysterectomy type. The pooled OR for AH and recurrence was 0.59 (95% CI: 0.44-0.79, P < 0.05) with low cross-study heterogeneity (P = 0.289 and I² = 17.8), favoring the AH group. However, this pattern was not observed in the subgroup analysis for the randomized trials. There was no evidence of publication bias.

Conclusion

In this meta-analysis, AH following chemoradiotherapy did not improve survival in patients with LACC, although it seemed to reduce the risk of recurrence. Concerning the significant morbidity of AH after chemoradiotherapy, routine use of AH should be avoided.
PTEN DOWN REGULATION INDUCE APOPTOSIS AND CELL CYCLE ARREST BY AN ACTIVATION OF P53 IN UTERINE CERVICAL CANCER CELL.

J.W. Shin

Gachon University Gil Medical Center, Obstetrics and gynecology, Incheon, Republic of Korea

Aims

PTEN and p53 are known as tumor suppressor proteins that are frequently mutated or down regulated in various human cancers. Down regulation of PTEN, however, may induce anti proliferative effect via p53 activation.

The authors investigate the proliferation and apoptosis of cancer cells after down regulation of PTEN in cervical cancer cell.

Method

Cervical cancer cells, HeLa and CaSki, were cultured with 10% FBS in culture medium. Before starting each experiment, the cells were cultured for 48 hours as fasting state for cell cycle synchronization. The siRNA for PTEN and control were constructed and tranfected with Lipofectamine. The experiments were FACS for investigating cell cycles, Western blot for proteins analysis, and MTT assay for cell proliferation.

Results

Apoptosis cell portion was significantly increased (p<0.001) and S1 phase cell portion was significantly decreased in PTEN down regulated cells (p<0.001) on FACS analysis. Expression of p53, p27, p21, p-ERK, and cleaved Caspase 3 were increased and expression of cyclin A2 and cyclin D1 decreased in PTEN down regulated cells on western blots. Cell viability was significantly lower in PTEN down regulated cells than control (p=0.002) on MTT assay.

Conclusion

Down regulation of PTEN induce apoptosis and block G1/S shifting of cell cycle in cervical cancer cell and could be a new strategy for cervical cancer treatment.

RARELY CASE REPORT OF MINIMAL DEVIATION ADENOCARCINOMA
E. Shirali
1Tehran Medical University, Gynecology Oncology, Tehran, Iran

Aims

This case report present one of this patient with chief complaint of watery vaginal discharge.

Method

case report

Results

case report

Conclusion

One of the diagnostic challenging in gynecology is Minimal Deviation Adenocarcinoma (MDA) of the uterine cervix which is adenoma malignum. A rare variation of cervical adenocarcinoma with incidence rate between 1% and 3% with unrelated pathology to HPV (human papillomavirus). The origin of MDA is not clear but association between MDA and gastric metaplasia.

Minimal Deviation Adenocarcinoma is well-differentiated cell types and a subcategory of gastric-type mucinous carcinoma. As the tumor is presenting benign features, MRI and ultrasound mostly play less role in diagnosis.

A CASE REPORT OF PYODERMA GANGRENSUM AFTER GENITAL SURGERY

L. Shirinzadeh1, Z. Yousefi2

1 Ghaem Hospital, Obstet and Gynecol, Mashhad, Iran
2 Ghaem Hospital, Obstet and Gynecol, Mashhad, Iran

Aims

In this report, a case of PG after the vaginal surgery with history of ulcerative colitis is introduced.

Method

A 37-years old woman was admitted with history of 2 weeks subsequent genital surgery, with chief complaint of fever, painful tenderness ulcerative lesion and inflammatory papule represented on surgical site and surface of right thigh. She suffered of fever despite received one cycle of oral and of wide spectrum intravenous antibiotic. Blood cultures were negative and we observed negative wound culture. Treatment was administered as second intravenous antibiotic. In addition, topical wound debridement was performed. Despite the absence of improved treatment of the lesion, biopsy of the lesion was performed. The patient's medical history included associated ulcerative colitis from 18 years ago and she was under irregular orally receiving of Asacol. Histopathology features of biopsy specimen indicated prominent neutrophils mixed inflammation and lymphocytic vasculitis. Based on the histopathology and clinical findings, the diagnosis of Pyoderma gangrenosum was established. Intravenous corticosteroid was administered that led to response of skin of right thigh and surgical site inflammation. Now, after 3-months follow-up, the patient is still in good condition.

Results

none

Conclusion

Based on major variable clinical manifestations and no diagnostic serologic test of PG, diagnosis of this disease is difficult. Increased awareness about PG and exclusion of other etiologies such as inflammatory and immunologic disease will aid in prompt ion of pyoderma gangrenosum diagnosis and proper management of the disease.

PROGNOSTIC EVALUATION OF NERVE-SPARING RADIAL HYSTERECTOMY IN TREATING LOCALLY ADVANCED CERVICAL CANCER

T. Shu1, Y. Wang1, S. Liu1, D. Zhao1, P. Li1, B. Li1
1National Cancer Center/Cancer Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Gynecological Oncology, Beijing, China

Aims

The study aimed to evaluate clinical security and prognosis of nerve-sparing radical hysterectomy (NSRH) for locally advanced cervical cancer (LACC).

Method

A retrospective cohort analysis was conducted in National Cancer Center of China. Patients with LACC (stage in Ib2 or Ia2) were recruited from Jan.1, 2008 to Dec.31, 2014. Of all the patients, 69 cases underwent NSRH, while other 320 cases underwent conventional radical hysterectomy (RH). Clinical-pathological characteristics and operative parameters as well as bladder function were compared. After median 67 months' follow-up, PFS and OS were evaluated.

Results

Basic information on two groups were matched. Multivariate analysis showed that lymph-vascular space invasion (LVSI) (P<0.001) and SCC level at diagnosis (P<0.01) were independent prognostic factors of PFS. Moreover, LVSI (P<0.001), SCC level (P<0.05) and efficacy evaluation of neoadjuvant therapy (P<0.05) were independent prognostic factors of OS. Compared to RH, patients who underwent NSRH presented less blood loss (366ml vs. 457ml, P<0.05), shorter urethral catheterization time (11.0 days vs. 15.5 days, P<0.01) and lower proportion of bladder dysfunction (6.1% vs. 16.3%, P<0.05). For patients in need of adjuvant radiotherapy, there was no superiority to the recovery of bladder function 1 year after NSRH (P=0.311).

Conclusion

NSRH is safe and feasible for patients with LACC. More importantly, compared with RH, NSRH not only demonstrated similar prognosis, but also improve operation quality as well as bladder function for patients with LACC. However, there is limited benefit at the recovery of bladder function for patients who underwent NSRH followed by pelvic radiotherapy.
SURGICAL STAGING IN TREATMENT OF LOCALLY-ADVANCED CERVICAL CANCER

E. Bezhanova¹, A. Sidoruk¹,², A. Urmancheeva²,³, E. Ulrikh², I. Berlev¹,²

¹North-Western State Medical University named after I.I Mechnikov, Gynaecological Department, Saint-Petersburg, Russia
²Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia
³North-Western State Medical University named after I.I Mechnikov, Oncological Department, Saint-Petersburg, Russia

Aims

The aim of the study is to determine the facilities of laparoscopic surgical staging in treatment of patients with locally-advanced cervical cancer. The study assesses and compares clinical and surgical staging of patients with locally-advanced cervical cancer.

Method

55 women with hystopathologically confirmed clinical stage IB-IIB invasive cervical cancer underwent pretreatment laparoscopic staging, including detection of intraperitoneal spread of tumor and pelvic lymphadenectomy in the period 2012-2016 years in the N.N.Petrov Research Institute of oncology. The patients had no contraindications to the surgical procedure and had no evidence for distant metastases.

Results

The median age of patients was 45.9 (26-81) years old and BMI was 27.9 (16.9-46.8) kg/m². Most lessions were squamous (n=53; 94.9%); clinical stage was: IB2 - 9 (16.4%); IIA - 2 (3.6%); IIB - 44 (80%). Median operative time was 140.7 min with average of 13.7 lymph nodes removed. Median blood loss were 65.0 ml. There were no major intraoperative complications. The stage changes occurred in 27 (49.1%) cases: from IB2 to IIB in 6 (10.9%) and in 21 (38.2 %) cases from IIB to IIIB. For preoperative lymph node staging with MRI, sensitivity was 52%, and specificity — 50%. Of the 55 patients 43 received pelvic radiation; 3 — extended field radiation and 9 received radical hysterectomy.

Conclusion

Diagnostic laparoscopic staging of patients with locally-advanced cervical cancer offers valuable information for individualized treatment planning with minimal morbidity.
DOSE-DENSE NEOADJUVANT CHEMOTHERAPY IN COMBINED TREATMENT OF IN LOCALLY ADVANCED CERVICAL CANCER: EXPERIENCE AND PROSPECTS

N. Bondarev¹,², I. Berlev¹,³, N. Mikaya¹, O. Smirnova¹, E. Bezhanova³, A. Petrova⁴, A. Mishchenko⁴, K. Guseynov¹, A. Sidoruk¹,³, H. Mkrtchyan¹, E. Nekrasova¹, E. Ulrikh¹, A. Urmancheeva¹,⁵

⁴Petrov Research Institute of Oncology, Department of Radiologic Diagnostics, Saint-Petersburg, Russia
⁵North-Western State Medical University named after I.I Mechnikov, Oncological department, Saint-Petersburg, Russia

Aims

Assessment of efficacy and toxicity of dose-dense intravenous neoadjuvant cisplatin - doxorubicin chemotherapy (NACT) followed by radical surgery in patients affected by locally advanced cervical cancer.

Method

The efficacy and toxicity of 3 cycles of NACT cisplatin (75 mg / m2) and doxorubicin (35 mg / m2) on the first day of a 2-week cycle with the support of colony-stimulating factors were studied in 27 patients (mean age 48 years) treated in N.N.Petrov Research Institute of Oncology. An important criterion for inclusion was the absence of infiltration of the anterior parameters according to the gynecological examination and MRI data.

Results

An objective response to treatment was registered in 72.7% of cases. The progression of the disease was observed in one case (3.7%): increase of the cervical tumor (MRI), appearance of single ileal lymph node (CT of abdominal organs). The operability rate was 95.4%. The pathological response was 40.9%. Complete clinical regression of the tumor was confirmed by complete pathologic response (ypCR) in 9.1%.

Conclusion

The dose-dense intravenous neoadjuvant cisplatin-doxorubicin chemotherapy did not lead to a significant increase of the incidence of toxicity and surgical complications. The analysis of the direct results showed that NACT is a highly effective method in the treatment of locally advanced cervical cancer.
MINIMALLY INVASIVE SURGERY IN TREATMENT OF CERVICAL CANCER PATIENTS

I. Berlev1,2, E. Kozlova1, A. Sidoruk1,2, A. Urmancheeva1,3

1Petrov Research Institute of Oncology, Gynaecological Oncology Department, Saint-Petersburg, Russia
2North-Western State Medical University named after I.I. Mechnikov, Gynaecological department, Saint-Petersburg, Russia
3North-Western State Medical University named after I.I. Mechnikov, Oncological department, Saint-Petersburg, Russia

Aims

The purpose of this study was to assess the morbidity and disease free outcomes in patients with early-stage cervical cancer after treatment: nerve-sparing laparoscopic radical hysterectomy

Method

Data of 80 cervical cancer patients (stages IA1, IA2, IB1, IIA1, IIB) after laparoscopic nerve-sparing radical hysterectomy (LSNSRH) treated in “N.N.Petrov Research Institute of oncology” in the period of 2012-2016 years were analyzed.

Results

The average age of patients was 44.2 years (27-67). The average duration of the first 40 operations was 240 ± 0.75 min (200 to 250), as the surgery methodology improved - duration of operation decreased by 30 minutes and was 210±15 minutes. Self-urination in the majority (78/80) of the patients was achieved on the next day after the removal of the urinary catheter (4th day after surgery), improvement of bowel activity - on the 3rd day. In 16 of 80 patients (20.0%) asymptomatic pelvic lymphocele were found (size from 3 to 5 cm). In three cases postoperative complications were observed: ureterovaginal fistulas (8, 23, 25 days after surgery). Number of relapses during the follow-up period of 6-36 months was 4 (4/80 - 5.0%); in 3 patients with adenocarcinoma of the cervix (pT1b1N0M0 stage (2 patients), pT2aN0M0 (1 patient)) 6, 7 and 17 months after combined treatment. Local pelvic recurrence occurred in two patients, lung metastases – in one case (pT2aN0M0 stage).

Conclusion

Laparoscopic nerve-sparing radical hysterectomy in the cervical cancer patients is safe and efficient operation with low morbidity, fast postoperative recovery, early rehabilitation of patients.

ESGO7-1367

INTERVENTION Hysterectomy in the management of Invasive carcinoma of the cervix

A. Słabuszewska-Jóźwiak\textsuperscript{1}, G. Panek\textsuperscript{1}

\textsuperscript{1}Centre of Postgraduate Medical Education, Department of Obstetrics and Gynecology, Warsaw, Poland

Aims

The study presents the results of the observation of 52 women with stage IIA-IIB, IIIB invasive carcinoma of the cervix primary allocate radical radiation therapy in whom intervention hysterectomy (both simple and radical was performer at some point of the treatment process)

Method

Indication for surgical intervention were afford:

- current hemorrhage from the tumor
- intolerance of the radiation
- lack of the anatomical condition for intra cavitary radiation
- persistent tumor after completion of the radiation therapy

Results

Radical Wertheim’s hysterectomy was carried out in 24 patients and simple hysterectomy in 28 patients. All patients were sequential treated with postoperative brachytherapy. 37 patients completed pelvic external bean radiation. The follow up was at 3 year (3.7 year). The influence of the following prognostic factors for survival were calculated: nodal status, cervical measure, completion of radiation therapy. 46 % of patients were alive at 35 % at 5 years. The survival negatively influences by: positive for metastatic pelvic and persistent tumor cervix after completion of the radiation \( (p<0.05) \)

Conclusion

Our experience of cervical intervention in the locally advance cervix carcinoma has proved clinical value only in individual cases- when the plan of radiotherapy could not been completed. There is no proof that this treatment strategy improves long term survival in patients with pelvic node involved with persistent tumor after radiotherapy

THE ROLE OF HPV TESTING WITH HPV16/18 GENOTYPING IN FOLLOW-UP OF CERVICAL CANCERS STAGES IA2-IIA2
J. Slama¹, D. Cibula¹, D. Fischerova¹, A. Germanova¹, M. Zikan¹, R. Kocian¹, F. Fruhauf¹
¹General University Hospital and First Faculty of Medicine - Charles University, Gynecologic Oncology Center, Prague, Czech Republic

Aims

The aim of our study was to evaluate the role of HPV testing with HPV 16/18 genotyping for detection of local recurrence in patients who underwent surgical treatment for cervical cancers in stages IA2-IIA2.

Method

Patients underwent primary surgical treatment including radical or simple hysterectomy or fertility sparing procedure (trachelectomy or conization) and pelvic lymphadenectomy with sentinel lymph node biopsy. Adjuvant chemoradiotherapy was administered in patients with positive nodes. All women were followed in 3 months interval for the first 2 years and then semiannually. HPV tests (Cobas, Roche) were collected between 6-12 month of follow-up.

Results

Altogether 108 patients were included (IA2 - 20, IB1 - 80, IB2 - 7, IIA1 - 1), from them 51 underwent radical hysterectomy, 14 simple hysterectomy and 43 fertility sparing surgery (FSS). Four patients had subsequent adjuvant chemoradiotherapy. In 11 patients HPV test was positive. Disease recurred in vagina or cervix in 10 patients with 9 recurrences in patients after FSS. Six of them were HPV 16/18 positive. The rest 4 recurrences were detected within 6 months after the treatment before HPV testing.

Conclusion

Local recurrences were detected predominantly in patients after FSS. Nearly half of recurrences were detected before HPV test collecting. No case of recurrence were detected within HPV negative women.

IMPACT OF EXTENDED FIELD IRRADIATION ON ACUTE HEMATOLOGICAL TOXICITY IN PATIENTS WITH LOCALLY ADVANCED CERVICAL CANCER UNDERGOING RADIOCHEMOTHERAPY USING VOLUMETRIC MODULATED ARC THERAPY

S. Smet1,2, K. Johnson3, M. Buschmann1, E. Umbrarescu4, Y. Seppenwoolde1, M. Schmid1, A. Sturdza1

1Medical University of Vienna- Comprehensive Cancer Center, Department of Radiation Oncology, Vienna, Austria
2University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium
3University of Manitoba, CancerCareManitoba Radiation Oncology, Winnipeg- Manitoba, Canada
4Hospital Santa Creu i Sant Pau, Department of Radiation Oncology, Barcelona, Spain

Aims

To evaluate the impact of para-aortic (PA) irradiation on acute hematological toxicity (HT), overall treatment time (OTT) and number of chemotherapy cycles in patients with locally advanced cervical cancer (LACC) undergoing concurrent radiochemotherapy using volumetric modulated arc therapy (VMAT).

Method

We analyzed 54 consecutive patients (Jan 2015 – March 2017) undergoing primary radiochemotherapy with weekly Cisplatin 40mg/m². Based on nodal involvement, irradiation fields included pelvic nodal irradiation in 29 patients and pelvic + PA nodal irradiation in 25 patients. Impact of PA irradiation was evaluated on HT, OTT and missed chemotherapy cycles. HT was assessed using the common terminology criteria for adverse events v.4.0. Dosimetric parameters (V10Gy, V20Gy, V30Gy, V40Gy, mean dose) were calculated for pelvic and lumbar bone marrow, which were contoured for each patient.

Results

Grade 3 leucopenia was observed in 20% vs 21% (with vs without PA irradiation), grade 2 in 36% vs 34%, and grade 1 in 32% vs 34%. Grade 3 anemia was not observed, grade 2 in 56% vs 37%, and grade 1 in 40% vs 41%. Bone marrow doses were acceptable, irrespective of field borders. For all but 1 patient, OTT of 50 days was respected. 75% got 4 to 5 chemotherapy cycles. There was no significant difference in HT (p=0.76), OTT (p=0.76), or chemotherapy cycles (p=0.45) among irradiation fields using linear mixed models.

Conclusion

PA irradiation using VMAT for LACC results in acceptable bone marrow doses, does not lead to increased HT, respects OTT and enables high compliance to concurrent chemotherapy.

SENTINEL LYMPH NODE DETECTION IN A SOUTH AFRICAN CERVICAL CANCER POPULATION

L. Snyman¹, G. Lindeque²

¹University of Pretoria, Gynaecologic Oncology Unit- Department Obstetrics & Gynaecology, Pretoria, South Africa
²University of Pretoria, Gynaecologic Oncology Unit- Department Obstetrics & Gynaecology, Pretoria, South Africa

Aims

To determine the detection rate, bilateral detection rate, sensitivity, specificity, positive and negative predictive values of sentinel lymph nodes in cervical cancer, with sub-group analysis to identify characteristics impacting on detection rates.

Method

Seventy-eight women were recruited. Methylene blue, ⁹⁹Technesium nanocolloid and indocyanine green were used to detect SLNs. Standard full pelvic lymphadenectomy was performed on all and ultrastaging on SLN negative women.

Results

Data of 72 women were available for analysis with 65% HIV positive. The mean age was 47.2 years; HIV-negative women 52.8 years compared to 44.2 years for HIV-positive women (p<0.0001). The mean BMI was 27.5 kg/m² (SD 5.41). The mean tumour diameter was 24 mm. Forty-eight patients (66.67%) were stage IB1 and 11 (15.3%) were IB2. Eighteen patients (25%) had pelvic lymph node metastases. The mean pelvic lymph node count was 25.16.

The SLN detection rate was 65.3% and the bilateral detection rate was 30.5%. The SLN detection rate in HIV positive was 68% and 60% in HIV negative women (p = 0.49). The sensitivity, specificity, positive and negative predictive values were 85.7%, 100%, 100% and 98.33% respectively.

Detection rates in women with tumour size < 2cm, early stage, node negative and BMI < 25 kg/m² were 77.1%, 74.5%, 72.2% and 77.7% respectively.

Conclusion

This is the first SLN study in African cervical cancer women of which large proportion had HIV infection. The SLN detection rate is much lower in this group compared to the published literature. Sensitivity, specificity, PPV, and NPV are comparable to the published literature.

ASSOCIATION BETWEEN PREOPERATIVE NEUTROPHIL TO LYMPHOCYTE RATIO AND PELVIC LYMPH NODE METASTASIS IN EARLY STAGE CERVICAL CANCER

S. Tangijitgamol, S. Sriappracharoen

Navamindradhiraj University, Obstetrics and Gynecology, Bangkok, Thailand

Aims

To assess the association of pre-operative neutrophil to lymphocyte ratio and pelvic lymph node metastasis in early stage cervical cancer

Method

Early stage cervical cancer patients undergoing radical hysterectomy with pelvic lymphadenectomy between January 1, 2008 and December 31, 2015 were identified. Clinical and pathological data of the patients and tumors were collected.

Results

A total of 121 patients with FIGO stage IA-IIA underwent radical hysterectomy and pelvic node dissection with or without para-aortic lymphadenectomy were included in the study. Mean age was 45 years (SD 10.32). After surgery, 47 patients (38.8%) had adjuvant treatment. After median follow-up of 38 months (range 6 to 114 months), 8 had recurrences (6.6%) and 3 were dead (2.5%). The five-year OS rate 93.8% and the PFS rate was 91.8%. Median of NLR was 2.03 (range, 0.74-30.0). High NLR (≥ 2.03) was significantly associated with higher FIGO stage (stage II) and pelvic lymph node metastases. Only FIGO stage and adjuvant treatment, but not high NLR, were significantly associated with survivals.

Conclusion

High NLR was associated with LN metastasis in cervical cancer patients initially treated with radical surgery. The high NLR failed to predict both PFS and OS in this group of patients.
NATIONWIDE CERVICAL CANCER SCREENING IN KOREA: DATA FROM THE NATIONAL HEALTH INSURANCE SERVICE CANCER SCREENING PROGRAM AND NATIONAL CANCER SCREENING PROGRAM, 2009–2014

J.H. Suh¹, S.H. Chae², S.H. Shin², H. Kim³, S.J. Lee², S.N. Kim³, K. Lee³, S. Chang³

¹Kun-kuk univ. medical center, Obstetric and gynecology, Seoul, Republic of Korea
²Konkuk university medical center, Department of Obstetrics and Gynecology, Seoul, Republic of Korea
³Konkuk University School of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea

Aims

We sought to determine rates of participation and of abnormal results in the Korean nationwide cervical cancer screening.

Method

Using the database of the National Health Insurance Service, participation rates and abnormal result rates in the cervical cancer screening test were determined during the study period (2009–2014).

Results

The participation rate increased from 41.10% in 2009 to 51.52% in 2014 (APC = 4.126%; 95% CI = 2.253–6.034). During the study period, women aged ≥70 years showed the lowest rate (ranging from 21.7 to 31.9%) and those aged 30–39 years showed the second-lowest (ranging from 27.7 to 44.9%). The participation rates of National Health Insurance beneficiaries (ranging from 48.6 to 52.5%) were higher than those of Medical Aid Program (MAP) recipients (ranging from 29.6 to 33.2%). Abnormal result rates were 0.65% in 2009 and 0.52% in 2014, with a decreasing tendency in all age groups except the youngest group (30–39 years). In every year, abnormal result rates tended to decline from the group aged 30–39 years to the group aged 60–69 years, but rose again in those >70 years old. The ratio of ASC-US to SIL increased from 2.71 in 2009 to 4.91 in 2014.

Conclusion

Differences were found in participation rates and abnormal result rates by age and over time. Further efforts are needed to encourage participation in cervical cancer screening, especially for MAP recipients and elderly women and women aged 30–39 years. Additionally, quality control measures for cervical cancer screening programs should be enforced consistently.
ATTITUDES REGARDING HPV VACCINATIONS OF CHILDREN AMONG MOTHERS WITH ADOLESCENT DAUGHTERS IN KOREA

P. Sung Taek¹, P. Sung-ho¹, L. Kyong-No¹
¹The Hallym University of Korea, Department of Obstetrics & Gynecology, Seoul, Republic of Korea

Aims

The aim of this study, carried out before the beginning of human papillomavirus (HPV) vaccinations as a National Immunization Program (NIP) in Korea in 2016, is to assess the ranges of perceptions and personal experience and their influences on attitudes regarding HPV vaccinations of children, among mothers of adolescent (9–14 years of age) daughters in Korea.

Method

From November 2015 to February 2016, we distributed a written questionnaire to mothers who had daughters aged 9–14 years. The questionnaire consisted of several questions, related to knowledge of HPV, personal experiences of HPV vaccination, and attitudes toward HPV vaccinations of their adolescent daughters. Of the 260 questionnaires distributed, 140 participants returned answered ones.

Results

although only 51% of participants were aware that cervical cancer is highly related with HPV infection, 70% said they were willing to vaccinate their daughters, showing that awareness does not coincide with intention to vaccinate. Among the participants showing negative attitudes, 50% were concerned about the vaccination side effects. The more the participants' preknowledge about HPV infection, and about the relationship of HPV to cervical cancer, the more positive their attitudes (P = 0.002, P < 0.001)

Conclusion

Our study showed that, as the level of education rose, the proportion of mothers with negative attitudes toward vaccinating their adolescent daughters rose as well. Thus, the provision of correct education by health care providers and accurate information through active advertising may play an important role in increasing the vaccination rate among adolescent girls in Korea.

8Imperial College Institute of Reproduction and Developmental Biology, Surgery & Cancer, London, United Kingdom

Aims

Although cervical intraepithelial neoplasia grade 2 (CIN 2) is often considered the histological cut-off to proceed to conisation, a substantial proportion of CIN 2 lesions regress spontaneously, particularly in young women. We aimed to estimate the rates of regression, persistence, progression and compliance with follow-up in women with CIN 2 managed with active surveillance.

Method

Medline, Embase and CINAHL were searched from 1.1.1973 to 20.8.2016 for studies reporting on outcomes of histologically-confirmed CIN 2 in non-pregnant women, managed with active surveillance for at least three months. Data extraction and risk of bias assessments were performed independently and in duplicate. Pooled proportions for each outcome were calculated with random-effects model and inter-study heterogeneity was assessed using I² statistics.

Results

We identified 36 studies (seven control arms of randomised controlled trials, 16 prospective and 13 retrospective cohort studies) that reported on the outcomes of 3093 women. At 24 months, the regression rate was 50% (95% confidence interval (CI) 43%-67%; I² 77%), the persistence rate 32% (95%CI 23%-42%; I² 82%), while the progression rate 18% (95%CI 11%-27%; I² 90%). In a subgroup analysis of 4 studies that included 1039 women under the age of 30, the rates were 60% (95%CI 57%-63%; I² 0%), 23% (95%CI 20%-26%; I² 97%) and 11% (95%CI 5%-19%; I² 67%), respectively.

Conclusion

The majority of CIN 2 lesions regress spontaneously, particularly in young women. Close active surveillance is justified for selected young women with CIN 2 that are likely to adhere to monitoring.

CHARACTERISTIC FINDINGS OF HIGH-GRADE CERVICAL INTRAEPITHELIAL NEOPLASIA OR MORE ON MAGNIFYING ENDSCOPY WITH NARROW BAND IMAGING

Y. Takahashi1, K. Uchita2, A. Kawada2, K. Hirano1, H. Kobara2, N. Nishiyama3, K. Kanenishi4

1Kochi Red Cross Hospital, Department of Obstetrics and Gynecology, Kochi shi, Japan
2Kochi Red Cross Hospital, Department of Gastroenterology, Kochi shi, Japan
3Kagawa University- Faculty of Medicine, Department of Gastroenterology, Takamatsu shi, Japan
4Kagawa University- Faculty of Medicine, Department of Gynecology, Takamatsu shi, Japan

Aims

Colposcopy, which is a standard modality for diagnosing cervical intraepithelial neoplasia (CIN), can have limited accuracy due to poor visibility. Currently, magnifying endoscopy with narrow band imaging (ME-NBI) has excellent diagnostic accuracy for early gastrointestinal neoplasms and is expected to be highly useful for CIN diagnosis. This study aimed to determine the characteristic findings and evaluate the diagnostic ability of ME-NBI using gastroscopy for lesions \( \geq \) CIN 3.

Method

A total of 24 patients who underwent cervical conization with a preoperative diagnosis of high-grade squamous cell intraepithelial lesions (HSILs) or lesions \( \geq \) CIN 3 were enrolled. Prior to conization, still images and video of ME-NBI were captured to investigate the cervical lesions. The images were retrospectively reviewed based on histological examination of the resected specimens. The NBI-ME images revealed the following abnormal findings: (1) light white epithelium (l-WE), (2) heavy white epithelium (h-WE), and (3) atypical intra-epithelial papillary capillary loop (IPCL).

Results

Pathological examination of the resected specimens confirmed cervical lesions \( \geq \) CIN 3 in 21 patients. The ME-NBI findings were classified into four groups, l-WE, l-WE with atypical IPCL, h-WE, and h-WE with atypical IPCL, at rates of 0%, 23.8%, 9.5%, and 66.7%, respectively. Additionally, all 3 patients with MIC showed strongly irregular IPCLs.

Conclusion

The detection of h-WE or l/h-WE with atypical micro-vessels using ME-NBI can be indicative for diagnosing lesions \( \geq \) CIN 3. This study indicates that ME-NBI may have novel value for CIN diagnosis.

IMMUNE CHECKPOINT SYSTEM FOR EARLY STAGE CERVICAL CANCER WITH HIGH-RISK FACTORS

M. Takekuma1, O. Takuma2, A. Masato2, M. Ayako1, Y. Emi1, K. Yuka1, K. Nobuhiro1, T. Nobutaka1, A. Masakazu1, H. Yasuyuki1

1Shizuoka Cancer Center, Gynecology, Shizuoka, Japan
2Shizuoka Cancer Center, Pathology, Shizuoka, Japan

Aims

The aim of this study was to evaluate the relationship between the expression of PD-L1 and survival in early stage cervical cancer with high-risk factors.

Method

Patients with high-risk factors of recurrence due to pathologically confirmed parametrial invasion and/or pelvic lymph node metastasis from 2002 to 2012 were included. Formalin-fixed, paraffin-embedded material of each patient was obtained through extraction after radical hysterectomy. Standard immunohistochemical staining was done using PD-L1 antibody. We also tested each tissue specimen for PD1 to evaluate the status of tumor-infiltrating lymphocytes (TILs). At least 1% of tumor cells expressing PD-L1 was defined as PD-L1(+) 50% or more TILs expressing PD1 was defined as high-PD1, less than 50% TILs expressing PD1 was defined as low-PD1, and no TILs expressing PD1 was defined as non-PD1.

Results

In total, 96 patients were enrolled. Patients with PD-L1(+) numbered 29 (30.2%), in which 12 (12.5%) had at least 50% of tumor cells expressing PD-L1. Patients with high-PD1 numbered 16 (16.7%). There were significantly more PD-L1(+) patients than PD-L1(-) patients with high PD1 (41.4% vs 6.0%, p=0.001). The 5-year progression free survival (PFS) rate of all patients in this study was 70.0%. The 5-year PFS rate of high-PD1 was higher than non-, and, low-PD1 (87.5% vs. 66.4%, p=0.054). 5-year PFS rate of patients with PD-L1(+) had no difference with PD-L1(-) (79.3% vs. 65.9%, p=0.101).

Conclusion

In patients with early stage cervical cancer, the patients with high-PD1 would tend to have a longer survival duration. The expression of PD-L1 would not affect the survival duration.

PELVIC EXENTERATION IN PATIENTS WITH RECURRENT OR ADVANCED GYNECOLOGIC MALIGNANCIES

1Nagoya University, Obstetrics and Gynecology, Nagoya- Aichi, Japan

Aims

Pelvic exenteration (PE) can be indicated for patients with central recurrent or advanced gynecologic malignancies. The purpose of this study was to evaluate surgical outcomes after PE in our institute.

Method

Retrospective analysis of all patients with PE for recurrent or advanced gynecologic malignancies between 2006 and 2017 at our institution was performed.

Results

Sixteen patients were included. The diagnosis of them were cervical cancer in 6 patients, corpus cancer and sarcomas in 2 patients, ovarian cancer in 3 patients, and vaginal cancer in 4 patients, and unknown in 1 patient. Eleven patients underwent total pelvic exenteration and 5 underwent anterior pelvic exenteration. Six of them were performed laparoscopically. The median blood loss was 2601ml (range 88-15700ml) and the median operation time was 677minutes (range 338-954 minutes). Sciatic nerve injury was observed as an intraoperative complication. Postoperative complications were urinary tract infection in 5 patients, wound infection in 4 patients, and intestinal obstruction in 2 patients. Complete tumor resection was achieved in 15 patients. Microscopically positive surgical margin was detected in 3 patients of them. During a median follow-up of 22 months (range 1-85 months), 5 patients experienced recurrence. Tow of 3 patients who had positive surgical margin experienced recurrence. Nine Of 12 patients who had negative surgical margin are alive without recurrence.

Conclusion

Despite frequent complications, PE is feasible and could be the effective treatment alternative in selected patients with recurrent gynecologic malignancies.

THE PLACE OF ENDOCERVICAL CURETTAGE ADJUVANT TO HPV POSITIVE PATIENTS WITH ASCUS CYTOLOGY AND NORMAL COLPOSCOPY

A. Tal1, S. Romano1,2, Y. Ben David1,2
1Emek Medical center, Obstetrics and Gynecology, Afula, Israel
2Technion Rappaport Faculty, Medicine, Haifa, Israel

Aims

To examine the additive information of ECC in the management of patients with ASCUS cytology, normal colposcopy and positive HPV result.

Method

A population based cohort study conducted at a single institution in the north of Israel between January 2007 and December 2014. All women with ASCUS cytology on routine PAP screen referred to colposcopy. All women with normal colposcopy were tested for HPV. Women with positive HPV referred to ECC.

Results

Of 11100 PAP smears taken in the study period, 980 (8.8%) were diagnosed as ASCUS. 910 of them had normal colposcopy and 260 of the normal colposcopy group (28.5%) were HPV positive. The mean age was 33 (18-55) and 85% of them were Jewish. HPV 16 was the most prevalent type (30%) in these patients. All the patients with positive HPV, had ECC test and 67 (25.7%) had cervical dysplasia – LGSIL or HGSIL. In 2 patients, squamous cell carcinoma in situ and adenocarcinoma in situ were found ultimately.

Conclusion

Preforming ECC to women with ASCUS cytology, normal colposcopy and positive HPV enable us to detect precancerous dysplasia and even carcinoma in situ and it is justified in these patients.

PALLIATIVE PELVIC EXENTERATION USING ILIOFEMORAL BYPASS WITH SYNTHETIC GRAFTS FOR ADVANCED CERVICAL CARCINOMA

B. Tatar¹, Y. Yalcin¹, K. Ceviker², E. Erdemoglu¹

¹Suleyman Demirel University Hospital, Gynecologic Oncology, Isparta, Turkey
²Suleyman Demirel University Hospital, Cardiovascular Surgery, Isparta, Turkey

Aims

Recurrent cervical cancer can cause severe morbidity. Despite severe morbidity is high after the surgery, pelvic exenteration is still used today for mainly curative intent. This intention is neither based on randomized controlled trials (RCTs) nor high quality non-RCTs with adequate patient numbers comparing medical management with surgery. The same is true for exenteration for palliative intent, so the patient selection for either curative or palliative intent must be considered on patient basis.

Method

35 year old patient who had undergone primary chemo-radiotherapy for advanced cervical cancer, presented with intractable pain on the swollen left leg and pelvis 8 months later. Left lower extremity doppler ultrasound revealed echogenic thrombus in external iliac, femoral and popliteal veins consistent with acute deep vein thrombus. She underwent total exenteration, end colostomy, ileal urinary conduit, pelvic lymphadenectomy, paraaortic lymph node sampling and ilio-femoral arterial and venous bypass.

Results

Results: The procedure relieved her pain, leg diameter dramatically decreased from 75cm to 44 cm and circulation of the leg reestablished. The procedure deferred leg amputation for about five months.

Conclusion

Conclusions: To the best of our knowledge, this is the first report of a palliative pelvic exenteration for cervical cancer with combined ilio-femoral arterial and venous bypasses. These procedures with high morbidity and mortality are also more controversial when undertaken for just palliation of symptoms. They must be considered in basis of each patient, benefits and risks must be discussed thoroughly in a realistic perspective with the patient.

EFFECTIVENESS OF AWARENESS PROGRAMME ON KNOWLEDGE, ATTITUDE AND PRACTICES FOR EARLY DETECTION AND PREVENTION OF CERVICAL CANCER IN EDUCATED WOMEN

A. Pal¹, V. Singh², S. Singh³, N. Shrivastava³, P. Thakur⁴

¹All India Institute of Medical Science Raipur, Preventive and Social Medicine, Chattisgarh, India
²All India Institute of Medical Sciences Raipur -Chattisgarh India, Obstetrics and Gynaecology, Raipur, India
³All India Institute of Medical Science Raipur, Surgery, Raipur, India
⁴All India Institute of Medical Science Raipur, Obstetrics and Gynaecology, Raipur, India

Aims

To evaluate the effectiveness of structured awareness programme on knowledge, attitude and practices for early detection and prevention of cervical cancer among educated women.

Method

Method: 5000 participate included for study from different teaching institution in whom structured awareness information related to cervical cancer was provided and ask them to fill pre and post test questionnaire

Results

There was significant difference in the of pre test knowledge, attitude and practices score among the women after administration of structured awareness programme for early detection and prevention of cervical cancer.

Conclusion

Conclusion- study shows there is need to spread awareness among the women in relation to early detection and prevention of cervical cancer.
CLINICAL VALUE OF FERTILITY PRESERVING MANAGEMENT IN WOMEN WITH ADENOCARCINOMA IN SITU OF THE UTERINE CERVIX

¹University General Hospital "Alexandra", 1st Department of Obstetrics & Gynecology - Division of Gyn/Oncology, ATHENS, Greece
²Department of Histopathology- Alexandra Hospital Athens- Greece., Department of Histopathology, Athens, Greece

Aims

The aim of our study is to determine the outcomes of women with AIS in correlation with their initial management and to establish the impact of pathologic parameters identified at cervical conization.

Method

Retrospective analysis of medical records, from 2000 to 2016, of patients with AIS histologically confirmed, who underwent either conservative or radical surgery was conducted. Follow up ranged from 8 to 60 months (median 34) were also collected.

Results

A total of 33 patients aging 26 to 68 years old (median 47), were including in the study.

Eleven patients (33%) underwent hysterectomy: 2 cases (18%) of adenocarcinoma and 2 cases (18%) of residual AIS with positive surgical margins. 7 patients (64%) underwent hysterectomy due to undesired fertility and no residual disease was identified at final histology.

The remaining 22 women (67%) were treated conservatively – 20 women with LEEP and 2 women with abdominal radical trachelectomy – and all of them were free of disease at the last contact.

No significant difference was noted: 1) in age between patients with residual AIS or adenocarcinoma and those without residual disease, and 2) between those with AIS/progressive disease and those free of disease in regards to adenosquamous/squamous dysplasia, disease extent or the marginal status in either the whole group of participants or hysterectomy group alone.

Conclusion

Our results demonstrate that conservative management with strict follow up – given the risk of recurrent AIS or invasive cancer - may be an acceptable approach in the management of AIS.
A CASE OF ADULT EMBRYONAL RHABDMyOSARCOMA OF THE CERVIX WITH A REVIEW OF THE CURRENT LITERATURE

C. Thompson¹, S. Alken², C. O’Riain³, C. Grant², W. Kamran¹

¹St James’s Hospital, Gynaecological Oncology, Dublin, Ireland
²St James’s Hospital, Medical Oncology, Dublin, Ireland
³St James’s Hospital, Histopathology, Dublin, Ireland

Aims

Embryonal rhabdomyosarcoma (EMRS) is a rare malignant mesenchymal tumour showing evidence of skeletal muscle differentiation. It is more commonly detected in children <5 years old and within the vagina in 90% of cases. Adult presentation is much less common but frequently involves the cervix. This presentation of a case report will also review current evidence for treatment of this rare tumour.

Method

Case reported and literature search performed. Keywords applied to searches with PUBMED and MEDLINE.

Results

Case

32 year old with irregular PV bleeding. An exophytic cervical tumour was discovered. Biopsy confirmed embryonal rhabdomyosarcoma. CT demonstrated a 5cm cervical mass (confirmed on MRI), with an 8mm aortocaval lymph node. PET-CT demonstrated a bulky cervical mass extending into the endometrial cavity, but no evidence of metastatic disease. Incidental finding of absent corpus callosum on MRI Brain. Excellent response seen post 2nd cycle IVAD (Ifosfamide, Vincristine, Actinomycin D, Doxorubicin) with tumour regression to containment within cervix. Progressed to surgical resection following 3rd cycle.

Review:
Adult ERMS is rare and has a worse prognosis than the childhood form. Overall survival has improved with the advancement of multi modal treatment. High dose chemotherapy and surgery is now advocated as in childhood disease. Although overall guidance for the adult group is still lacking, the Intergroup Rhabdomyosarcoma Study Group (ISRG) are moving more from radical surgery to intensive primary chemotherapy (VAC) and have shown survival up to 84%.

Conclusion

With the use of multimodal treatments of chemotherapy and surgery the prognosis for adult ERMS is improving.
AWARENESS ON HPV AND HPV VACCINE AND ACCEPTANCE OF VACCINATION AGAINST HPV AMONG HIGH SCHOOL STUDENTS AND THEIR PARENTS: A PRIVATE HIGH SCHOOL BASED STUDY

B. Tulpar¹, E. Gucer², S. Ceydeli³, Z. Yılmaz⁴
¹Robert College High School, 11th Grade, Istanbul, Turkey
²10th Grade, Istanbul, Turkey
³9th Grade, Istanbul, Turkey
⁴Department of Obstetrics and Gynecology, Istanbul, Turkey

Aims

The aim of this study was to evaluate the awareness, knowledge, and risk perception about HPV and HPV vaccines among high school students and their parents. Another aspect assessed was the parent’s acceptance of the vaccine and willingness to vaccinate their children against HPV.

Method

Two different standardised electronic questionnaires, one for the students and one for the parents, were sent out. All subjects were students currently in school and their parents. Questionnaires were first sent in December 2016 and then twice more with 4 week intervals. All data from answered questionnaires were stored automatically by a computer program designed for the study (E.G.).

Results

The overall response rate was 34% for students and 27% for parents. The proportion of students who knew what the symptoms of HPV were was 21%, while 32% of students had heard about HPV only namely. 26% knew that there was a vaccine for the prevention of cervical cancer. Only 9.9% had been vaccinated against HPV, 86% vaccinated students were female. 70% of the students would like to be further informed.

Among parents, 74% had heard about HPV. Of 96 parents who have daughters in RC, 15 (16%) had vaccinated their child already. Reimbursement of HPV vaccine may influence on the decision of vaccination in 86% of parents.

Conclusion

This study is the first study evaluating the knowledge on HPV and the HPV vaccine among the high school students and their parents. Compared to vaccination rates in USA and Canada the vaccination rate in our population is very low.
USE OF AORTO-ILIAC GRAFT FOR RECURRENT VILLOGLANDULAR PAPILLARY CERVICAL CARCINOMA

M. Arvas¹, H. Turan¹, I. Kahramanoglu¹, F. Demirkiran¹, T. Bese¹
¹Cerrahpasa Medical Faculty, Obstetrics and Gynecology, Istanbul, Turkey

Aims

Isolated pelvic and paraaortic recurrences of cervical cancer can be potentially cured with surgery. It may be necessary to remove and reconstruct major blood vessels to obtain complete resection.

Method

A 33-year old woman with a diagnosis of stage 1B1 villoglandular papillary cervical adenocarcinoma underwent type III hysterectomy and pelvic lymph node dissection. Patient did not receive any adjuvant treatment. After a 6-year of disease-free interval, a 6 cm in diameter recurrence occurred covering the lower abdominal aorta and bilateral common iliac arteries (Figure 1).

Therefore, we resected the area from the aortic bifurcation to the bilateral common iliac arteries and replaced them with a Y-shaped graft (Figure 2).

Results

Follow-up 24 months after surgery showed no evidence of recurrence.

Conclusion

The extended resection involving the replacement of major vessels is sometimes useful when dealing with tumor recurrence on paraaortic and pelvic areas.
CERVICAL CANCER

ESGO7-1188

FEASIBILITY OF TWO FRACTIONS INTRACAVITARY/INTERSTITIAL BRACHYTHERAPY IN THE TREATMENT OF LOCALLY ADVANCED CERVICAL CANCER

K. Akbarov1, I. Isayev1, E. Guliyev1, T. Nadirova1, N. Aliyeva1

1National Center of Oncology, Radiotherapy, Baku, Azerbaijan

Aims

Today the standard treatment for locally advanced cervical cancer is chemoradiotherapy consisted of external beam radiotherapy, weekly cisplatin and brachytherapy. Recently introduced combined intracavitary / interstitial (IC/IS) brachytherapy allows to increase radiation dose delivered to the tumor. In this study we evaluated treatment outcomes of patients with IIA-IIIB stage cervical cancer treated by chemoradiotherapy and two fractions of IC/IS brachytherapy.

Method

Methods. Eighty nine IIA-IIIB stage cervical cancer patients were treated at National Center of Oncology, Baku, Azerbaijan from 2012 to 2015. Median age of patients was 51 years; 16 (18%) patients had IIA, 41 (46.1%) – IIB, 4 (4.5%) – IIIA and 28 (31.4%) – IIIB stage cervical cancer. Histological analysis showed 82 (92.1%) cases of squamous cell cancer and 7 (7.9%) adenocarcinomas. All patients received external beam radiotherapy (without central shielding) to the pelvis in 2 Gy daily fractions, 5 times weekly up to 46 Gy with concurrent weekly cisplatin in dose 40 mg/m2. After that high dose rate IC/IS brachytherapy was initiated: two weekly fractions of nine Gy. Planning was done on 2 mm paratransversal MRI slices.

Results

Results. All patients completed radiotherapy as planned and 91.4% patients received at least four cycles of chemotherapy. Mean dose to high risk clinical target volume (HRCTV) was 87.7±11 Gy. Actuarial five year overall survival rate for all patients was 68.9%. We did not reveal any significant early and late treatment related toxicity.

Conclusion

Conclusion. Our data shows that chemoradiotherapy by two fractions of IC/IS brachytherapy regimen is feasible for wider clinical use.

ESGO7-0953

SENTINEL NODE MAPPING VS. SELECTIVE DISSECTION OF THE PELVIC LYMPHATIC CENTER IN EARLY STAGE CERVICAL CANCER < 2 CM

S. Uccella1, L. Pedone Anchora1, M.V. Carbone1, F. Francesco2, P. Zorzato1, M. Bruno1, G. Scambia1, A. Fagotti1

1Università Cattolica del Sacro Cuore, Gynecologic Oncology, Rome Italy, Italy
2University of Chieti, Gynecology Division, Chieti, Italy

Aims

To compare sentinel node mapping vs. dissection of the pelvic lymphatic center (both without full pelvic lymphadenectomy) in terms of overall morbidity and incidence of lymphatic complications.

Method

Consecutive women with cervical cancer < 2 cm, who underwent radical hysterectomy and sentinel node detection (SN group) or dissection of the interiliac and superficial obturator nodes (pelvic lymphatic center group) without completion of systematic full pelvic lymphadenectomy in the period between May 2012 and January 2017. Patients were matched in a 1:2 ratio for age, BMI, histological type and presence/type of medical comorbidities.

Results

Thirty women were included: 10 in the SN group and 20 in the pelvic lymphatic center group, respectively. The groups were similar in terms of tumor diameter, histological subtype, grading, lymphovascular space invasion, blood loss, and hospital stay. No intra-operative complication was registered. Post-operative adverse events (other than lymphatic complications) occurred in 1 (10%) and 3 (15%) patients in the SN and pelvic lymphatic center groups, respectively (p=1.00).

A median(range) of 4(2-8) and 7(3-12) lymph nodes were removed in the SN and pelvic lymphatic center groups, respectively (p=0.03). One symptomatic lymphocele was diagnosed in the pelvic lymphatic center group, vs. none in the SN group (p=1.00). No asymptomatic lymphoceles, lymphedema or lymphorrhea were registered.

Conclusion

Sentinel node mapping is associated with a low risk of complications in cervical cancer < 2 cm. Dissection of the pelvic lymphatic center may represent an alternative to full pelvic lymphadenectomy if the technology for sentinel node detection is not available or in cases of inadequate mapping.
NEOADJUVANT-CHEMOTHERAPY IN LOCALIZED BULKY CERVICAL CANCER: A SINGLE INSTITUTION EXPERIENCE

Z. Vaknin1, M. Yekutieli1, S. Kovel2, D. Schneider1

1Yitzhak Shamir Medical Center- Zerifin- affiliated to the Sackler Faculty of Medicine- Tel Aviv University- Tel-Aviv- Israel, Obstetrics and Gynecology, Beer-Yakov, Israel
2Yitzhak Shamir Medical Center- Zerifin- affiliated to the Sackler Faculty of Medicine- Tel Aviv University- Tel-Aviv- Israel, Oncology, Beer-Yakov, Israel

Aims

Cervical cancer is very rare in Israel. Radical-surgery is usually reserved for small localized lesions. The aim of this work is to present our experience with neoadjuvant-chemotherapy (NACT) in highly-selected patients (Bulk I-B1/IIA1 and I-B2/IIA2, with negative lymph-nodes per PET-CT).

Method

In 2004-2016 we treated 12 patients fulfilling the above-mentioned criteria with NACT prior to planned radical-surgery. All were included in the retrospective analysis. All NACT was IV platinum-based mostly with paclitaxel for at least 3-cycles. Response rate was measured according to RECIST-criteria. The need for adjuvant radiation-therapy was decided according to Seldis-criteria.

Results

Median age was 42 years (range, 26-68). Overall toxicity was very low, while clinical-response was high (10 patients, 83%). Two patients (17%) had stable-disease and were subsequently treated with chemoradiation. Clinical-response was defined as complete in 6 patients (50%) and as partial in 4 patients (33%). All these patients had radical-surgery. As for the pathological response: 7 patients had suboptimal-response (stromal-invasion >3 mm), 2 had complete-response and one had minimal residual-disease (<3 mm stromal-invasion). Only two patients required adjuvant radiation-therapy. Overall, 3 patients (25%) had persistent-disease, 2 patients that weren't eligible to surgery and one patient that had surgery and needed adjuvant radiation-therapy. Two of these patients (one in each group) died of the disease.

Conclusion

In highly-selected patients with early, localized bulky cervical cancer, neoadjuvant-chemotherapy can generate high clinical-response which allows radical-surgery without subsequent radiation. This approach can achieve satisfactory outcomes, with few benign complications. We believe it could be applied as a valid alternative to primary chemoradiation.
SQUAMOUS CELL CARCINOMA ANTIGEN AND CARCINOEMBRYONIC ANTIGEN IN CERVICAL CANCER: THE PROGNOSTIC VALUE BEFORE AND AFTER RADIATION THERAPY

K. van den Berg\textsuperscript{1}, J. Mongula\textsuperscript{1}, L. Lutgens\textsuperscript{2}, T. van Gorp\textsuperscript{1}, R. Kruitwagen\textsuperscript{1}, B. Slangen\textsuperscript{1}

\textsuperscript{1}Maastricht University Medical Centre, Department of Gynecologic Oncology, Maastricht, The Netherlands
\textsuperscript{2}MAASTRO clinic, Department of Radiation Oncology, Maastricht, The Netherlands

Aims

Recurrence of cervical cancer after primary treatment has a poor prognosis but early detection might contribute to a better survival based on individualized adjuvant treatment. However, no standardized protocols are available for identifying patients at high risk for recurrence. Measurement of squamous cell carcinoma antigen (SCC-Ag) and carcinoembryonic antigen (CEA) might contribute.

Method

This is a retrospective cohort study of cervical cancer patients treated with (chemo)radiation (Maastricht University Medical Centre, 2007 - 2016). SCC-Ag and CEA levels before and approximately three months after treatment, tumor histology, treatment strategy, local and metastatic recurrence, disease free survival and follow-up period were collected from medical files. The prognostic value of SCC-Ag and CEA was evaluated using receiver operating characteristic (ROC) curves and Kaplan-Meier survival analysis. Pre-defined cut-off points of 1.9µg/L and 2.5µg/L were used, respectively. A p-value<0.05 was considered statistically significant.

Results

Based on preliminary data, elevated SCC-Ag and CEA before or after treatment were not of statistically significant value in predicting a worse progression-free survival (p>0.05). However, patients with SCC-Ag levels of more than 0.9µg/L after treatment (based on the optimal cut-off point of the ROC curve (AUC 0.73)) show a significantly worse progression-free survival in comparison with patients with non-elevated levels (p=0.006).

Conclusion

This retrospective analysis suggests that SCC-Ag levels above 0.9µg/L three months after (chemo)radiation might be useful in identifying patients with a worse progression-free survival.
CERVICAL CANCER

ESGO7-1352

PATHOLOGY REVIEW OF 159 CASES OF MICROINVASIVE CERVICAL CANCER

B. Vranes¹, A. Stefanovic¹, S. Kadija¹, K. Jeremic¹, V. Kesic¹, A. Jovic Vranes²

¹Clinical Center of Serbia, Clinic for gynecology and obstetrics, Belgrade, Serbia
²University of Belgrade School of medicine, Institute of social medicine, Belgrade, Serbia

Aims

Current FIGO definition of microinvasive cervical cancer (MICC) from 1994, limits stages IA1 and IA2 to 3 and >3<5 mm of invasion, respectively. Treatment options have greatly varied and changed within this period, new techniques have evolved, and the data of case series and reviews are becoming more available. Our study reviews the pathology in 159 cases in both stages of MICC primarily focusing on the possible spread of the disease beyond cervix and the spread pathways.

Method

Retrospective study of patients primarily treated for MICC where pathology review excluded over 100 due to missing data and primary pathology not complying with up to date standards, leaving 159 cases to review fulfilling all the criteria for MICC, including the „third dimension” measure not exceeding 7 mm. Most of the excluded patients would have had to be staged as small IB1 on the basis of requirements of our pathology review.

Results

Of 159 reviewed pathologies 126 were stage IA1 and 33 IA2. Most frequent surgical treatment was radical hysterectomy, followed by simple hysterectomy and cone biopsy. LVSI in 12 patients and invasion to the middle third in one patient were registered. Pelvic nodes were found positive in 2 patients, both with LVSI, whilst parametrial invasion was not found in analyzed group. Positive pelvic nodes correlate with LVSI and deeper stromal invasion.

Conclusion

Despite current surgical treatment standard of modified radical hysterectomy or radical trachelectomy for stage IA2 patients it seems like an unnecessary procedure leading to over treatment of patients with possible complications.

BOWEL-, BLADDER- AND SEXUAL FUNCTION AFTER ROBOTIC ASSISTED RADICAL HYSTERECTOMY FOR EARLY STAGE CERVICAL CANCER- A ONE YEAR PROSPECTIVE STUDY

E. Wallin1, K. Bergmark2, H. Falconer1, A. Flöter Rädestad1
1Karolinska Institute, Dep of Women’s and Children’s Health, Stockholm, Sweden
2Oncology and Pathology, Oncology Salgrenska Academy, Gothenburg, Sweden

Aims

To prospectively assess the impact of robot-assisted laparoscopic radical hysterectomy (RRH) for early stage cervical cancer on sexual-, bowel-, bladder and lymphatic function. Further to investigate the impact of RRH on androgen levels and ovarian reserve.

Method

Women consecutively scheduled for RRH during 2011-2013 were included in the study. Participants answered a validated questionnaire regarding psychological well-being, sexual-, bladder-, bowel-function and lymphoedema at baseline and one year after treatment. At the same time, serum samples for sex hormones and anti-Müllerian hormone were measured.

Results

50 women were included in the study and 32 were eligible for analysis one year after surgery. Six women needed adjuvant treatment. Vitality, anxiety and depression deteriorated in 50-60% of the women. Further, a significant proportion of the women treated with surgery alone (n=26) reported distress of sexual function including shortness and numbness of the vagina and deep dyspareunia. Lymphoedema was reported by 50% and micturition problems by 32% of the women. Sexual arousal and orgasm were significantly impaired among women receiving adjuvant treatment. FSH and LH levels were significantly increased and AMH decreased one year after surgery in women <45 years with preserved ovaries.

Conclusion

RRH is associated with sexual distress as well as micturition problems, lymphoedema and affects the ovarian function. Adjuvant treatment worsens the situation. Identifying women with impaired sexual and natural functions after RRH is important in order to provide adequate counseling and treatment. Patient reported experience measures should be incorporated in the follow-up after RRH for cervical cancer.

MICRORNA-221-3P, A TWIST2 TARGET, PROMOTES CERVICAL CANCER METASTASIS BY DIRECTLY TARGETING THBS2

W. Wang1, W.F. Wei2, C.F. Zhou1, L.N. He3

1Nanfang Hospital- Southern Medical University, Department of Obstetrics and Gynecology, Guangzhou, China
2Nanfang Hospital- Southern Medical University, Department of Obstetrics and Gynecology, Guangzhou, China
3Zigong First People’s Hospital, Department of Obstetrics and Gynecology, Sichuan, China

Aims

MicroRNAs (miRNAs) have been implicated in the relapse and metastasis of cervical cancer (CC), which is the leading cause of CC-related mortality. But the underlying molecular mechanisms need to be further elucidated.

Method

MiRNAs microarray analyzed abnormal expression of miRNAs in CC with lymph node metastasis (LNM) or SiHa-tw2 cells. qRT-PCR, in situ hybridization (ISH) were used to study the expression of miRNAs. Western blot detected the expression of EMT markers. Transwell and wound healing assays were used to evaluate the invasion and migration abilities of cells, respectively. Subsequently, we established in vivo models to show the function of promoting LNM of miR-221-3p. Bioinformatics predicted the upstream transcription factors and the putative targets of miR-221-3p. Luciferase reporter assays determined the association between miR-221-3p and the THBS2 3'untranslated region, and TWIST2 and the miR-221-3p promoter.

Results

The level of miR-221-3p was significantly increased in CC tissues with LNM and SiHa-tw2 cells. Increased expression of miR-221-3p promoted CC cells migration and invasion in vitro, and LNM in spontaneous metastasis model. TWIST2 bound to the promoter of miR-221-3p and activated its transcription. Inhibitors of miR-221-3p drastically decreased the induction of EMT mediated by TWIST2. ISH or immunohistochemical staining in serial tissue sections of CC showed that miR-221-3p is positively correlated with TWIST2. By bioinformatics and dual-luciferase reporter assay, THBS2 was recognized to be an important target gene of miR-221-3p.

Conclusion

miR-221-3p, which is up-regulated by the transcription factor TWIST2 and targets to down-regulate THBS2 to promote LNM, may constitute a potential therapeutic target in CC.

THE CLINICAL SIGNIFICANCE OF THE CD163+ AND CD68+ TUMOR-ASSOCIATED MACROPHAGES IN HIGH-RISK HPV-RELATED CERVICAL CANCER

W. Wang¹, X. Chen¹, J. Ma¹, L. Han²
¹Nanfang Hospital- Southern Medical University, Department of Obstetrics and Gynecology, Guangzhou, China
²Shanghai First Maternity and Infant Hospital- Tongji University School of Medicine, Department of Minimally Invasive Gynecologic Surgery, Shanghai, China

Aims

Objective. To explore the influence of M2-polarized tumor-associated macrophages (TAMs) on high-risk human papillomavirus (hr-HPV) related cervical carcinogenesis and metastasis.

Method

Methods. CD68+/CD163+ macrophages were examined immunohistochemically in a series of 129 samples, including 26 cases of normal cervical tissues, 59 cases of cervical intraepithelial neoplasia (CIN) and 44 cases of squamous cell carcinoma (SCC). Hr-HPV testing was carried out using the Hybrid Capture 2 assay (HC-II).

Results

Results. High counts of CD68+/CD163+ macrophages were associated with hr-HPV infection (both \( p<0.05 \)) and positively correlated with cervical carcinogenesis (Spearman’s rho=0.478, \( p=0.000 \); Spearman’s rho=0.676, \( p=0.000 \), respectively). The immunostaining pattern of CD163 exhibited cleaner background compared with CD68. Notably, a high index of CD163+ macrophages is significantly associated with higher FIGO stages and lymph node metastasis (\( p=0.009, p=0.007 \), respectively), while CD68+ macrophages not (\( p=0.101, p=0.070 \), respectively).

Conclusion

Conclusions. Our study supported a critical role of TAMs as a prospective predictor for hr-HPV-related cervical carcinogenesis. CD163, as a promising TAMs marker, is superior to CD68 for predicting the malignant transformation and metastatic potential of cervical cancer.

ESGO-0751

IS CLINICAL STAGING OF CERVICAL CANCER STILL BETTER THAN IMAGING?
P. Widschwendter1, N. DeGregorio1, J. Wolfgang1, S. Christoph1, B. Emanuel1, F. Thomas1
1Medical University, Obstetrics and Gynecology, Ulm, Germany

Aims

Cervical cancer is still staged by clinical examination following the International Federation of Gynecology and Obstetrics (FIGO) classification. Computed tomography (CT) and magnetic resonance imaging (MRI) show different accuracy in predicting the correct stage of disease compared to clinical examination.

Method

We retrospectively analysed patients with operable cervical cancer treated at the Department of Obstetrics and Gynaecology of the University Hospital Ulm from 2000-2012. All included patients (n = 206) had a clinical pelvic examination; in addition, 57 patients had a CT scan, 26 patients had MRI, and 61 patients had both a CT and MRI. Surgicopathological findings were used as the reference for evaluation of diagnostic performance.

Results

To evaluate diagnostic efficacy with respect to detection of parametrial involvement, patients were divided into those with histopathological confirmed stage IIA or less disease (n = 133; 64.6%) and those with stage IIB or higher disease (n = 73; 35.4%). The diagnostic accuracy (percentage correctly classified) was 73.3%, 67.3% and 56.0% for clinical staging, CT, and MRI, respectively. Sensitivity and specificity were 47.9% and 87.2% for clinical staging, 42.9% and 84.7% for CT, and 35.0% and 75.0% for MRI. Positive and negative predictive values were 67.3% and 75.3% for clinical staging, 66.7% and 67.6% for CT, and 56.0% and 55.9% for MRI.

Conclusion

Clinical examination showed better diagnostic features than both CT and MRI for presurgical evaluation of early invasive cervical cancer.

ONCOLOGICAL AND OBSTETRIC OUTCOME OF ABDOMINAL RADICAL TRACHELECTOMY (ART): AN UPDATED SERIES OF CERVICAL CANCER FROM A 13-YEAR EXPERIENCE

X. Wu¹, J. Li², X. Li³
¹Fudan University Shanghai Cancer Center, Dept. Gynecologic Oncology, Shanghai, China

Aims

To update the oncological and obstetric outcome of our study on ART for young patients with cervical cancer.

Method

We conducted a retrospective review of a prospectively maintained database of patients undergoing ART for cervical cancer at our institution from 04/2004 to 12/2016.

Results

Three hundred and forty-eight cases were planned for ART. Among 310 patients who successfully underwent ART, 47 had IA1 disease (with positive margin or LVSI), 27 had IA2 and 236 IB1 (123 had tumor ≥2 cm). Histology included 46 with adenocarcinoma, 256 squamous and 8 adenosquamous carcinoma. With a median follow-up of 48 months, 10 patients recurred and 3 died. For patients with tumors ≥2 cm, 6 recurred and 3 died. The 5-year RFS and OS were 96.7% and 99%, respectively. Tumor size ≥2 cm and adenosquamous carcinoma impact RFS significantly on univariate analysis. On multivariate analysis, however, only adenosquamous carcinoma retained independent predictive value. Among 103 patients who attempted to get pregnant, 21 succeeded with 23 pregnancies. Assisted reproductive technology was utilized more often recently with a success rate of approximate 60%.

Conclusion

Recurrent cases accumulated as the follow-up getting longer. However, with recurrent rate of 3.3% and 5-year OS of 99%, ART still seems to be a reasonable option for selected patients with larger tumor. Adenosquamous carcinoma may have intrinsic risk for recurrence. The unsatisfactory obstetric outcome was largely attributed by the proportion of patients who did not attempt to conceive. Assisted reproduction technology was utilized to improve obstetric outcomes.

NEoadjuvant Chemotherapy (NACT) and Abdominal Radical Trachelectomy (ART) for Stage IB1 Cervical Cancer with Tumor Size ≥2cm: Preliminary Results from Chinese Patients

X. Wu¹, J. Li¹
¹Fudan University Shanghai Cancer Center, Dept. Gynecologic Oncology, Shanghai, China

Aims

To assess the effectiveness of NACT and ART for IB1 cervical cancer with tumor size ≥2cm

Method

From April 2016 to March 2017, all patients with IB1 cervical cancer whose tumor ≥2 cm and fit the inclusion criteria for ART were considered for this study. Laparoscopic lymphadenectomy was performed before NACT to rule out lymph node metastasis. Three courses with cisplatin 50mg/m², paclitaxel 135 mg/m² were followed by ART, and 3 more cycles after surgery.

Results

Seven young women considered eligible for ART were included. Median age was 30 years and tumor size before treatment was 31.4 mm. One (14.3%) had positive lymph node confirmed by frozen section during laparoscopic lymphadenectomy and converted to hysterectomy, although her PET-CT showed no suspicious lymph node before surgery. Adenocarcinoma was present in 1 (14.3%) and squamous carcinoma in 6 (85.7%). Pathological microinvasive residual tumor was observed in 2 cases, and 3 patients had tumor less than 2cm by final pathology. After a median follow-up of 7.1 months no relapses were observed. No patients had ever attempted to conceive.

Conclusion

Preliminary results from our data didn’t suggest a perfect pathological response although the regimen was well tolerated. We are now planning a further study with dose-dense regimen, to explore more effective pre-surgery treatment for reducing the tumor volume and performing less radical surgery.
HPV INFECTION VERSUS VAGINAL INTRAEPITHELIAL NEOPLASIA AND CERVICAL STUMP CANCER IN WOMEN RECEIVED SUBTOTAL HysterECTOMY

Z. Xi¹, ¹
¹Sichuan University, Gynecology Oncology, Chengdu, China

Aims

To retrospectively report series cases of patients received subtotal hysterectomy, evaluate their relationship with human papillomavirus (HPV) infections and vaginal intraepithelial neoplasia (VAIN) or cervical stump cancer.

Method

We retrospected and analyzed the data of patients with cervical cancer or cervical stump cancer in the West China Second University Hospital, Sichuan University (the largest women hospital in the western of China) from 2005 to 2015.

Results

There were 9481 patients received subtotal hysterectomy in our hospital and 3218 losing following-up. Among the rest 6263, there were 1071 got HPV infections (mean HC II value of 124.3), HPV-16, HPV-18, HPV-58 were the most common types. And 311 with grade I of vaginal intraepithelial neoplasia (VAIN), 108 with VAIN II, 89 with VAIN III and 61 occurred with cervical stump cancer. Fifty-six among the 61 suffered cervical stump HPV infections after the subtotal hysterectomy with a mean HC II value of 483.18. The interval time between subtotal hysterectomy and stump cancer was 8.89 years. Women with HPV positive versus negative results had non-benign cytology 77.2% versus 28.3% (p<0.001).

Conclusion

Among the patients who received subtotal hysterectomy, there are strong relationships between HPV infection and VAIN or cervical stump cancer. With gynecologic surgeons more experienced and operation technology progressed, it is significant to weigh the necessity to operate subtotal hysterectomy against the risk of cervical stump cancer. If the operation cannot be avoided, further HPV and cervical stump cancer screening is mandatory.

ESGO7-0829

OVARIAN PRESERVATION IS ASSOCIATED WITH BETTER SURVIVAL IN YOUNG PATIENTS WITH T1N0M0 CERVICAL ADENOCARCINOMA: A SEER-BASED STUDY

X. Tang¹, H. Xu¹, J. Qiu¹, X. Zhang¹, J. Ding¹, K. Hua¹

¹Obstetrics and Gynecology Hospital of Fudan University, Department of gynecology, Shanghai, China

Aims

Ovarian preservation is controversial in patients with cervical adenocarcinoma due to the risk of ovarian metastasis. The aim of this study is to evaluate the association of ovarian preservation with survival outcomes in young patients with T1N0M0 cervical adenocarcinoma.

Method

Women at 45 years old or younger with T1N0M0 cervical adenocarcinoma from 1988 to 2013 recorded in the Surveillance, Epidemiology, and End Results (SEER) Database who underwent hysterectomy were included. Propensity score weighting was used to balance the intragroup differences in baseline demographic and clinical characteristics. Cause-specific survival (CSS) and overall survival (OS) were compared through Kaplan-Meier estimates. Multivariate cox model was used to adjust for covariates including propensity score.

Results

A total of 1368 patients with T1N0M0 cervical adenocarcinoma, including 1090 (79.7%) patients underwent oophorectomy and 278 (20.3%) patients preserved ovaries were identified. Patients who preserved ovaries were younger, with lower T classification and less likely to undergo pelvic lymphadenectomy (all p<0.05). The median follow-up was 89 months for oophorectomy group versus 91 months for ovarian preservation group. In weighting cohort, ovarian preservation group had better CSS (5-year 98.8% versus 97.1%, 10-year 98.0% versus 95.2%, p=0.0370) and OS (5-year 98.8% versus 97.1%, 10-year 96.5% versus 93.5%, p=0.0025). After adjusting for covariates, the CSS benefit of ovarian preservation was marginally significant (p=0.051) and OS benefit was still significant (p=0.006).

Conclusion

Among young women with T1N0M0 cervical adenocarcinoma, ovarian preservation is associated with better survival.

ERBB2 MUTATION: A PROMISING TARGET IN NON-SQUAMOUS CERVICAL CANCER

L. Xiang¹, H. Yang¹, S. ye¹, W. Jiang¹
¹Fudan University Shanghai Cancer Center, Gynecology Oncology, Shanghai, China

Aims

Oncogenic mutations of ERBB2 have emerged as promising therapeutic targets in human cancers, whereas KRAS and PIK3CA mutations are predictors of resistance. ERBB2 mutations have been found in a subset of invasive cervical cancer (ICC). Nevertheless, the prevalence, mutation spectrum, clinicopathological relevance, human papillomavirus (HPV)-genotype association, prognostic significance, and other genetic background information of ERBB2-mutated ICCs have not been well established.

Method

In this study, ICC samples (N=1015) were assessed for mutations in ERBB2, KRAS, and PIK3CA by cDNA-based Sanger sequencing and were measured for HPV genotype by TaqMan fluorescent quantitative PCR. In addition, 157 ICC specimens were examined for HER2 overexpression and amplification by immunohistochemistry and fluorescence in situ hybridization.

Results

Somatic ERBB2 mutations were detected in 3.15% patients. The ERBB2 mutation rate was significantly higher in adenocarcinoma (4.52%, 7/155), adenosquamous carcinoma (7.59%, 6/79) and neuroendocrine carcinoma (10.34%, 3/29) than that in squamous carcinoma (2.14%, 16/749) (P=0.004, Fisher exact test). In addition, 18.75% of the patients carrying ERBB2 mutations concomitantly harbored PIK3CA or KRAS mutations. Patients with ERBB2-mutated ICCs tended to have a worse prognosis than those with wild-type or PIK3CA-mutated ICCs but a better prognosis than those with KRAS-mutated ICCs. The ERBB2 overexpression/amplification rate was 3.82 % in ICCs.

Conclusion

This study provided a promising rationale for the clinical investigation of tyrosine kinase inhibitors for the treatment of cervical cancer with ERBB2 mutations. Patients with non-squamous cell carcinomas have priority as candidates for ERBB2-targeted therapy. Concurrent PIK3CA/RAS mutations should be considered in the design of clinical trials.

A COMPARATIVE STUDY OF THE LAPAROSCOPIC AND OPEN SURGERY IN THE MANAGEMENT OF LOCALLY ADVANCED CERVICAL CANCER

L. Yao¹, L. Yuan¹, Z. Ji¹, M. Chen¹, Z. Wu¹, C. Xu¹
¹Obstetrics and Gynecology Hospital- Fudan University, Department of gynecology, Shanghai, China

Aims

To compare the efficacy and outcomes of laparoscopic surgery in treating patients with locally advanced cervical cancer with open surgery.

Method

Three hundred and four consecutive patients with FIGO stage Ib2 and IIa2 cervical cancer, who underwent either laparoscopic radical hysterectomy (LRH) or abdominal radical hysterectomy (ARH) between 2006 and 2015 in the OB/GYN Hospital of Fudan University, were enrolled in our study. Medical charts and clinical data were retrieved and retrospectively reviewed. The Kaplan-Meier method and Cox regression model were used for survival analysis.

Results

Of all 304 patients, 214 women underwent LRH and the other 90 ones underwent ARH. When compared with ARH, patients in LRH group had less intraoperative blood loss and less surgical complications including bladder fistula, ureteral injury and poor wound healing (P<0.005). Among patients without neoadjuvant chemotherapy, the rate of preoperative ureter stenting was higher in patients underwent LRH than those with ARH (P=0.03), whereas this tendency was not obvious among patients with neoadjuvant chemotherapy (P=0.076). The overall 5-year survival rate in LRH and ARH group was 75.6% and 87.8%, respectively (P>0.05). Multiple Cox regression analysis indicated that only lymph node involvement, but not surgical approach, was the risk factor for overall survival (P<0.05).

Conclusion

Laparoscopic surgery is as effective as open surgery in treating patients with locally advanced cervical cancer. With the advantage of reducing intraoperative blood loss and surgical complications, laparoscopy maybe popularized in developing countries, where there is limited access to radiotherapy but have relatively large population of patients.
PARADOXICAL OUTCOME OF URINARY FUNCTION REHABILITATION IN PATIENTS WITH CERVICAL CANCER FIGO STAGE 1B1 AFTER NERVE–SPARING RADICAL HYSTERECTOMY

J. Yoon¹, B.L. Lee², J.H. Ahn¹, S.I. Kim¹, M.J. Song³, S.J. Lee¹
¹St. Vincent's Hospital- College of Medicine- The Catholic University of Korea, Obstetrics and Gynecology, Suwon-si- Gyeonggi-do, Republic of Korea
²Medinstru cooperation, medical instrument development, Yongin-si- Gyenggi-do, Republic of Korea
³Daejeon St. Mary's Hospital - College of Medicine- the Catholic University of Korea- Seoul- Republic of Korea, Obstetrics and Gynecology, Obstetrics and Gynecology, Republic of Korea

Aims

Method

Evaluation of urinary system function in patients with cervical cancer (CC) FIGO stage IB1 has been performed in 2011-2016. The study enrolled 37 patients (average age of 45.3±6.9 years) treated with radical hysterectomy (RH) : 21 patients (group I) underwent RH with sparing of pelvic splanchnic nervous plexus (PSNP), and 16 patients underwent RH without PSNP sparing (group II).

Results

In patients of groups I and II we have evaluated the urinary difficulty (UD). Patients of group I were distributed in 2 subgroups: subgroup A – patients with CC of stage IB1 with laparoscopic RH with PSNP preservation (18 patients), and subgroup B – patients with laparotomic RH (3 patients). Group II was distributed in 2 subgroups: subgroup A – laparoscopic RH without PSNP preservation (3 patients), and subgroup B – laparotomic RH without PSNP preservation (13 patients). Removal of urinary catheter in group IA and IB was performed on days 3-7, with 5-13 bed-days. There is no significant difference between 2 subgroups. Removal of catheter in group IIA and IIB was performed on days 3-5, with 7-20 bed-days. There is no significant difference between 2 subgroups. But, There is unexpected difference between group I and II.

Conclusion

Removal of urinary catheter in group II was performed on days 3-5, while in group I on days 3-7, which showed the paradoxical outcome. We postulated the possibility of neuropraxia caused by PSNP sparing procedure might induce transient neurogenic bladder.

THE STUDY OF THE POSTOPERATIVE FERTILITY AND SEXUAL FUNCTION AFTER LEEP TREATING HIGH-GRADE SQUAMOUS INTRAEPITHELIAL LESION

M. Yu¹, J. Ding¹, K. Hua¹
¹Obstetrics and Gynecology Hospital of Fudan University, Gynecology, Shanghai, China

Aims

This study was designed to investigate the postoperative fertility and sexual function after LEEP.

Method

Patients with high-grade squamous intraepithelial lesion who were treated with LEEP from 11 obstetrics and gynecology hospitals were enrolled in the study. The clinical and follow-up data were collected.

Results

Twenty-seven of the 125 patients who had live birth after LEEP were preterm birth. The risk of preterm birth was significantly increased in the conization group (RR 2.634, 95% CI 1.689-4.108). With the increase of the depth and volume of conization, the risk of premature births increased gradually. The premature births happened mostly at the 32-36 weeks. But the incidence of the premature birth at the 20-28 gestational weeks also increased after LEEP. The risk of cesarean section (RR 1.667, 95% CI 0.598-4.644) was not increased significantly (P = 0.220). The weights of the neonates were significantly lower than that of the control group (P <0.001). With the increase of volume and depth of conization, the risk of newborns with low birth weight increased. With the increase of the depth and volume of the conization, the pain of postoperative sexual intercourse gradually increased, and the scores of sexual function reduced.

Conclusion

LEEP increase the risk of preterm birth and low birth weight infants. The scores of sexual function decreases with the increase of depth and volume of conization.
ARE WE APPROPRIATELY SELECTING THERAPY FOR FIGO STAGE IIB CERVICAL CANCER PATIENTS? —— A 10-YEAR RETROSPECTIVE STUDY OF A SINGLE CHINESE CENTER

L. Yuan¹, J. Guo¹, M. Chen¹, Z. Wu¹, C. Xu¹, L. Yao¹
¹Obstetrics and Gynecology Hospital- Fudan University, Department of gynecology, Shanghai, China

Aims

Standard care in NCCN guidelines for FIGO IIB is definitive chemoradiation. However in developing countries, where there is limited access to radiotherapy, locally advanced cervical cancer may be treated with a combination of radical hysterectomy and adjuvant chemoradiotherapy. The aim of this study was to evaluate the feasibility and outcomes of patients with FIGO stage IIB cervical cancer who received surgery.

Method

Seventy-four women with FIGO stage IIB were treated with radical hysterectomy, with or without adjuvant radio/chemoradiotherapy, in the OB/GYN Hospital of Fudan University between 2004 and 2015. Medical charts and clinical data were retrieved and retrospectively reviewed. The Kaplan-Meier method and the Cox regression model were used for survival analysis.

Results

The percentage of patients with pathologically verified parametrial involvement was only 28.3% (21/74). Although the usage of imaging technology including MRI/PET-CT was increased after 2010 compared to prior to 2010, the accuracy of MRI/PET-CT in detecting parametrial involvement was lower than physical examination with intravenous anesthesia (P<0.05). Surgical complications were found in 6.8% (5/74) including bladder fistula, intestinal obstruction and ureteral injury. The 2 and 5-year overall survival rate was 84.1% and 68.9%, respectively. Cox regression analysis indicated that common iliac lymph node involvement, pathological parametrial involvement and intra-operative complications were risk factors for overall survival (p=0.025, 0.023, 0.031).

Conclusion

Surgery in FIGO stage IIB is safe and feasible. As pre- and after-operative accordance rate of parametrial involvement is relatively low, how to appropriately select patients who will benefit from surgery via pretreatment evaluation needs to be further studied.

DOES SIZE MATTER? MICROSCOPIC VERSUS GROSS TUMOR IN STAGE IB1 CERVICAL CANCER TREATED WITH RADICAL HYSTERECTOMY: IS THERE A DIFFERENCE?
N. Zhou¹, A. Palileo², S.S. Tedjarati¹, Y.C. Lee², T.S. Pradhan¹
¹Westchester Medical Center, Obstetrics and Gynecology, Hawthorne, USA
²SUNY Downstate Medical Center, Obstetrics and Gynecology, New York, USA

Aims

There is ongoing debate regarding the extent of radical dissection for stage IB1 cervical cancer. However, limited data exists regarding microscopic versus gross tumor presentation. This study compares pathologic outcomes of microscopic and gross stage IB1 cervical cancer in patients undergoing primary Type 3 radical hysterectomy (RH) at two large U.S. academic medical centers.

Method

All patients (1995-2017) with stage IB1 cervix cancer undergoing RH with pelvic lymphadenectomy were retrospectively analyzed using clinical and pathologic data. Pathology slides were reviewed by gynecologic pathologists. Squamous cell, adenocarcinoma, and adenosquamous carcinoma were included. Mann-Whitney U test was used to define age differences. Chi-squared test was utilized to calculate differences in pathologic variables with two-tailed p<.05 considered statistically significant.

Results

A total of 71 patients were identified, 60 met inclusion criteria. Mean age at diagnosis in the microscopic vs gross tumor cohort was 51.1 vs 49.5, p = .20. For microscopic confirmation of IB1 disease, 22 of 33 patients (67%) underwent cone biopsy or LEEP prior to RH.

</table>

Conclusion

Though limited by low numbers, no parametrial invasion was seen in the microscopic cohort. According to our analysis, microscopic and gross IB1 have similar incidences of intermediate and high-risk features, affirming FIGO staging criteria. Further studies are warranted to better individualize treatment according to tumor burden to lessen treatment related adverse effects without compromising clinical outcomes.

REDUCING THE NUMBER OF CONE BIOPSIES IN 10-YEAR PERIOD BY ACHIEVING THERAPEUTIC EFFECT WITH PUNCH BIOPSIES OF TARGET LESIONS

G. Zovko¹, V. Kukura², V. Madžarac¹
¹University Hospital Merkur, Obstetric and Gynecology, Zagreb, Croatia
²University Hospital Merkur, Obstetrics and Gynecology, Zagreb, Croatia

Aims

The aim of this study was to evaluate outcomes after conservative management of precancerous lesions of cervix in 10 year period.

Method

Cone biopsy after biopsy of target lesions in selected cases were replaced with cytology and colposcopy examinations every six months. Initial pathohistological findings were compared with findings during follow up to see whether there was a progression, persistance or regression of lesions.

Results

A total number of 786 patients with HSIL cytological findings were included in study. In first 5 year period between 2002 and 2006, cone biopsies were performed in 264 out of 450 patients. In a second five year period from 2007 to 2012 selected cases were managed conservatively with reduction in number of cone biopsy procedures, 50 out of 336 patients. During 5 year follow up in first group there was a 4% progression rate. However in a group managed conservatively there were no cases with progression of findings.

Conclusion

Due to continuous development of team work and acquisition of the diagnostic equipment of higher quality, with mentioned conservative approach we were able to significantly reduce number of conisations, as well as the number of patients with progression to higher grade lesions in ten year period.
CAN TUMOR MARKERS HE4 AND CA125 BE USEFUL IN DIFFERENTIATION OF DIFFERENT STAGES OF INTRAPELVIC ENDOMETRIOSIS?

N. Abdalla¹, R. Piorkowski¹, A. Timorek¹, P. Stanirowski¹, K. Cendrowski¹, W. Sawicki¹
¹Medical University of Warsaw, Chair and Department of Obstetrics- Gynecology and Oncology, Warsaw, Poland

Aims

Aim of the study was to compare serum level of tumor markers HE4 and CA125 between different stages of intra-pelvic endometriosis.

Method

A total of 52 patients were included in the retrospective study. Serum level of tumor markers was measured for each patient before surgical intervention. Staging of endometriosis was done intraoperatively according to revised American society for reproductive medicine classification of endometriosis.

Results

The mean of age of patients was 37.73 (SD 8.84) years. The number of patients with stage I, II, III and IV was 2 (3.85%), 1 (1.92%), 24 (46.15%) and 25 (48.08%), respectively. The results of serum level of HE4 and CA125 for comparing different stages of endometriosis is presented in table 1 and 2 respectively.

Table 1. Results of serum level of HE4 (pmol/L).

PRIMARY HPV-BASED SELF-SAMPLING SCREENING WITH THE COBAS® HPV TEST FOR UNDERSERVED GREEK WOMEN. PRELIMINARY RESULTS OF THE GRECOSELF STUDY

1Aristotle University of Thessaloniki- Hippokratio General Hospital, 4th Department of Obstetrics and Gynecology, Thessaloniki, Greece
2Aristotle University of Thessaloniki- Hippokratio General Hospital, 2nd Department of Obstetrics and Gynecology, Thessaloniki, Greece
3Centre for Research & Technology - Hellas, Institute of Applied Biosciences, Thessaloniki, Greece
4Hippokratio General Hospital, Department of Neonatology, Thessaloniki, Greece
5PEDY, 25th Martiou, Thessaloniki, Greece
6Hippokratio General Hospital, Laboratory of Cytology, Thessaloniki, Greece
7Hippokratio General Hospital, Department of Histopathology, Thessaloniki, Greece

Aims

To assess the performance of self-sampling HPV-based screening in underserved Greek women, in comparison to historical real-life cytology-based screening results, and the acceptability of the Roche® self-collection cervicovaginal specimen device.

Method

Women (sample size n=12,700) 25-60 years old, residing in rural Greek areas, are contacted by midwives, via public announcement, and are provided, after written informed consent, with a self-sampling kit (Roche®). After sampling each woman fills in a questionnaire designed to assess cervical cancer screening participation and outcome history during the last 10 years, and the acceptance of the self-sampling procedure. Samples are tested using the cobas® HPV Test, Roche®, which detects HPVs 16 and 18 separately, and HPVs 31,33,35,39,45,51,52,56,58,59,66 and 68 as a pooled result. HPV-positive women are referred for colposcopy. In case of Cervical Intraepithelial Neoplasia (CIN) grade 1 or 2 or worse (CIN2+) they are referred to follow up or appropriate treatment respectively.

Results

Between May 2016 and April 2017 7,143 samples were collected, 6,456 were tested, of which 489 (7.6%) were HPV-positive, 249 colposcopies were performed and CIN 1, 2 and 3 was detected in 21, 12, and 10 cases respectively. There was a case of vaginal intraepithelial neoplasia and a case of cervical adenocarcinoma. The prevalence of high-grade disease or cancer among HPV-positive women examined was 9.6%.

Conclusion

The preliminary report of the GRECOSELF study shows that HPV-testing with individual HPV16/18 genotyping on self-collected cervicovaginal samples is a feasible and effective cervical cancer prevention method for Greek women residing in rural distant areas.

INFLUENCE OF AGE ON HISTOLOGIC OUTCOME OF CERVICAL INTRAEPITHELIAL NEOPLASIA: RESULTS FROM A LARGE COHORT, SYSTEMATIC REVIEW AND META-ANALYSIS

C. Bekos1, C. Grimm2, E. Joura3, R. Horvat3, A. Reinthaller2, S. Polterauer2

1AKH Wien, Department of General Gynaecology and Gynaecological Oncology, Vienna, Austria
2Medical University Vienna, Department of Obstetrics and Gynecology - Division of General Gynecology and Gynecologic Oncology, Vienna, Austria
3Medical University Vienna, Department of Pathology, Vienna, Austria

Aims

Age is one of the crucial factors influencing the natural history of cervical intraepithelial neoplasia (CIN). Aim of this study was to investigate the histologic outcome of CIN during observational management in young women.

Method

This analysis included 783 women presenting with CIN at our outpatient clinic between 2006 and 2010. At least one colposcopically guided biopsy (CGB) for histologic diagnosis had to be obtained and observational management for at least three months was mandatory. The histologic findings of initial and follow-up visits were collected and rates of persistence, progression and regression were assessed. Uni- and multivariate analyses were performed. In addition, a systematic review of the literature and meta-analysis of published data was performed.

Results

In our cohort CIN I, II, and III was diagnosed by CGB in 42.5%, 26.6% and 30.9%, respectively. Younger patients had higher rates of regression (p<0.001) and complete remission (<0.001) and lower rates of CIN progression (p=0.003). Among women aged <25, 25<30, 30<35, 35<40, and >40 years, regression rates were 44.7%, 33.7%, 30.9%, 27.3%, and 24.9%, respectively. Pooled analysis of published data showed similar results. Multivariable analysis showed that with each five years of age, the odds for regression reduced by 15% (p<0.001) independently of CIN grade, and presence of HPV high-risk infection.

Conclusion

Patient’s age has a considerable influence on the natural history of CIN – independent of CIN grade and HPV high-risk infection. Observational management should be considered for selected young patients with CIN. Results of this analysis can be useful for patient counselling.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0013

THE ACCURACY OF FROZEN SECTION OF UTERINE LESIONS IN THE PRACTICE OF GYNECOLOGIC SURGERY. A RETROSPECTIVE ASSESSMENT STUDY IN A GOVERNMENT TERTIARY TRAINING HOSPITAL

J. Billod¹, E. Domingo², N. Geraldino³

¹Baguio General Hospital and Medical Centre, Obstetrics and Gynecology- Gynecologic Oncology, Baguio, Philippines
²Philippine General Hospital, Manila, Philippines
³Philippine General Hospital, Pathology, Manila, Philippines

Aims

To determine of accuracy, sensitivity and specificity of frozen section in the diagnosis of uterine neoplasms.

Method

A retrospective validation study from 2004 -2015 involving cases of uterine lesions from Gynecologic surgeries. All histopathologic results of frozen and paraffin sections were retrieved and reviewed.

Chi square test with 2x2 Fischer Exact test adjustment were used to test associations. Accuracy indices of FS tool were estimated such as sensitivity, specificity, likelihood rations, negative and positive predictive values, and overall accuracy.

Results

A total of 143 uterine specimens were submitted for frozen section (FS) diagnosis. The utilization rate of FS is 1% per year. The FS results were associated with the final histopath results with 96% agreement rate. Utilizing a median number of 3 sections per specimen provides an overall accuracy rate of 97%. The accuracy rate of FS is equal between combined benign- premalignant and malignant cases at 96%. The accuracy rate is not statistically affected by the procedure by which the specimen was taken; the source and gross morphology of the specimen. Moreover, a minimum of 11 sections per specimen is needed to arrive at 99-100% accuracy rate. The accuracy rate particularly for endometrial lesions is between 94 and 100 %.

Conclusion

Accuracy rates of frozen section on uterine lesions is high regardless the sampling procedure and source of the specimen. Increasing the number of section during FS parallels that of the final histopathologic diagnosis. FS for uterine lesions is vital and cost- effective intraoperative decision tool to maximize care of patients.

BORDERLINE HIGH RISK-HPV CYTOLOGY: IS OUR BIOPSY RATE SUFFICIENT TO DETECT HIGH-GRADE CIN?

V. Ghirardi1, C. McLaughlin1, N. Bizzarri1, S. Rundle1, R. Naik1, A. Kucukmetin1, N. Ratnavelu1, C. Ang1, A. Fisher1, R.L. O'Donnell1

1Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom

Aims

Patients with borderline cytology and high-risk (HR)-HPV are referred to colposcopy in accordance with British guidelines. Following normal colposcopy, patients should be discharged to routine recall (3 or 5 years), pressuring colposcopists to make long-term management decisions based upon examination alone. Aims of this study were: to determine the incidence of high-grade (HG) CIN (CIN2+) in this population; to determine the incidence of further cytological abnormality; to consider the role of colposcopy directed biopsies.

Method

Retrospective review for all patients with borderline cytology (HR-HPV+) between 04/2013-04/2014. Cytological, colposcopic and histological data were collected including follow-up (FU) cytology from 2013 to 2017.

Results

294/321 (85.8%) patients underwent punch biopsy, of which 40% demonstrated koilocytosis at worst. 1.4% patients underwent see-and-treat loop biopsy for HG-colposcopy appearance. The overall incidence of CIN2+ was 14.8%. The PPV and NPV of colposcopy examination for CIN2+ was 0.61 and 0.88 respectively. The incidence of negative FU cytology in patients with normal colposcopy (no biopsy) was 64.4% and 82.3% in those treated for CIN2+. In patients with low grade colposcopy/koilocytosis at worst on punch biopsy, the incidence of HG-dyskaryosis on FU cytology was 4.4% (but 25% of these did not attend the FU).

Conclusion

Management of women with borderline (HR-HPV+) cytology continues to represent a challenge with clear evidence of a strong commitment to biopsy. Our study demonstrates that colposcopy alone is poor at predicting HG-CIN and single punch biopsy may miss CIN2+. In patients with low grade colposcopy, multiple biopsies are desirable to increase the detection of CIN2+.

NOMOGRAM-BASED PREDICTION OF CERVICAL DYSPLASIA PERSISTENCE / RECURRENCE

G. Bogani1, A. Ditto1, F. Martinelli1, M. Signorelli2, V. Chiappa1, U. Leone Roberto Maggiore1, E. Tagliabue1, L. Domenica1, F. Raspagliesi2

1National Cancer Institute, Gynecologic Oncology, Milan, Italy

Aims

To indentify predictors of cervical dysplasia persistence/recurrence among women undergoing primary conization.

Method

Data of consecutive women undergoing LASER CO2 conization were retrospectively evaluated. The risk of developing cervical dysplasia persistence/recurrence was assessed with Kaplan-Meier and Cox hazard models. Additionally, two nomograms were built to estimate probability of cervical dysplasia persistence/recurrence: the first based on baseline and operative parameters and the second focusing on type-specific HPV detected. The performance of the above nomograms was assessed using concordance index (c-index).

Results

Overall, 2680 patients were included. After a mean (SD) follow-up of 47.7 (±20.7) months, 149 (5.5%) patients required secondary conization. Via multivariate analysis, HIV infection (HR: 8.22 (95%CI. 3.81, 17.7); p<0.001), positive margins (HR: 10.1 (95%CI: 5.73, 17.8); p<0.001) and persistence of HPV (HR: 11.4 (95%CI: 7.94, 16.49); p<0.001) correlated with CIN2+ persistence/recurrence. The importance of those variables was corroborated by our first nomogram (Figure). The second nomogram suggested the impact of type-specific HPV infection in predicting cervical dysplasia recurrence. HPV16, 33, 35 and 45 were the most common HPV types associated with cervical dysplasia persistence/recurrence. The c-index was 0.73 for both nomograms, thus suggesting the reproducibility of our models.

Conclusion

No other nomogram estimated the risk of developing cervical dysplasia persistence/recurrence is still published. We developed the first two nomograms predicting this risk. Although the large sample size and the high performance of our nomograms, external validation of our data is needed. Once validated our data might be useful to plan a tailored postoperative surveillance of women having conization.
Aims

Ovarian cancer is the most common type and lethal of gynecological malignancy. Distinguish between benign and malignant ovarian masses is very important to refer patients to centers with experience in the surgical. The aim of this study was to investigate the validity of the risk ovarian malignancy algorithm (ROMA) in ovarian mass.

Method

One-hundred patients who had been diagnosed with ovarian masses were assessed for the tumor markers CA125, and the ROMA. The sensitivity and specificity of each parameter were calculated using receiver operating characteristic curves according to the area under the curve (AUC) for each method.

Results

The median CA125, and ROMA serum levels had different significant between benign and malignant tumors in the overall assessment (P<0.001). The areas under the curve (AUC) were 0.83(CA125), and0.92 (ROMA) for benign vs malignant tumors in whole patients. The ROC curves were compared using a pairwise comparison method, and no differences were detected between the CA125, and ROMA. At specificity 75 percent, sensitivity was 64.7 for CA125, 82.4 ROMA generally.

Conclusion

The results based on the area under the curve markers of CA125 and ROMA show that ROMA had the best accuracy of AUC-ROC than CA125 in all patients and each group pre- and post- menopausal patients.

PREDICTORS OF CANCER PRECURSOR LESIONS IN BRCA MUTATION CARRIERS UNDERGOING RISK-REDUCING SALPINGO-OOPHORECTOMY

M. Bradbury¹, S. Cabrera², A. Garcia³, J.L. Sanchez-Iglesias², A. Perez-Benavente², A. Gil-Moreno², A. Santamaria¹, J. de la Torre²

¹Vall d’Hebron Research Institute, Gynaecological Oncology, Barcelona, Spain
²Vall d’Hebron University Hospital, Gynaecological Oncology, Barcelona, Spain
³Vall d’Hebron University Hospital, Pathology, Barcelona, Spain

Aims

BRCA1/2 mutation carriers are at increased risk of developing ovarian carcinoma arising from precursor lesions in the tubal epithelium (p53 signature/STIL/STIC lesions). Risk-reducing salpingo-oophorectomy (RRSO) is still recommended between the age of 35-40 years. We aimed to analyse the presence of preinvasive lesions in BRCA1/2 mutation carriers undergoing RRSO and associated clinical predictors.

Method

Retrospective study of BRCA1/2 mutation carriers undergoing RRSO at the Vall d’Hebron Hospital over a seven year-period. Data was collected on women’s age at RRSO, parity, personal history of breast cancer, CA125 levels, TVUS results and final histology. All tubes/ovaries were assessed using the SEE-FIM protocol.

Results

Out of 133 women undergoing RRSO, 73(55%) had a BRCA1 mutation and 60(45%) BRCA2. The median age was 46 years (range 35-70) and CA125 levels 10.8 U/mL (2.6-48). Twenty-five women were nulliparous (19%) and eighty (60%) had a personal history of breast cancer. Four women had a simple cyst on TVUS. Final histology confirmed p53 signature/STIL lesions in 10 women (7.5%) and one was diagnosed with invasive carcinoma. Multivariate analyses showed a positive correlation between age over 50 years [OR 4.46 (95%CI 1.12-17.6); p=0.033] and abnormal TVUS [OR 13.03 (95%CI 1.39-121); p=0.024] with the presence of preinvasive lesions.

Conclusion

About 8% of BRCA1/2 mutation carriers will have a preinvasive lesion at the time of RRSO and this risk significantly increased in women over 50 years. This suggests that the identification of new markers that predict the development of precursor lesions may help us in the future to defer RRSO when possible. Thus, efforts and future research should be devoted in this direction.
INCIDENCE AND COSTS OF CERVICAL INTRAEPITHELIAL NEOPLASIA IN THE KOREAN POPULATION
S.W. Byun¹, H.K. Chang², T.C. Park¹, J.H. Kim¹
¹Uijeongbu St Mary's hospital - Catholic University Medical College, obstetrics and gynecology, Uijeongbu-si- Gyeonggi-do, Republic of Korea
²National Cancer Center Korea, obstetrics and gynecology, Goyang-si Gyeonggi-do, Republic of Korea

Aims

we aim to identify differences in the incidence of CIN(Cervical intraepithelial neoplasia) and its medical costs, with respect to age. A 5 years retrospective study was conducted using data collected on cervical cancer, from 2010 till end of 2014

Method

These cases were procured from the database of the Health Insurance Review and Assessment Service (HIRA), and included both high grade-CIN(Cervical intraepithelial neoplasia grade 3) and low grade-CIN (cervical intraepithelial neoplasia grade 1 or 2). Evaluation was done using the Standardized Disease Classification Code and the Standardized Medical Treatment Code.

Results

the crude rates of cervical cancer and high grade-CIN are reducing with passage of time, whereas low grade-CIN is getting significantly higher ($p$ for trend<0.001). Incidence of Low grade-CIN showed an increasing trend in all age groups. The crude incidence of Low grade-CIN had increased by approximately 30% compared to 5 years ago. High grade-CIN showed a significantly increasing trend in individuals of age group 35-39 years. The incidence of Cervical cancer was significantly reduced in all ages, except the 35-39 year olds age bracket. Cervical cancer is associated with high health care costs. The treatment of cervical cancer requires $3,342 per year, whereas treatment of High grade-CIN and low grade-CIN requires $467 and $83 per year, respectively.

Conclusion

Although the incidence of cervical cancer shows a decreasing trend over time, the rate of high grade-CIN and cervical cancer is increasing among the younger generation between 30 to 40 years old in Korea.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-1356

USUAL VULVAR INTRAEPITHELIAL NEOPLASIA. AN ENTITY IN WHICH TO THINK.
S. Carballo Rastrilla¹, A. Lubrano Rosales², N.F. Medina Ramos¹, M. Andújar Sánchez³, L. León Arencibia⁴, O. Arencibia Sánchez², M. Esparza Martín⁴, V. Benito Reyes²
¹Complejo Hospitalario Universitario Insular Materno Infantil, Patología del Tracto Genital Inferior, Las Palmas de Gran Canaria, Spain
²Complejo Hospitalario Universitario Insular Materno Infantil, Ginecología Oncológica, Las Palmas de Gran Canaria, Spain
³Complejo Hospitalario Universitario Insular Materno Infantil, Anatomía Patológica, Las Palmas de Gran Canaria, Spain
⁴Complejo Hospitalario Universitario Insular Materno Infantil, Ginecología y Obstetricia, Las Palmas de Gran Canaria, Spain

Aims

ISSVD recognizes in 2015, only uVIN and dVIN, (VIN II-III before), advising to avoid the term VIN I since it is not considered a precursor of vulvar cancer.
Know the incidence in our population and the characteristics of it.

Method

67 cases 18 VIN I, 48 uVIN and 1dVIN.

Results

Mean of 3.76 cases/year[1-13], with gradual increase.
Mean age 47.9 years [22-93], smokers58.3%, 33.3% menopausal, 5(10.4%) immunosuppression (3HIV+2 inmunosupresor treatment).
22(45.8%) multicentric lesions, a history of vulgar condyloma in 31.2%.
Multifocal lesions 54.2%, and only 41.7% reported any symptoms, pruritus(65%), the most frequent.
The treatments varied from topical(imiquimod), destructive(laser) or excision. Increasing in the last years combined therapies.
12cases of relapses(25%), without significant relation with other variables, multifocality was the factor that most touched the significance but did not reach it(p = 0.089).
Regarding cases of vulvar neoplasia, 4(8.3%) carcinomas hidden in lesions biopsies previously as uVIN. Only age 46 vs 67 years was found(p = 0.007).

Conclusion

Increased diagnoses is probably due to the greater sensitivity of the professionals during the physical examination, most of them asymptomatic, and to a broader knowledge
Immunosuppression plays an important role in the recurrence and progression of uVIN although we do not find any relation in our series.
In the future we should find an impact in the reduction of these cases in vaccinated patients, but the absence of screening and homogenization in the appearance-progression of precursor lesions requires us to pay attention to the physical examination of the vulva.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-1368

ATYPICAL GLANDULAR CELLS, MANY POSSIBILITIES
1. Patología del Tracto Genital Inferior, Las Palmas de Gran Canaria, Spain
2. Ginecología y Obstetricia, Las Palmas de Gran Canaria, Spain
3. Ginecología Oncológica, Las Palmas de Gran Canaria, Spain

Aims

To know the prevalence, the characteristics of our population as well as the definitive diagnosis of women with cytology of ACG screening.

Method

Retrospective descriptive study of database in 2015.

Results

798 patients were seen in the consultation for the first time, of which 55 with a GCA result: 6.9%. Mean age 45.1 years and 30.9% smokers.

Beginning of sexual relations: 18.3 years, number of sexual partners average 6.3.

The mean number of pregnancies was 2.4, with the vaginal route being the most frequent, 1.78. 16 of these patients were menopausal (mean 49.7 years). 26 patients had HPV: 47.3%.

We found that 5 of them had been vaccinations against HPV, but all of them subsequently to have had contact with HPV. None of these patients had a previous history of CIN. 3 cases (5.4%): neoplastic processes, 16 cases (29%) HSIL, 65.6% without pathology.

All patients with cervical cancer were menopausal (p: 0.021), with no other significant relationships. When choosing HSIL variable, we found the presence of HPV and the highest number of sexual partners.

Conclusion

In our study, the prevalence of GCA was slightly higher than that published in the literature.

It can be explained by the wide interobserver variety and the high number of benign situations that simulate glandular alteration. The probability of pathology is high, 34.4% of the total, being for neoplastic processes of 5.4%.

They are a population at high risk of having an underlying pathology, so the assessment in consultation should be made consciously.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-1370

ANALYSIS OF THE MARGINS IN THE CONIZATION PIECE AS A PREDICTOR OF RECURRENCE / PERSISTENCE OF INTRAEPITHELIAL LESION

N. Medina Ramos1, S. Carballo Rastrilla1, V. Benito Reyes2, A. Lubrano Rosales2, O. Arencibia Sánchez2

1. Patología del Tracto Genital Inferior, Las Palmas de Gran Canarias, Spain
2. Ginecología Oncológica, Las Palmas de Gran Canarias, Spain

Aims

Clinical-anatomopathological factors such as margins involvement and HPV test as predictors of relapse/persistence after CIN 2-CIN 3 conization

Method

A retrospective descriptive study of 1,349 patients using Lletz between January 2000-December 2013.

Results

630(46%) are CIN 2 and 719(54%) CIN 3.

Average age = 37 years, 29%nulliparous, 60%smokers, onset of sexual intercourse mean=17 years and a half couples=6.

60% free margins, 35% affected and 5% non-valued, with no difference between endocervical margins (44%), exocervical margins (40%) and affection of both (16%).

Endocervical canal biopsy was positive in 11%.

Patients with CIN 2 had affected margins(27%) versus 41% of CIN 3, p <0.0001, with no difference in margins.

The cases of CIN 3, presented greater affectionation of the channel 14% vs 7% of the CIN 2 p<0.001.

69% of patients with nerve heart disease have a hpv negative test compared to 85% of patients with free margins, p <0.0001.

7% are remitted a second time.

Multivariate analysis: CIN 3 presented OR 1.92 CI (1.5-2.4), P<0.0001 for affected margins than CIN 2. HPV test positive for high OR 10.7, 95% CI(6.6-17.2), P<0.0001, margins affected OR 0.9, 95% CI (0.6-1.5) P=0.9

Conclusion

A result of CIN 3 is more likely to affect both margins and endocervical biopsy. Before performing a second treatment, it is recommended histological confirmation, since in a high percentage with negative HPV. The most potent factor that conditions recurrence/persistence is the persistence of HPV infection.
Aims

Pathologic diagnosis of placental hydatidiform mole is inaccurate and imprecise if based upon histopathology only. We present our 5-year experience using immunohistochemical and genotyping methods in a Placental-Molar Disease diagnostic pathology service.

Method

Starting in 2012, we established a specialist pathology service to assess abnormal villous morphology in missed and therapeutic abortions. In addition to histopathology, pathologists selectively used p57 immunohistochemistry (IHC) and quantitative-fluorescence-PCR-based analysis for microsatellite markers on chromosomes 13, 18, 21, X, and Y—on routine formalin-fixed paraffin-embedded tissues. Final diagnoses reflected IHC and genotyping data. (Table 1)

Results

Within 5 years, we evaluated 443 cases: 161 were from our institution and 282 were consultative referrals from 6 of 10 Canadian provinces. We diagnosed 113 complete mole (CM), 141 partial mole (PM), 189 non-molar abortus (NMA) (Table 2). In cases of CM, p57 IHC confirmed the diagnosis in 97/113 (86%) cases, with a 100% interpretable rate.

Genotyping was informative in 196/243 (81%) of attempts. Rates of non-informative testing due to poor quality DNA or maternal cell contamination were similar in intramural and consultation cases. In Year 1, only 13/46 (28%) PM and NMA were diagnosed by the preferred method due to variability in tissue suitability and pathologist practice. By Year 5, this rate had improved to 68/95 (72%).
Table 2. Placental Molar Disease Service, 2012 to 2016 (N=443 cases)

*Genotyping was attempted in 249/309 (74%) of PM + NMA (see Text).

Conclusion

Molecular placental molar diagnosis by a regional pathology practice can be provided successfully. Barriers to success include: availability/suitability of paraffin blocks, failure to separate maternal and villous tissue, and DNA degradation. These represent opportunities to improve molecular placental-molar diagnosis and obstetrical care.
THE INCIDENCE OF CO-TWIN PREGNANCY INCREASES IN HYDATIDIFORM MOLE CASES

H. Çilgin¹, H. Arpacı²
¹Kafkas University School of Medicine, Department of Obstetrics and Gynecology, Kars, Turkey
²Kafkas University School of Medicine, Obstetrics and Gynecology, Kars, Turkey

Aims

A co-twin may occur alongside either complete or partial hydatidiform mole in one per 20,000–100,000 pregnancies. The study was planned to investigate the incidence of co-twin pregnancy in the patients presenting with Gestational Trophoblastic Disease (GTD).

Method

The present study was conducted in a tertiary center as a prospective study over a period of 3 years. Total 188 cases with GTD were included the study. In addition to co-twin pregnancy all subjects having GTD were evaluated on the basis of their mean age, theca lutein cyst, preeclampsia, hypertroidism, postmolar GTD history, hyperemesis gravidarum, need for chemotherapy, unembryonic pregnancy, blood group and villous structure.

Results

The incidence of co-twin pregnancy accompanying gestational trophoblastic disease was 9% with the mean age of patients being 30.3 years. 80% of all participants had the diagnosis of partial mole. The remaining 20% had the diagnosis of complete mole. Two most common chief complaints at presentation was vaginal bleeding (65.6%) and hypertroism (23.7%). The incidence of hyperemesis was (20%). While the occurrence of theca lutein cyst was 8.7% the incidence of preeclampsia and unembryonic pregnancy were 2.5% and 2.5% respectively. 28.7% of the cases developed postmolar GTD and 11.2% out of the required chemotherapy. Most common blood group of subjects was ARh (+) followed by 0 (+). Histopathological evaluation revealed villous structure formation in 60% of all subjects.

Conclusion

Detection of high co-twin pregnancy rates contrary to expectations suggest that biparental triploid genotype incidence increase in cases with hydatidiform mole.
HIGH-RISK HPV E6/E7 MESSENGER RNA TESTING VERSUS HPV DNA TESTING IN WOMEN WITH SQUAMOUS CELL ABNORMALITIES OF THE UTERINE CERVIX

D. Dabeski1, S. Duvlis2, M. Micevska3, N. Basheska4, A. Dabeski1, V. Antovska1, G. Dimitrov1, M. Trajanova1, I. Krstevska1, B. Pavlovski1

1University Clinic for Gynecology and Obstetrics, Department of Gynecology, Skopje, FYR Macedonia
2Institute of Public Health of Republic of Macedonia, Laboratory of Virology and Molecular Diagnostics, Skopje, FYR Macedonia
3University Clinic for Gynecology and Obstetrics, Laboratory for HPV testing, Skopje, FYR Macedonia
4University Clinic for Radiotherapy and Oncology, Department of Histopathology and Clinical Cytology, Skopje, FYR Macedonia

Aims

The study is performed in order to compare the results of two HPV screening methods: High-risk HPV E6/E7 mRNA and HPV DNA.

Method

Comparative prospective study, conducted in the period for April 2016 to March 2017 at the University Clinics for Gynecology and Obstetrics and Radiotherapy and Oncology in Skopje and Institute of Public Health of Republic of Macedonia of 98 sexually active women, age groups of 20 to 60 years, with squamous cell abnormalities on the cervical cytology. In all 98 women were done: HPV DNA testing, High-risk HPV E6/E7 mRNA testing and colposcopy and directed biopsy with endocervical curettage for histopathological analysis.

Results

Histopathologically, there were: 36.7% non-neoplastic lesions, 20.4% LGSIL cases, 29.6% HGSIL cases and 13.3% invasive squamous cell carcinomas. HPV DNA was found 78.6% of the cases; E6 and E7 transcripts were found in 58.2%. The rates of detection of HPV DNA and E6 and E7 transcripts were 83.3% and 22.2% for cases with non-neoplastic finding; 65.0% and 45.0% for cases with LGSIL; 75.9% and 93.1% for cases with HGSIL and 100% for cases with invasive squamous cell carcinoma. High-risk HPV E6/E7 mRNA testing showed a higher sensitivity than the HPV DNA testing (79.0% and 75.8%), higher specificity (77.8% and 16.7%) and a higher positive predictive value for HGSIL (93.1% and 75.9%) and invasive squamous cell carcinoma (100% and 92.3%).

Conclusion

High-risk HPV E6/E7 mRNA testing could be more powerful then HPV DNA testing for screening and investigation of HGSIL and invasive squamous cell carcinoma.
IMMUNOHISTOCHEMICAL EVALUATION OF IMMUNE RESPONSE AFTER LEEP IN PATIENTS DIAGNOSED WITH HSIL AND THE EFFECT OF THIS RESPONSE ON ERADICATION OF HPV DNA

N.U. Dogan¹, A. Pota¹, G. Erdogan², S. Dogan¹, M. Sakinci¹, M. Ozcan²
¹Akdeniz University School of Medicine, Ob&Gyn, Antalya, Turkey
²Akdeniz University School of Medicine, Pathology, Antalya, Turkey

Aims

The effect of LEEP on HPV eradication in patients undergoing LEEP due to HSIL and role of Toll Like Receptors in the development of immunological response and HPV eradication in patients with LEEP due to HSIL were investigated.

Method

Between February 2016 and December 2016, 30 patients who were admitted to Gynecology Department of Akdeniz University for cytological abnormality and who proved to be HSIL in final pathology were included prospectively. HPV status in sixth month control and immunohistochemical staining of TLR 4, 5, 9 was evaluated in first admission and six month control.

Results

Mean age of patients was 40.6 years and median parity was two. On the LEEP material of patients, seven of them were HPV negative or low-risk HPV type (23.3%) and 23 of them were high-risk HPV type (76.7%). HPV screening results of patients at 6 months; 24 HPV screening was negative (80%) and six was positive (20%). Cervical tissues were stained with TLR 4, 5, 9 kits before LEEP and at 6 months after LEEP. The IHC staining of TLR 4, 5, 9 in two time period (immediately before LEEP and 6 months after LEEP) was comparable. Although not statistically significant, HPV positive patients showed more TLR 5 staining tendency than negative ones. Moreover although not statistically significant, in case of infection with multiple HPV types, there was a trend towards more TLR 4 staining tendency 6 months after LEEP.

Conclusion

HPV eradication increases after LEEP treatment. TLR expression is observed in cervical tissue and cervical intraepithelial carcinogenesis.

ESGO7-0473

LONG-LASTING INCREASED RISK OF HPV-RELATED CARCINOMAS AND PREMALIGNANCIES AFTER CERVICAL INTRAEPITHELIAL NEOPLASIA GRADE 3: A POPULATION-BASED COHORT STUDY

R. Ebisch\textsuperscript{1}, D. Rutten\textsuperscript{1}, J. IntHout\textsuperscript{2}, W. Melchers\textsuperscript{3}, L. Massuer\textsuperscript{1}, J. Bulten\textsuperscript{4}, R. Bekkers\textsuperscript{1}, A. Siebers\textsuperscript{4}

\textsuperscript{1}Radboud university medical center, Obstetrics and Gynaecology, Nijmegen, The Netherlands
\textsuperscript{2}Radboud university, Radboud institute for Health Sciences, Nijmegen, The Netherlands
\textsuperscript{3}Radboud university medical center, Medical Micobiology, Nijmegen, The Netherlands
\textsuperscript{4}Radboud university medical center, Pathology, Nijmegen, The Netherlands

Aims

The aim of this study was to determine the risk of HPV-related carcinomas and premalignancies in women diagnosed with cervical intraepithelial neoplasia grade 3 (CIN3). Knowledge on this risk is important to consider HPV vaccination and/or increased attention on other HPV-related carcinomas and premalignancies when CIN3 is identified.

Method

Women diagnosed with a CIN3 between 1990 and 2010 were identified from the Dutch nationwide registry of histopathology and cytopathology (PALGA) and matched with a control group without CIN3. Subsequently, all hrHPV associated high-grade lesions and carcinomas in the ano-genital region and oropharynx between 1990 and 2015 were extracted. Incidence rate ratios (IRR) were estimated for carcinomas and premalignancies of the vulva, vagina, anus and oropharynx.

Results

178,036 women were identified; 89,018 with a previous diagnosis of CIN3, and 89,018 matched controls without a history of CIN3. Women with a history of CIN3 showed increased risk of HPV-related carcinomas and premalignancies with IRRs of: 3.85 (95%CI 2.32-6.37) for anal cancer, 6.68 (95%CI 3.64-12.25) for AIN3, 4.97 (95%CI 3.26-7.57) for vulvar cancer, 13.66 (95%CI 9.69-19.25) for VIN3, 86.08 (95%CI 11.98-618.08) for vaginal cancer, 25.65 (95%CI 10.50-62.69) for VAIN3, and 5.51 (95%CI 1.22-24.84) for oropharyngeal cancer. This risk remained significantly increased, even after long-term follow-up, up to 20 years.

Conclusion

This population-based study shows a long-lasting increased risk for HPV-related carcinomas and premalignancies of the ano-genital and oropharyngeal region after a CIN3 diagnosis. Studies investigating methods to prevent this increased risk in this group of patients, like intensified screening or vaccination, are warranted.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0264

FINAL STAGE IN PATIENTS WITH OVARIAN CANCER AND NEGATIVE PRE-SURGICAL CT SCAN
F. Fargas Fabregas, C. Blancafort Casabón, R. Fabregas Xaudaro, F. Tresserra Cases
1Hospital Universitari Quiron-Dexeus, Ginecology, Barcelona, Spain
2Hospital Universitari Quiron-Dexeus, Pathologist, Barcelona, Spain

Aims
According to a recent meta-analysis, 13% - 24% of patients are overestimated from an apparent initial stage I or II to a III after complete staging. In our Center, the practice of annual gynecological ultrasounds allows us to diagnose a higher proportion of ovarian cancers in the early stages. The objective of this study is to assess the initial staging of ovarian cancer in our setting and how the stage varies after the surgical procedure.

Method
Between 2010-2016, 93 patients with ovarian cancer underwent surgery at our Center. In these patients the clinical history has been reviewed to determine the presence or not of ganglion or peritoneal disease by CT scan. Only 42 patients with pre-operative negative CT have been included in the study. The variables that have been considered have been the type of surgery, the histology, the nodal involvement, the postoperative stage and the evolution.

Results
Of the 42 patients with clinical or radiological suspicion of disease in the initial stage, only 5 (8%) have been overexplained by surgery, becoming a stage IIIa with affected lymph nodes. Almost half of the patients (49%) were operated by laparoscopy. As for the histological type, 11 (26%) were endometrioids and 18 (43%) were serous. Only the serous were the ones that finally showed positive nodes.

Conclusion
If gynecological ultrasound is performed by experts and CT scan does not detect affected nodes, a few cases that were "clinical-radiological" considered as initial stages, change to advanced stages with surgery. In all cases they were serous-papillary tumors, and no disease-free survival or overall survival varied in any way compared to the rest of the group. The main limitation of the study is the short follow-up.
SENTINEL NODE DETECTION IN GYNECOLOGICAL CANCER, OUR EXPERIENCE.
F. Fargas Fabregas¹, C. Blanchafort Casabón¹, R. Fabregas Xaudaró¹, M. Cusidó Gimferrer², F. Tresserra Casas¹
¹Hospital Universitari Quiron-Dexeus, Gynecology, Barcelona, Spain
²Hospital Universitari Sagrat Cor, Gynecology Oncology, Barcelona, Spain

Aims

The sentinel lymph node biopsy (SLN) in cervical and endometrial cancers is used to simplify the surgical procedure and decrease morbidity. It has been shown that in addition, it can have other advantages, such as more reliable detection of key nodes in atypical localizations, detection of small metastasis, and intraoperative triage of patients, due to identification of this nodes for pathologic evaluation. We present our experience in 50 cases.

Method

Since 2010 we have been performing the detection of the sentinel lymph node in gynecological cancers. On the same day of the surgery, we injected the technetium at the 4 cardinal points of the cervix, injecting 1 cc at each point. Then the detection of the migration of technetium in the department of nuclear medicine is proceeded. Subsequently, in the operating room, the injection of methylene blue is performed at the same points.

Results

38 cases (76%) were endometrial cancers and 12 (24%) cervical. Our detection rate with double technique reaches up to 97%, detecting it with one of two techniques or both. The detection rate with tc99m was 93.7%, and by the methylene blue technique, it drops to 71.5%. The 12.6% (n=6) were positive nodes. According the migration site, 96% were pelvic, and 2% only aortic. A mean of 2.1 GC per patient was obtained. The FN rate was 2.6%.

Conclusion

In cervical cancer, the presence of micrometastasis is associated with shortened survival. In endometrial cancer, SLN biopsy incorporating an institutional mapping algorithm and ultrastaging has been shown to significantly reduce false-negative rates and increase sensitivity and negative predictive value. The sentinel lymph node biopsy seems to be an standarized procedure for endometrial and endocervical cancer with a low false negative detection rate that allows the detection of metatstatic lymph nodes in pelvic and aortic region.
Aims

This is the first UK-based study aiming to assess the detection rates of CIN2+ by different methods of biopsy selection, and evaluate if and how using the dynamic spectral imaging (DSI) digital colposcope affects outcomes compared to conventional colposcopy.

Method

This is a nested case control study including women referred with LG high-risk (HR) HPV positive cervical cytology from 11/2015 until 1/2017 to Musgrove Park Hospital, Taunton, who were examined using the DSI digital colposcope (DSI group). Biopsies were taken from sites identified: (1) before DSI map (internal control); (2) using map to confirm/refine biopsy area; (3) map only identified sites. A contemporaneous control group (4), examined by conventional colposcopy, was used to compare results (external control).

Results

Seventy-one women were in the DSI group. Of those, 22 (31%) were found to have CIN2+ lesions. Colposcopy pre-DSI predicted 5 (22.7%) of the CIN2+ cases as “high-grade”. However, as some areas considered “low-grade” were also biopsied, standard pre-DSI colposcopy (sub-group 1) detected 9 CIN2+ cases and a further 8 with use of the DSI map (sub-group 2) (p=0.008). Biopsies based exclusively on DSI (sub-group 3) detected 5 additional CIN2+ cases (p=0.044).

The control group included 390 women. Baseline characteristics were comparable to the DSI group. Of those, 79 were found to have CIN2+ lesions, a detection rate of 20.3%, which is lower than in the DSI group (p=0.0637).

Conclusion

These data suggest that DSI has an adjunctive role, on many levels, for this important, challenging population.
CORRELATING DYNAMIC SPECTRAL IMAGING AND HIGH-GRADE HISTOPATHOLOGY MAPPING OF THE CERVIX: A FEASIBILITY SERVICE EVALUATION.

C. Founta\textsuperscript{1}, E. Papagiannakis\textsuperscript{2}, J. Morriso\textsuperscript{n}\textsuperscript{1}, A. Karmolinski\textsuperscript{1}
\textsuperscript{1}Musgrove Park Hospital, Gynaecological Oncology, Taunton, United Kingdom
\textsuperscript{2}DySIS Medical, Clinical Research, Edinburgh, United Kingdom

Aims

This is the first comparison of Dynamic Spectral Imaging (DSI) and histopathological mapping of the cervix, aiming to assess the potential of DSI to assist the precise colposcopic description of high-grade lesions.

Method

Five women (age range 24-39 years) who had DSI colposcopy prior to a large loop excision of the transformation zone (LLETZ), due to CIN2+ biopsies (n=3) or high-grade cytology (n=2), were included. LLETZ specimens were oriented by the colposcopist and processed by an expert histopathologist blinded to colposcopy findings. Samples were serially cut in 2-3mm slices perpendicular to the os and at least three levels were taken from each slice. CIN was measured and mapped onto a diagram that divided the cervix in eight slices (octants), and each octant in two parts (closer and farther from the os), providing 16 evaluable areas per case. Each area was characterized, independently, as either HG or not by the DSI map and histopathology.

Results

All five colposcopies were satisfactory. Four had histology showing CIN2+ and one showed CIN1 only. In total, CIN2+ was found in 31 areas. One satellite CIN2+ lesion was missed by DSI and overall 25 of the CIN2+ areas were mapped correctly. Three areas that were predicted as HG by DSI were not confirmed by histopathology.

Conclusion

These data suggest excellent correlation between DSI mapping and high-grade histology and justify future prospective studies to explore uses of DSI beyond improved sensitivity and biopsy site selection.
DOES DEPTH OF EXCISION OR MARGINAL STATUS SIGNIFICANTLY INFLUENCE TEST OF CURE OUTCOME FOLLOWING A LLETZ? RESULTS OF A RETROSPECTIVE COHORT STUDY.

C. Founta\textsuperscript{1}, A. Wiggans\textsuperscript{1}, J. Morrison\textsuperscript{1}

\textsuperscript{1}Musgrove Park Hospital, Gynaecological Oncology, Taunton, United Kingdom

Aims

The National Health Service Cervical Screening Programme (NHSCSP) document 20 states minimum and maximum suggested depth of excision for large loop excision of the transformation zone (LLETZ). Involved endocervical margins have been found to increased risk of residual and recurrent disease. This study aims to assess if excision parameters influence the post-treatment cytology result.

Method

This is a retrospective cohort study including all women who had LLETZ for high-grade (HG) lesions, from 01/10/2013 until 30/09/2015 in Musgrove Park Hospital, Taunton. All women with no HG CIN in the LLETZ specimen, invasive cancer or glandular abnormalities were excluded from analysis. Mann Whitney and Fisher’s exact tests were used to compare groups.

Results

A total of 554 women who had LLETZ for HG CIN during the study period were identified. Of those, all information including TOC cervical cytology results were available for 503, and these data were analyzed. There was a correlation between depth of excision and marginal involvement of the LLETZ by HG CIN (p=0.038). However, LLETZ excision margin involvement did not influence the follow up cytology result or HR HPV status (p=0.89 and p=0.11, respectively). Depth of excision also did not correlate with presence of high risk HPV status in the TOC smear (p=1.000).

Conclusion

Neither depth of excision nor marginal status appear to influence cytology or HR HPV positivity at the TOC smear. More importantly, marginal involvement seems to have no impact on follow up cytology result. These data support the recommendations in NHSCSP Document 20, albeit only for short-term outcomes.
DIAGNOSTICS AND PREINVASIVE DISEASE

PERITONEAL FLUID MESOTHELIN CONCENTRATION AND MENOPAUSAL STATUS OF PATIENTS WITH OVARIAN CANCER

K. Frąszczak¹, B. Barczyński¹, G. Polak¹, K. Kulak¹, R. Tarkowski¹, P. Ziober-Malinowska¹, M. Sobsty³, I. Wertel¹, W. Bednarek¹, J. Kotarski¹
¹Medical University of Lublin, I Klinika Ginekologii Onkologicznej i Ginekologii, Lublin, Poland
²Medical University of Lublin, Department of Endocrinology and Gynaecological Endocrinology, Lublin, Poland

Aims

The risk of developing epithelial ovarian cancer increases after menopause. Lack of symptoms and insufficient tumor markers contribute to late diagnosis and poor prognosis. Mesothelin, which is overexpressed in ovarian cancer, may serve as a potential marker for epithelial ovarian neoplasms. The aim of the study was to assess the concentration of soluble forms of mesothelin in peritoneal fluid of patients with advance ovarian cancer and stratify the results according to menopausal status.

Method

The study group consisted of 47 patients with ovarian malignancies (47% serous, 32% endometrioid, 13% mucinous, and 8% undifferentiated tumors). Commercially available enzyme linked immunoassay (ELISA) kits (Quantikine Human Mesothelin Immunoassay, R&D Systems) were used to quantify mesothelin levels in the peritoneal fluid, which was aspirated intraoperatively during the surgery. Samples were processed in duplicate according to manufacturer's guidelines. The results were stratified according to patients' menopausal status.

Results

Median mesothelin peritoneal fluid concentration was 53.88 ng/ml and ranged from 4.98 to 233.04 ng/ml, and it varies in different histological cancer types. There was no significant correlation between general mesothelin peritoneal fluid concentration and patients' menopausal status (p>0.05).

Conclusion

Peritoneal fluid mesothelin concentration is not correlated with patients' menopausal status, and possibly hormonal status. Alterations in hormones levels after menopause probably does not influence mesothelin expression and peritoneal fluid concentration in ovarian cancer patients.
A FALLOPIAN MASS AND ELEVATED CA125; A CLINICAL, RADIOLOGICAL AND PATHOLOGICAL CHALLENGE
C. Goudeli1, N. Koufopoulos2, J. Syrios3, E. Terzakis1
1Hellenic Anticancer Hospital- "Saint Savvas", Gynecology, Athens, Greece
2Hellenic Anticancer Hospital- "Saint Savvas", Pathology, Athens, Greece
3Hellenic Anticancer Hospital- "Saint Savvas", Oncology, Athens, Greece

Aims

Serum Ca125>95u/ml has 96% positive predictive value for postmenopausal women, while its specificity is lower for premenopausal women because of possible adenomyosis, uterine fibroids, pelvic inflammatory disease, pregnancy, menstruation or endometriosis. We present a case of hyperplasia of fallopian tubes with chronic salpingitis and elevation of serum ca125 mimicking tubal cancer.

Method

A 24-year-old nulliparous woman was referred to our hospital due to lower abdominal pain, bilateral adnexal masses and a highly elevated Ca125 (936U/ml). MRI showed bilateral adnexal complex cystic masses with papillary projections and thick wall, indicating mucinous cystadenocarcinoma. Colonoscopy was performed until 16cm due to external pressure. Intraoperative frozen sections were negative. Left oophorectomy with bilateral salpingectomy and appendectomy were performed.

Results

The diagnosis was set histologically based on many morphologic features, absence of mitotic figures and immunohistochemistry (p16, Stathmin1, p53, Ki-67). Microscopical examination revealed extensive mucosal hyperplasia associated with chronic active salpingitis often called pseudocarcinomatous hyperplasia. Postoperative Ca125 was 250u/ml and her recovery was uneventful. Few cases are described in the literature concerning women 17-40 years-old due to chronic salpingitis, pyosalpinx, tubo-ovarian abscess, hydrosalpinx and female genital tract tuberculosis.

Conclusion

Ca-125, identified since 1981, is elevated in 50% in patients with FIGO stage I disease while in 90-94% in greater stages. When the marker is highly elevated, the patient must be referred to a surgeon who routinely performs thorough abdominal exploration, keeping in mind that benign situations can provoke its high elevation. Genomic and proteonomic technologies should identify additional novel markers.

MIXED TUMORS MULLERIENNES OVARIAN, RETROSPECTIVE STUDY ABOUT 9 CASES WITH REVIEW OF THE LITERATURE

F. Hadjarab

1center pierre marie curie algiers, medical, algiers, Algeria

Aims

to show through this study and the review of the literature which it is about a mixed tumour, rare, aggressive, the treatment primarily surgical is followed by chemotherapy, but it is about a not very sensitive tumor and it only found prognostic factor is the stage initial of the tumor

Method

we used medical records of our patients, 9 cases of Mullériennes ovarian

Results

The median age is 52 year, all the patients profited from a surgery of exérèse tumoral followed by chemotherapy

Stages

IA : 2, IIA :1, IIB :1, IIIC : 5

Surgery =

-Carcinological = hysterectomy , annexectomy bilateraland omentectomy, pelvic clearing out and lomboaortic =5 ,
- Reducing surgery =4

Chemotherapy: used in all the patients, two types of protocol CAP = 5 ENDOXAN, ADRIAMYCINE, CISPLATINE, PACLITAXEL CARBOPLATINE

RC=3, RP=2, PR=3, ET=1,

alive in remission= VR=3,

Alive under chemotherapy= VM=1, died =5

1° = RC/VR/ time of follow-up = 16 years, 2°= Failure/DIED =she died 20 days after the 3rd cycle of chemotherapy =6 months

3°= PR/DIED =14 months

4°=PR/DIED = 7 months 5°= PR/DIED = 8 months , 6°=PR DIED = 12 months

7°= RC/ VR I =8 years 8°= RC/VR =14 months , 9°= RP/VM = 16 months

Conclusion

The ovarian Tumors mullériennes are a rare and aggressive pathology considering the sarcomateuse component associated with L weak chemotherapy sensitivity and the frequent relapses. The only found prognostic factor is the initial stage. The rate of answer to chemotherapy is of 20 % approximately.

TUMORS OF THE GRANULOSA OF THE OVARY IN CONNECTION WITH 24 CASES, RARE TUMOR OF THE STROMA AND SEXUAL CORDS WITH REVIEW OF LITERATURE

F. Hadjarab

1 center pierre marie curie algiers, medical, algiers, Algeria

Aims

The goal of this work was to describe the epidemiologic characteristics and anatomoclinical tumors of the granulosa and to study the various factors of forecast in order to determine a correct therapeutic attitude.

Method

Retrospective study of 24 cases, diagnosis of tumor granulosa during the 10 years January 2006 to December 2016 parameters studied: (the age, circumstance of discovery, initial imaging, the stage, surgery, chemotherapy, answer, total survival)

Results

23 patients were standard adult Granulosa, only one waits were standard Granulosa jévunile the age at the time of the diagnosis varied from 22 to 72 years, the circumstances of discoveries were dominated by pains abdomino-pelvic = 15 case (62%), the pelvic echography was practised at all our patients the tumor was solidokystic at 60% of our patients, and solid in 35% cases. Tumors were bulky with a size varies from 7 to 27 cm

Stages: (79.66%) = I, 4, 16% = II, 12, 50% = III, 4.16% = IV, all the patients profited from a exérèse surgical, radical in 18 cases (hysterectomy with annexectomy bilateral), 6 cases unilateral annexectomy (young woman) 6 patients have received of auxiliary chemotherapy stage I with two types of protocols: cisplatin, vinblastine, bleomycin, 4 with the protocol: paclitaxel, carboplatin

Median of survival = 26 month

Conclusion

garnulosa Tumors, rare, often diagnosed at an early stage, treatment relies on surgery, we note in our series that age, stage at diagnosis was correlate with that of literature

ESGO7-0696

UMBILICAL RARE METASTASES SECONDARY WITH A ADVANCED CANCER OF THE OVARY IN CONNECTION WITH TWO OBSERVATIONS WITH REVIEW OF THE LITERATURE

F. Hadjarab1, A. TAIBI1, K. BOUZID1
1Center Pierre Marie Curie Algiers, Medical Oncology, Algiers, Algeria

Aims

to showing the rare metastases cutaneous umbilical in the advanced ovary cancer, it said the nodule of Sister Mary Joseph

Method

we used the clinical data of the file of the patient treated in our structure, two cases of epithelial malignant tumors of the ovary associated with umbilical metastases

Results

Case 1: 52 years woman operated for ovarian tumor: bilateral annexectomy + biopsies of peritoneum - the histological results are in favor of a bilateral mucineux cystadenocarcinoma of the ovary, stage III B

The patient received chemotherapy: Paclitaxel Carboplatine follow-up complementary surgical Colpohysterectomy + ganglionic clearing

treated by chemotherapy which had answered well, 6 months after it progressed at the pelvic and hepatic, appearance umbilical repetition, a treatment by oral Endoxan, No answer was observed died 7 months after the discovery of metastasis

Case 2: 44 years woman presents cancer of the ovarian stage IV, Pelvic echography, and CT scan: it had shown bulky pelvic mass of heterogeneous lesions hepatic with nodules péritonéales metastasis umbilical, CA 125= 900 UI/ml, Surgery: biopsy was carried aspect of ovarian carcinoma, the patient had received chemotherapy by evolutionary continuation of the lesions after 10 months

Conclusion

umbilical metastases of an epithelial cancer of the ovary fortunately are rare, are associated has a very bad forecast, resistance has any chemotherapy, with a short survival; and we confront these cases with the data of the literature.

BEVACIZUMAB (BEV) IN FIRST LINE WITH STANDRAT TREATMENT IN OVARY CANCER IN ADVANCED STAGE

**Aims**

To show the effectiveness of BEV in the cancer of the advanced ovary.

**Method**

We used the clinical data of the files of the treated patients with chemotherapy and bevacizumab in first line in ovary cancer. The cancer of the ovary is a not very frequent female cancer but its forecast remains a serious dependent high mortality rate. We bring back 40 patients treated between (2012 - 2016) for a cancer of the ovary having received Bevacizumab in 1st line with Paclitaxel Carboplatine.

The median age 51 (36-73).

**Results**

Stage: IIIb (15%), IIIc: (62.5%), IV: (22.5%), the metastatic sites hepatic, 4 case ganglionic.

The initial surgical: radical 71.5%, 21.5% biopsy, 7 surgery of reduction.

The most frequent is the serous cystadenocarcinomist 29 case, 3 endométrioïde, 2 with clear cells, 2 mixed with transitional cells, endométrioïde and with clear cells and the other malignant of Brenner with transitional cells, 1 mucineux tumor.

Complete response: 57.5%

Partial response: 30%

Objective response: 87.5%

Failure Thérapeutique ET: 7%

RESPONSE STABILITE: 11.7%

A live under chemotherapy: 45%

Complete response a live in Rémission: 40%

Died: 15%

The total survival between 5 and 60 months an average from 19.5 months.

**Conclusion**

Toxicity observed was 1 cas of venous thrombosis, 2 cas of HTA, 2 cas of hemorrhagic syndrome (épistaxis), 1 case of nephritic.

Our remain modest this can be explained by the low number of recruited patients, the recruitment of one plus a large number of patients with more passing would allow us better an evaluation of its effectiveness.

ALGERIAN EXPERIMENT IN THE USE OF THE BEVACIZUMAB IN ADVANCED OVARY CANCER AFTER RELAPSE OF THE STANDARD TREATMENT

F. Hadjarab 1, A. TAIBI 1, K. BOUZID 1
1 Center Pierre Marie Curie Algiers, Medical Oncology, Algiers, Algeria

Aims

to show the effectiveness of BEV in the cancer of the advanced ovary

Method

we used given files of our patients treated for cancers advanced of the ovary in relapse, by using several parameters: old, the standard histological one, stage of the disease, treatment used before the relapse

The cancer of the ovary is regarded as one of the gynecological cancers most serious.

We treated during the period active (2012/2015) 52 patients who had relapsed after the standard, stage: III, IV, two groups are considered according to their sensitivity or not to salts of platinum

Platinosensibles = CT+SELS of PLATINUM + BEV = 29 Sensitive

NPS = NOT platinosensitive = CT + BEV = 23

Median age: 54 (21-6 years),

al presented advanced stages of epithelial cancer of the ovary

Results

Evaluation of the patients in Relapse Platino-sensitive = 29/52,

Complete response: 45% Partial response: 24% Objective response: 69% Failure: 4% Alive in remission: 31% Died: 14%

Evaluation of the patients in Relapse Not Platino-sensitive = 23/52

Complete response: 4% Partial response: 22% Objective response: 26% Failure: 44% Alive in remission: 4% Died: 39%

Toxicity

péritonite aigue 5%, - Arterial hypertension 5%, - épistaxis+hémorragie genital faibleabondance: 3% • neurotoxicity: 3% • Functional renal toxicity = 4 (créalémie>14mg/l) • (protéinurie >2g) = 2

Conclusion

the targeted therapy is a profit confirmed in rate of answer and survival Interest of a multidisciplinary dialogue (oncologists, gynaecologists, surgeons oncologists and anatomopathologists) for the best taken in charge of this cancer considered frightening

CORRELATION BETWEEN HISTOLOGICAL ASPECTS OF THE EPITHELIAL TUMORS OF THE Ovary AND MARKER CA125

F. Hadjarab, S. HABAK, A. TAIBI, K. BOUZID

1Center Pierre Marie Curie Algiers, Medical Oncology, Algiers, Algeria

2Pierre Marie Curie d’Alger, Laboratory of Biochemistry, ALGER, Algeria

Aims

Our study aims to search the interest of CA125 in the histological types of the ovarian tumors.

Method

This study (2014-2016), 67 cases of the ovarian tumors of various histological types whose biological follow-up is carried by the proportioning of the CA125.

The proportioning of the CA125 is carried out by method TRACES (Time-Resolved Amplified Cryptate Emission)

The distribution of histological type shows the cancer ovary of the serous type is most frequent 48%

Results

serous (31 cases): CA125, Average show: 1700 UI/ml (48 X NR).

This clear rise is found in 90% of the cases (28/31).

mucineux (5 cases): the normal CA125 (<35UI/ml) for 3 cases present. The two other cases

CA125 which does not exceed 3xN, they correspond at a advanced stage of cancer or a repetition.

endométroides (8 cases): rates, normal CA125 (<35UI/ml) for 5 cases present. The 3 other cases show a rate of CA125,

they correspond at a advanced stage with the endometrium or a repetition.

clear cells (6 cases): a rate of CA125 raised at 3 cases presents but which do not exceed 2xN; only one case shows a CA125 to 6xN, it corresponds at a advanced stage.

transitional cells (1 case) and tumors mixed (2 cases): a normal CA125 present. undifferentiated tumors (2 cases):

CA125 raised to 11xN, they correspond to a presence of carcinoses

Conclusion

CA125 is an effective tool for the monitoring of ovarian serous epithelial cancers;

the reduction in CA125 always corresponds to a therapeutic good answer and the absence of its decrease with a resistance to the treatment.

TUMORS NON EPITHELIAL MALIGNANT RARE OVARIAN RETROSPECTIVE STUDY WITH REVIEW OF LITERATURE

F. Hadjarab1, A. TAIBI1, K. BOUZID1

1center pierre marie curie algiers, medical oncology, algiers, Algeria

Aims

The malignant non epithelial tumors of the ovary, two groups the stroma sexual cords, the germinal tumors earlier median age, clean tumoral markers aspecific genomics a stage more often located, a surgery whose major target is to preserve the fertility

Method

1 malignant germinal tumors 44 young, median age 22 (15– 43 years). All the patients have a surgery first, it has was preserving in 42 and complete in 2

2 stroma, sexual cords which 2 groups (Granulosa, sertoli, leydig), here will be approached only tumors of sertoli and leydig

09 patients, median age 23 (16– 43 years). 07 are nulliparous the average of the diagnosis is 2-4 months. 8 IA, 1 IC

Results

1 malignant germinal tumors

17 dysgerminomist, 17 tératoma, 6 : TSE the mixed germinal : 4

I=32, stage II: 1 stage III : 10 stage IV: 1
1st line protocol PVB (29 patients), in 2nd line BEP : 8 and , 15 = monitoring.

39 Complete answer, 3 partial answer

37 a live incomplete remission, 7 patients are die

2 stroma, sexual cords

the surger was preserving = 07, radical =2,

chemotherapy = 06 the evolution was marked progressive disappearance about the signs of virilisation

08 are alive in remission, 01 deceased

Conclusion

ovarian malignant tumors, the assumption of responsibility of these tumors is complex because of their weak incidence, the frequent absence of preoperative diagnosis and of need for taking in to account the desire of procreation

LONG SURVIVAL OF A TUMOR OF KRU肯BERG: IN CONNECTION WITH A CASE
F. Hadjarab\textsuperscript{1}, A. TAIBI\textsuperscript{1}, K. BOUZID\textsuperscript{1}
\textsuperscript{1}center pierre marie curie algiers, medical oncology, algiers, Algeria

Aims

The tumor of Krukenberg is defined as being an ovarian metastasis of a cancer of colonist, stomach, breast and appendix, it represents 1 à 2\%
touches primarily the woman 35 - 50 years, often bilateral it is characterized by the presence of cells out of kitten ring.
The treatment is above all surgical, their evolution is quickly fatal

Method

38 years old since 2007 tumor of Krukenberg, a scanner objective in 2006 a bulky tissue mass evoking a process aggressive of the ovary, a decision taken to operate the patient for goal diagnosis and therapeutic,
chirurgie N°1 = laparotomy biopsies exploring

Results

anatomopathologic N°1: returning in favour of a tumor of Krukenberg (primitive site to search of which the pancreas)
The search for primitive site is negative,
surgery N°2 total hysterectomy and annexectomy,
anatomopathologic N°2 Mucineux Adenocarcinomists of bilateral ovarian localization and endocervicale,
(tumor of Krukenberg), 4 cures of chemotherapy

Docetaxel - Cisplatine with good a complete answer 6 months after a repetition with the echography suspect of a vesical retro solid lesion
of 17mm /11mm evokes a repetition confirm by a scanner objective a tissue nodular formation 24 mm latéro vesical,
The patient is incomplete remission, with a long passing,
survival a 10 years

Conclusion

The tumor of Krukenberg is an uncommon illness,
touches the young woman, it is a metastasis of another cancer: gastric, breast, a pejorative forecast, a weak survival, a death less than 6 months

EVALUATE A REAL TIME MID-IR SPECTROSCOPIC METHOD BASED ON ATR-FTIR AS AN ADDITIONAL METHOD TO 'FROZEN SECTION' IN GYNEONCOLOGY PROCEDURE – A PRELIMINARY STUDY

I. Bruchim1, G. Haran2, D. Malonek3, A. Blecher2, R. Reens Carmel1, H. Ben-Amram2, S. Midler2, G.M. Groisman4, M. HALLAK1, D. Ben-Zion3

1Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
2Hillel Yaffe Medical Center, Gynecologic Oncology Division- Department of Obstetrics and Gynecology, Hadera, Israel
3Academic Center Ruppin, School of Engineering, Emek-Hefer, Israel
4Hillel Yaffe Medical Center, Department of Pathology, Hadera, Israel

Aims

The sensitivity of the 'frozen section' test is in the range of 75% to 100% and the specificity is 80% to 100%. Increasing those measures is needed to improve the clinical decision-making process. ATR-FTIR spectroscopy is a rapid and sensitive technique that measures changes in molecular structures. Hence, it has the potential to differentiate between malignant and benign tumors. The objective of the current study was to explore the potential of mid-IR ATR-FTIR technique in improving the accuracy of pathology evaluation during surgical procedure.

Method

18 samples extracted from suspected tumors were tested using an ATR-FTIR system. Absorption spectrum were measured and analyzed. 'Frozen section' and histopathological results of these samples were used to develop a discriminant model using multivariate classification methods.

Results

Preliminary results of our study suggest that measured spectra of malignant and benign tumors differ from each other (Figure 1). The model demonstrated that the ATR-FTIR technique was able to correctly differentiate between malignant and benign tumors with 100% sensitivity and 93% specificity.

Conclusion

The ATR-FTIR technique was able to discriminate between malignant and benign tumors. Thus, it has the potential to be used as an additional or alternative technique to the 'frozen section' test during the clinical decision-making process. Further study is needed to support this finding.
HUMAN PAPILLOMAVIRUS DNA METHYLATION PREDICTS RESPONSE TO TREATMENT USING CIDOFOVIR AND IMIQUIMOD IN VULVAL INTRAEPITHELIAL NEOPLASIA 3

S. Jones¹, S. Hibbitts², C. Hurt², D. Bryant³, A. Fiander¹, N. Powell⁴, A. Tristram¹
¹Cardiff University, School of medicine, Cardiff, United Kingdom
²Cardiff University, Wales Cancer Trials Unit, Cardiff, United Kingdom
³University of Southampton, School of medicine, Southampton, United Kingdom
⁴Cardiff University, School of Medicine, United Kingdom, United Kingdom

Aims

Response rates to treatment of vulval intraepithelial neoplasia (VIN) with imiquimod and cidofovir are approximately 57% and 61% respectively. Treatment is associated with significant side effects and, if ineffective, risk of malignant progression. Treatment response is not predicted by clinical factors. Identification of a biomarker that could predict response is an attractive prospect. This work investigated HPV DNA methylation as a potential predictive biomarker in this setting.

Method

DNA from 167 cases of VIN 3 from the RT3 VIN clinical trial was assessed. HPV positive cases were identified using: Greiner PapilloCheck and HPV 16 type-specific PCR. HPV DNA methylation status was assessed in three viral regions: E2, L1/L2, and the promoter, using pyrosequencing.

Results

Methylation of the HPV E2 region was associated with response to treatment. For cidofovir (n=30), median E2 methylation was significantly higher in patients who responded (p = <0.0001); E2 methylation >4% predicted response with 88.2% sensitivity and 84.6% specificity. For imiquimod (n=33), median E2 methylation was lower in patients who responded to treatment (p = 0.03 (not significant after Bonferroni correction)); E2 methylation <4% predicted response with 70.6% sensitivity and 62.5% specificity.

Conclusion

These data indicate that cidofovir and imiquimod may be effective in two biologically defined groups. HPV E2 DNA methylation demonstrated potential as a predictive biomarker for the treatment of VIN with cidofovir and may warrant investigation in a biomarker-guided clinical trial.
LONG TERM RESULTS FROM RT3VIN: A MULTI-CENTRE, RANDOMISED, PHASE II TRIAL OF CIDOFOVIR OR IMIQUIMOD TREATMENT FOR VULVAL INTRAEPITHELIAL NEOPLASIA 3
S. Jones\textsuperscript{1}, C. Hurt\textsuperscript{2}, T. Madden\textsuperscript{3}, A. Fiander\textsuperscript{1}, A. Nordin\textsuperscript{4}, N. Powell\textsuperscript{1}, A. Tristram\textsuperscript{6}
\textsuperscript{1}Cardiff University, School of Medicine, Cardiff, United Kingdom
\textsuperscript{2}Cardiff University, Wales Clinical Trials Unit, Cardiff, United Kingdom
\textsuperscript{3}Cardiff University, Wales Cancer Trials Unit, Cardiff, United Kingdom
\textsuperscript{4}Queen Elizabeth the Queen Mother Hospital, East Kent Gynaecological Oncology Centre, Margate, United Kingdom
\textsuperscript{5}Queen Elizabeth Hospital, Northern Gynaecological Oncology Centre, Gateshead, United Kingdom
\textsuperscript{6}TristramAJ@cardiff.ac.uk, TristramAJ@cardiff.ac.uk, Cardiff, United Kingdom

Aims

Vulval intraepithelial neoplasia (VIN) is a chronic condition, which, if untreated, may become cancerous. Currently standard treatment VIN is surgery, but this does not guarantee a cure and can cause significant physical and psychological problems. The RT3 VIN trial demonstrated that topical treatment with cidofovir and imiquimod are effective in 46% of patients with acceptable levels of adverse events. This study reports the long-term (24 month) follow up of these patients.

Method

Participants with complete response were followed up for a further 24 months. Events were either “new lesion” (any new lesion either biopsied or not biopsied) or “new VIN” (biopsied lesions with histologically proven VIN). All statistical analyses were pre-planned and conducted using Stata SE 14.

Results

Median length of follow up was 18.4 months. At 18 months, 50% on imiquimod (95% CI: 33.6-64.5%) and 69% of patients on cidofovir (95% CI: 51.2-82.0) remained lesion free. At 18 months, 71.6% on imiquimod (95% CI: 52.0-84.3) and 94% of patients on cidofovir (95% CI: 78.2-98.5) remained VIN free. There were no grade 4+ adverse events reported and the number of grade 2+ events was similar between treatment arms (imiquimod: 24/42 (57%) vs. cidofovir: 27/41 (66%), $\chi^2=0.665$, $p=0.415$).

Conclusion

Long-term data indicates that response is maintained for longer following treatment with cidofovir compared to imiquimod with no difference in the rates of adverse events between the two drugs. Overall, the levels of adverse events and the absence of grade 4 events, indicates acceptable safety of use of these drugs in this setting.

FACTORS ASSOCIATED WITH RESIDUAL DISEASE AFTER COLD-KNIFE CONISATIONS
S. Kadija1, A. Stefanovic2, I. Likic-Ladjevic2, K. Jeremic3, M. Radojevic1, Z. Vilendecic2, R. Sparic1
1Clinic of Obstetrics and Gynecology - Clinical Center of Serbia, General Gynecology, Belgrade, Serbia
2Clinic of Obstetrics and Gynecology - Clinical Center of Serbia, Surgery I, Belgrade, Serbia
3Clinic of Obstetrics and Gynecology - Clinical Center of Serbia, Surgery II, Belgrade, Serbia

Aims

Increasing number of young nulliparous women suffering from cervical dysplasia imposes pressure of avoiding re-intervention due to residual disease after the first conisation. The aim of the study was to investigate factors contributing positive margins after conisation.

Method

Case-control study of the patients treated with cold-knife conisation during the three years at the Clinic for Gynecology and Obstetrics (Clinical Center of Serbia, Belgrade) was conducted. All surgical samples were analyzed by experienced gynecological pathologists and following data was extracted from patients records: age, parity, abortions, indications for conisation, final pathological finding, surgical margins status, cone dimensions. Cone volume was calculated.

Results

Among 250 patients treated with cold-knife conisation, 104 met inclusion criteria. Eleven patients (11%) had positive margins and 93 had negative margins. No statistically significant difference was found in age, abortions number and deliveries number between the groups. Cone volume was statistically greater in patients with positive margins (4.69 cm³ vs. 8.05 cm³). Cone diameter analysis indicates significant difference in shorter diameter of the cone basis (p=0.001) and no difference in cone height (although the p value is close to the significance limit [0.079]). No statistically significant difference was found between the groups according to indications for conisation. No statistical difference was found in the positive margins incidence when surgeons were stratified according to the colposcopic experience.

Conclusion

In order to avoid positive margins large volume cones should be made, when reproductive history allows. Colposcopic experience does not affect positive margins incidence.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0647

HPV GENOTYPE IS IMPORTANT IN PREDICTING DISEASE PROGRESSION IN WOMEN WITH ATYPICAL SQUAMOUS CELL OF UNDETERMINED SIGNIFICANCE (ASC-US) CYTOLOGY.

W. Kang 1, U.C. Ju1, S.M. Kim1

1Chonnam National University Medical School, Obstetrics and Gynecology, Gwangju, Republic of Korea

Aims

Our aim was to estimate the risk of disease incidence in women with atypical squamous cell of undetermined significance (ASC-US) without histology-proven cervical intraepithelial neoplasia grade 2 or worse (CIN2+) by human papillomavirus (HPV) genotype.

Method

Between January 2002 and September 2010, incidence of CIN2+ in 2,880 women including 2,172 with ASC-US and histology-proven negative and 708 with ASC-US with histology-proven CIN1 was investigated. Baseline HR-HPV status was determined by the hybrid capture II assay (HC2) and HR-HPV genotype by the HPV DNA chip test (HDC). Cumulative incidence and hazard ratios were estimated to explore differences between index data and associations with CIN2+.

Results

Of the 2,880 women, the HC2 was positive in 1,509 women (52.4%) and the HDC was positive in 1,563 women (54.3%). The overall agreement between the HDC and HC2 was 97.4%. One hundred ninety (6.6%) patients developed CIN2+. The 5-year cumulative incidence rate of CIN2+ in HPV-16, HPV-31, HPV-52, and HPV-58 were 16.7%, 15.1%, 12.6%, and 12.9%, respectively. On multivariate analysis, being positive in HPV-16 (hazards ratio [HR] = 2.431; 95% CI, 1.789-3.332; P < 0.01), HPV-31 (HR = 2.335; 95% CI, 1.373-3.971; P < 0.01), HPV-52 (HR = 1.592; 95% CI, 1.031-2.458; P = 0.03), and HPV-58 (HR = 1.650; 95% CI, 1.132-2.407; P < 0.01) were significantly associated with developing CIN2+ compared to being negative for that type.

Conclusion

Among women with ASC-US, HPV-16, HPV-31, HPV-52, or HPV-58 positive women may need intensified follow-up as they have the highest risk of becoming CIN2+.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0050

ANALYSIS OF PATIENTS WITH CYTOLOGY NEGATIVE AND HPV 16/18 POSITIVE ON CERVICAL CANCER SCREENING PROGRAM: EXPERIENCE FROM A SINGLE CENTER IN EASTERN REGION OF TURKEY

E. Karaman¹, I. Alkış¹, A. Kolusarî¹
¹Yuzuncu Yil University, Obstetric and Gynecology, VAN, Turkey

Aims

The aim is to evaluate and analyse the outcomes of patients with the cytology negative for malignity and positive for HPV 16/18.

Method

The medical records of patients who were admitted to our gynecologic oncology clinic between January 2015 and January 2017 with complaint of negative cytology and positive HPV test either type 16 and/or 18 and underwent colposcopic examination including cervical biopsy and endoservical curettage results were reviewed.

Results

106 cases were referred to our clinic. 56 of these cases were positive for HPV 16 (52.8%) and 32 were HPV 18 + (30.1%). 18 of patients were positive both for HPV 16 and 18 (16.9%). All patients had a negative cervical cytology. The median age of cases was 41.6 (range:29-67). 76 out of 106 cases were pre-menapousal (71.6%) and 30 patients were post-menapousal (28.3%). All patients underwent colposcopic examination and biopsy procedure was applied to 96 patients (90.5%). HGSIL was detected in 21 % of cases with positive HPV 16 (12/56) and 12.5% of HPV 18 positive (4/32). And also, 33.3 % of HPV positive for both type 16 and 18 cases had HGSIL (6/18). Only one case of microinvasive cancer was detected in HPV 16 positive patient (1.7 %, 1/56).

Conclusion

The high risk HPV positivity necessitates the colposcopic examination even in the presence of negative cytology. It was found rationally that the high grade lesion can be seen in colposcopically quided biopsies. Also, the presence of both types of HPV 16 and 18 together increases the possibility of high grade lesion.
Aims
Cervical cancer is the second most common cancer among women. High-risk human papillomavirus (hr-HPV) persistence is the primary cause of cervical neoplasia. Early detection of hr-HPV is important for identifying women at risk for developing cervical lesions. Approximately 85% of new cases of cervical cancer worldwide and 50% of the total cervical cancer deaths occurred in developing countries.

Method
In a cross-sectional study, two hundred women aged 21-51 years for screening tests always care HPV (cervical), and PCR Pap tests and biopsies were targeted. Women who screened positive were referred for colposcopy and histology results were confirmed. Sensitivity, specificity and predictive values for each screening test to check for CIN-I and higher tracking tests were compared.

Results
The sensitivity of Care™ HPV for detection of CIN-I and higher neoplasia grade I was higher than other methods and also the specificity of the Pap test was also higher for other procedures. The positive and negative predictive value of Care™ HPV test was higher than other tests. There was no significant difference between Care™ HPV and PCR tests for detection HPV-DNA results and CIN-I and higher neoplasia grade I.

Conclusion
Care™ HPV test have sensitivity and predictive value for HPV infection and also Care™ HPV testing is superior to Pap test for the detection of high-grade CIN in and is better in low-income areas to be used as a screening test.
PERSISTENCE AND CLEARANCE OF HUMAN PAPILLOMAVIRUS-58 IN KOREAN WOMEN

C. Kim¹, J. Koo¹, M. Jeong¹, K. Lee¹, Y. Lee¹, T. Park¹, J. Park¹
¹The Catholic University of Korea- Medical college, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

HPV-58 accounts for higher proportion of cervical cancers in Korea than other types. We followed the women with HPV-58 positive over 6 month. Here, we evaluated the clearance of HPV-58 and identified other co-factors with persistence of HPV-58.

Method

This study was conducted on 176 patients with CIN or ASCUS cytology at the St Paul’s Hospital of the Catholic University of Korea from Dec, 2010 until Dec, 2014. They all were positive for high risk HPV at initial visit. Patients were followed in 4-6 month interval with Pap smear and Anyplex TM Real time PCR HPV 28 detection method which detect 19 high-risk HPV genotype , 9 low-risk genotypes.

Results

The mean age of 176 patients was 53.7 years and the mean age of the 16 patients diagnosed with HPV-58 was 46.1 years. Of the women with HPV-58, seven were CIN1, four was CIN2/CIN3, and 5 were chronic cervicitis. Women with multiple HPV infection inclding HPV-58 were 10. The median clearance time of those infected with HPV after conization was 25 months. Of these, HPV-16 and HPV-18 were 23 months, HPV-58 was 69 months, and the other types were 22 months.

Conclusion

In a follow-up situation after HPV-58 positive cases, they showed relatively long time persistence and identification for the HPV-58 could stratify the high-risk recurrent group after HPV positive state. The future study for the HPV-58 types will require follow-up epidemiological studies with a large-scale and prospective design.

EXPRESSION OF NOD1 AND NOD2 DURING PROGRESSION OF HUMAN CERVICAL NEOPLASIA AND THEIR CORRELATION WITH P16INK4A EXPRESSION

C.J. Kim1, M.S. Kwon2, D.J. Kim3

1Konyang University Hospital, Obstetrics and Gynecology, Daejeon city, Republic of Korea
2College of Medicine, Konyang University, Department of Obstetrics and Gynecology - College of Medicine - Konyang University - Daejeon, Daejeon, Republic of Korea
3Institute of Science and Technology DGIST, Laboratory Animal Resource Center, Daegu, Republic of Korea

Aims

Nod1 and Nod2 are cytosolic receptors which recognize pathogen-associated molecular pattern (PAMPs) and initiate the innate immune response. In this study, we examined the expression of Nod1 and Nod2 to determine whether their expression is associated with the tumor progression in cervical neoplasia.

Method

The expression of Nod1 and Nod2 was evaluated by immunohistochemistry (IHC) in 80 formalin-fixed paraffin-embedded cervical tissues; 20 normal cervical specimens, 20 low-grade cervical intraepithelial neoplasias (CINs), 20 high-grade CINs, and 20 invasive squamous cell carcinomas (ISCCs).

Results

IHC staining showed that Nod1 was constantly expressed in normal cervical epithelium, CINs, and ISCCs with variable staining intensity. However, Nod2 expression was detected in 40.0% of normal cervical epithelium (8/20), 45.0% of low-grade CIN (9/20), 70.0% of high-grade CIN (14/20) and 55.0% of ISCC (11/20). Interestingly, the Nod2 expression was more frequently observed in the high-grade CINs and ISCCs compared with that in normal cervical epithelium, but this association was not statistically significant. In addition, Nod2 expression was significantly more frequent in high Nod1 expression group compared to low Nod1 expression group (P=0.044) and increased frequency of Nod2 expression was associated with increased expression of P16INK4a (P=0.033) which is believed to be associated with human papillomavirus (HPV)-induced transformation of cervical tissue.

Conclusion

Our results showed the increased frequency of Nod2 expression in CINs compared with that in normal cervical epithelium and suggests Nod2 may be associated with the cervical tumor progression of CINs.

HPV TESTING WITH AND WITHOUT CYTOLOGY AFTER LASER DESTRUCTION OR LARGE LOOP EXCISION OF THE TRANSFORMATION ZONE

J. Hansen¹, J. Waibel¹, A. Clad³, S. Timme², G. Gitsch¹, M. Oehler³, M. Klar¹
¹University Clinic of Freiburg, Obstetrics and Gynecology, Freiburg, Germany
²University Clinic of Freiburg, Institute of Surgical Pathology, Freiburg, Germany
³University of Adelaide, Gynaecological Oncology, Adelaide, Australia

Aims

HPV DNA or mRNA tests may provide better validity parameters than cytology smears alone at follow-up examinations after surgical management of cervical intraepithelial neoplasia (CIN) lesions.

Method

266 women with an abnormal colposcopy finding after large loop excisions of the transformation zone (LLETZ, n = 153) or laser treatment (n = 113) were included into this study. Routine cytology and HPV genotyping smears were obtained in addition to cervical biopsies of the colposcopically suspicious area. Digene Hybrid Capture 2 HR-HPV DNA (HC2) and APTIMA HPV assays were performed. Validity parameters including positive and negative predictive values (PPV, NPV) were calculated using the cervical biopsy result as the gold standard.

Results

The median follow-up time was 25 months and the median age of the study population was 34 years (IQR: 19-69). The post-treatment recurrence rate of CIN II or III was 17.3 %. 29 patients (10.9 %) had a post-treatment CIN II and 15 patients (5.6 %) a CIN III recurrence. 2 patients developed cervical cancer (0.07 %). For CIN II recurrences, the NPV/PPV for HC2 was 0.93/0.44, for APTIMA 0.94/0.58 and for cytology alone 0.91 / 0.62. For CIN III recurrences, NPV/PPV for HC2 was 0.98/0.18, for APTIMA 0.98/0.25 and for cytology 0.99 / 0.36. Combined testing of HC2 with cytology improved the NPV/PPV to 0.95 / 0.46.

Conclusion

In this study, co-testing of cytology smears with HC2 or APTIMA assays yielded to excellent NPVs and moderate PPVs in the post-treatment follow-up of CIN patients.
CORRELATION OF HPV, CYTOLOGICAL AND HISTOPATHOLOGICAL FINDINGS WITH DIFFERENT COLPOSCOPIC IMAGES

V. Krsic1, B. Jocic Pivac1, J. Krsic2, J. Milojevic2, D. Jovanovic1, V. Jovanovic4
1Clinic Ob Gyn Narodni Front, OB GYN, Belgrade, Serbia
2Military Academy belgrade, chirurgico department, Belgrade, Serbia
3Hospital Lazarevac, obgyn, Belgrade, Serbia
4Higher education school of professional health studies, obgyn, Belgrade, Serbia

Aims

The aim of this study is to determine the level of correlation between present of HPV infection and cytological and histopathological findings with different colposcopic images.

Method

Chi square test were used to determine the level of correlations among 1927 examined patients.

Results

Altogether 612 women (31.76%) were positive for one or more HR HPV types. HPV16(11.36%) and 33(6.43%) were the most prevalent types. HPV31 in 5.24%, HPV18 in 5.03% and HPV51 in 3.68% of all with normal colposcopic findings. 82.31% had normal cytology and 17.69% had abnormal cytology and among them 2.1% were HRHPV positive. There was a statistical difference between the findings of colposcopy and cytology in patients with HRHPV (x²=35.33, p=0.000). Abnormal colposcopy findings and normal cytology had 49.71%, among them there were 29.5% HRHPV positive and 9.5% LRHPV. There was no statistically significant difference between colposcopic and cytological findings (x²=0.394, p=0.530). Patients with normal colposcopy findings had histologically LGSIL changes in 53.81%, 11.95% were HRHPV positive. There was statistically significant difference between histopathology and colposcopy in patients with HRHPV (x²=10.17, p=0.001). 438 patients had abnormal colposcopy images and histopathological LSIL (71.51) and 2 patients had normal colposcopic images and histological HSIL. There was no statistically significant differences between histopathological and colposcopic exam in LRHPV patients (x²=1.71, p=0.190). HPV16 type was found in LGSIL statistically significant presence and in group age >35 years, HPV33 was the most often in age group 24 till 34 years. Abnormal findings on colposcopy was found in 93.3% patients with LGSIL and 68.05% patients with LGSIL had normal cytology and that 70.15% was HRHPV negative.

Conclusion

Our study showed that HPV testing could help for better screening for preinvasive lesions.

DIAGNOSTICS OF CANDIDA ISOLATES FROM VAGINAL BIOTOPES OF PATIENTS WITH ESTABLISHED DIAGNOSES: BEHAVIOR OF CANDIDA IN CULTURES IN THE PRESENCE OF HUMAN MUCOSAL PROBIOTIC LECTINS

V. Lakhtin1, M. Lakhtin1, A. Bayrakova1, M. Afanasiev1, S. Afanasiev1
1G.N. Gabrichevsky research Institute for Epidemiology & Microbiology, Medical Biotechnology, Moscow, Russia

Aims

Probiotic lectins (PL) recognize glycoconjugates (GC: antigens and biomarkers). The aim was to evaluate antitumor prospects of PL.

Method

Candida isolates were from patients with established diagnoses. Altered urogenital biotopes studied were without lactobacilli and/or bifidobacteria, with established relatively pathogenic microbes and viruses, and leukocytes. Acidic PL of lactobacilli or bifidobacteria (PLL, PLB) were added to Candida suspensions in microplates to control turbidimetry during 3 days (37°C). PLL and PLB were identified by glycoconjugates-biotin (GC) (www.lectinity.com) on blots treated with streptavidin-peroxidase. Chemiluminescence of peroxidase was registered in BioChemi System (UVP).

Results

1. Groups of PL-typing Candida strains established: Non-albicans Candida (urethritis, vaginitis, vaginose); C.krusei (urethritis, vaginose); C.tropicalis (cervicit, vaginose). Examples of PL-typing strains: Exposed mannan on C.tropicalis 738[PLB+PLL]≥ 665[PLB2+PLL] ≥ 633[PLB+PLL2] or C.krusei 687 [PLB2+PLL] ≥ 396[PLB+PLL] on the background of availability of mucins in 665 and 633; 687< 584 in accordance to affinity to PLL; similarity between 633 and 73 (in the presence of PLL or PLB), 73 and 42 (PLL), 73 and 4 (PLB). 2. PLL and PLB recognized mucin-like glycoantigens with exposed GalNAc residues (Adi and Fs, intensity of recognition significantly higher than in case of exposed non-antigenic GalNAc), and were able to bind fucan-like GC (PLB> PLL, probiotic strain dependent).

Conclusion

Results indicate the early appearance (before inflammation) of functionally different active Candida cells of increased affinity to the PLB and/or PLL in pathological biotopes of urogenital tract. The data indicate potential of PL (reversible carriers) and GC (support of decor of normal mucosal cells, therapeutics) against vaginal and intestinal mucosal tumors.

E2/E6 RATIO AND L1 IMMUNOREACTIVITY AS MARKERS FOR DETECTING HPV TYPE 16 POSITIVE > CIN2 LESIONS AND CERVICAL SQUAMOUS CELL CARCINOMA

S. Kim¹, Y. Choi², K. Lee², J. Yoon¹, D. Park¹, S. Lee¹
¹St. Vincent's Hospital- The Catholic University of Korea, Obstetrics and Gynecology, Suwon, Republic of Korea
²Seoul St. Mary's Hospital- The Catholic University of Korea, Obstetrics and Gynecology, Seoul, Republic of Korea

Aims

The objective of the study is to identify whether of HPV type 16 L1 capsid protein detection and measurement of E2/E6 ratio are potential biomarkers that would determine cervical pre-malignancy and squamous cell carcinoma (SCC)

Method

226 cervix samples with HPV type 16 single infection were collected from Seoul St. Mary’s Hospital. Real-time polymerase chain reaction (PCR) was done in order to determine E2/E6 ratio of HPV type16 DNA and Cytoactiv® HPV L1 screening Set was performed to detect the L1 capsid protein.

Results

We found that E2/E6 ratios of CIN2/3 (mean, 0.481) and SCC (mean, 0.355) were significantly lower than normal pathology (mean, 0.792) and CIN1 (mean, 0.736) (p < 0.05) (Fig 1). Moreover, difference in HPV L1 positivity predicted >CIN2 cervix lesions and discriminated CIN2/3 (22%, 17/79) from SCC (3%, 1/48) with significant difference (p < 0.05) (Fig 2). Moreover, receiver operating characteristic (ROC) curve revealed that the combination of HPV L1 immunohistochemistry and E2/E6 ratio measurement predicted >CIN2 cervix lesions (Area Under Curve (AUC), 0.871 (95% CI; 0.826-0.917)) better than the individual test (Fig 3).

Conclusion

To our knowledge, we are the first to identify that the combination analysis of HPV E2/E6 ratio measurement and HPV L1 capsid protein detection may be a powerful predictive marker for >CIN2 cervix lesions.

SENSITIVITY OF NON-INVASIVE PRENATAL FOR CANCER DETECTION AND TREATMENT MONITORING IN PREGNANT WOMEN

L. Lenaerts\textsuperscript{1}, J. Vermeesch\textsuperscript{2}, M. Verheecke\textsuperscript{1,3}, L. Dehaspe\textsuperscript{4}, N. Brison\textsuperscript{2}, F. Amant\textsuperscript{1,3}

\textsuperscript{1}KU Leuven - Gynaecologic Oncology, Oncology, Leuven, Belgium
\textsuperscript{2}KU Leuven, Department of Human Genetics, Leuven, Belgium
\textsuperscript{3}University Hospitals Leuven, Gynaecological Oncology, Leuven, Belgium
\textsuperscript{4}KU Leuven, Genomics Core Facility, Leuven, Belgium

Aims

We recently developed a massive parallel sequencing-based analysis pipeline for non-invasive prenatal testing (NIPT), allowing genome-wide detection of foetal and maternal chromosomal imbalances. On cell-free DNA samples of 20,000 asymptomatic pregnant women we incidentally identified 7 genomic imbalance (GI) profiles reminiscent of cancer-related copy number variations. Six women were subsequently diagnosed with cancer. We now aim to explore the sensitivity of routine NIPT testing for cancer detection and treatment monitoring in pregnant women, potentially contributing to enhanced prognosis.

Method

Pregnant women (≤ 40 years) diagnosed with breast, ovarian, cervical or haematological cancer (the 4 most prevalent cancer types encountered during pregnancy) are recruited in UZ Leuven or via the International Network on Cancer, Infertility and Pregnancy. A plasma sample is taken for GI-profiling. In case of an aberrant GI-profile, consecutive samples are taken to assess treatment response.

Results

Of the 23 pregnant cancer cases included, cell-free plasma DNA of 9 cases showed chromosomal abnormalities (either segmental or genome-wide). Sensitivity of cancer detection was highest for haematological (67%) and breast cancers (40%). No GIs were detected in cell-free DNA of the ovarian (n=1) and cervical (n=4) cancer cases. For the true positive cases, GI-profiling of tumor biopsy DNA showed comparable genomic imbalances as seen in cell-free plasma DNA. Furthermore, GI-profiling of cell-free DNA was able to follow treatment response.

Conclusion

Primary results indicate that GI-profiling of circulating cell-free DNA is able to detect cancer in a proportion of cancer cases. Further recruitment is ongoing and supplementary analyses are planned to understand false negative results.
SUBJECTIVE ULTRASOUND ASSESSMENT AND THE ADNEX MODEL TO DIFFERENTIATE BETWEEN BENIGN AND MALIGNANT OVARIAN TUMORS.

U. Leone Roberti Maggiore, V. Chiappa, G. Bogani, S. Perotto, M. Signorelli, F. Martinelli, A. Ditto, S. Ferrero, D. Lorusso, F. Raspagliesi

1Fondazione IRCCS - Istituto Nazionale dei Tumori - Milano, Gynecologic Oncology Unit, Milan, Italy
2IRCCS AOU San Martino-IST, Academic Unit of Obstetrics and Gynecology, Genoa, Italy

Aims

This study aimed to compare subjective ultrasound assessment and the mathematical multiclass model developed by the International Ovarian Tumour Analysis (IOTA), the ADNEX model, to differentiate benign and malignant ovarian tumors.

Method

This was a retrospective study including women with ovarian tumors who underwent surgery for these lesions. All patients underwent both transabdominal and transvaginal examination to assess tumor morphology and extent of the disease. Two expert sonographers performed all the scans. The ultrasound examiner assessed tumor morphology according to the IOTA protocol. Finally, the sonographer predicted the tumor as benign or malignant. This assessment was based on subjective evaluation based on knowledge from previously published IOTA studies and was given without knowledge of the results of the ADNEX model. Accuracy of the ADNEX was calculated for the cut-offs of 3% (ADNEX-3%) and 10% (ADNEX-10%) total risk of malignancy.

Results

A total of 207 women were included in the study with a median (range) age of 52 (15-81) years. Subjective ultrasound evaluation had a significantly higher accuracy (91.8%) in discriminating benign and malignant ovarian tumors in comparison with ADNEX-3% (77.3%; p<0.001) and ADNEX-10% (81.6%; p<0.001). Sensitivity and sensibility of subjective ultrasound evaluation, ADNEX-3% and ADNEX-10% were respectively: 92.2% and 92.4%, 94.0% and 68.9%, 99.1% and 50.0%.

Conclusion

This study shows that subjective ultrasound assessment performed by an expert sonographer is more accurate than ADNEX model using two different cut-off points in differentiating benign and malignant ovarian tumors. Future prospective studies with larger population of patients should confirm these preliminary findings.

UTERINE MASS IN PELVIC MRI: THE "ATYPICAL" MYOMA PUZZLE FOR THE RADIOLOGIST AND THE GYNECOLOGIST

G. Levy1, S. Taieb1, L. Boulanger2, L. Bresson2, T. Fourquet3, H. Franquet4, A.S. Lemaire5, J. Haudebourg6, E. Leblanc6, F. Narducci2, P. Collinet7, D. Beaugrand Van Klaveren8, E. Barranger9, L. Ceugnart1

1Centre Oscar Lambret, Radiology, Lille, France
2Centre Oscar Lambret, Surgery, Lille, France
3CHRU hôpital Jeanne de Flandre, Radiology, Lille, France
4CHRU hôpital Jeanne de Flandre, Anatomopathology, Lille, France
5Centre Oscar Lambret, Anatomopathology, Lille, France
6Centre Antoine Lacassagne, Anatomopathology, Nice, France
7CHRU hôpital Jeanne de Flandre, Surgery, Lille, France
8Centre Antoine Lacassagne, Gynecology, Nice, France
9Centre Antoine Lacassagne, Surgery, Nice, France

Aims

The aim of this iconographic review (benign and malignant uterine pelvic masses) is to illustrate MRI diagnostic pitfalls and how the radiologist's interpretation between two diagnoses (myoma or sarcoma) impacts the surgical therapeutic decision.

Method

Review of clinical cases that had make discussed or suspected in MRI some opposing diagnoses in their therapeutic management: atypical or variant leiomyoma, leiomyosarcoma, other etiology?

Results

- myoma and leiomyoma variants: degenerative modifications are frequent in ordinary myomas and will change their appearance in MRI (cystic, oedematous, myxoid, hyaline, hemorrhagic, fatty, hypercellular, necrotic pseudo-invasive), their vascularization is also variable (hyper or hypovascular).

- leiomyosarcoma,

- endometrial stromal tumor: stromal nodule, endometrial stromal sarcoma of low grade to high grade,

- STUMP (smooth muscle tumor of uncertain malignant potential),

- adnexal fibrous tumor and plurimyomatous uterus,

- pelvic lymphoma.
Conclusion

Frequency argument: 2 leiomyosarcomas per 1000 uterine myomas.

A single uterine tumor discovered after 45 years must remind one of sarcoma, without forgetting the frequent degenerative changes in the myoma that modify its MRI signal.

Full pelvic MRI protocol is justified if "atypical" myoma in pre-therapeutic associating the morphological sequences T2 correlated with the diffusion (b1000 / ADC) and the perfusion: MRI diagnostic accuracy >90%.

Surgical consequences: fertility in young woman in case of radical hysterectomy for leiomyoma and overall survival in case of "failed" sarcoma with tumoral morcellation.

Pelvic MRI in myomas is indicated for mapping of a large polymyomatous uterus / before myomectomy or if atypical myoma in ultrasound or increase in size in post menopause.
Aims

There has been a recent shift from cytology-only screening to HPV DNA testing in cervical cancer screening. The aim of this study is to identify outcomes of women with positive oncogenic HPV.

Method

This is a retrospective study of 4867 women who underwent HPV testing as part of cervical cancer screening between January 2013 and December 2016 in a tertiary institution in Singapore.

Results

Cotesting was performed in 58.1% and HPV primary screening in 23.5% of women. Of the 42 positive HPV 16 results, 2 had biopsy-proven CIN1 and 4 had biopsy-proven CIN2+. Two patients with normal colposcopy had negative random punch biopsies. Of the 15 positive HPV 18 result, 2 had biopsy-proven CIN1 and 3 had biopsy-proven CIN2+. One patient with normal colposcopy had negative multiple random biopsies and another had a negative diagnostic LEEP procedure. One patient had both HPV 16 and HPV 18 positivity and underwent diagnostic LEEP procedure of which histology was negative. Of the 183 positive non 16/18 HPV results, 1 had biopsy-proven CIN1 and 7 had biopsy-proven CIN2+. Two patients with normal colposcopy had negative diagnostic LEEP and another had negative hysterectomy. The sensitivity, specificity, positive predictive value and negative predictive value were 100%, 94.39%, 4.48%, 100% for HPV primary testing and 100%, 93.40%, 4.48%, 100% for co-testing respectively.

Conclusion

While HPV DNA tests can increase detection of high grade CIN, there is a need to strike a balance between increased sensitivity and over-treatment that may lead to recognised future fertility implications.
AGGRESSIVE FIBROMATOSIS OF THE BREAST: TWO CASES REPORT

M. Bouhani1, I. Zemni1, S. Sakhri1, O. Adouni2, S. Haddad1, M. Slimene1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1

1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Fibromatosis or desmoid tumour of the breast is an extremely rare, locally aggressive tumour with a tendency to relapse. The main clinical and pathological characteristics of this rare disease are illustrated, emphasizing the difficulties encountered in the diagnosis of the primary lesion.

Method

Two patients diagnosed with fibromatosis tumour of the breast at Salah Azaiez institute, Tunis, Tunisia, in the period from 2002 to 2016, from retrospective chart review and histologic analysis.

Results

Case n1:

We report a case of desmoid-type fibromatosis in the breast in a 38 year-old female who presented with a two-month history of a palpable right breast mass. Her imaging was discordant. She underwent surgical excision of the mass. Margins were positive. She underwent re-excision with free margin. The patient is currently fifteen years out from her local excision of fibromatosis of her right breast and she remains disease-free.

Case n2:

We report a case of desmoid-type fibromatosis in the breast in a 23 year-old female who presented with a four-month history of a palpable left breast mass. Her imaging was discordant, so she underwent surgical excision of the mass. Margins were free. The patient is currently five months out from her local excision of fibromatosis of her left breast and she remains disease-free.

Conclusion

Primary fibromatosis of the breast is a very rare pathology which looks like a malignant tumor, clinically and radiologically. Fibromatosis of the breast is characterised by a local invasion and a risk of recurrence. Positive diagnosis is provided by histology and its treatment is surgical.
DIAGNOSTICS AND PREINVASIVE DISEASE

ESGO7-0645

INTRAVENOUS LEIOMYOMATOSIS: ABOUT TWO CASES
B. Malek1, M. Slimene1, S. Haddad1, N. Boujelbene2, S. Sakhri1, M. Hechiche1, J. Ben Hassouna1, K. Rahal1
1Institut Salah Azeiz of Oncology, Department of Oncologic Surgery, Tunis, Tunisia
2Institut Salah Azeiz of Oncology, Department of Pathology, Tunis, Tunisia

Aims

Intravenous leiomyomatosis (LIV) is characterized by intraluminal growth of benign smooth muscle into either venous or lymphatic vessels outside the limits of myoma. It commonly extends into the pelvic veins and manifests as worm-like protrusions of tumor emanating from veins at the parametrial margins of hysterectomy specimen. The tumor can cause life-threatening symptoms if it involves inferior vena cava or right atrium.

Method

two patients diagnosed with LIV at Salah Azeiez institute, Tunis, Tunisia, in the period from 2006 to 2016, from retrospective chart review and histologic analysis.

Results

Case one:
A 48-year-old woman was admitted with complaints of abdominal swelling and pain since 6 months. She had no medical history before. Abdominal examination revealed irregular, non tender uterine mass of 20 cm of diameter. The uterus is measuring 23 cm in the pelvic ultrasound examination, with multiple hypoechoic lesions in anterior and posterior myometrium. Computed tomography (CT) scan showed an heterogeneous, well vascularized mass. The patient underwent hysterectomy and bilateral adnexectomy. The diagnosis of LIV was confirmed in the histological examination.

Case two:
We report a case of 70 year-old female who presented with a four-month history of a abdominal swelling and pain. Her imaging showed a right latero-uterine mass, well circumscribed with a right thickened fallopian tube. She underwent hysterectomy and bilateral adnexectomy. The diagnosis of LIV was confirmed in the histological examination.

Conclusion

IVL may grow within veins along various routes. Long-term follow-up is recommended, and familiarity with rare forms of benign smooth muscle uterine tumors is essential in avoiding misdiagnosis and overtreatment.
SECONDARY TRIAGE TEST FOR CERVICAL CANCER SCREENING AMONG WOMEN SCREENED POSITIVE ON VISUAL BASED TESTS
G. Mishra1, S. Pimple1, M. Rokade1
1Tata Memorial Hospital, Preventive Oncology, Mumbai, India

Aims

WHO has recommended visual based techniques for primary screening of cervical cancers in countries with limited resources. However, there is need to triage these screen positive women with test with higher specificity in order to reduce referrals for Colposcopy.

To comparatively evaluate the performance of HPV Hybrid Capture 2 (HC2) and Cytology as triage tests among VIA/ VILI screen positive women, using CIN 2 as threshold.

Method

Community based cervical cancer screening using VIA and VILI was conducted in Mumbai. The screen positive women underwent Cytology, HC2 and diagnostic Colposcopy and/or biopsies. Gold standard was histopathology or negative Colposcopy.

Results

237 primarily screened positive women by VIA/ VILI underwent HC2 and Cytology, followed by Colposcopy. Biopsies were obtained in 207 cases. The sensitivity and specificity in detecting cervical dysplasia or cancer were 70 and 91.62 for HC2 and 70 and 89.43 for cytology. The positive and negative predictive values were 26.92 and 98.58 for HC2 and 22.58 and 98.54 respectively for cytology. The false positivity rate and the false negativity rate were 8.37 and 30 for HC2 and 10.57 and 30 for cytology respectively.

Conclusion
